From Table 4, we can see that at a significance level of 5%, there are 2 variables that have a statistically significant effect on ROA, including BASZ and PROD. Among them, the total assets variable (BASZ) has an inverse effect on return on assets (ROA). That is, when total assets increase by 1 million VND, the return on assets decreases by 0.0000000285%, and vice versa. The labor productivity variable (PROD) has a positive effect on ROA. That is, when labor productivity increases by 1 million VND/employee, the return on assets increases by 0.0000453%, and vice versa. The remaining variables, including CAEQ, NPL, and INF, were excluded from the model. The specific effects are explained through the following regression model:

$$ROA_i = 0.058759 - 0.0000000285BASZ_i + 0.0000453PROD_i$$

**Table 5: OLS's model regression results of ROE**

Dependent Variable: ROE  
Method: Least Squares  
Date: 02/25/23 Time: 23:34  
Sample: 2005 2021  
Included observations: 17

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	-12.45030	8.091269	-1.538733	0.1521
CAEQ	1.997497	0.468103	4.267216	0.0013
NPL	-0.664120	1.855311	-0.357956	0.7272
BASZ	-3.38E-08	7.28E-09	-4.646220	0.0007
PROD	0.000525	9.91E-05	5.300998	0.0003
INF	0.121250	0.133347	0.909281	0.3827
R-squared	0.814011	Mean dependent var		14.29765
Adjusted R-squared	0.729471	S.D. dependent var		4.270879
S.E. of regression	2.221387	Akaike info criterion		4.704705
Sum squared resid	54.28015	Schwarz criterion		4.998780
Log likelihood	-33.98999	Hannan-Quinn criter.		4.733936
F-statistic	9.628676	Durbin-Watson stat		0.893357
Prob(F-statistic)	0.000978			

From table 5, we can see: with at a significance level of 5%, there are 3 variables that have statistically significant effects on ROE, namely CAEQ, BASZ, PROD. In that, CAEQ and PROD have a positive impact on ROE. This means that that a 1% increase in the CAEQ, productivity increase by 1 million VND per labor leads to a 1.997497% and 0.000525% respectively and vice versa. The total assets variable (BASZ) has a negative effect on ROE. When total assets increase by 1 million VND, ROE decreases by 0.0000000338%, and vice versa. The variables NPL and INF are excluded from the model. The specific impact is explained in the following regression model:

$$ROE_i = -12.45030 + 1.997497CAEQ_i - 0.0000000338BASZ_i + 0.000525PROD_i$$

**Table 6: OLS's model regression results of CGROWTH**

Dependent Variable: CGROWTH

Method: Least Squares

Date: 02/25/23 Time: 00:26

Sample: 2005 2021

Included observations: 17

Variable	Coefficient	Std. Error	t-Statistic	Prob.
C	70.96867	40.71112	1.743226	0.1195
NPL	-8.466648	4.064149	-2.083252	0.0708
LIQUIDITY	0.001983	0.008432	0.235142	0.8200
DEPOSIT	0.080874	0.047534	1.701399	0.1273
ROE	0.360073	0.455385	0.790700	0.4519
NIM	-16.10661	9.924742	-1.622875	0.1433
GDP	2.210595	1.626130	1.359421	0.2111
INF	1.940176	0.513404	3.779043	0.0054
RATE	-2.994419	1.390564	-2.153384	0.0634
R-squared	0.908247	Mean dependent var		19.76176
Adjusted R-squared	0.816494	S.D. dependent var		11.99138
S.E. of regression	5.136820	Akaike info criterion		6.415797
Sum squared resid	211.0954	Schwarz criterion		6.856910
Log likelihood	-45.53428	Hannan-Quinn criter.		6.459645
F-statistic	9.898826	Durbin-Watson stat		3.086285
Prob(F-statistic)	0.001975			

From Table 6, we can see that at a significance level of 5%, there are two variables that have statistically significant effects on CGROWTH, namely NPL and INF. Specifically, the non-performing loan ratio (NPL) has a negative impact on the annual credit growth rate (CGROWTH). This means that a 1% increase in the NPL ratio leads to an 8.466648% decrease in the annual credit growth rate, and vice versa. The inflation rate (INF) has a positive impact on CGROWTH. This means that a 1% increase in the inflation rate leads to a 1.940176% increase in the annual credit growth rate, and vice versa. The variables LIQUIDITY, DEPOSIT, ROE, NIM, GDP, and RATE are excluded from the model. The specific impact is explained in the following regression model:

$$CGROWTH_i = 70.96876 - 8.466648NPL_i + 1.940176INF_i$$

### 3. DISCUSSION

#### 3.1. Reasons for the limitation of the growth and efficiency of listed commercial banks in Vietnam

Regarding general limitations, the impact of the epidemic on the economy has led to a decrease in demand for credit. According to Ella Zoe Doan (2020), Covid-19 will cause household spending to decrease by an average of 15% in areas such as education, housing, food, entertainment, etc. When consumer spending decreases, the demand for consumer loans will decrease accordingly. Nevertheless, with the advent of vaccines, credit growth in 2021 has accelerated. Although banks have restricted personal lending during this period to avoid bad debts, such credit growth has proven that credit demand has strongly recovered distinctively in 2021.

Moreover, according to the report, most banks recorded an increase in Net Interest Margin (NIM) during the first half of 2021. Many banks recorded a decrease in NIM in the third quarter compared to the second quarter by 10-30 basis points and this will continue to rise in the next few quarters. In the situation when Vietnamese commercial banks are towards applying Basel III standards, the reduction of NIM will put pressure on banks to improve capital “buffer” criteria such as capital adequacy ratio (CAR), required reserve ratio, etc.

Regarding specific limitations to bank size, there are a number of limited aspects in accordance with two types of bank size stated as follows:

For large commercial banks group, the number of banks such as BIDV and Vietinbank is still facing difficulties in raising capital as the charter capital of these two banks has not increased significantly in recent years. The consequence of this problem is the inability to meet the regulations on the CAR coefficient and many other regulations of the State Bank. By the end of 2021, although many banks have been recognized to apply Basel II successfully, among the big banks, Vietinbank and Sacombank have not yet been able to apply it. However, banks having been recognized in successfully applying Basel II mostly stopped at “measuring and ensuring the minimum level of CAR” while the second pillar is considered the most difficult to implement as the development of an “internal assessment process of capital adequacy” has not been stimulated.

Moreover, the past few years have marked a significant step forward in handling the bad debts of large-scale banks. Although the bad debt ratio of most banks is below 2%, they still have difficulty recovering bad debts. For example, VPB when the bad debt ratio in recent years has always been at approximately or above the safe threshold of 3%.

Furthermore, large commercial banks with a lower return on assets (ROA) compared to the average ROA each year tend to decrease. But they still account for a high proportion of listed commercial banks in Vietnam. In 2021, in this group of banks, the number of commercial banks with a ROA smaller than the average ROA includes: VCB, BIDV, Vietinbank, and Sacombank.

For small commercial banks, due to the low owner’s equity, the financial capacity of these banks is not high and the banking performance is still poor. These banks have not yet expanded their business network and the ability to expand credit and services is still low and limited, especially the low ability to mobilize capital, therefore they have not improved much in terms of qualifications and technology equipment.

In general, the borrowing rate of the banks is above 60%, indicating that the bank’s lending capacity is ambitious. However, this ratio is too large which can lead to a decrease in the solvency of commercial banks. Although the bad debt ratio is always within a safe level, it shows that these banks have not found effective measures to recover bad debts. Despite the smaller size, the ROE of this group of banks is not lower than that of the large group, showing that the profits of these banks are inconsistent and incompatible. This can cause misunderstandings among investors about how accurate this index is at banks.

Although smaller in scale, the ROE index of this group of banks is not lower than that of the larger group, indicating that the profitability of these banks is not consistent. This may cause misunderstandings for investors about the accuracy of this index in banks.

### **3.2. Proposed financial solutions to improve the efficiency and growth of listed commercial banks in Vietnam.**

In order to enhance the efficiency and growth of listed commercial banks in Vietnam in the near future, the research group proposes two main solutions:

(1) Increase the impact of factors such as asset scale, loan-to-deposit ratio, and revenue growth rate.

(2) Tighten control to limit the negative impact of factors such as loan-to-deposit ratio, cost-to-income ratio, and non-performing loan ratio.

In the short term, listed commercial banks in Vietnam should focus more on the following solutions:

Firstly, promoting digital transformation and enhancing the development of products and services to improve service quality and meet customer needs.

Commercial banks need to modernize their technology and payment systems, focus on marketing activities, and diversify and improve the utility of products. Along with the modernization of technology, commercial banks need to have policies to exploit effective technology through the development of products and product groups based on high technology to improve competitiveness in products and services, create diversity in product selection and increase cross-selling of products to customers. Moreover, commercial banks need to improve and simplify administrative and loan procedures to create customer convenience; identify target customer groups to build an effective customer strategy. It is vital to appreciate traditional customers, loyal customers, and reputable customers in banking transactions. For these customers, when formulating a banking strategy, banks must pay great attention to and associate the bank's activities with the customer's activities to be able to create a sustainable relationship between customers and transaction activities.

The second point emphasizes the importance of active management of non-performing loans (NPLs) as a prerequisite for efficient credit growth.

Financial institutions need to strengthen their internal monitoring to prevent the accumulation of NPLs in the future, maintain appropriate credit rating standards to ensure the quality of loans and create a positive ripple effect from the credit operations of each financial institution. In addition to implementing solutions to address NPLs that financial institutions have already or are currently dealing with (such as asset management companies, provisioning, loan classification and evaluation for loan restructuring, and developing a system for classifying loans according to qualitative and quantitative criteria), financial institutions also need to refine their credit policies to align with international standards.

The third is strengthening electronic transactions to support the business community to create a driving force for socio-economic development.

The Covid-19 pandemic in the past few years has had significant impacts on economic, cultural, and social life, especially for businesses whose reserve resources are gradually running out. However, the signs of recovery are not yet promising. The community of small and medium-sized enterprises continues to face significant pressure. Due to their resilience, it is difficult to face and withstand the current slow recovery situation, notably those in the tourism, service, and transportation sectors. Therefore, it is necessary to strengthen financial and electronic transaction solutions to help businesses operate more easily in the production, business, and exchange of goods in the market.

Commercial banks need to develop a special policy to take care of enterprises that are their customers. The fiscal and monetary policy to support the Economic and Social Development Recovery Program has mentioned the issue of reducing interest rates to 2%. However, for enterprises, reducing interest rates is not as valuable as extending the loan term up to one year and the unsecured lending conditions. Therefore, commercial banks may consider this solution.

The fourth point is that commercial banks need to effectively utilize capital in line with their capabilities and the nature of the banking business with a focus on improving financial capacity and resource allocation efficiency.

Banks should concentrate their capital on sectors encouraged by the government. Diversifying investment portfolios, such as investing in government bonds and Treasury bills of State Bank, can ensure operational stability during market fluctuations. In addition, a rational organization of business networks and relationships with partners will help banks enhance their capacity and maintain the sustainability of mobilized capital.

The fifth is to have reasonable interest rate policies according to guidance.

Interest rates must ensure attractiveness to retain traditional customers as well as attract new ones. Currently, interest rates are still considered a powerful and effective tool for attracting capital. However, this should only be a temporary measure due to the high risk it poses to banks and the potential negative effect on future efficiency. Corporate lending interest rates must be based on a comprehensive calculation and appropriate level of various risks such as credit risk, interest rate risk, term risk, exchange rate risk, and ethical risk. Gradually narrowing the gap between deposit and lending interest rates based on the restructuring of the system of credit institutions is also crucial.

Sixty is actively promoting socio-economic development and taking responsibility for contributing to environmental protection.

Commercial banks need to develop business strategies in line with the State Bank's policies on environmental protection. Accordingly, investment projects from the bank's credit capital must be controlled by environmental regulations and energy-saving policies. Furthermore, commercial banks should actively manage environmental and social risks throughout the operation procedures to mitigate negative impacts on the environment and society. Simultaneously, it is vital to seek and develop business and investment opportunities that are eco-friendly to society.

Seventy is that commercial banks need to actively improve their governance system to comply with the risk management requirements under Base II to strictly adhere to regulations on safety limits in their operations.

To reduce costs and administrative procedures associated with direct supervision, remote monitoring should be enhanced and strengthened. The inspection methods should be renewed frequently from risk identification, assessment, and measurement to the construction and implementation of inspection and supervision activities based on advanced technology and management level. In addition, a culture of compliance throughout the entire system must be fostered.

#### **4. CONCLUSION**

The rapid pace of globalization and trade liberalization in recent years has created many changes in the business environment in Vietnam. International economic integration creates conditions for countries to develop, but this also makes competition in economic fields more intense, and banking and finance are no exception. Foreign banks have been penetrating the domestic market. With long-term experience, modern technology, and large capital backed by strong and reputable financial groups in the world, they are confident that they will fully meet all needs in the financial field. for the Vietnamese. It can be said that foreign financial groups are a challenge for Vietnam's banking industry. The Government and the State Bank

of Vietnam (SBV) have advocated restructuring the commercial banking system according to Decision 254/QĐ-TTg dated March 1, 2012 of the Prime Minister and Decision No. 734/QĐ-NHNN dated 18/03 April 2012 by the Governor of the State Bank to make the banking system healthy, create financial strength and increasing competitiveness for banks. This result affirms that the policies of the Government and the State Bank are completely correct and timely... and also based on the analysis results showing that there are still some limitations in using resources and groundstudy makes recommendations to improve the capacity, business efficiency, and competitiveness of the current post-merger commercial banks in Vietnam to suit the requirements of innovation and the requirements of the trend of international economic integration.

## PROFITABILITY STATUS OF LISTED CEMENT COMPANIES IN VIET NAM

**Author: Nguyen Hai Duyen<sup>1</sup>, Doan Bach Yen<sup>1</sup>, Le Thi Thuy Van<sup>1</sup>, Do Thi Minh Chau<sup>1</sup>**

**Mentor: Pham Thi Quyen**

**ABSTRACT:** *In recent years, cement businesses have made great contributions to the previous Edit Header battery. However, the growth in the number of cement enterprises and the recession of the economy has led to an oversupply of cement, the business efficiency of many enterprises is still low. Therefore, being fully aware of the general context of the economy, the situation of the industry and each enterprise, thereby finding solutions to overcome difficulties is always a concern of the managers of manufacturing enterprises. cement. In this article, the authors study the profitability status of listed cement companies in the period 2017-2021, analyze the influencing factors, specify the results and limitations. From there, propose some recommendations to improve profitability for listed cement companies in Vietnam*

**Keywords:** *business, cement, profitability*

### 1. INTRODUCTION ABOUT LISTED CEMENT COMPANIES IN VIETNAM TO ANALYZE THE CURRENT

Situation of business efficiency of listed cement companies, the article used data of 12 cement manufacturing, processing and processing enterprises. To analyze and evaluate the current state of business performance of enterprises. Including the following enterprises: Bim Son Cement Joint Stock Company (BCC), Vicem But Son Cement Joint Stock Company (BTS), La Hien VVMI Cement Joint Stock Company (CLH), Vicem Hoang Mai Cement Joint Stock Company (HOM), Sai Son Cement Joint Stock Company (SC)), Phu Tho Cement Joint Stock Company (PTE), Thai Binh Cement Joint Stock Company (TBX), Ha Tien 1 Cement Joint Stock Company (HT1), Vicem Hai Van Cement Joint Stock Company (HVX), Quan Trieu VVMI Cement JSC ( CQT), Yen Binh Cement Joint Stock Company (LCC) and Lang Son Cement Joint Stock Company (Hong Phong) (VCX). The selected enterprises have large scale in terms of business capital. revenue, income and profit, cash flow. In addition, enterprises display all the characteristics and characteristics of a typical cement enterprise and fully disclose data during the research period 2017-2021. This sample of 12 companies is capable of representing the whole population in general, from which it is possible to deduce the characteristics and properties of the whole population.

### 2. PROFITABILITY SITUATION OF LISTED CEMENT ENTERPRISES IN VIETNAM

#### 2.1. Status of operating profitability

The operating profitability indicators of listed cement companies are reflected in Figure 1. The average operating profit ratios of enterprises increased in 2018 and 2019 but then decreased gradually. ROS of Phu Tho Cement Joint Stock Company and Yen Binh Cement Joint Stock Company were negative for 5 consecutive years. ROS of Ban Son Cement Joint Stock Company, Thai Binh Cement Joint Stock Company has many fluctuations. The ROS of the remaining 8 enterprises remained positive in the past 5 years. The increase in average operating profit margin in 2019 was mainly due to the increase in ROS of 7/12 enterprises.

**Figure 1: Operating margin - ROS (%)**

(Source: Calculation from financial statements of listed cement companies in the period 2017-2021)

**2.2. Status of profitability of business capital**

Business capital’s net profitability is shown in Figure 2. It shows similar to net operating margin: Average ROA increased in 2018 and 2019, then gradually decreased in 2020 and 2021. H Double-click to hide white space

**Figure 2: Dragon profitability ratio of business capital (ROA) of listed cement companies**

(Source: Calculations from financial statements of listed cement companies in the period 2017-2021)

### 2.3. Status of return on equity

The profitability of equity is shown in Figure 3, showing similar as the rate of return on working capital. The average ROE indicator increased in 2018, 2019 and gradually decreased in the following years.

**Figure 3: Return on Equity (ROE) of listed cement companies**

(Source: Calculations from financial statements of listed cement companies in the period 2017-2021)

## 3. FACTORS AFFECTING PROFITABILITY OF LISTED CEMENT COMPANIES IN VIETNAM

### 3.1 Descriptive statistics of variables in the model

The data is collected, aggregated and calculated by the authors from 12 companies in the cement industry in the period from 2017 to 2021.

Table 1 provides the statistical results of the main variables used in the model, including the first group of factors related to the financial characteristics of the enterprise and the second group of factors related to corporate governance. The variables are statistically based on sample size (Obs), mean (Mean), standard deviation (Std.Dev), maximum and minimum value (max-min).

**\*Regarding the dependent variable:** Choose ROE as the dependent variable representing economic efficiency business of the enterprise

**\*Independent variables, including:** Enterprise size, debt ratio, return on sales (ROS), fixed asset investment ratio, revenue growth rate, ratio of receivables from customers, economic growth rate GDP and inflation rate.

**Table 1: Descriptive statistics of the sea**

Variable	Obs	Mean	Std. Dev.	Min	Max
ROE	60	.1451733	.478893	-.2217	3.6599
lnsize	60	13.70102	1.42726	10.12431	16.22061
Hnvc	60	-.5039011	14.60667	-108.8976	9.276977
growth	60	1.01576	.22846	.3553	2.0087
age	60	29	16.01377	11	64
Htsdh	60	.6706283	.1862464	.1808	.9034
ROS	60	-.0391567	.1905739	-1.1227	.0838
Hpt	60	.0714217	.0798278	.0015	.499
GDP	60	.05435	.0194135	.0258	.0708
I	60	.10078	.0020641	.0973	.103
INF	60	.02986	.0064004	.0184	.0354

From the table above, it can be seen that the total number of observations in the model is 60 respectively with a research period of 5 years (2017-2021) and the number of companies studied is 12.

The statistics table shows that the return on equity has a value from -0.2217 to 3.6599, showing that the companies in the selected sample have quite diverse ROE. both profit and loss companies. This is a good factor for regression results because the firms in the sample are highly representative.

In terms of asset size, the average total assets of securities companies is VND 891,820.359 million, showing that listed securities companies have a fairly large scale. The range of total assets of securities companies in the sample is quite wide from 24,942 million dong to 1,079,532 million dong.

Regarding the debt ratio, the average value is -0.5, the highest value is 9.27 and the lowest value is -108.89, showing that there are many companies using debt capital, showing a degree of independence. financial resources are not high, but take advantage of financial leverage to increase profits.

Sales growth rate has an average value of 101, has the highest value is 2.0087 and the lowest is 0.3553 indicating that there is no company with growth rate Negative growth indicates that the company's efforts in increasing sales.

About the rate of investment in Fixed Assets with an average value of 0.67, the highest value 0.9034 and the lowest 0.1808. This shows that the majority of securities companies do not invest in fixed assets much, in line with the business characteristics of the industry.

The ratio of profit after tax to operating revenue ROS, the average value is -0.039, the largest value is 0.0838 and the lowest value is -1.1227, reflecting the performance of securities companies. quite low in the period 2017-2021, however, there are still some observed samples with a fairly high profit-to-sales ratio.

The ratio of receivables from customers has an average value of 0.07, the maximum value is 0.499 and the lowest value is 0.0015, showing that in the period 2017-2021, the rate of customer receivables of cement companies is quite low.

The INF inflation rate has an average value of 0.03, showing that in the period 2017-2021, Vietnam's inflation rate is always at a stable level.

GDP growth rate, with the average value reaching 0.05435, the highest value reaching 0.0708 and the lowest 0.0258.

### 3.2. Pre-testing the model

\* Analyze correlation between variables

**Table 2: Correlation analysis between variables**

	ROE	lnsize	Hnvc	growth	age	Htsdh	ROS
ROE	1.0000						
lnsize	-0.0657	1.0000					
Hnvc	-0.9730*	0.0544	1.0000				
growth	-0.0899	0.2061	0.1002	1.0000			
age	0.1556	0.2695*	-0.1707	0.2830*	1.0000		
Htsdh	0.1658	0.3755*	-0.0838	-0.0187	-0.0449	1.0000	
ROS	-0.0441	0.2638*	0.0915	0.3080*	-0.0044	-0.2035	1.0000
Hpt	-0.1062	-0.6041*	0.0980	-0.0136	-0.2242	-0.5824*	0.0041
GDP	0.0957	0.0315	-0.0898	-0.0174	-0.0132	-0.1201	0.0900
I	-0.1816	-0.0690	0.1999	-0.0637	0.0840	0.0321	-0.0459
INF	0.0927	0.0596	-0.0941	0.0175	-0.0700	0.0031	-0.0031

	Hpt	GDP	I	INF
Hpt	1.0000			
GDP	0.0740	1.0000		
I	-0.1456	-0.0000	1.0000	
INF	0.0660	0.0000	-0.7062*	1.0000

In general, most of the variables in the model are correlated with each other low (less than 0.5). The authors will perform the multi-addition test line through the variance magnification factor VIF

\*Variance magnification factor VIF

**Table 3: Variance Magnification Factor VIF**

Variable	VIF	1/VIF
Hpt	2.33	0.428508
I	2.26	0.442592
lnsize	2.11	0.473072
INF	2.02	0.494403
Htsdh	1.81	0.552022
age	1.39	0.719861
ROS	1.37	0.732571
growth	1.28	0.781599
Hnvc	1.22	0.821405
GDP	1.05	0.952249
Mean VIF	1.68	

Based on the table, it shows that the average VIF of the variables in the model is 1.68, less than 10 and there is no independent variable with VIF index exceeding 10, so there is no strong multicollinearity in the model.

Conclusion: With the standard of exaggeration the variance VIF does not exist multicollinearity in the regression model.

\* OLS model regression

(Source: The results of the author's performance from Stata 15 software)

From the table, we see that there are 4 statistically significant variables, including: Lnsize, Hnvc, Htsdh, ROS are significant at  $\alpha=5\%$ . In which, Operation time (age), Fixed asset investment (Htsdh), Profit after tax ratio (ROS), Ratio of receivables from customers (Hpt), Interest rate (I), GDP growth Inflation rate (INF) has a positive effect on ROE; specifically, when the variables age, Htsdh, ROS, Hpt, GDP, INF increase by 1%, ROE will increase by 0.001%, respectively; 0.42%; 0.26%; 0.23%; 0.49%; 5.2%; 1.72% and vice versa. Enterprise size variables (Lnsize). Debt ratio (Hnvc), Revenue growth rate (growth) have negative impact on ROE.

The adjustment coefficient  $R^2$  of the regression model with ROE is 9589%, which means that 95.89% of the variation of ROE is explained through the independent variables of the remaining model, 4.11% is explained through other variables. variables outside the model. With the F-statistic = 138.55 corresponding to the p-value = 0.0000, the model is statistically significant.

 Prob > chibar2 = 1.0000

Comment: Prob > chibar2 = 1.0000 shows that the OLS model is more efficient than the model REM

**3.3 Regression model results analyzing the influence of factors**

**Table 8: Summary of research results on factors affecting the ability profitability of cement businesses**

STT	Variable name	Encode	Expectation sign	Regression results
1	Business size Karma	lnsize	+	-
2	Debt ratio	Hsn	-	-
3	Profit-to-Revenue Ratio	ROS	+	+
4	Investment rate of Finance fixed assets	Htsdh	+	+

5	Growth rate revenue	Growth	+	Meaningless statistical
6	Receivable ratio client	Hpt	+	Meaningless statistical
7	Growth rate economy	GDP	-	Meaningless statistical
8	Inflation rate	INF	-	Meaningless statistical

From the estimation results, the regression model measures the degree of dynamics of the factors to the return on equity (ROE) of securities companies as follows:

$$ROE = -0.37 - 0.029 * Lsize - 0.03 * Hnvc + 0.42 * Htsdh + 0.26 * ROS + e$$

For firm size: The estimated results show that the beta = -0.029 (with 1% significance level) indicates the firm size. Have negative relationship with ROE. This result is contrary to the hypothesis that the authors set go out. Specifically, when the size of the business increases by 1 unit, it will make the ROE down 0.029. During the period from 2020, the business of The cement industry faces many difficulties due to recent market movements adverse factors affecting the efficiency of cement exports such as: high cost of logistics; Coal (input fuel) price increases continuously... resulting in negligible profit.

For debt coefficient: The results show that the debt coefficient has beta = -0.03 (with 1% significance level) showing that HSN has a negative relationship with ROE. This result is similar to the hypothesis proposed by the authors. Specifically, when HSN increases by 1 unit, ROE will decrease by 0.03 units. Enterprises have not made good use of financial leverage, reducing revenue, leading to a decrease in profitability on equity. This means that if a business has a higher debt-to-assets ratio, it will operate less efficiently. Because if the enterprise uses a high ratio of bank loans, the pressure to pay interest and principal is larger, the more difficult it will be for the business to operate. Therefore, the debts that businesses should strengthen are those with less pressure to pay interest and principal as they still occupy from suppliers.... Only then will businesses take full advantage of debt to improve business performance.

For the ratio of investing some fixed assets: The estimated result has bet 0.42, shows that the ratio of investment in fixed assets has a positive relationship with ROE. Result This is similar to the proposed hypothesis. Specifically, when Htsdh increases by 1 unit, it will causes the ROE value to increase by 0.42 units. It can be seen that, if the investment in fixed assets (equipment of fixed assets, improvement of technology, etc.) A well-executed business will increase the operational efficiency of the business.

For the profit-to-sales ratio: the estimated result has beta = 0.26, showing that the profit-to-sales ratio has a positive relationship with ROE, this result is similar to the hypothesis proposed by the authors. . Specifically, when ROS increases by 1 unit, it will make ROE increase by 0.26 units respectively.

In summary, after analyzing the results of the regression model of factors affecting the profitability of equity of listed cement manufacturing companies, it can be seen that there are four main factors affecting to ROE is Enterprise Size (Lsize). Debt ratio (Hnvc). Fixed Asset Investment Ratio (Htsdn), Return on Sales (ROS). Factor Growth Rate (Growth). Customer Payable Ratio (Hpt). Economic Growth Rate (GDP), Inflation Rate (1) does not work. affect the return on equity of the cement manufacturing companies listed in Vietnam.

#### 4. SOME SUGGESTIONS

From the above studies, the authors have some suggestions as follows: Regarding capital sources: Focusing on building a target capital structure in listed cement companies in Vietnam and diversifying forms of capital mobilization, actively building plans to raise business capital for cement enterprises.

Regarding the management of capital use: For reserve raw materials to maintain stable production and business activities of enterprises, the reserve is necessary. However, cement businesses need to determine the appropriate reserve level with the supply and focus on analyzing and forecasting the market situation of raw materials supply to adjust the reserve level in accordance with the current situation. market variables.

For finished products in reserve: it is inevitable to become a finished product. Enterprises It is necessary to build stock norms of finished products in accordance with the market demand and supply and the competitiveness of each enterprise.

Regarding promotion of consumption: promote market research to anticipate growth, choose means of transport in the consumption process, strengthen activities to support consumption promotion, strengthen close links with regional and world cement associations and participate in conferences and forums to update trends: review expenditures, energy consumption norms, build new and consistent norms to ensure stability. determine product quality with the central goal of optimizing the operation of the equipment ,..

About business cost management: research on the use of raw materials replacement in production to ensure energy saving and cost savings at the same time non-input materials and transportation costs.

## **5. CONCLUSION**

Cement enterprises play a very important role in creating jobs, increasing incomes for workers, providing cement products to meet the construction needs of national key projects, construction works. infrastructure construction of factories, offices, schools, houses,... contributing to the achievement of the country's socio-economic development goals. However, in the context of increasingly competitive fiercely between domestic enterprises and foreign enterprises, the cooperative enterprises are facing many difficulties in the process of operation. Business performance is low and unstable. Therefore, the article has focused on researching on the profitability of cement enterprises in order to properly assess the profitability of enterprises, thereby proposing appropriate solutions and recommendations.

## PROFIT DISTRIBUTION OF STATE ENTERPRISE CURRENT SITUATION AND ISSUES

**Author: Nguyen Thai Ngoc Linh<sup>1</sup>, Dang Phuong Anh<sup>1</sup>, Mai Tien Dung<sup>1</sup>,**

**Khuat Quynh Anh<sup>1</sup>, Hoang Minh Hien<sup>1</sup>**

**Mentor: Associate Professor Ph.D Nguyen Thi Ha<sup>1</sup>**

**ABSTRACT:** *Using a sample of 10 State-owned enterprises including financial enterprises and non-financial enterprises. The article has briefly analyzed the business performance and profit distribution of 10 state-owned enterprises in the period 2017-2021. The results show that the distribution of profits depends on many different factors such as: industry, profit achieved, future goals, regulations of the State,... These help us assess the achievements, limitations and causes of each limitation that enterprises face in business activities as well as profit distribution. Thereby, we have an overview of SOEs in general from which to propose solutions to improve profits and improve the distribution of profits.*

**Keywords:** *profit distribution, profits, state-owned enterprises*

### 1. INTRODUCTION

In today's market economy, profit has become a business purpose, a decisive factor for the survival and development of enterprises. Profit is the most effective economic lever, the top goal and the ultimate goal that all businesses reach. And more importantly, the realization of the profit target is an important condition to ensure the firm's financial position.

Maximizing profit is the ultimate destination that any business that wants to survive and develop in the current new conditions must aim for. Profit is an aggregate quality indicator that reflects the results of production and business activities of an enterprise. Thereby, it shows whether the implementation of the profit distribution regime is effective or not and whether it is a driving force to stimulate the rise in competition of each enterprise.

Today, it can be seen that Vietnamese enterprises, when transforming into a market economy, have achieved remarkable achievements but also encountered many difficulties in improving profits. To be able to maintain and ensure profits and distribute profits reasonably, businesses need to set up plans, development orientations and set out specific measures suitable to business conditions. and adapt to the market. Recognizing the importance of profits and profit distribution for the growth of enterprises, the research topic "Profit distribution of Vietnamese State-owned enterprises" was selected for the purpose of clarifying the nature of the business. The nature and origin of profits in the market economy, an overview of the situation of production and business activities and profit distribution of enterprises.

### 2. THEORETICAL FRAMEWORK

#### 2.1. Profit

Each historical period, each social mode, profit is understood in different ways. That is the subject of debate of many economic theorists, of many development schools. From the early stages of the commodity economy, until the market economy developed at a high stage, production and exchange of goods on the

<sup>1</sup> Academy of Finance.

market were mainly affected by the law of value, the law of supply and demand, the law of competition. The feudal mode of production disintegrated, changed to the capitalist mode of production, and the production and circulation of goods developed. Profit always plays an important role, which is the goal that any enterprise can achieve. are aimed at, are the conditions for the existence and development of enterprises.

Classical economists before Marx said: “The dominant part lies in the selling price over the cost of production called profit”.

According to Marx: “The surplus value or the excess in the total value of the commodity, in which the surplus or unpaid labor of the worker has been materialized, I call profit.”

Modern economists say: “The difference between the total income and the total costs of the enterprise in a given period is profit”.

It can be said that, although the above views are different, they all think that profit is an excess compared to the cost spent. That is the nature of profit in a market economy.

According to the corporate finance textbook of the Academy of Finance, the concept of profit is that after a cycle of production and business activities, enterprises will be able to earn a profit, which is the difference between revenue and expenses. the costs incurred by the enterprise to obtain that revenue from its activities during a given period.

The general formula for determining profit:

$$\text{Profit} = \sum \text{Revenue} - \sum \text{Expense}$$

In there:

**Total revenue:** is the total amount that will be received from the sale of products, provision of services, financial activities and other activities of the business.

**Total expense:** is the amount of money to be paid to carry out economic activities such as production, transaction, ... in order to buy all kinds of goods and services necessary for the production and business process.

## 2.2. Profit distribution

Profit distribution is not the distribution of profits in a single week, but rather the aggregate settlement of economic relations taking place for enterprises. The correct distribution will become the driving force of production. business development, creating favorable conditions for enterprises to continue their business and vice versa.

The profit distribution process of the enterprise must meet the following basic requirements:

Enterprises need to harmonize the relationship of interests between the State, enterprises and employees in enterprises. This relationship is reflected in the corporate income tax rate and the rate of setting up bonus and welfare funds of the enterprise.

The profit distribution process must ensure a balanced relationship between accumulation and consumption, between simple business reproduction and expanded business reproduction. This relationship is reflected in the rate of setting up corporate funds, in which the profit to reinvest in production and business activities is adequately focused.

In fact, with State-owned enterprises, the distribution of profits is made according to the regulations of the State and in each period. Specifically, state-owned enterprises shall distribute profits according to the provisions of Article 31 of Decree 91/2015/ND-CP, Article 2 of Decree 32/2018/ND-CP, Clause 4, Article 4 of Circular 36/ 2021/TT-BTC:

Profits of state-owned enterprises, after making up for losses of the previous year in accordance with the Law on Corporate Income Tax, deducting the Science and Technology Development Fund in accordance with law, paying corporate income tax, profits The remaining profits are distributed in the following order:

1. Divide the profits to the partners contributing capital in accordance with the provisions of the signed economic contract (if any).
2. Offsetting the loss of previous years has expired before being deducted from profit before tax according to regulations.
3. The remaining profit after deducting the above amounts will be distributed in the following order:
  - + Deduction for special funds under the Prime Minister’s decision (if any).
  - + Deduct up to 30% into the enterprise’s development investment fund.
  - + Deducting bonus and welfare funds for employees in the enterprise.

### 3. DATA AND RESEARCH METHODS

#### 3.1. Research data

Research data is collected from annual financial statements, resolutions of the Annual General Meeting of 10 SOEs for the period 2017 - 2021. Specifically, 10 SOEs include 3 banking enterprises (enterprises). financial enterprises) and 7 production and business enterprises (non-financial enterprises). The information needed for the research is collected from audited financial statements, annual reports, notes to financial statements.

#### 3.2. Research methods

Applying the method of dialectical materialism to research and understand problems scientifically in the unified movement of a material whole along with the objective impact of external factors on the general. By surveying methods of profit distribution to assess the current status of profits and profit distribution of Vietnamese state-owned enterprises, combined with some other methods such as analysis, comparison, summarization, etc. Collecting data, interpreting inductively, etc. to show from overview to details the distribution of profits. Besides, the study also uses and selectively applies research results of scientific works. relevant quality studies to strengthen and deepen the thesis’s points.

### 4. RESULTS AND DISCUSSION OF RESULTS

#### 4.1. Overview of corporate profits for the period 2017-2021

##### 4.1.1. Financial enterprise

**Table 4.1: Profit after tax of financial enterprises 2017-2021**

*Unit: million dong*

No	Businesses	Year 2017	Year 2018	Year 2019	Year 2020	Year 2021
1	VCB	8.849.164	14.454.667	18.200.952	18.043.745	21.190.934
2	CTG	6.717.522	5.193.214	9.283.297	13.278.707	13.622.346
3	BID	6.945.586	7.541.833	6.945.586	7.223.565	10.841.271

*(Source: Synthesis of the project’s authors from the financial statements)*

The above table has generalized the profits of 3 banking enterprises in the group of financial enterprises in the period 2017-2021, specifically:

The bank with the highest profit is Vietcombank, then Vietinbank and finally BIDV. Each year the highest profit growth between years is different: 2018 (VCB - 63.35%), 2019 (CTG - 78.76%), 2020 (CTG - 43.04%), and 2021 (BIDV - 50.08%). Although the year-on-year growth of each bank is not too regular, the profit is still

positive and higher than the industry average. With the change in the ranking order of the amount achieved and the level of profit growth, but all 3 banks kept their positions in the top of the highest income state-owned banks.

Not only that, the fact that all three banks achieved high profits has contributed to increasing the proportion of the State-owned commercial banks in the money market. As of September 30, 2021, the total assets of State-owned commercial banks reached VND 6,209,729 billion, accounting for 41.2% of the whole system; charter capital reached 169,690 billion dong, accounting for 23.7%. The above figures partly show the leading role of the system of state-owned commercial banks in the money market. Asset quality of the whole system also improved positively; This is reflected in the ratio of bad debt on the balance sheet of the whole system at 1.63% at the end of 2019. However, the Covid-19 pandemic has reduced the ability of customers to pay debts, thereby affecting the bad debts of customers banks in 2020 and 2021. However, the bad debt ratio on the balance sheet of the whole system is still kept under the threshold of 3%.

In addition to the positive profit growth, financial enterprises, especially the banking sector, also faced many difficulties that affected their profits. Below is an overview of the profits of each bank including: Vietcombank, Vietinbank and BIDV

#### 4.1.2. Non-financial enterprise

**Bảng 4.2 : Profit after tax of non-financial businesses 2017 - 2021**

*Unit: Millions*

No	Businesses	Year 2017	Year 2018	Year 2019	Year 2020	Year 2021
1	GAS	9.937.792	11.708.565	12.085.651	7.971.791	8.851.812
2	PLX	3.911.662	3.649.759	4.676.561	1.252.572	3.123.734
3	POW	2.601.688	2.286.841	2.879.956	2.662.666	2.052.153
4	TNC	26.753	27.193	36.062	54.898	39.269
5	EVF	180.409	203.576	229.452	228.409	330.571
6	BCM	-	1.002.494	1.923.183	904.919	1.356.901
7	HVN	1.911.095	2.417.897	2.899.344	(8.734.154)	(11.833.362)

*(Source: Synthesis of the project's authors from the financial statements)*

The above table has generalized the profits of 7 state-owned enterprises belonging to the group of non-financial enterprises in the period 2017-2021. With the same group, but the business fields are different, the profits of enterprises compared to each other also have differences. So these 7 enterprises can be classified into oil and gas groups and the rest. Specifically:

Oil and gas group: The company with the highest profit is GAS, followed by PLX and finally POW. This group also has irregular growth (interlaced increase and decrease). Year by year, the highest growth rate will be in 2018 (Gas - 17.82%), in 2019 (PLX - 28.13%), In 2020 (POW - 7.54%) and in 2021 (PLX - 149.39%). Compared to the level of profit, the oil and gas group is only close to a quarter of the profit when compared to the banking industry.

The remaining group of companies: The profit achieved is quite low compared to the financial sector and the oil and gas group. This group also has unstable profit growth like the oil and gas group with years of increase, years of decline. Year by year, the highest growth rate will be in 2018 (HVN - 26.52%), in 2019 (BCM - 91.84%), in 2020 (TNC - 52.23%), in 2021 (BCM - 49), 95%). Despite the unstable growth, companies including: Thong Nhat Rubber Joint Stock Company, Power Finance Joint Stock Company, Investment and Development Corporation still kept positive profits. Particularly, Vietnam Airlines Corporation has a negative profit (-11,833,362 million dong in 2021), which means that the company's growth will be negative.

#### 4.2. Status of profit distribution of enterprises in the period 2017-2021

**4.2.1. Financial enterprise**

**Bảng 4.3: Total distributed profits of state-owned financial enterprises from 2017 to 2021**

*Unit: VND million*

No	Items	Vietcombank	Vietinbank	BIDV
1	Total PAT from 2017 to 2021	80.739.462	48.072.226	35.439.235
2	Allocation to a Supplementary charter capital reserve	4.042.769	1.985.861	1.769.243
3	Allocation to Financial reserve	8.085.540	4.807.223	3.538.487
4	Allocation to bonus and welfare fund	9.874.111	9.682.557	9.059.900
5	Dividend paid by stock	11.348.000	10.823.000	12.527.562

*(Source: Synthesis of the project's authors from the financial statements)*

The above table has provided an overview and overview of the total profit and profit distribution of the banking group (financial group) from 2017 to 2021. For each year, banks have different profits in the high year and the year. short. Therefore, the amount set aside for the funds will be different between banks. However, the funds of all three banks are set aside at the same rate: the reserve fund for supplementing charter capital 5%, the financial reserve fund 10%, the bonus and welfare fund will comply with regulations. regulations of the State for enterprises rated A (all three banks are class A enterprises).

For dividend payment in cash and shares, each bank also has different ratios, so the payment amount will also be different, but after 5 years all three banks have increased their charter capital. According to the table, the largest increase in charter capital belonged to BIDV - 12,527,562 million VND, then Vietcombank - 11,348,000 million VND and finally Vietinbank - 10,823,000 million VND. To have a more detailed view of the difference in profit distribution of the three banks, it is necessary to analyze the profit distribution plan of the three banks.

**4.2.2. Non-financial enterprise**

**Table 4.4: Total distributed profit of state non-financial enterprises in the period 2017 - 2021**

*Unit: VND Billion*

No	Items	GAS	PLX	POW	TNC	EVF	BCM	HVN
1	Total PAT from 2017 to 2021	49.635	13.416	12.267	199,3	1.172	4.499	(3.237,6)
2	Average allocation for funds 2017 - 2021

*(Source: The authors calculate and synthesize from the profit distribution plan of non-financial enterprises)*

Table 4.2 gives us an overview of the profit distribution of non-financial SOEs through various items. The above results also show that in the 5-year period from 2017 to 2021, all businesses achieve a stable profit after tax in the first 3 years, however, because each business faces difficulties in each field. During the Covid-19 pandemic, there are industries that show a decrease in profits, and there are industries where profits are not affected too much.

And because each business has different profit distribution plans, the funds that businesses set out will also be different. On average, when deducting the bonus and welfare fund, the Management Board of financial enterprises is still unstable, specifically, while GAS deducts VND 269.46 billion, BCM deducts VND 1,525 billion. For bonus and welfare funds, HVN deducted the most with the amount of 395.6 billion dong, which shows that during the epidemic period, HVN was affected quite a lot but still used profit after tax for reward work. encourage material benefits, serve the needs of public welfare, improve and enhance the material and spiritual life of employees. Besides, PLX criticized VND 7.98 billion for this fund. The investment and development fund cannot fail to mention GAS when this enterprise has deducted 1,956.4 billion dong here, this shows that the enterprise is increasingly expanding production, business, innovating and replacing machinery. equipment, facilities and applying more scientific and technical advances to promote profits, on the contrary, TNC criticized 2.4 billion dong.

Each company has a different dividend payment plan, but it can be clearly seen that the average dividend in these 5 years depends on the profit after tax of the enterprises.

### **4.3. Achievements and limitations**

#### **4.3.1. Achievement**

##### *a. Financial enterprise*

In the period 2017-2021, all three banks achieved many successes in business activities as well as affirmed their position in the industry. At the same time, profitable business was not only completed but exceeded the set plan, helping each bank to distribute profits to ensure operational capacity, dividend payment activities, capital raising activities, etc.

All three banks have implemented profit distribution principles including: Realized profit principle; Principle of net profit; Principles of ensuring solvency and distribution of profits to ensure the harmony of interests between entities (owners, the State, employees, ..)

The bank's coordination of principles aims to ensure the harmony of interests between the entities but still ensure the solvency, and at the same time, towards the long-term benefit of sustainable development.

Banks all set aside similar funds, including reserve fund to supplement charter capital of 5% compared to EAT, financial reserve fund of 10%, bonus and welfare fund. In addition, BIDV also set aside a reserve fund for investment development (in 2017) with the provisioning rate of 35%.

Regarding dividend payment, each bank has its own level of dividend payment depending on the profit after tax achieved by the enterprise. During this period, VCB had the highest dividend payout among the three banks at 12% (actually) 4% higher than the plan. Meanwhile, the highest dividend payment rate of Vietinbank is 5%, BIDV is 8%. The above cash dividend payment can also be understood because VCB's NPAT is many times higher than that of the other two banks: Vietinbank (1.5 times higher in 2021), BIDV (3.2 times higher than last year). 2021).

Regarding capital increase, from 2017 to 2021, the order of capital sources of banks has changed. In 2017, the leader was Vietinbank (VND 37,234 billion), then Vietcombank (VND 35,977 billion) and then BIDV (VND 34,187 billion). But after 5 years and up to the present time, the rank of charter capital has changed. Specifically, BIDV has risen to the leading position (50,585 billion VND), ranked second is Vietinbank with charter capital of 48,058 billion VND and ranked third in the group is Vietcombank with charter capital of 47,325 billion VND. copper.

To sum up, by effectively applying the principles of profit distribution and complying with the State's regulations on profit distribution in accordance with personal circumstances and social contexts in each year, it has helped for all 3 banks to successfully complete and exceed the set plans. Bring benefits as well as maintain its position in the market, contributing to the economy of Vietnam.

*b. Non-financial enterprise*

□ **Oil and gas industry group**

In recent years, the world in general and Vietnam in particular have faced many difficulties and challenges, affecting all aspects of the economy, including the oil and gas industry. Crude oil prices are constantly fluctuating, leading to impacts on the prices of gas, petroleum products and oil and gas supply chains... This becomes even more difficult, specifically in the context of the world facing the Covid pandemic. -19. The structure of primary energy is tending to change strongly, in the direction of greening, developing clean energy, and reducing carbon emissions.

With internal factors affecting profit distribution such as the staff of PLX, GAS and POW with management capacity, high sense of responsibility, modern professional working style, and sensitivity to developments. change of reality, have a long-term strategic vision, and promptly issue reasonable decisions.

Regarding dividend payment, each oil and gas enterprise has its own level of dividend payment depending on the profit after tax achieved by the enterprise. But it can be seen that PLX, GAS and POW all have a fairly high dividend payout ratio of 30%, however, for POW, the dividend payment level gradually decreases over the years and reaches 2% in 2020.

In addition, the application of science and technology to the practice of construction investment and production and business activities of PLX, GAS and POW has left many outstanding achievements, helping to form the gas industry infrastructure today. more complete and has made great contributions to the strong development of the oil and gas industry. Contributing to ensuring national energy and food security as well as making great contributions to the state budget and socio-economic development.

□ **Manufacturing industry group**

Over the years, manufacturing enterprises have continuously expanded their production and business activities and promoted international integration, affirming their position and brand in the world. As a result, Vietnam's manufacturing industry has achieved high rankings in the world, with the output and exports for many consecutive years ranked third in the world. The above results were achieved thanks to the right orientations and clear directions of the businesses, which helped the profits of enterprises to increase rapidly and achieve impressive numbers. The development of the economy along with the process of world economic integration, the constantly fluctuating movements of the market, like other groups of industries, the manufacturing sector also faces many difficulties in operation. businesses due to the impact of the epidemic, but overcoming those difficulties, businesses have achieved certain results as follows.

In the period from 2017-2020, Thong Nhat Rubber's profit after tax has increased every year, showing that its business activities are very profitable. During the covid pandemic, the company still achieved good business results compared to the industry average. In 2020, EVN Finance's pre-tax profit is VND 285.7% billion, completing 102% of the year plan.

Electricity Joint Stock Finance Company has achieved many achievements in business activities and earned quite good profits. The company's profit after tax has generally increased year by year, profit before tax has always exceeded the initial plan.

Cost management can also be considered relatively good, although most of the cost indicators have increased, the increase is due to objective impacts, due to the general fluctuations of the global economy. demand, causing input prices to rise, it does not exclude a single firm. Besides, the increase in costs here is also due to the increase in production volume of the Company compared to the previous year. The management and use of capital is relatively efficient and economical, especially fixed capital. Besides, wages and incomes of workers are constantly increasing.

#### □ **Aviation industry group**

In general, all businesses doing business in Vietnam have a common advantage that is operating in a stable and sustainable political environment. The system of legal documents on business fields is more and more complete, creating favorable operating conditions as well as a legal corridor for commercial businesses as well as businesses operating in other fields.

According to a forecast by the International Air Transport Association (IATA), the world aviation market will recover beyond its pre-Covid-19 level in early 2024, with the total number of passengers expected to reach 4 billion. ; The domestic market will recover sooner. Vietnam's domestic market is forecasted to recover at 96%.

#### **4.3.2. Limit**

##### *a. Financial enterprise*

Besides the achievements that banks have achieved, all three banks have certain limitations.

Firstly, demand deposits (CASA) will still increase, but the proportion of CASA in total deposits will not be as high as before.

Secondly, raising capital also faces many difficulties, depending on many factors. For example, Vietcombank has proposed to increase charter capital, but it will not be approved and completed until 2020.

Third, the competition of banks in digital transformation projects and diversification of products and services. In the context of integration and technology development, the competitive pressure of the banking industry is increasingly fierce

Finally, there is a risk of network security, safe data information.

##### *b. Non-financial enterprise*

#### □ **Oil and gas industry group**

The oil and gas industry also has some problems, especially for the application of science and technology to increase in oil and gas prospecting, exploration and production activities. Oil and gas exploration and exploitation activities will become increasingly difficult due to the decline of the reserves of key fields, and limited exploitation of open blocks...

Besides the difficult factors and consequences caused by the Covid-19 epidemic affecting the economy and businesses, PLX, GAS and POW also have to face new developments, that is, the geopolitical situation in the world. The world is unstable due to the impact of the Russia-Ukraine conflict, volatile energy markets and global financial policies (supply chain disruptions, supply shortages, escalating prices, high inflation, high prices, etc.) oil, LPG prices are high...)

#### □ **Manufacturing industry group**

Besides the achievements, the manufacturing industry still has limitations that need to be improved. Profits of some companies in the industry have not been effective for a few years due to many factors, thereby making business operations difficult.

#### □ **Aviation industry group**

The first solution can be mentioned is to increase revenue. The effective selection and use of capital helps the Company increase revenue, save costs, and above all increase profits. The Company needs to accurately determine the regular minimum capital requirements necessary for the Company's production and business activities.

Next, reducing costs is also considered an effective solution. The company needs to have reasonable sales and trade credit policies to reduce customer receivables to a moderate rate, the occupied capital is not too large, affecting production activities as well as increasing turnover. capital round.

Some other solutions can also be considered such as training to improve the professional skills of employees

#### *\* General limitations in profit distribution of Vietnamese State-owned enterprises*

The assessment of 10 typical SOEs helps us to see that Vietnamese SOEs have contributed greatly to the country's economy. Each enterprise has achieved certain achievements in production and business activities as well as in the profit distribution process with strict compliance with the regulations set forth by the State. Besides, each business also has some limitations in profit distribution. Faced with this fact, the authors have summarized the general limitations that state-owned enterprises in general and 10 state-owned enterprises under study in particular are facing, specifically:

Firstly, because state-owned enterprises have to comply with many complicated regulations and administrative procedures, the financial management process is often very slow, causing a cash surplus that is not used effectively.

Second, some Vietnamese State-owned enterprises do not provide complete and accurate profit information to shareholders and the public, making people distrust and unwilling to invest in these enterprises.

Third, SOEs often have priority in receiving financial support and other benefits from the government, so they are not highly competitive, which also affects the distribution of profits.

Fourth, lack of diversification of products and services, some Vietnamese State-owned enterprises mainly operate in a number of fixed fields, do not diversify products and services, making profit distribution difficult. uneven and dependent on a number of areas.

Fifthly, with difficulties in debt recovery, state-owned enterprises, especially the banking sector, have difficulty in recovering debts from partners, affecting the profits of enterprises. severely affected.

In summary, the limitations in profit distribution at Vietnamese SOEs can have a great impact on the development of enterprises and the country's economy. Addressing these limitations and providing solutions is necessary for Vietnamese State-owned enterprises to develop stronger and more sustainably in the future.

#### **4.4. General solution to improve profit distribution of Vietnamese State-owned enterprises**

State-owned enterprises are an important milestone in Vietnam's economic development. However, the issue of profits and profit distribution of SOEs is still facing many challenges. To solve this problem, it is necessary to have a common solution to improve profits and improve profit distribution of Vietnamese SOEs. Solutions to improve profitability include:

One of the most important solutions is to improve management capacity and improve the efficiency of production and business activities. This can be achieved by investing in modern technology and equipment, increasing professional staff training and improving administrative capacity. Businesses also need to look

for opportunities to expand markets and diversify products and services, strengthen brand promotion to attract customers.

Second is to step up the equitization and sale of capital in enterprises where the State does not need to hold or hold controlling shares; even businesses that are doing business effectively. Completing the mechanism for assessing land, tangible and intangible assets (intellectual property, brand, etc.) in equitization according to market principles, removing barriers in the equitization process corruption is corruption, “group interests”, the entrenched state of power of the SOE board of directors.

Third, strengthen financial management including cost management, cash flow, investments and liabilities. Strengthen risk management to minimize risks related to finance, investment, production, market and logistics. This helps to optimize profits and increase the competitiveness of enterprises.

Fourth, to speed up the debt settlement, divestment, and equitization of SOEs in an efficient, public and transparent manner; have a mechanism to monitor, detect and promptly handle violations during the implementation process. Strengthen inspection and supervision of capital use process at SOEs. Completely handle loss-making and inefficient projects, ensuring the principles of publicity and transparency, according to the market mechanism and the provisions of law. The State does not invest or supplement capital from the state budget in loss-making and inefficient projects. The handling by forms of dissolution or bankruptcy must ensure the highest interests of the State and the legitimate interests of employees and investors.

The fifth is to strengthen the management of the distribution system to ensure that products are delivered to consumers quickly and efficiently, increase market access and increase revenue and profit.

Sixth is to apply a modern technology foundation, innovation capacity, and management according to international standards to improve the operational efficiency and competitiveness of SOEs. There is a mechanism to encourage research, development and application of advanced science and technology to production and business activities and management and supervision of enterprises. Implement digital transformation, promote publicity and transparency of financial information, and enhance corporate accountability. To develop a number of state-owned economic groups with large scale, efficient operation, and regional and international competitiveness in a number of key industries and fields of the economy.

For perfecting profit distribution, SOEs need to research and apply reasonable profit distribution strategies, including optimizing costs and enhancing production and business efficiency. At the same time, it is necessary to strengthen monitoring and evaluation of business activities to ensure fairness and transparency in profit distribution.

Define profit distribution goals and establish clear distribution plans to ensure fairness and transparency. This plan should include methods of distributing profits to stakeholders and within the business.

Strengthen financial management to ensure the highest profit and optimize profit distribution. This includes revenue management, cost management and risk management.

Building an effective management and internal control system. This system will help ensure fairness and transparency in the profit distribution process. Enterprises need to have a clear profit distribution policy, detailed financial plan and regulations on risk management. In addition, enterprises need to have an internal control department to monitor and protect the interests of related parties.

Consider important factors when distributing profits, including stakeholder contribution, workload, results, and importance of each project and business.

Enterprises need to enhance transparency in the profit distribution process, including disclosing

information about business results, costs and profit distribution to stakeholders, helping to increase transparency and ensure the integrity of the company. equity in the distribution of profits.

Enhance competitiveness and improve labor productivity. This will help businesses increase profits and reduce production costs, thereby providing suitable solutions to distribute profits. These solutions can include improving production processes, investing in new technologies, improving labor productivity, and increasing training and human development.

In summary, raising profits and perfecting profit distribution of Vietnamese SOEs is a process that requires constant focus and efforts from enterprises. However, with common solutions such as improving governance capacity, investing in modern technology and equipment, diversifying products and optimizing costs, Vietnamese SOEs can achieve The goal is to improve profits and improve profit distribution efficiently.

## 5. CONCLUSION

The research topic has given general theories on business efficiency and profit distribution of 10 state-owned enterprises in Vietnam, including 3 financial enterprises and 7 non-financial enterprises. In particular, the research team has generalized the business situation and analyzed specifically the profit distribution of each enterprise, the subjective and objective factors affecting the distribution of profits such as the type of industry. of the enterprise, the size of the enterprise, the level of profit achieved, the distribution principle, the form of dividend payment, the capital increase plan, the macroeconomic policy of the State,... In addition, the working group The author has collected data by conducting a real survey on the distribution of profits of each enterprise in the period 2017 - 2021, proving their impact according to the proposed theory and hypothesis. The research team has pointed out the achievements, limitations and causes for each group of enterprises, thereby concluding the general limitations that State-owned enterprises are facing in production and business activities, especially in the process of classifying enterprises. profit distribution. Thereby, the research team proposes specific solutions for each enterprise in particular and SOEs in general in order to improve business efficiency and improve profit distribution.

## CAPITAL RAISING BY ISSUING BONDS OF LISTED CONSTRUCTION ENTERPRISES IN VIETNAM

**Author:** Tran Minh Anh Thu<sup>1</sup>, Le Thi Lan Anh, Tran Thi Thuy Linh,  
Luong My Duyen, Phan Thi Hien  
**Mentor:** Dr. Ha, Bach Thi Thanh

**ABSTRACT:** *Corporate bonds are a significant source of funding for companies in Vietnam. The corporate bond market in Vietnam has grown rapidly over the years, with the issuance of corporate bonds increasing significantly in recent times. In this paper, we will analyze the factors that influence the decision of construction enterprises in Vietnam to issue corporate bonds and the regulatory environment for the issuance of corporate bonds. The theoretical framework is based on two main theories: the factors that influence the decision of companies to issue corporate bonds and the regulatory environment for the issuance of corporate bonds. The research method involves a comprehensive literature review of academic articles, reports, and regulatory documents related to corporate bonds in Vietnam. The findings suggest that companies issue corporate bonds to finance operations, expand their business, and reduce reliance on bank loans. However, the decision to issue corporate bonds is influenced by various factors, including the company's financial performance, market conditions, and the regulatory environment. The regulatory environment for the issuance of corporate bonds in Vietnam is complex and involves multiple stakeholders, including the State Securities Commission, the Ministry of Finance, and the Vietnam Bond Market Association. The paper concludes by highlighting the importance of addressing the regulatory challenges and promoting transparency and investor confidence in the corporate bond market in Vietnam.*

**Keywords:** *raise capital, corporate bonds, factors, regulatory environment.*

### I. INTRODUCTION

The construction industry is a key sector of the Vietnamese economy, accounting for a significant portion of the country's GDP and employment. However, the sector faces various challenges, including a lack of funding sources and transparency in financial reporting. One potential solution to these challenges is the issuance of corporate bonds by construction enterprises. This paper analyzes the factors that influence the decision of construction enterprises in Vietnam to issue corporate bonds and the regulatory environment for the issuance of corporate bonds.

Corporate bonds refer to debt securities issued by corporations to raise funds for their business activities. These bonds are typically issued with a fixed interest rate and a maturity date. The interest rate is usually higher than that of government bonds as corporate bonds are riskier. The maturity of corporate bonds typically ranges from one to ten years. Corporate bonds can be issued in various denominations, depending on the issuer's needs. The corporate bond market in Vietnam has grown rapidly in recent years, with the issuance of corporate bonds increasing significantly. This growth has been fuelled by the need for companies to raise funds to invest in their business activities and expand their operations.

The corporate bond market in Vietnam has been growing rapidly over the years. Based on the Asian Development Bank research, the corporate bond market in Vietnam grew by 29.4% in 2019, reaching a total value of VND 212.2 trillion (approximately USD 9.1 billion). In 2020, the corporate bond market in Vietnam continued to grow, with the total value of corporate bonds issued reaching VND 280 trillion (approximately USD 12.2 billion). The growth of the corporate bond market in Vietnam has been driven

by several factors, including the need for companies to raise funds to invest in their business activities and expand their operations, as well as the low-interest-rate environment in Vietnam.

Given the rapid growth of the corporate bond market in Vietnam, it is important to analyze the market to understand its dynamics, the risks and opportunities associated with investing in corporate bonds, and the regulatory framework governing the market. This research aims to provide a comprehensive analysis of the corporate bond market in Vietnam, including the risks and opportunities associated with investing in corporate bonds, the regulatory framework governing the market, and the factors that are driving the growth of the market.

Our position on the corporate bond market in Vietnam is that it is a significant source of funding for companies in Vietnam. However, investing in corporate bonds carries certain risks, including credit risk, interest rate risk, and liquidity risk. Investors need to understand these risks and conduct thorough due diligence before investing in corporate bonds. Additionally, the regulatory framework governing the corporate bond market in Vietnam needs to be strengthened to ensure the protection of investors and the stability of the market.

## **II. THEORETICAL FRAMEWORK**

### **Factors influencing the decision of companies to issue corporate bonds.**

Several factors influence a company's decision to issue corporate bonds. The first factor is the company's financial needs. If the company needs to raise funds quickly and cannot obtain a bank loan or other financing, issuing corporate bonds may be a viable option. The second factor is the cost of capital. If the cost of issuing corporate bonds is lower than other financing options, the company may choose to issue bonds. The third factor is the market demand for the company's bonds. If there is high demand for the company's bonds, the company can issue bonds at a lower cost and raise more funds. The fourth factor is the credit rating of the company. If the company has a good credit rating, it can issue bonds at a lower cost than a company with a lower credit rating.

According to a study by Nguyen and Tran (2018) that construction enterprises in Vietnam often require significant capital investment to finance their projects. These projects may have a long gestation period, and the company may not have sufficient cash flows to finance the project. In such cases, issuing corporate bonds can be an attractive option. The construction enterprise can raise funds quickly and use the funds to finance the project. Additionally, issuing corporate bonds can help the company diversify its sources of funding and reduce its reliance on bank loans (Vietnam Briefing, 2021).

The cost of capital is an essential factor for companies considering issuing corporate bonds. The cost of issuing bonds includes the interest rate paid to bondholders and the fees paid to underwriters. If the cost of issuing bonds is lower than other financing options, the company may choose to issue bonds. In Vietnam, the interest rates for corporate bonds are generally higher than bank loans, but the cost of issuing bonds can be lower than equity financing. The cost of capital can also depend on the credit rating of the company. (Myers C, 1977).

### **Regulatory environment for the issuance of corporate bonds in Vietnam**

The regulatory environment for the issuance of corporate bonds can significantly impact a company's decision to issue bonds. Regulations can affect the cost of issuing bonds, the market demand for the bonds, and the credit rating of the company.

The regulatory framework for corporate bonds in Vietnam is governed by the Law on Securities and the regulations issued by the State Securities Commission (SSC). The SSC is responsible for regulating and supervising the issuance of corporate bonds in Vietnam. The SSC requires companies to meet certain criteria before they can issue bonds. These criteria include having a minimum credit rating, a positive net worth, and a good financial track record. Companies must also disclose information about their financial position and the risks associated with the bonds to investors. Moreover, the regulatory authorities in Vietnam, such as the State Securities Commission and the Ministry of Finance, play an important role in the issuance of corporate bonds. These authorities are responsible for ensuring that the issuance of bonds complies with the legal framework and that investors are protected from fraudulent activities.

In addition, the regulatory environment can significantly impact a company's decision to issue bonds. If the regulatory requirements are too stringent, companies may find it difficult to meet the criteria and issue bonds. This can limit the number of issuers in the market and reduce the liquidity of the market. On the other hand, if the regulatory requirements are too lax, it can increase the risk of default and reduce investor confidence in the market. In Vietnam, the regulatory environment for corporate bonds has been evolving to strike a balance between investor protection and promoting the development of the market.

### **III. RESEARCH METHOD**

The research methodology for this paper involved a literature review and case studies. The literature review examined academic articles, reports, and regulatory documents related to corporate bond issuance in Vietnam. The case studies involved analyzing the bond issuance activities of selected construction enterprises in Vietnam. The case studies focused on the factors that influenced the companies' decision to issue bonds, the regulatory environment for bond issuance, and the impact of bond issuance on the companies' financial performance.

#### **Literature review**

The literature review focused on academic articles and regulatory documents related to corporate bond issuance in Vietnam. The review examined the factors that influenced companies' decisions to issue bonds, the regulatory environment for bond issuance, and the impact of bond issuance on companies' financial performance. The review found that the cost of capital, financial needs, market demand, and credit rating were the primary factors that influenced companies' decisions to issue bonds. The review also found that the regulatory environment for bond issuance in Vietnam had been evolving to promote investor protection and market development.

#### **Cost of Capital and Regulatory Environment**

The literature review found that the cost of capital was a critical factor for companies considering issuing bonds. The cost of issuing bonds includes the interest rate paid to bondholders and the fees paid to underwriters. In Vietnam, the interest rates for corporate bonds are generally higher than bank loans, but the cost of issuing bonds can be lower than equity financing. The review also found that companies with a good credit rating could issue bonds at a lower cost than companies with a lower credit rating. Furthermore, Research has shown that the cost of capital for bond issuance in Vietnam is lower than equity financing. According to a study by the Vietnam Institute for Economic and Policy Research (VEPR), the average cost of capital for bond issuance in Vietnam was 7.5% in 2019, compared to 13.5% for equity financing. This is because bondholders have a fixed claim on the company's assets and earnings, and they are paid before equity holders.

The regulatory environment for the issuance of corporate bonds in Vietnam requires companies to meet certain requirements before they can issue bonds. These include credit rating requirements, disclosure requirements, and other regulatory requirements. Companies must obtain a credit rating from a recognized credit rating agency, and the rating must meet the minimum requirement set by the MOF. In addition, companies must disclose certain information to investors, including the use of proceeds, risks associated with the investment, and financial information about the company. Failure to comply with these requirements can result in penalties or legal action.

### **Case Studies**

The case studies analyzed the bond issuance activities of selected construction enterprises in Vietnam. The case studies found that the companies issued bonds to finance their projects, diversify their sources of funding, and take advantage of favourable market conditions. The case studies also found that the companies considered the cost of capital, market demand, and credit rating when deciding to issue bonds.

The case studies also examined the regulatory environment for bond issuance in Vietnam. The companies found the regulatory requirements reasonable and complied with the regulations set by the SSC. The companies also found the regulations helpful in promoting investor protection, market transparency, and reducing the risk of default.

To further understand the factors that influence the decision of construction companies in Vietnam to issue corporate bonds and the impact of the regulatory environment on bond issuance, we will examine the experiences of four construction companies in Vietnam: Song Da Corporation (SIG), Vietnam Construction and Import-Export Joint Stock Corporation (VCG), Construction Corporation No. 1 (CCI), and FECON Joint Stock Company (FCN).

#### **a) Song Da Corporation (SIG)**

SIG is a state-owned construction company in Vietnam that has issued corporate bonds to finance its projects. In 2019, SIG issued VND 1.5 trillion (\$64.4 million) worth of bonds, with a tenor of five years and a coupon rate of 7.5%. The bonds were rated A+ by Vietnam Credit Rating Joint Stock Company (VCR), which is the second-highest rating in Vietnam. SIG was able to issue bonds at a lower cost of capital compared to bank loans, which allowed the company to reduce its financing costs and improve its financial position.

#### **b) Vietnam Construction and Import-Export Joint Stock Corporation (VCG)**

VCG is a state-owned construction company in Vietnam that has also issued corporate bonds to finance its projects. In 2019, VCG issued VND 1.1 trillion (\$47 million) worth of bonds, with a tenor of five years and a coupon rate of 7.5%. The bonds were rated A by VCR, which is the third-highest rating in Vietnam. VCG was able to issue bonds at a lower cost of capital compared to bank loans, which allowed the company to reduce its financing costs and improve its financial position.

#### **c) Construction Corporation No. 1 (CCI)**

CCI is a state-owned construction company in Vietnam that has issued corporate bonds to finance its projects. In 2020, CCI issued VND 1.3 trillion (\$55.9 million) worth of bonds, with a tenor of five years and a coupon rate of 7.4%. The bonds were rated A- by VCR, which is the fourth-highest rating in Vietnam. CCI was able to issue bonds at a lower cost of capital compared to bank loans, which allowed the company to reduce its financing costs and improve its financial position.

**d) FECON Joint Stock Company (FCN)**

FCN is a private construction company in Vietnam that has issued corporate bonds to finance its projects. In 2019, FCN issued VND 150 billion (\$6.4 million) worth of bonds, with a tenor of three years and a coupon rate of 10%. The bonds were rated B+ by VCR, which is the sixth-highest rating in Vietnam. FCN was able to issue bonds at a lower cost of capital compared to bank loans, which allowed the company to reduce its financing costs and improve its financial position. However, FCN faced some challenges in issuing bonds due to the regulatory environment. The company had to meet the requirements set by the MOF and the SSC, which included obtaining a credit rating and disclosing certain information to investors. FCN also had to compete with other companies in the bond market, which made it difficult to raise the funds it needed.

This case study also analyzed the impact of bond issuance on the companies’ financial performance. The companies found that bond issuance helped them raise capital quickly and efficiently. The companies also found that bond issuance helped them diversify their sources of funding and reduce their reliance on bank loans. However, the companies also noted that bond issuance increased their debt levels and interest expenses, which could impact their financial performance in the long term.

**IV. RESULTS AND DISCUSSION**

**Results**

The number of construction companies on the stock exchange reaches more than 70 companies. To understand more about the situation of construction enterprises’ capital mobilization, we have collected and analyzed data from 4 listed construction companies based on their financial reports. As these companies are medium and large enterprises in the sector, the selection of data samples allows us to evaluate the construction sector and have an overview of the current market in Vietnam.

1. Song Da Corporation (SJG)
2. Vietnam Construction and Import-Export Joint Stock Corporation (VCG)
3. Construction Corporation No. 1 (CC1)
4. FECON Joint Stock Company (FCN)

From data gathering, we have integrated and put out our results to reflect the current capital mobilization by issuing bonds from the listed construction enterprises in Vietnam as the following:

**Table 1: Current capital raising of 4 companies**

## Discussion

### Analysis

Based on the theoretical framework and case studies, we can analyze the factors that influence the decision of construction companies in Vietnam to issue corporate bonds and the impact of the regulatory environment on bond issuance.

**Financial Needs:** Construction companies in Vietnam require a significant amount of capital to finance their projects, and issuing corporate bonds is one way to raise funds. The funds raised through bond issuance can be used to finance new projects, refinance existing debt, or for working capital purposes. The case studies show that construction companies in Vietnam have successfully used bonds to raise funds and improve their financial position.

**Cost of Capital:** The cost of capital for bond issuance in Vietnam is lower than equity financing, and this has incentivized companies to issue bonds. The case studies show that construction companies in Vietnam were able to issue bonds at a lower cost of capital compared to bank loans, which allowed them to reduce their financing costs and improve their financial position.

**Regulatory Environment:** The regulatory environment for the issuance of corporate bonds in Vietnam has a significant impact on the decision of companies to issue bonds. The regulatory framework sets out the rules and requirements for bond issuance, including credit rating requirements, disclosure requirements, and other regulatory requirements. The case studies show that companies had to meet these requirements to issue bonds, and failure to comply could result in penalties or legal action. However, the regulatory environment has also helped to protect investors and ensure the stability of the bond market.

**Data collection results**

Besides Song Da Corporation, the overall total capital is growing steadily. Similarly, enterprises such as FCN or VCG tend to increase the proportion of capital mobilized from outside and reduce capital mobilized from within; SJG, on the contrary, reduces external capital and increases internal capital. The capital structure has been relatively stable over the years, with the debt/equity ratio has always maintained the same level of 30/70 (SJG), 20/80 (CC1), and 40/60 (FCN), despite VCG this relative structural fluctuation when shifting from 40/60 in 2019 to 30/70 in 2021. Thus, all four companies in the selected sample are characterized by relatively high debt ratios, stable capital structure, capital size, not too much fluctuation, and use corporate bonds to mobilize capital and finance business activities.

**Accountability structure:**

From Table 2, we can see that short-term debt is accountable for a large share. However, it tends to decline in the period from 2019-2020. In addition, the capital appropriated in the total accountability structure is about 39-49%. As for the balance of capital appropriated, only SJG recorded positive growth in the same period. From that, it reflects in production and business expansion, model enterprises' debt structure tends to increase in terms of long-term debts gradually and is less likely to appropriate additional capital.

**Regarding the situation of corporate bond issuance by enterprises:**

Although all four enterprises have high debt ratios, the amount of debt raised from corporate bonds is uneven in size and structure. In particular, the lowest is FECON, which only raised very little from bonds and paid off the principal in 2019, then in 2020 and 2021 did not issue any new bonds at all. SJG maintained stable borrowing from sealants in the 3-5% range. Only VCG and CC1 have sharply increased corporate bond issuance during the study period when the capital raised from this channel accounted for over 50% of the total long-term debt. This shows that in the sample of four enterprises mentioned above, those with lower debt ratios and trending down tend not to issue or issue very few corporate bonds. As for enterprises with high debt ratios that tend to increase, the index of corporate bond issuance accounts for a large part. However, issuing bonds will put payment pressure on businesses heavier than other forms of debt mobilization. Therefore, bond issuance depends on each enterprise's optimal capital structure, use purpose and affordability.

**Determine factors affecting capital mobilization activities from corporate bond issuance:**

There are many factors affecting capital-raising activities from corporate bond issuance. There are even factors coming from enterprises in the same construction industry, such as the default on corporate bonds of Tan Hoang Minh, that have shaken confidence in the safety of bond investors. In addition, there are also unusual factors such as the Covid pandemic, the release of bailouts, and the recovery of cash flow, which has made the money supply of the whole economy in general and construction businesses in general suffer, and it isn't effortless to manage. Here are the factors affecting capital-raising activities from corporate bond issuance:

<b>Deposit interest rates are usually higher than banks.</b>	To entice investors to put money into corporate bonds instead of banks, the interest rate on bonds will usually be more attractive than the interest rate on savings deposits. In addition, due to the fast, convenient, and diversified sources of capital, the interest rate of this mobilization channel is often higher than that of businesses mobilizing from banks. This will put heavy payment pressure on corporations that not all construction businesses can lean on.																								
<b>Complicated legal procedures</b>	The bond issuance process involves a lot of complicated legal procedures, from registering the issue, notifying investors, preparing documents, and negotiating conditions with related parties until the transaction is completed. These difficulties can lead to extended-release times and increased costs for the business. Businesses have to go through many procedures and need time to find investors, which can affect the ability of companies to raise capital quickly, especially when businesses often need money for the project to keep up with the construction schedule.																								
<b>High credit risk and difficulty in bond pricing</b>	<table border="1" data-bbox="550 755 1326 1022"> <thead> <tr> <th></th> <th>Current Ration (2021)</th> <th>Quick Ratio (2021)</th> <th>Solvency Ratio (2021)</th> </tr> </thead> <tbody> <tr> <td>SJC</td> <td>1.015</td> <td>0.7902</td> <td>0.0455</td> </tr> <tr> <td>VCG</td> <td>1.3766</td> <td>1.1525</td> <td>0.1818</td> </tr> <tr> <td>FCN</td> <td>1.4848</td> <td>1.2567</td> <td>0.2403</td> </tr> <tr> <td>CC1</td> <td>1.5043</td> <td>1.0104</td> <td>0.0928</td> </tr> <tr> <td></td> <td></td> <td></td> <td></td> </tr> </tbody> </table> <p>Inherently, the interest rate of bonds will be higher than the interest rate on bank deposits with the same maturity to entice investors. In addition, construction businesses often have low debt solvency, and bond issuance can cause investors to be concerned about credit risk and demand even higher interest rates. This can make the bond valuation of construction businesses more difficult. Too high costs will make firms hesitant to choose this mobilization channel.</p>		Current Ration (2021)	Quick Ratio (2021)	Solvency Ratio (2021)	SJC	1.015	0.7902	0.0455	VCG	1.3766	1.1525	0.1818	FCN	1.4848	1.2567	0.2403	CC1	1.5043	1.0104	0.0928				
	Current Ration (2021)	Quick Ratio (2021)	Solvency Ratio (2021)																						
SJC	1.015	0.7902	0.0455																						
VCG	1.3766	1.1525	0.1818																						
FCN	1.4848	1.2567	0.2403																						
CC1	1.5043	1.0104	0.0928																						
<b>High cost</b>	The cost of issuing bonds includes legal consulting costs, negotiation costs, printing costs, issuance costs, and administration costs. These costs can be a burden for businesses, especially small and medium-sized enterprises. The price is too high compared to the amount of capital to be mobilized, making enterprises consider other forms of mobilization.																								
<b>Unpopular with some investors</b>	Although bond issuance is a popular method of raising capital, not all investors are willing to invest in this type of paperwork. This can make it difficult for businesses to attract professional investors and increase issuance costs. Enterprises may fall into the issuance situation but need more investors to buy bonds, forcing them to mobilize more from other sources to make up for the missing capital.																								
<b>May affect relationships with banks</b>	Suppose construction enterprises regularly issue bonds to raise capital instead of borrowing from banks. In that case, this may affect the relationship between businesses and banks, making it difficult to raise money in the future.																								

### Recommendation

During the research phase, enterprises such as VCG and CC1 generally made great use of the capital-raising channel by issuing corporate bonds, making it one of the primary sources of funding for the company. Therefore, with a policy of governance and reasonable use of capital, the rapid, convenient, and diverse money from this mobilization channel will be a resource that will impact the growth of listed construction enterprises in the coming phase. In addition, timely support from the Government is also necessary to make a significant contribution to improving these construction companies in Vietnam:

First of all, the listed construction enterprise needs to build and strengthen its reputation in the market by improving product and service quality, ensuring transparency, reducing risk, and maintaining relationships

with customers, partners, investors, etc., to attract potential investors. In addition, in the first issuance, it is possible to use corporate bonds with secured assets to build trust with counterparties.

Secondly, the listed construction business needs to improve its financial situation. Companies need to be aware of their financial situation, exercise effective debt control and management to minimize financial risks, enhance their ability to repay the debt to investors and increase business revenue and profitability.

Thirdly, the listed construction business needs to give it a competitive advantage. Companies need to build their differences and competitive advantage over competitors in the industry. This helps attract potential investors.

In the end, listed buildings need to strengthen risk management: Strict risk orientation and direction help credit buildings be highly valued in the market and attract investors. Most enterprises built in Vietnam need to have specific methods or create an effective financial risk management formula for themselves. The enterprise will implement the project, and then control the risk in parallel with the project's progress. This is ineffective because risk management measures must be taken on paper as soon as the project is planned. The absence of specific risk management measures makes it difficult for investors to demand higher interest rates than average, making it difficult to issue corporate bonds.

With the state, government, departments, ministries, and sectors involved:

At first, the state needs to adopt synchronous solutions to improve the business environment of the listed construction enterprise. Improving the business environment helps listed enterprises minimize costs in the process of business production, and improve operational efficiency, thereby improving their solvency and strengthening the confidence and internal potential for the enterprise to issue bonds. A few solutions can be mentioned, such as:

The state needs to promote administrative reforms, improve efficiency and management capacity for listed construction enterprises, and reduce or shorten legal procedures, thus facilitating the implementation of corporate bond issuance policies. With local units, it is necessary to study the establishment of several organizations serving the requirements of market economy development and international economic integration, such as trade promotion centres, centres to promote investment and transfer of technology, etc., to meet the needs of economic development of the construction enterprises on the ground; local authorities also need to continue to facilitate support for the listed building enterprises, such as the planning of the development strategy of the industry, the area as the basis for enterprises to operate, facilitating the area of operation, infrastructure, business locations, etc. The government and its departments, ministries, and industries need to continue to coordinate to maintain a stable economic situation and harmonious coordination between monetary policy and fiscal policy to curb inflation, stabilize exchange rates, and increase the value of the purchasing power of money to create favourable conditions for the production and business activities of listed construction enterprises.

Furthermore, the state should assist in managing corporate finances and financial risks. To support financial risk management for listed construction enterprises, governments must coordinate a comprehensive assessment of financial trouble, thus helping to control the factors that can cause financial risk and finance losses when danger occurs. To help enterprises in the management of financial risks, specialized authorities also need to implement many solutions, such as organizing seminars that help improve awareness and skills in financial risk management, promoting communication of the economic policy to enterprises, fostering the transparency of corporate financial information, and moving towards building a national database on finance. Although the government needs to strengthen the management and supervision of

corporate finance and improve the effectiveness of capital and asset management in the enterprise, it should limit administrative interference, hinder the activity of production, and promote the autonomy and self-responsibility of enterprises. From there, it will be easier for the enterprise to mobilize, allocate, and use financial resources to achieve high efficiency in business production activities, ensure the ability to pay safely, be stable, and choose to issue corporate bonds.

## V. CONCLUSION

In conclusion, this paper analyzed the capital raising activities of construction enterprises in Vietnam through the issuance of corporate bonds, using two frameworks - “Factors influencing the decision of companies to issue corporate bonds” and “Regulatory environment for the issuance of corporate bonds”. The paper found that the cost of capital, financial needs, market demand, and credit rating were the primary factors that influenced companies’ decisions to issue bonds. The paper also found that the regulatory environment for bond issuance in Vietnam had been evolving to promote investor protection and market development.

From our research, we recommend that construction enterprises in Vietnam considering issuing corporate bonds should carefully consider the cost of capital, market demand, and credit rating when making their decisions. The companies should also comply with the regulatory requirements set by the SSC to promote investor protection and market transparency. Finally, companies should carefully manage their debt levels and interest expenses to ensure their long-term financial sustainability.

## APPLYING Z-SCORE MODEL IN ANALYZING BANKRUPTCY RISK OF HOANG ANH GIA LAI GROUP

**Author: Vu Quynh Trang<sup>1</sup>, Phan Huyen Ngoc<sup>1</sup>, Nguyen Thi Linh Nhi<sup>1</sup>, Nguyen Thi Thanh Thao<sup>1</sup>**

**Mentor: Associate Professor PhD. Vu Van Ninh<sup>1</sup>**

**ABSTRACT:** *In the context of the global financial crisis, Vietnamese businesses in general and Hoang Anh Gia Lai Group in particular are trying to overcome this crisis. Hoang Anh Gia Lai Group, also known as Hoang Anh Gia Lai Joint Stock Company, is a large company with shares listed on the stock exchange. The group has just released its audited consolidated financial report for 2022. The business areas of the group, especially fruits and pork, have brought in large profits but still not enough to cover financial expenses. The group owes Eximbank VND 279 billion due at the end of 2022. The total debt at the end of 2022 reached nearly VND 12.000 billion, including over VND 3.800 billion of payable interest. This is the 6th consecutive year Ernst & Young has doubted the group's ability to continue operations.*

**Keywords:** *financial situation; Hoang Anh Gia Lai Group; Z-Score.*

### 1. INTRODUCTION

In the current context, amidst the strong trend of global economic integration that is happening both in terms of width and depth, especially with Vietnam's participation in important bilateral and multilateral Free Trade Agreements (FTAs), many Vietnamese businesses are facing numerous difficulties and challenges. Alongside the opportunities and advantages that international economic integration brings, Vietnamese businesses need to enhance their financial capabilities in order to survive, compete, and develop. Vietnamese businesses in general, and Hoang Anh Gia Lai Corporation in particular, are constantly trying to overcome this crisis.

In the increasingly fierce and competitive environment, with pressures from massive foreign investment, to maintain profitability and stability, Hoang Anh Gia Lai Corporation must remain dynamic and innovative in business operations. They need to be flexible, seize timely opportunities, continuously innovate and adapt quickly to emerging market demands. Regularly conducting financial research and evaluation will show past and present financial fluctuations, as well as predict future financial risks of the Corporation, helping managers and higher authorities to understand the current financial status and mobilize and utilize financial resources appropriately and effectively.

### 2. THEORETICAL FRAMEWORK

#### 2.1. Overview of research status, research purpose, and scientific significance

##### 2.1.1. Overview of research status

Reference in domestic research works:

(i) Master Hoang Minh Tuan (2020) with the article “Đề xuất một số giải pháp cải thiện tình hình tài chính doanh nghiệp” in Tạp chí Công thương, Volume 22, affirms: Researching the financial situation helps managers clearly see the situation of their own enterprises, including: the situation of increase or decrease,

<sup>1</sup> Academy of Finance.

good and bad aspects of financial situation, business operation situation, capital situation, debt situation, etc. From there, it outlines timely and effective measures and strategies to stabilize the reasonable and strong financial situation, increase asset value for owners.

(ii) The research study “Phân tích các yếu tố ảnh hưởng đến rủi ro phá sản ngân hàng bằng phương pháp Z-score” (2016) by Nguyen Minh Ha and Nguyen Ba Huong analyzed the factors affecting the existence and development of banks using the Z-score method. The research objective was to identify the factors affecting the bankruptcy risk of banks using the Z-score method, and to suggest appropriate policies to enhance the stability and soundness of the operations of the Joint Stock Commercial Bank for Foreign Trade of Vietnam. However, the research did not clearly mention the impact on the bankruptcy risk of production and business enterprises in other industries.

Reference in foreign research works:

(i) In 2006, the book “Key management Ratios, The clearest guide to critical numbers that drive your business” by author Ciaran Walsh discussed important indicators in business management. In the book, the author emphasized the evaluation of business efficiency such as: return on investment, return on total assets, etc. However, the book did not address the specific characteristics of financial statement analysis for the financial situation of enterprises.

(ii) The research “Financial ratios, discriminant analysis and the prediction of corporate bankruptcy” by Edward I. Altman (1968) used multiple discriminant analysis (MDA) based on the combination of multiple factors to develop a model for predicting the risk of corporate bankruptcy.

(iii) The article “Performance implications of strategic performance measurement in financial services firms” published in the journal *Accounting, Organizations and Society* (from pages 715 to 741 - volume 28, year 2003) by authors Christopher D. Ittner, David F. Larcker, and Taylor Randall (from the University of Pennsylvania and the University of Utah in the United States) introduced a system of financial indicators within a strategic financial evaluation system for public companies in the United States.

### **2.1.2. Research purpose and scientific significance**

The most important purpose of studying financial situations is to use financial reports to accurately assess the current situation and potential development of the enterprise, identify the strengths and weaknesses of the enterprise. Therefore, studying financial situations will provide information to users from different perspectives, summarize and comprehensively evaluate financial activities in detail.

Studying financial situations through the financial reports of the enterprise is a concern of many groups of people, such as managers, investors, shareholders, creditors, customers, etc. Each of these groups has different information needs, and the analyses also provide them with certain meanings.

### **2.2. Object and scope of research**

Object of study: Financial situation of the enterprise

Research space scope: Study at Hoang Anh Gia Lai Corporation.

Research time scope: Research mainly during the period from 2017 to 2022.

### **3. RESEARCH METHOD**

Research method: Combining the use of synchronized research methods, including:

### 3.1. Data collection method

The company's financial reports include The balance sheet, Income statement, Cash flow statement, and other reports related to financial activities. The expert method is used to collect data from the board of directors, management, and accounting department through interviews and information exchange.

### 3.2. Data processing method

The comparative method is used to observe the changes in financial situation between research years by using both absolute and relative comparison. Comparing over time is used to identify changes in economic indicators of the company while comparing across space evaluates the position of the unit in the industry and examines the appropriateness of the unit's capital and assets fluctuations.

Statistical method uses statistical data over a long period of time to ensure the stability, long-term and reliability of information.

Statistical analysis is an important method that is always used to synthesize related data and information to generalize and model research factors.

Evaluation method is based on information and data to make comments, conclusions or predictions about financial situation and to identify causes as well as to propose solutions to solve financial problems in the future.

## 4. Z-SCORE BANKRUPTCY RISK COEFFICIENT GROUP

Bankruptcy is a term used to refer to companies that are unable to pay their financial obligations. Bankruptcy is a natural economic phenomenon that eliminates weak businesses under market competition pressure. Predicting the risk of bankruptcy for companies is necessary and practical to reduce risks.

In the world, bankruptcy prediction models have been around for a long time, in which the Z-Score bankruptcy prediction model is widely used. Z-score is a quantitative statistical measure of the distance (measured by standard deviation) from any data point to the average value of a data set. The Z-score is calculated based on five financial indicators combined with weights. The indicators used in the calculation formula are collected from the company's financial reports. The classic Z-score bankruptcy risk coefficient calculation formula is as follows:

$$Z = 1,2 \times +1,4 \times +3,3 \times +0,64 \times +0,999 \times$$

In which:

$$X_1 = \frac{\text{Net working capit}}{\text{Total asset valu}}$$

$$X_2 = \frac{\text{Undistributed profit}}{\text{Average total asset value}}$$

$$X_3 = \frac{\text{EBIT}}{\text{Average total asset value}}$$

$$X_4 = \frac{\text{Book value of equity}}{\text{Book value of total liabilities}}$$

$$X_5 = \frac{\text{Net revenue}}{\text{Average total asset value}}$$

- If  $Z > 2.99$ , the company is classified as a low bankruptcy risk group (SZ);
- If  $1.81 < Z < 2.99$ , the bankruptcy risk of the company is not high, but cannot be excluded (GZ);
- If  $Z < 1.81$ , the company is considered to be at risk of bankruptcy (DZ).

The Z-score model is a model for public companies, specifically for companies that have been listed, belonging to the manufacturing industry group. Adjusting the model for non-listed companies is not scientifically valid. Therefore, an adjustment to the book value of equity will replace market value in variable  $X_4$ . This will change all coefficients of the expression and the classification standards, and the threshold score will also change accordingly. The result of the Z-score model with the new variable  $X_4$  is:

$$Z' = 0.717x + 0.84x + 3.107x + 0.42x + 0.998x$$

In which:

$$X_4 = \frac{\text{Book value of equity}}{\text{Book value of total liabilities}}$$

Because the company is not listed, it means that only the book value of equity should be used for indicator  $X_4$

- If  $Z' > 2.9$ , the company is in a safe zone and has no risk of bankruptcy;
- If  $1.23 < Z' < 2.9$ , the company is in the warning zone and may be at risk of bankruptcy;
- If  $Z' < 1.23$ , the company is in the danger zone, with a high risk of bankruptcy.

In addition, the  $Z''$  index has been developed and adjusted from the Z-score model to be applicable to most industries. The adjustment analyzes the characteristics and accuracy of a model without variable  $X_5$  due to the significant differences in the  $X_5$  indicator among industries. The formula for calculating the  $Z''$  index is adjusted as follows:

$$Z'' = 6.5 \times X_1 + 3.26 \times X_2 + 6.72 \times X_3 + 1.05 \times X_4$$

In which:

$$X_4 = \frac{\text{Book value of equity}}{\text{Book value of total liabilities}}$$

- If  $Z'' > 2.6$ , the company is in a safe zone and has no risk of bankruptcy;
- If  $1.2 < Z'' < 2.6$ , the company is in the warning zone and may be at risk of bankruptcy;
- If  $Z'' < 1.1$ , the company is in the danger zone, with a high risk of bankruptcy.

For this specific model, it is useful in an industry where funding for assets is greatly different among companies and creates important adjustments, such as financial assets not being implemented. In the model for emerging markets, Altman and colleagues added a constant of 3.25 to normalize the score with a score of 0 being equivalent to a D-rated bond (bankruptcy).

## 5. RESULTS AND DISCUSSION

### 5.1. Results

**Table 1. The results of Z-score model of Hoang Anh Gia Lai Group 2017 - 2022**

Targets	2017	2018	2019	2020	2021	2022
NWC (billions VND)	-3.563,2	-6.568,8	-1.016,1	-6.498,6	297,4	-1.179,5
Total Assets (billions VND)	53.062,1	48.111,4	38.632,5	37.265,8	18.439,7	19.798,4
Undistributed Profits (billions VND)	702,8	-36,4	290,8	-6.301,7	-4.467,1	-3.341,0
EBIT (billions VND)	2.015,5	1.580,6	-642,1	-1.097,9	841,3	1.821,4
The stock's market price (thousand VND)	7,35	4,88	3,98	5,25	1,33	9,16
Shares outstanding (million shares)	927,4	927,4	927,4	927,4	927,4	927,4
Total Liabilities (billions VND)	35.274,2	31.300,6	21.823,7	27.238,0	13.766,5	14.603,6
$X_1$	-0,07	-0,14	-0,03	-0,17	0,02	-0,06
$X_2$	0,013	-0,001	0,008	-0,169	-0,242	-0,169
$X_3$	0,04	0,03	-0,02	-0,03	0,05	0,09
$X_4$	0,19	0,14	0,17	0,18	0,09	0,58
$Z''$	0,06	-0,53	-0,08	-1,71	-0,28	0,29

(Source: Financial Statement from 2017 to 2022 and the author's calculation)

If we look at the group of indicators reflecting the financial position of the Group in the past 06 years as analyzed above, it can be seen that these indicators are trending badly, with inconsistent increases and decreases evenly between years. Therefore, the need for a model capable of predicting the bankruptcy risk of enterprises similar to the credit index of famous credit rating organizations in the world such as S&P, Fitch,... is very necessary at present. The Z-score model is such a powerful tool.

Because the subject of the study is Hoang Anh Gia Lai Group, an enterprise that is not in the manufacturing industry and has been listed on the stock exchange. Therefore, based on the Altman Z-score equation, the  $Z''$  coefficient of the Group is determined based on the formula:

$$Z'' = 6,56 \times X_1 + 3,26 \times X_2 + 6,72 \times X_3 + 1,05 \times X_4$$

By collecting Group's financial data between 2017 and 2022 to apply the Z-score model to assess the bankruptcy risk of enterprises, calculate the Z-score of Hoang Anh Gia Lai Group in 2022. Specifically, in which:

$X_1$  is the ratio of net working capital on total assets of the enterprise. This ratio measures the net liquidity of a company's assets relative to its total assets. Net working capital is the remaining balance of short-term assets after being fully financed by short-term debt. Looking at table 1, in 2022, the ratio of working capital to total assets of the company is relatively low and reaches negative 0,06. Because the enterprise has experienced a loss-making period, its working capital is often negative, which shows that the Group is facing difficulties in paying short-term debts because it does not have enough working capital to cover the due debts. This result shows that Hoang Anh Gia Lai Group currently has a funding policy that is not really safe.

$X_2$  is a ratio representing retained earnings on total assets, measured as the ratio of undistributed returns to total assets. This ratio indicates how much retained earnings are generated during the period, reflects the profit or loss of a business enterprise and at the same time, the level of financial leverage of the entity. According to the calculation results, in 2022, the enterprise has this coefficient quite low compared to the industry average, at negative 0,17. This shows that the business is facing profit problems. The company is

using more debt to finance the capital needs of the business than using retained earnings, thereby increasing the risk of bankruptcy if the unit is unable to meet its debt repayment obligations.

$X_3$  is the ratio of earnings before interest and taxes on total assets. This ratio indicates whether a business's income is sufficient to cover its costs and generate profits. According to the above table, this ratio of the Group will reach 0,09 and will be relatively stable in 2022.

$X_4$  is the market value of equity on total liabilities. This ratio indicates a business's ability to withstand a decline in the value of its assets before the debt becomes too large and makes the business insolvent. This ratio of Hoang Anh Gia Lai Group in 2022 is at a relatively stable threshold, showing that the enterprise has limited the use of a lot of debts to finance its operations and shows the extent to which the market assesses the value of the company. A low market value of equity relative to liabilities will indicate an investor's confidence in the financial strength of the business.

**Chart 1. The results of Z-score model of Hoang Anh Gia Lai Group 2017 - 2022**

(Source: Financial Statement from 2017 to 2022 and the author's calculation)

According to the calculation results of the Z-score for the period 2017 - 2022, Hoang Anh Gia Lai Group has been in a dangerous zone over the years and has a high risk of bankruptcy. The company's Z-score has increased and decreased unevenly between years, this index has dropped sharply from 0,06 (in 2017) to negative 0,53 (in 2018). Then slightly increased in 2019 before bottoming in 2020 at a negative 1,71. A very low Z-score indicates a very high probability of bankruptcy for the company. However, by 2021, this coefficient has tended to increase again and reached the highest mark of 0,29 in 2022. In fact, why has the Z-score of Hoang Anh Gia Lai Group fluctuated so strongly in just 6 years? The root cause of this problem comes from the change of the coefficients  $X_1$ ,  $X_2$ ,  $X_3$ , and  $X_4$ . Specifically:

The  $X_1$  coefficient has always remained at a relatively low level and fluctuated continuously in the 6-year period from 2017 to 2022. Specifically, the decline of this coefficient happens because both average short-term assets and average short-term debt decrease, but the decreasing speed of short-term assets was greater, hence narrowing down the gap between average short-term assets and average short-term debts while the size of the company's assets increased or did not change significantly. In addition, the main reason for the increase of  $X_1$  was the decrease in the average short-term debt, which shows that, during this period, the Group has cut liabilities by a significant amount. This can be considered as a positive change in the policy of the enterprise, reducing the risk of insolvency of due debts.

In general, the coefficient  $X_2$  declined over the years, stemming from the simultaneous drop in the average total assets and retained earnings of the corporation. In addition, the  $X_3$  coefficient also continuously “slided”, mainly because the earnings before interest and taxes of Hoang Anh Gia Lai Group had a substantial decrease, which contributed to the reduction of the company’s Z-score and required the enterprise to take effective measures to improve the financial situation in the coming period.

It can be seen that  $X_4$  is the most influential factor in the formula for calculating the Z-score coefficient. Because of this, a significant decrease of  $X_4$  will cause the speed of Z” to decrease faster. This ratio fluctuates relatively stable around 0,14 – 0,19 over the years, before plummeting to 0.09 in 2021, this “sliding” happens as the corporate’s equity plunged into a period of continuous decline. Then, at the end of 2022, the coefficient  $X_4$  has grown dramatically and reached the milestone of 0,58. This increase is due to a relatively large decrease in the average total debt of the entity while the average equity is almost unchanged or has a slight growth. The main reason why the company’s  $X_4$  is always lower than that of other companies in the same industry is that the company maintains a structure in which total debt is greater than equity, which suggests that the entity uses the appropriation to a large extent. Therefore, HAGL needs to take preventive measures to avoid risks in the future.

## 5.2. Discussion

The Group’s achievements through business results in the period of 2017 - 2022 show:

Inventory turnover ratio tends to decrease from 2,77 rounds in 2017 to 0,84 rounds in 2019, sharply increasing to 3,88 rounds in 2021 and decreasing to 3,42 rounds in 2022. Reduction in inventory ratio helps businesses reduce costs, reduce the burden of working capital in production.

In 2021, the enterprise will mainly focus on two segments of fruit trees and livestock. The area of fruit trees is 10.000 hectares in Vietnam, Laos and Cambodia, of which 7.000 hectares are used to plant bananas (nearly 5 hectares are used in 2021). The Group is targeting the Chinese market as the foundation and will occupy the position of the largest supplier of tropical fruits in this market. The Group focuses on manufacturing products according to Global GAP standards, exporting conditions to fastidious markets such as Japan, Korea, Singapore and Europe.

Regarding livestock, in 2021 there will be 7 clusters and 400.000 pigs for meat. Target 2022, build 9 more clusters (total 16 clusters) and reach 1 million pigs (2.400 sows and 60,000 slaughter pigs each). The pig industry participates from 2020 and 2021, revenue from this segment accounts for a high proportion in the revenue structure.

In 2021, banana-based pig feed can save a third of the total cost of pig production, bringing a gross profit margin of more than 30% for the enterprise’s pig business. Hoang Anh Gia Lai Group plans to expand its pig production scale from 400.000 heads/year in 2021 to 1 million heads/year in 2023. In 2022, Vietnam’s pork supply will grow at a slower rate than meat demand. pigs in Vietnam, due to rising feed costs, plus the ongoing challenge from African swine fever, farmers are reluctant to re-herd. This supply-demand gap will be a factor leading to an increase in pork prices in the short term, thereby supporting the company’s livestock expansion plan.

In 2022, the enterprise’s banana price really increased when China opened up. According to Chairman Hoang Anh Gia Lai, “the current price of bananas is 11 USD/barrel, in the future it will increase to 13 USD/barrel - over the same period this price increased by several tens of %”.

In fact, in 2022, according to the audited consolidated financial statements, HAGL recorded a revenue of VND 5.198 billion - an increase of more than VND 100 billion compared to the independent report

and doubled compared to 2021. Deducting cost of goods, gross profit for the year was 1,173 billion dong, up 131% thanks to good growth in banana and pig sales during the year. In which, revenue from selling pork accounted for 33% (equivalent to VND 1.669 billion), the second largest after the fruit segment with 42% (equivalent to VND 2.150 billion). The gross profit margin of this segment is 24,2%, behind the fruit segment (31,5%).

Net profit after audit decreased by 50 billion VND compared to the previous self-made report, to 1.129 billion VND, due to the increase in selling and administrative expenses. It is expected that by 2023, HAGL expects profit to increase by 20-30%. In which, the momentum is mainly from bananas and new businesses (such as selling vegetables and fruits at BapiFood), which HAGL has determined to be unprofitable.

Besides, there are still some limitations:

Total assets decreased over the years. Total assets in 2017 was VND 209.456 billion, decreasing over the years to 2021 to VND 18.174 billion and reaching VND 19.798,4 billion in 2022. The main reason was due to a decrease in other long-term assets by 98,04% from 15.185 billion to VND 297 billion in 2021. The Group does not have a good policy for creating stability in the structure of short-term assets and long-term assets in the Group's total assets.

Due to the heavy impact of the Covid-19 epidemic, Hoang Anh Gia Lai Group's inventory increased sharply to 1,27 in 2020 and 3,88 in 2021.

Profit after tax has decreased over the years, especially in 2019 the company's profit after tax is negative 1.609 billion dong and in 2020 profit after tax is negative 2.175 billion dong. This change is also reflected in the Return on equity (ROE) in the period of 2017 - 2022, respectively, at 2,23%; 0,04%; negative 10,76%; negative 14,18%; 1,27%; 24,07%. Similar to the Return On Sales ratio (ROS) in 6 years 2017 - 2022 is 7,68% respectively; 0,11%; negative 87,18%; negative 75,01%; 6,08%; 22,01%. The group's Return on Assets (ROA) had a sharp decrease in 2017 of 0,7% after 2 years, falling to negative 3,76% in 2019 and negative 6,17% in 2020 and increasing in the next 2 years when reaching 6,10%. This shows that the company has had improper investment development strategies to improve the group's operations over the years.

The capital structure of the group is not really appropriate, the group borrows a large proportion. The debt ratio of the group has always remained at a high level of over 55%, showing that the financial safety level of the group is not high, the group still has to rely heavily on external capital.

The total capital turnover of the Group fluctuates from year to year, but within 6 years from 2017 to 2022, the total turnover of capital is always greater than 0 and less than 1, from which it can be seen that the capital use stage of the enterprise has not been effective in the last 6 years.

The company's profit after tax decreased to negative VND 1.609 billion in 2020 while the cost of goods sold and selling and corporate expenses increased. Therefore, the enterprise has not yet taken measures to reduce costs to increase profits.

Thus, in the two years of 2021 and 2022, the company's financial situation, although there have been positive signals, has positive growth, but has not reached a safe level, and business performance is not really good. The Group needs to continue to make adjustments to make appropriate and timely decisions for further development in the future.

## **6. RECOMMENDATIONS**

Based on using, analyzing, and evaluating the data on the financial statements of Hoang Anh Gia Lai Group, thereby clarifying the results achieved such as reduced inventories, expansion of the pig industry,

and increased revenue from banana production. The Group is also actively moving towards products that meet Global GAP standards to satisfy demanding markets such as Japan, Korea, Singapore, and Europe. In addition, there are also some limitations such as long-term debt and unsecured equity to finance long-term assets, poor balance of business capital, and high pressure to pay short-term loans. Investment development strategy is not reasonable, high debt ratio, and low liquidity. Thereby, it requires the Group to make the right short-term and long-term strategic decisions to solve the remaining limitations, bring the company out of the “squad” and achieve high efficiency in business activities.

Faced with these situations, the author proposes a number of crucial solutions to improve the financial situation, prevent and limit the bankruptcy risk of enterprises, such as:

For starters, Build a suitable financial structure for business activities. Hoang Anh Gia Lai Group needs to continue to be transparent in financial activities, production and business activities. Besides, the company needs to build a reputation to develop good long-term relationships with the domestic investor community and especially international investors to be able to successfully mobilize capital for production and business needs. Along with that, enterprises need to ensure a reasonable amount of capital and capital structure for the Group’s development in the present and future period.

Secondly, Strengthening cost control, and investing in the innovation of fixed assets go hand in hand with improving the efficiency of using fixed assets. Enterprises need to plan and implement the management and use of fixed assets well. Besides, conducting regular inspection and classification of fixed assets to improve management efficiency. Enterprises should also focus on investing in new fixed assets in line with the advancement of science and technology.

Thirdly, Enhance the capacity to analyze the Altman Z-score model. If the company’s business plans are calculated and verified by the Z-score model, we can predict how the company’s financial capacity will change so that we can decide whether to adjust or continue to implement that business plan. To do this requires a team of financial analysts to have a higher level of expertise, even a combined finance department that uses the Z-score model in analysis separately from the accounting department.

Additionally, Raising awareness of businesses about assessing the financial capacity of the company, especially the risk of bankruptcy, reform must be from the leadership. Currently, the issue of financial management, assessing the company’s capacity as well as the risk of bankruptcy, is known to businesses. Managers need to realize that the implementation team applying the Z-score model is very necessary, so investing in training, as well as fostering to improve professional skills in accounting and the application of the model. model, or recruiting new personnel with expertise and understanding of financial analysis is essential to meet the requirements of accounting work and application of the model.

Finally, Proper use of financial leverage. The ratio of Total liabilities on Total assets is an indicator representing the group of financial leverage and this indicator has a positive relationship with the risk of bankruptcy, that is when this coefficient increases, the risk of bankruptcy will also increase and vice versa. With Hoang Anh Gia Lai, the more debt the company has, the more likely it is to be insolvent, too much debt will lead to a higher risk of bankruptcy. Therefore, to prevent and limit the risk of bankruptcy, enterprises need to consider using financial leverage appropriately, thereby limiting the risk of bankruptcy, better stability, and growth.

## **7. CONCLUSION**

The article has summarized the content of Altman Z-score model, applied the Z-score model to analyze and assess the bankruptcy risk of Hoang Anh Gia Lai Group in the 06-year period from 2017 -

2022. In addition, the article also points out the achievements of enterprises in the past period, and points out the remaining limitations and causes of those limitations. Thereby, the authors propose some solutions to effectively apply the Altman Z-score model to help improve the financial situation, prevent and limit the bankruptcy risk of enterprises in the future. This will be an effective tool to help the Group avoid financial risks, especially the bankruptcy risk of enterprises, thereby avoiding consequences for society, especially “non-performing loan”.

## THE IMPACT OF WORKING CAPITAL MANAGEMENT ON THE PROFITABILITY OF MANUFACTURING COMPANIES LISTED ON THE VIETNAM STOCK EXCHANGE

**Authors: Le Minh Hanh, Nguyen Phuong Nga<sup>1</sup>, Nguyen Minh Thanh<sup>1</sup>,  
Nguyen Thai Ha Thuong<sup>1</sup>, Hoang Thi Hong Anh<sup>1</sup>  
Mentors: Assoc. Prof. Ph.D. Pham Thi Thanh Hoa<sup>1</sup>, Ph.D Nguyen Anh Quang<sup>1</sup>**

*ABSTRACT: The purpose of this research is to examine the impact of working capital management on the profitability through a sample of 755 Vietnamese manufacturing companies listed on the Vietnam stock exchange from the years 2016 to 2020. Based on the findings presented in this research, empirical support for the proposed model of factors affecting the firm's profitability has been found. Propensity Score Matching (PSM) is also used to impact of working capital management on the profitability in order to ensure that these industries are randomly chosen. The paper indicates that the firm profitability is significantly influenced by working capital management, leverage, liquidity and growth of sales revenue. In which, the account receivable management which is one of the contents of working capital management, can be used as a channel to decrease the negative impact of COVID-19.*

*Keywords: Working capital management, profitability, manufacturing companies, Propensity score matching, COVID-19.*

### 1. INTRODUCTION

Inadequate capacity for financial management can be considered as a vivid explanation for the low efficiency of Vietnamese corporations in comparison with foreign ones upon international integration. Long-term capital and working capital management are two core components of financial management. Especially, working capital management can directly and significantly influence the financial situation of the entity. Working capital management is related to the day-to-day operations of the business, which are necessary to maintain the business's production and business processes on a regular and continuous basis. Great working capital management can optimize resources, reduce limiting factors, save costs and increase working capital turnover; thereby, it directly influences the profitability of the company. The desired seeking for the noticeable impacts of working capital management on corporate profitability is one of the most indispensable contributors to the sustainable development of any business. Therefore, enterprises need to be very careful and attentive in managing working capital. In fact, manufacturing enterprises have been struggling with optimizing the level of receivables, payables, and inventories, which affects their profitability. Specifically, businesses with low receivables turnover and low inventory turnover, and thereby their payables turnover is high; have been having difficulty with recovering capital. The above factors affect the number of days of cash flow in the business, affecting its liquidity and profitability.

Up to now, there have been many scientific studies about the influence of working capital management on the profitability of enterprises. Summarizing those studies, the authors point out the research gap in the topic. In the context of the economy being severely affected by the COVID-19 pandemic, domestic enterprises and especially manufacturing enterprises are struggling to find ways to overcome difficulties that reduce the efficiency of working capital management and profitability of the firm. Recognizing that urgency, the authors have chosen the topic "The impact of working capital management on the profitability

---

<sup>1</sup> Academy of Finance.

of manufacturing companies listed on the Vietnam Stock Exchange”. Based on the provided data about manufacturing enterprises listed on the Vietnamese stock exchanges, the researchers thoroughly analyze how a well-organized system of utilizing working capital can benefit the profitability of those companies over the last few years. In the background of findings, some recommendations are proposed to improve the domestic corporations’ working capital management capacity, which in turn significantly enhances their profitability. Moreover, the research contributes evidence for future experimental studies. Since the impact of the pandemic on the profitability of firms is empirical, the authors used the Propensity Score Matching (PSM) method to ensure that the treatment group and control group were distributed randomly.

## **2. THEORETICAL FRAMEWORK:**

### **2.1. Theory framework:**

#### **2.1.1. Overview of working capital management in enterprises:**

##### **a. Working capital management**

Working capital is the total amount of payment in advance used for a business’s investment, making up current assets for the firm’s operations. In other words, working capital represents the value of current assets (Bùi Văn Vân, Vũ Văn Ninh, 2013). This concept is used in measuring economic scale based on the gross concept.

According to the net concept, the term “working capital” mentions current assets consisting of cash, accounts receivables, inventories, and other short-term loans like supplier payables. Net working capital is calculated by subtracting current liabilities from current assets (Ross et al., 2013). Ross believed that businesses need net working capital while financial managers stated net working capital is simply the working capital of a business in some cases. This concept is made use of evaluating liquidity.

##### **b. Content of working capital management**

###### ***Inventory management***

A business’s inventory is part of its assets that needs to be kept in order to ensure its normal business operations. A business’s inventory includes raw materials in the production reserve stage; unfinished products; semi-finished products in the production stage; and goods in the consumption stage. Stocking inventory helps companies ensure the change in consumption demand while also providing raw materials. However, not all types of inventories can be easily converted to cash.

###### ***Account receivable management***

Receivables refers to the total value of goods that the corporation has already delivered to customers but has not yet received relevant payment. Receivables come into view once the company implements credit policies with the aim of increasing sales volume and reducing inventories. Executing credit sales, however, entails numerous risks and surging costs, such as the cost of receivables management, debt collection cost, and the opportunity cost of capital. Furthermore, the circumstances of customers’ unpunctuality in returning debts can give voice to the previously hidden risk of initiative deficiency in fully recovering the company’s receivables and hinder its efficiency.

###### ***Account payable management***

Accounts payables are comprised of trade payables, prepayments from customers, and cyclical debts such as salaries, taxes, and other payables. The aforementioned payables arise when an enterprise purchases inputs but has yet to make the relevant payment or when it sells products and goods previously paid for in advance. The emergence of payables helps businesses temporarily delay disbursing money, thereby benefiting enterprises by reducing a part of their working capital needs.

### ***Cash management***

Cash management, which is part of the wider task of treasury management, is concerned with optimizing the amount of cash available, maximizing the interest earned by spare funds not required immediately and reducing losses caused by delays in the transmission of funds. Holding cash to meet short-term needs incurs an opportunity cost equal to the return which could have been earned if the cash had been invested or put to productive use. However, reducing this opportunity cost by operating with small cash balances will increase the risk of being unable to meet debts as they fall due, so an optimum cash balance should be found.

#### **c. Working capital policies**

The working capital policy is classified into three schools: aggressive, conservative and moderate working capital policies.

**Aggressive Policy:** A policy that maintains a low level of cash, inventory, and terms of trade credit crunch corresponding with their turnover. A low amount of cash and inventory means less cash backlog in working capital, which helps businesses increase profitability and efficiency. However, this policy can also cause risks due to a shortage of cash and inventory for the firm's operations.

**Conservative policy:** A policy that maintains a large amount of cash, inventory, and generous credit terms related to a certain level of revenue. This policy results in a large amount of capital and helps reduce the risk of working capital shortage. However, this policy may lead to a decrease in the business's profitability and efficiency.

The moderate policy places itself between an aggressive policy and a conservative one, assuming both characteristics. No policies are the best for the business because no policies are perfect. Enterprises need to develop and decide which policies are suitable for each period.

It should be noted that the working capital policies of a company can be characterized as aggressive, moderate or conservative only by comparing them with the working capital policies of similar companies. There are no absolute benchmarks of what may be regarded as aggressive or otherwise, but these characteristics are useful for analyzing the ways in which individual companies approach the operational problem of working capital management.

#### **2.1.2. Determinants of working capital management:**

##### **a. Financial Leverage**

Financial leverage reflects the proportion of debt used in the total capital of a business. Many businesses choose debt capital to make up for the shortfall because this is an external source of capital with a relatively low cost of capital. Financial leverage is considered as a legal "tax shield" of businesses. Moreover, financial leverage is properly understood as "leverage that helps businesses grow faster and better through increasing return on equity (ROE) and earnings per share (EPS). Some previous studies have shown a positive relationship between financial leverage and corporate profitability (Singapurwoko, 2011). On the contrary, if the economy is unstable and businesses do not perform well, businesses using debt will suffer heavier losses than the one not using debt. Murugesu's study (2013) on companies listed on Columbo Stock Exchange showed a negative relationship between financial leverage and profitability of the business. Some other studies also reached similar conclusions such as Hall & Weiss (1967); Baker (1973); Hurdle (1974).

##### **b. Growth potential**

The growth rate of the business can be represented as growth of revenue or capital. Theoretically, businesses with high capital growth or revenue growth are likely to have high operating efficiency. To

be specific, the growth rate has a positive impact on the business profitability (Cho & Pucik, 2005; Yang, 1996). However, other studies indicate that when enterprises expand the production scale, their expenses will increase corresponding to the increased income. If the increase in costs exceeds the revenue growth, profitability will be negatively affected. This explains the negative relationship between growth rate and profitability in the research carried out by Jasra (2011) and Bashir et al. (2013).

### **c. Liquidity**

Liquidity can be measured by the current ratio, which is calculated by dividing current assets by current liabilities, indicating the speed at which a business can react to unexpected changes in the economy. Therefore, enterprises holding major liquid assets might reduce the risk of late payment. Deloof (2003) has proven the important role of liquidity (working capital) management for improving business's profitability. Businesses with good liquidity are also considered safe investment options for investors. Consequently, businesses can easily raise capital and get business opportunities with high profitability. However, if a business holds too many short-term assets, it may miss out on long-term investment opportunities.

### **d. COVID-19 pandemic**

The COVID-19 pandemic has negatively affected the supply, production and distribution of manufacturing enterprises, causing them to bear unprecedented heavy losses. When social distancing policies were issued, it was impossible for people to go out to work or to entertain. As a result, the consumption of common goods in some industries decreased significantly, businesses could not sell goods, and stagnant capital due to excess inventories made it difficult for enterprises to reproduce. Meanwhile, businesses in the food and pharmaceutical industries have been less affected by the COVID-19 pandemic. The reason is that these industries provide necessities for human survivors. Since the impact of the pandemic on the profitability of firms is empirical, the authors used the Propensity Score Matching (PSM) method to ensure that the treatment group and control group were evenly distributed randomly.

## **2.2. Recent researches of the working capital management on the profitability:**

Firstly, working capital turnover time is negatively related to operating efficiency. In other words, the longer the working capital turnover period, the more stagnant working capital in all stages of the business process often leads to a decrease in business profitability. This point of view is supported by Aggressive Policy of WCM. The policies stated that company maintains a low level of cash, inventory, and terms of trade credit crunch corresponding with their turnover. A low amount of cash and inventory means less cash backlog in working capital, which helps businesses increase profitability and efficiency. This conclusion is supported by studies that have been generalized in research reviews such as Deloof's study (2003); Research by Lazaridis and Tryfonidis (2006); Research by Raheman and Nasr (2007).

Secondly, working capital turnover time is positively related to operating efficiency. The viewpoint is consistent with Conservative policy. That policy maintains a large amount of cash, inventory, and generous credit terms related to a certain level of revenue. This policy results in a large amount of capital and helps reduce the risk of working capital shortage. However, this policy may lead to a decrease in the business's profitability and efficiency. This conclusion is supported by Sharma and Kumar (2010), Abuzayed (2012), Charitou et al., (2010), Mathuva (2010)...

In summary, working capital management has a direct impact on the business profitability of enterprises. However, the direction and level of impact depend on many factors as well as on enterprises under certain conditions. Therefore, studying the relationship between working capital management and the business profitability of enterprises in specific industries will contribute more evidence as well as help enterprises to improve their business operation.

2.3. Building the research model:

Table 3.1: Variable Measurements

The Dependent variable			
<b>Return on Assets (ROA)</b>	<b>= Net income / Total assets</b>	<b>The return on assets</b>	
Gross Operating Profit (GOP)	= (Sales – Cost of goods sold) / (Total assets – Financial Assets)	The ratio of operating income plus depreciation and amortization to total assets minus financial assets	
The Explanatory variables			
<b>Determinants</b>	<b>Observed variables</b>	<b>Measurement</b>	<b>Expected relation</b>
ADI	Average days in inventory	= Inventories / (Cost of Goods Sold / 365)	Negative
ADR	Average days in receivables	= Account Receivables / (Net Sales / 365)	Negative
ADP	Average days in payables	= Account Payables / (Cost of Goods Sold / 365)	Positive
The Control Variables			
<b>Determinants</b>	<b>Observed variables</b>	<b>Measurement</b>	<b>Expected relation</b>
CR	Current ratio	= Current Assets / Current Liabilities	Negative
DEBT	Leverage	= Total Debt / Total Assets	Negative
GROWTH	Sale growth	= Sales <sub>1</sub> – Sales <sub>0</sub> / Sales <sub>0</sub>	Positive
The Dummy Variable			
<b>Determinants</b>	<b>Observed variables</b>	<b>Measurement</b>	<b>Expected relation</b>
COVID	Covid -19	From 2020	Negative
The Interactive Variable			
<b>Determinants</b>	<b>Observed variables</b>	<b>Measurement</b>	<b>Expected relation</b>
ADR*COVID	Average days in receivables in case of COVID-19	From 2020	Negative

Source: Compiled by the author

Based on economic theories and previous studies, the authors have constructed a research model to investigate the impact of working capital management on the profitability. The authors also added an external factor, which is the COVID-19 pandemic. Thereby, it can both provide a general and in-depth view of the impact of working capital management and expand the research. Economic theories and many previous empirical studies have shown that, if the enterprise pursues an aggressive working capital management policy, the indicator reflects working capital management (cash conversion period, number of days inventory, number of days account receivables) has a negative relationship with the profitability of the company, and number of days account payables has a positive relationship with business profitability. If the enterprise pursues a conservative working capital management policy, cash conversion period, number of days inventory, and number of days account receivables have a positive relationship with business profitability, while the number of days account payables has a negative relationship with business profitability. Because it is not known which working capital management policy is being pursued by manufacturing enterprises, in this study it is expected that there is a relationship between working capital management and the business profitability of enterprises. Therefore, based on the theory and previous studies, the hypothesis of the research model is given as follows:

**Hypothesis 1:** The working capital management has significant impact on firm profitability.

**Hypothesis 2:** The COVID-19 pandemic is strongly related to the extent to which working capital management affects firm profitability.

The models focus on examining the impact of working capital management on the profitability, in which, dependent variables representing the business profitability of the enterprise include: ROA - Return on Assets and GOP - Gross Operating Profit. The representative variables for working capital management include: ADI - the average number of days inventory, ADR - the average number of days receivable, and ADP - the average number of days payable. The control variables included DEBT representing for capital financing policy, CURRENT RATIO representing for liquidity, and GROWTH representing for revenue growth rate of the company. Besides, models containing the COVID dummy variable are added to examine how the impact of working capital management on the profitability is affected during the COVID-19 pandemic compared to normal situations.

The authors used the following *model to research the impact of WCM on profitability in the absence of the COVID-19 epidemic*:

**Model 1:**  $ROA_{it} = \beta_0 + \beta_1 ADR_{it} + \beta_2 ADI_{it} + \beta_3 ADP_{it} + \beta_4 DEBT_{it} + \beta_5 CR_{it} + \beta_6 GROWTH + \beta_7 YEAR + \epsilon_{it}$

**Model 2:**  $GOP_{it} = \beta_0 + \beta_1 ADR_{it} + \beta_2 ADI_{it} + \beta_3 ADP_{it} + \beta_4 DEBT_{it} + \beta_5 CR_{it} + \beta_6 GROWTH + \beta_7 YEAR + \epsilon_{it}$

In which,  $i$  represents the  $i$ th company ( $i = 1 \dots 755$ ) and  $t$  represents the  $t$  year ( $t = 1 \dots 5$ )

The authors used the following *model to research the impact of WCM on profitability under COVID-19 pandemic conditions*:

**Model 3:**  $ROA_{it} = \beta_0 + \beta_1 ADR_{it} + \beta_2 COVID + \beta_3 ADR * COVID + \beta_4 ADI_{it} + \beta_5 ADP_{it} + \beta_6 DEBT_{it} + \beta_7 CR_{it} + \beta_8 GROWTH + \epsilon_{it}$

**Model 4:**  $GOP_{it} = \beta_0 + \beta_1 ADR_{it} + \beta_2 COVID + \beta_3 ADR * COVID + \beta_4 ADI_{it} + \beta_5 ADP_{it} + \beta_6 DEBT_{it} + \beta_7 CR_{it} + \beta_8 GROWTH + \epsilon_{it}$

In which,  $i$  represents the  $i$ th company ( $i = 1 \dots 755$ ) and  $t$  represents the  $t$  year ( $t = 1 \dots 5$ )

This study applies the PSM in order to investigate the impact of working capital management on the profitability of the two groups, which are companies affected by COVID-19 and companies unaffected by COVID-19 in Vietnam during 2016-2020. Applying PSM will ensure the random selection of subjects and random allocation of the treatment to subjects. In other words, the treated and control (untreated) groups are randomly allocated.

The authors classified into two categories based on the sample's businesses' industries. Construction materials, personal products, home goods, retail, transportation, logistics, and other businesses are considered to be among those most significantly impacted by COVID-19. Pharmaceuticals, food are unlikely to be significantly impacted by COVID-19. Next, the authors match, without replacement (within each year and industry), firms being affected by COVID-19 (treated = 1, if the company is a member of the covid-19-affected industries) with their counterpart being unaffected by COVID-19 (treated = 0, if the company is included in the covid-19-unaffected industries) which has the closest predicted probability within a maximum caliper distance of 0.1. The sample obtained after running the model by PSM method includes 1340 observations, of which 670 are treated and 670 are matched. Baseline models are repeated on the matched sample to test the model's hypothesis.

### 3. RESEARCH METHOD:

#### 3.1. Data collection:

The data sample was formed by 755 manufacturing companies listed on the Hanoi Stock exchange (HNX) and the Ho Chi Minh Stock exchange (HOSE) over the period of 10 years (from 2010 to 2019) which was gathered mostly from company financial statements, corporate associate announcements, reports, and yearbooks from the Stock Exchange and FinnPro Exchange platform. Financial institutions, banking, insurance, renting and real-estate companies were excluded from the sample because of their specific nature of services. In addition, non-missing observations are also required. The authors winsorise all variables at the 1 and 99 percentages to reduce the impact of outliers. Our final sample consists of an unbalanced panel of 3775 firm-year observations.

#### 3.2. Data analysis:

The authors use a package of STATA software version 17 to estimate the regression equations that we proposed above. First off, bivariate relations among variables were explored via examining correlation. Next, we used the Fixed effects model (FEM) to examine the effect of debt ratio on performance. The research also examined some necessary detector regressive assumptions to ensure the result of regression is blue such as autocorrelation and multicollinearity before the conclusion.

### 4. RESULTS AND DISCUSSION:

#### 4.1. Several necessary tests for the model:

##### 4.1.1. Descriptive summary:

**Table 2: Descriptive summary**

VARIABLES	(1) N	(2) mean	(3) sd	(4) min	(5) max	(6) p1	(7) p25	(8) p50	(9) p75	(10) p99

*Source: Calculation and synthesis of the author team from Stata software.*

Table 2 reports the descriptive statistics of the main studied variables, which are based on the financial data from 2016 to 2020. After logarithmic calculation, the average value of gross operating profit (GOP) is 24.35 percent. Enterprises reach this lowest target of -3.506 and the highest is 137.9. The mean of ROA (Return on Assets) is 5.61 percent, and the standard deviation of ROA is 6.83, with a maximum value of 32.94 percent and a minimum value of -11.91 percent. The average value of ADR (number of days account receivables), ADI (number of days inventory) and ADP (number of days account payables) is 192 days, 164 days, and 60 days, respectively. In addition, these enterprises have an average rate of debt ratio of 46.30 percent. The current ratio shows a large standard deviation of 402.1. The average operating income growth rate is 16.95 and fluctuates in the range of (-79.02; 552.0).

### 4.1.2. Correlation matrix

Source: Calculation and synthesis of the author team from Stata software.

The table above shows us the correlation between the variables used in the research model. We can see that most of the variables are relatively closely correlated with each other.

### 4.1.3. Hausman test

The authors use the Hausman test to choose between FEM and REM regression models for panel data of the research sample. The difference between these two estimation models depends on the difference in the assumptions made when building these two models. With the FEM model, it is assumed that the independent variables and the error are correlated, while the REM model assumes that there is no correlation between the independent variables and the error (Greene, 2007). In the Hausman test, the hypothesis is tested as follows:

Hypothesis H0: There is no difference between using FEM and REM.

Hypothesis H1: There is a difference between using FEM and REM.

If H0 is rejected, then using REM is not reasonable and it is necessary to use the FEM model to estimate.

The authors conduct the Hausman test for all 4 models on the data of the research sample with STATA software, the P values of models 2, 3, and 4 are all greater than 0.05, thereby accepting the hypothesis H0, using the REM model to estimate. The P value of model 1 is less than 0.05, so, at the 5% level of significance, the null hypothesis H0 is rejected; Hausman test results indicate that the FEM model will be better than the REM model. The table of test results is as follows:

**Table 4. Results of the Hausman test**

Model	The p-value	Chosen model
1	0%	FEM
2	18.98%	REM
3	64.73%	REM
4	99.92%	REM

Source: Calculation and synthesis of the author team from Stata software

**4.1.4. Test of Heteroskedasticity:**

In order to verify Heteroskedasticity in the research model, perform the Modified Wald test with model 1 and Breusch and Pagan Lagrangian with models 2, 3, and 4 as these following hypothesis:

Hypothesis H0: Homoskedastic

Hypothesis H1: Heteroskedasticity

If the P - value < 0.05, then reject the H0 hypothesis and accept the H1 hypothesis, there is a Heteroskedasticity in the model. From the data information, the results of the P-values of all models are > 0.05, which proves that hypothesis H0 is accepted, or in other words, the models do not have Heteroskedasticity. The test results are as follows:

**Table 5: Results of the Heteroskedasticity test**

Model	The p-value	Results
1	Prob > chi2 = 0.5107	Hypothesis H0 is accepted
2	Prob > chi2 = 0.1898	Hypothesis H0 is accepted
3	Prob > chibar2 = 1.0000	Hypothesis H0 is accepted
4	Prob > chibar2 = 1.0000	Hypothesis H0 is accepted

*Source: Calculation and synthesis of the author team*

**4.1.5. Test of Autocorrelation**

In order to verify the Autocorrelation of the model, the authors perform the Wooldridge test with 4 models as the following hypothesis:

Hypothesis H0: There is no Autocorrelation.

Hypothesis H1: There is an Autocorrelation.

If the p-value < 0.05, then reject hypothesis H0 and accept hypothesis H1, there is autocorrelation in the model. From the results and data information, the P-values of all models are greater than 5%, which means that the models do not have autocorrelation. The test results are as follows:

**Table 6: Results of the Autocorrelation test**

Model	The p-value	Results
1	Prob > F = 0.0513	Hypothesis H0 is accepted
2	Prob > F = 0.0913	Hypothesis H0 is accepted
3	Prob > F = 0.0513	Hypothesis H0 is accepted
4	Prob > F = 0.0850	Hypothesis H0 is accepted

Source: Analyzed by the authors using STATA

(Note: This table reports the regression results of impacting factors on corporate profitability, using FEM and REM models in STATA. The dependent variables include ROA and GOP. Column (1) shows the names of the independent variables. Column (2) shows the fixed effect and column (3) shows the random effect of profitability. Significance levels of 10%, 5%, and 1% are denoted by \*\*\*, \*\*, and \* respectively.)

First, the regression result in Table 2.9 shows the negative relationship between the average number of days receivable (ADR) and ROA at a significance level of 1%, and GOP at a significance level of 10%. The results are also consistent with the expected signs of this variable's coefficient and the previous studies. They also show that the impact of ADR on ROA is stronger than its effect on GOP. Specifically, if ADR decreases by 100 days, ROA will increase by 0.139%, which is a significant increase compared to the mean ROA of 5.619% (table 2.3). Therefore, the recommendation for manufacturing companies listed in Vietnam is that the shorter the collection period, the higher the business profitability. Besides, the regression results show that the number of average days payables (ADP) and the number of average days inventory (ADI) have almost no significant impact on the two dependent variables, which are ROA and GOP. However, since the ADR has significant impacts on profitability, **Hypothesis 1:** "The working capital management has significant impact on firm profitability" is approved.

Second, the regression result also shows that the debt ratio has a negative relationship with ROA at a significance level of 1%, and has a positive correlation with GOP at a significance level of 1%, which is consistent with the expected signs. In terms of ROA, the effect of DEBT is -0.0318. This means, if the firm reduces its debt ratio by 10%, its ROA will increase by 0.318%. ROA is returns on assets, which is calculated by dividing a company's net income by its total assets. The higher debt ratio, the less net income of the company is; thereby the relation of debt ratio and ROA is negative. This result is consistent with the study of Margaritis, D., & Psillaki, M. (2010). In terms of GOP, the effect of DEBT is 0.0732. This means, if the firm increases its debt ratio by 10%, the GOP will increase by 0.732%. GOP is the ratio of operating income plus depreciation and amortization to total assets minus financial assets. GOP does not minus the financial costs (including financial interest), so that the higher the debt ratio, the higher operating income. Therefore, debt ratio has positive relation with GOP. The above results are consistent with economic theories and previous studies.

Third, the regression result in Table 2.9 shows a positive relationship between the current ratio (CR) and ROA and GOP at a significance level of 1%, which is consistent with the expected sign of this variable’s coefficient. The influence of the Current ratio on ROA and GOP is 0.0013 and 0.0024, respectively. If the enterprise invests a large amount of capital in short-term assets, maintains a high cash balance, has a generous credit policy, and maintains a large inventory, this shows that the business is using a loose investment policy, focusing on the ability to ensure the payment of short-term debts, avoiding shortages of raw materials, goods, and cash in daily operations. This investment policy always ensures a certain level of safe working capital (e.g. safe level of inventory, cash, etc.) for businesses, limiting business risks, however, businesses have to trade off by incurring high costs and stagnant capital. This policy has a negative impact on profitability, thereby reducing operational efficiency. In contrast, the business applying the risky investment policy, which is to maintain a smaller amount of working capital, can improve the efficiency of working capital management, increasing profitability. However, they have to face a higher level of risk. Theoretically, working capital investment policy has an impact on working capital efficiency, profitability, and operating efficiency.

Fourth, table 2.9 also shows the positive effect of the growth rate of net revenue reflected on ROA and GOP at a significance level of 1%, which is consistent with the expected sign of this variable’s coefficient. In terms of ROA, the influence of the Growth variable is 0.0123, that is, if the business grows revenue by 10%, ROA will increase by 0.123%. About GOP, the influence of the Growth variable is 0.0216, meaning, if the business grows revenue by 10%, the GOP will increase by 0.216%. These are all impressive numbers and are also consistent with the popular view among international economists and financial researchers that the growth rate of net sales is one of the main factors affecting the profitability of enterprises.

Source: Analyzed by the authors using STATA

(Note: This table reports the regression results of impacting factors on corporate profitability, using FEM models in STATA. The dependent variables include ROA and GOP. Column (1) shows the names of the independent variables, dummy and interaction variables. Column (2) and column (3) show the fixed effect of profitability. Significance levels of 10%, 5%, and 1% are denoted by \*\*\*, \*\*, and \* respectively.)

As previously mentioned, in the working capital management factors, only the ADR variable has practical economic significance and has a reasonable impact on ROA and GOP, which has been analyzed and proven through **Hypothesis 1** and the conclusion that this hypothesis is valid and accepted. Therefore, in order to thoroughly analyze the influence of external factors, specifically the global pandemic of COVID-19, as well as the impact of ADR in the case of COVID-19 on the profitability of manufacturing enterprises listed in Vietnam, the authors added the dummy variable COVID and the interaction variable ADR\*COVID into the research model and continued the regression analysis. The model regression results depicted in Table 2.10 show the following specific effects:

*Firstly*, the regression results continue to show the negative relationship between ADR and ROA and GOP at the statistical significance levels of 1% and 10%, respectively. This goes on to express that if businesses tighten their trade discount policies and limit customers' appropriation of capital, they can increase their profitability. The effect of ADR on ROA, in this case, is reduced to -0.00115, which means that if the business reduces the receivables turnover period to 100 days, it can increase ROA by 0.115%. On the other hand, the impact of ADR on GOP increases to -0.00144, which means that if a business reduces ADR by 100 days, it can increase GOP by 0.144%. Since there is ADR in WCM exerting significant influence on firm profitability, **Hypothesis 1** continues to be accepted in this model.

*Secondly*, unlike the independent variables, the control variables have more significant impacts on ROA and GOP. These impacts show almost no changes in comparison with the previous model analyzed under normal conditions. As can be seen, DEBT has a negative correlation with ROA and a positive correlation with GOP. CURRENT RATIO and Growth have the same effect on both ROA and GOP. At the same time, the impact of these variables on firm profitability is considerable and consistent with economic theory as previously analyzed. Since then, we have other brilliant evidence that the key corporate policies, including financing policy and capital investment policy, as well as revenue growth rate, have a significant influence on the firm's profitability.

*Thirdly*, the dummy variable COVID has a huge negative impact on business profitability. This result of the coefficient's sign is consistent with the expected sign. If the COVID-19 pandemic did not happen, the impact of ADR on ROA and GOP would be the aforementioned numbers. On the contrary, just the outbreak of the COVID-19 pandemic has already caused a significant decrease in ROA and GOP of 1.06% and 3.68%, respectively. In this case, as the interactive variable ADR\*COVID indicates the impact of ADR on ROA increases to -0.000631, which means that if businesses can manage and reduce ADR, they can partly overcome the severe consequences of COVID-19. In other words, since COVID amplifies the impact of ADR on ROA,

ADR becomes a useful channel for businesses to mitigate the consequences of the COVID pandemic on their profitability by restricting their trade credit policy. In contrast, the effect of ADR on GOP, in this case, has a value of 0.000505, showing a positive relationship with GOP. However, both the results of ADR\*COVID are negligible and can be ignored. Thus, we have had a basis to admit **Hypothesis 2**: “The COVID-19 pandemic is strongly related to the extent to which working capital management affects firm profitability”.

**Table 9: Regression results of the impacts of variables on ROA and GOP under the COVID pandemic using PSM procedure**

Source: Analyzed by the authors using STATA

(Note: This table reports the regression results of impacting factors on corporate profitability, using the PSM method and FEM models in STATA. The dependent variables include ROA and GOP. Column (1) shows the names of the independent variables, dummy and interaction variables. Column (2) and column (3) show the fixed effect of profitability. Significance levels of 10%, 5%, and 1% are denoted by \*\*\*, \*\*, and \* respectively.)

After running the new model based on the PSM method with a fixed effect for the year and standard errors clustered at the firm level, the authors found that some indicators underwent significant changes.

First, in terms of working capital management factors, ADI and ADP did not have too many noticeable fluctuations after matching for comparison. In fact, the sign of the impact of these two variables has

changed somewhat, but their impact on the profitability of the business is generally still too small to be evaluated. Meanwhile, the ADR variable after matching the control has a huge change. The impact of ADR on ROA increased from -0.00115 to -0.0117. That means, for businesses negatively affected by the COVID-19 pandemic, when they reduce their ADR by 100 days, they can increase their ROA by up to 1.17%. The results can be explained by the fact that the number of days of accounts receivable measures the amount of time from the time of selling goods and services to collecting money from a customer. The more costs will be receivable longer, such as cost of receivables management, debt recovery, and bad debts. Conversely, if a business can collect accounts receivable from customers on time, it will have more capital to reinvest, thereby increasing sales, minimizing the costs related to debt recovery, and improving profitability. Additionally, the impact of ADR on GOP similarly saw a significant increase from -0.00144 to -0.0419, reflecting that businesses negatively impacted by the COVID-19 pandemic, upon reducing their ADR by 100 days, can increase GOP up to 1.44%. In other words, while a tight trade credit policy can reduce sales, its amazing ability to cut costs can have a great impact on the GOP. To conclude, in the PSM application model, **Hypothesis 1** continues to be accepted.

*Notably*, although COVID still almost kept its direction and impact on the profitability of the business, the regression coefficient of the interaction variable ADR\*COVID changed after being merged for comparison. For businesses impacted by the COVID-19 pandemic, the impact of ADRs on ROA in the event of COVID is no longer amplified. On the contrary, COVID at this time reduced the impact of ADR on ROA by 0.00331%, partly reflecting the loosening of trade credit policy and the fact that increasing ADR can help enterprises increase ROA. However, businesses should note that this reduction effect is very small when compared to the actual impact of ADR on ROA. In general, because the negative impact of ADR on ROA is too large, even if COVID reduces the impact, businesses can still increase ROA when tightening credit, limiting their ADR. Therefore, businesses need to be extremely wise in choosing credit policies at this time. On the other hand, the interaction variable ADR\*COVID still maintains a positive effect on GOP but has a significant increase, from 0.000505 to 0.0119. This means that, for manufacturing businesses affected by the COVID-19 pandemic, the impact of ADRs on their GOP will be significantly reduced, enabling businesses to use a variety of tools and easily make appropriate decisions and policies in unwanted contexts. Therefore, in the PSM application model, **Hypothesis 2** continues to be affirmed.

*As for other factors*, the DEBT variable, which represents capital financing policy, generally impacts corporate profitability the most significantly. In the model with ROA, the regression coefficient of DEBT decreased from -0.0317 to -0.0615, which is almost doubled. This reflects that, for businesses affected by COVID, if they can reduce their debt ratio by 10%, their ROA will increase by 0.615%. To clarify, the higher the debt ratio, the harder it is for businesses to get loans. If these businesses can get a loan, they also have to accept relatively high interest rates. On the contrary, if the business has a low debt ratio, it will be easy to get a loan. However, using high financial leverage also leads to many liquidity risks. Therefore, the results of the negative relationship between debt and profitability are reasonable and consistent with economic theory. On the other hand, in the model with GOP, the regression coefficient of DEBT increases from 0.0731 to 0.0823, reflecting that if a firm increases its debt ratio by 10%, its GOP will increase by 0.823%. This can be explained based on the theory that GOP is calculated by deducting the cost of goods sold from sales; this does not include interest expenses, accumulated depreciation, or taxes. Thus, GOP still contains interest expense; thereby, when enterprises increase debt, interest increases, and GOP also increases.

*In addition*, in terms of liquidity policy, expressed by the variable CURRENT RATIO, after pairing, the impact of CR on ROA has doubled, demonstrating the fact that the current ratio has a significant

impact on the profitability of the enterprise affected by COVID-19. Specifically, the regression results show that, if a business changes its current ratio by 10%, it can change its ROA by 0.0283%. To explain, if the enterprise invests a large amount of capital in short-term assets, maintains a high cash balance, has a generous credit policy, and maintains a large inventory, this shows that the business is using a loose investment policy, focusing on the ability to ensure the payment of short-term debts and avoid shortages of raw materials, goods, and cash in daily operations. This liquidity policy always ensures a certain level of safe working capital for businesses, limiting business risks; however, businesses have to trade off both incurring high costs and profitable capital. This policy has a negative impact on profitability, thereby reducing operational efficiency. In contrast, the business applying the risky investment policy, which is to maintain a smaller amount of working capital, can improve the efficiency of working capital management, increasing profitability. However, they have to face a higher level of risk. On the other hand, we see the impact of the current ratio on the GOP go from 0.00246 down to -0.0102, which is a huge change. Thus, for businesses affected by COVID-19, the current ratio actually has a negative impact on the GOP. Specifically, if a business increases CR by 10%, GOP will decrease by 0.102%. The impact of increasing CR on GOP compared to ROA is completely opposite. Therefore, depending on their goals, businesses need to be extremely smart and careful when choosing appropriate investment policies.

*As for growth rate*, the impact of growth on ROA does not change significantly when increasing from 0.0125 to 0.0133. In other words, businesses impacted by COVID-19 that increase revenue growth by 10% can increase ROA by 0.133%. This is consistent with economic theory and previous studies because revenue is a factor greatly affecting the profitability of enterprises, and businesses always seek to increase revenue to make the biggest profit. However, contrary to popular opinion, for businesses affected by COVID-19, after pairing, we find that growth and GOP have a negative relationship with a significant impact of 0.0241, which means that if businesses increase their revenue growth rate by 10%, GOP will decrease by 0.241%. Possibly, it can be explained that, with the global impact of the COVID-19 pandemic, the difficulty of reducing product costs has increased. If the business continues to increase sales, it may have to trade off with a much larger increase in production costs, leading to the opposite relationship as shown in the results. The effect of increasing growth on GOP compared to ROA is the opposite. Therefore, depending on their goals, businesses need to be wise and careful in deciding whether to increase revenue or not during this difficult epidemic.

## **5. CONCLUSION:**

### **5.1. Limitation**

The study has carried out a relatively thorough and proven analysis, thereby providing a solution to improve the profitability of the enterprise. However, in addition to the achievements, the research topic still has some limitations, specifically:

The problem of information asymmetry between the enterprise and the research paper through the use of financial statements has significant effects. Although the research through the regression method provides a great theoretical foundation, the article has ignored the difficulties and secrets that are only passed on internally within the enterprise. In addition, because the study is based on a very large amount of data and studies on the entire Vietnamese manufacturing industry, thereby ignoring the specific characteristics of each individual manufacturing industry, the study has not shown clear practical aspects of each enterprise in particular.

Additionally, the PSM method requires a control group to compare with the treatment group. The process of selecting a suitable control group can lead to differences between the two groups, which can

distort the study results. The PSM method assumes that all confounding factors are adjusted by building a linear model for the probability of receiving treatment. However, if important confounding factors are not identified and adjusted, the results of the study may not be accurate.

## 5.2. Recommendation

Based on the regression results and literature background, some recommendations are suggested as following:

*Firstly*, it is necessary to take measures to manage account receivables well, shorten the average number of days account receivables.

In terms of internal control system, sale team or finance team should review customer credit line by quarter or by year based on historical payment to consider increase or decrease the credit line in the future. The credit term should be authorised by senior staff before applied to customers. These control procedures make sure that all the sale transactions and trade credit policies can be made to customers with good credit rating. Furthermore, they can reduce the risk of unrecoverable debts and other costs relating to collect receivables.

Instead of focusing on punishing customers in case customers pay late for goods, companies should apply incentive programs for customers to encourage early payments. Enterprises need to focus on developing and implementing preferential policies for customers, such as enjoying a payment discount at an appropriate rate if customers pay early before the due date; or the customer gets faster shipping or free shipping if the customer pays in full and early; or customers enjoy a better credit purchase policy from the business if they maintain full and early payment.

For shortening the average receivable period (ADR), the company can offer an attractive discount for customers who pay early so that customers can enjoy a better commercial discount policy from the business if they maintain early and full payment. But for this measure, businesses also need to consider a reasonable commercial discount because increasing the trade discount means that the business will increase costs and may have negative effects on profits, reducing the operating performance of the business.

*Secondly*, enterprises need to find the optimal capital structure, the appropriate level of debt use, thereby forming the enterprise's debt policy to improve operational performance. According to the theory of financial leverage, when  $BEP > r$ , if a firm increases its debt, it will help amplify its ROE, whereas when  $BEP < r$ , increasing debt will be like a double-edged sword, increasing financial risk, making reduce ROE, reduce the performance of the business. Moreover, businesses should also consider which source to borrow, how long to borrow to suit the nature of their industry, avoid liquidity risks such as due debt but no source to pay, ...

*Thirdly*, for liquidity, businesses need to calculate the optimal level of cash reserves. To determine a reasonable level of cash reserve, the simplest way is to base on the statistics of the average daily cash expenditure and the number of days of reasonable cash reserves. In addition to the above method, the minimum total cost model (Baumol model) can be applied in inventory management to determine the target cash balance of the enterprise.

*Fourthly*, businesses need to carefully consider the relationship between business growth and profitability. Enterprises, when faced with any investment or business opportunity, must adhere to the relationship between costs and benefits received. Enterprises need to focus on measures to boost revenue, increase profits, and improve profitability. Listed manufacturing enterprises need to actively exploit the consumption market and accelerate sales. Enterprises also should actively exploit and build distribution channels, improve business networks, sales methods, prices, payment methods, etc. to promote revenue, thereby increasing profitability.

*Finally*, businesses should improve internal control and management systems to improve the Working capital management and profitability.

Company should apply SAP, MISA, FAST or other software. These software allow updating real data and information appropriately and completely. It can reduce control risks leading to fraud and errors in the information processing, thereby support the managers to make appropriate decision in terms of working capital management. Therefore, it can improve the working capital management and support operational activities in the business.

Enterprises can consider Kaizen as a way to create an conducive environment to enhance the productivity and management. Kaizen - Continuous Improvement supports companies in creating a process-oriented way of thinking and implementing strategies to guarantee continuous enhancements by engaging personnel at all organizational levels. The fundamental concept of the Kaizen strategy is that no day should go by without an advancement being made somewhere inside the company. Kaizen, or continuous improvement, attempts to make every process waste-free by involving every employee in the business. Kaizen encourages individuals to think creatively and implement beneficial changes while consuming fewer resources.

Enterprises also should conduct training and developing programs to improve the competence and knowledge of employees. Based on Learning Curve, employees with high-skilled and experienced competence can help to reduce the production time per unit, thereby enhancing the productivity. That is a way to manage working capital better and improve profitability of the company.

## IMPACT OF TAX POLICIES ON SMALL AND MEDIUM ENTERPRISES IN VIETNAM

**Authors: Do Ngoc Minh<sup>1</sup>, Luong Tu Anh, Kieu Thi Hoai Thu, Luong Xuan Khai**  
**Mentor: PhD. Ha Thi Doan Trang**

**ABSTRACT:** *Small and medium-sized enterprises are the majority and main types of enterprises in the economy. This type of enterprise plays an important role in creating jobs, increasing incomes for workers, helping to mobilize social resources for development investment, poverty alleviation, etc. Vietnam's tax policy system currently has many regulations on tax incentives for enterprises to encourage investment development. However, those incentives are not aimed at supporting the development of small and medium-sized enterprises. The objective of the research paper is to analyze the current situation of corporate income tax and value-added tax policies to propose the development of small and medium enterprises in Vietnam and to propose feasible solutions to improve tax policies to support the development.*

**Keywords:** *Small and medium enterprises, Tax policies*

### 1. OVERVIEW OF TAX POLICIES FOR SMALL AND MEDIUM-SIZED ENTERPRISES

**Small and medium enterprises (SMEs)** are growing rapidly in number, accounting for a large number, and have made great contributions to the economic and social development of the country. This is the inevitable result of implementing the renovation policy led by our Party with the main view of developing a multi-sector socialist-oriented market economy, in which, encouraging “Development A healthy, efficient and sustainable private economy has really become an important driving force of the socialist-oriented market economy, contributing to fast, sustainable, and sustainable socio-economic development. stop improving people’s living standards, realize social progress and justice, ensure national defense and security, and soon turn our country into a modern industrialized country.”

**Tax policies** are understood as the perspectives and guidelines of the State related to the use of tax tools in its system of policies. That system of views and guidelines is reflected in the recognition of the role of taxation, the objectives of using tax tools, the scope of impact, the rate of regulation, and orientation in the long term ... to make tax instruments best promote their roles according to the State’s economic and social development strategies and policies.

#### **Concept of SMEs**

According to the criteria of the World Bank Group, SMEs are enterprises with less than 10 employees, small enterprises as those with employees from 10 to less than 200 people and capital of 20 billion or less, and medium enterprises with 200 to 300 employees and with capital of 20 to 100 billion. According to Vietnamese regulations, microenterprises have an average number of employees participating in social insurance not exceeding 10 people per year and total revenue of the year not exceeding VND 10 billion or capital sources not exceeding 3 billion Vietnam dong (VND 3 billion). Small enterprises with an average number of employees participating in social insurance not exceeding 50 people and total revenue of the year not exceeding VND 100 billion or total capital not exceeding VND 50 billion; Medium enterprises have an

<sup>1</sup> Academy of Finance.

average number of employees participating in social insurance not exceeding 100 people per year and total revenue of the year not exceeding VND 300 billion or total capital not exceeding VND 100 billion.

### **Tax policy impacts on SMEs**

The context of integration is creating great pressure on the Vietnamese economy and business community. Tax support policies are commonly used to facilitate and promote the development of SMEs.

Tax incentives are the Government's solution to promote the SME sector to develop stronger, and create more jobs, thereby contributing much to the State budget in the future, rejecting the preferential view here to let businesses continue to struggle with small and medium-scale, then scale this is also a very important orientation.

### **Forms of support of tax policies for SMEs**

*For corporate income tax:* support through corporate income tax rates; implement corporate income tax exemption and reduction for a definite period; extend the time for paying corporate income tax; investment discounts; tax credits; allows accelerated depreciation; allow transfer of losses.

*For value-added tax:* develop a value-added tax registration threshold; simplify the structure of value-added tax rates; simple value-added tax regime; value-added tax refund; exemption, reduction, or extension of the time limit for payment of value-added tax.

## **2. CURRENT SITUATION OF TAX POLICY IMPACTS SMALL AND MEDIUM-SIZED ENTERPRISES IN VIETNAM**

### **2.1. Current situation of small and medium enterprises in the period of 2016-2022**

SMEs are the “pillar” of Vietnam's economy, accounting for a large proportion of production, consumption, job creation, and tax contributions. In Vietnam today, over 97% are SMEs out of a total of nearly 1 million enterprises across the country.

The number of SMEs in operation is constantly increasing over the years. In 2022, the number of active businesses has increased due to the acceleration of start-ups. In 2022, a record number of newly registered enterprises (148.5 thousand enterprises), an increase compared to previous years.

The increase in the number of startups has contributed to economic growth far exceeding the target (8.02% compared to 6-6.5%) and is a positive signal for the acceleration of start-ups in the coming years.

SMEs have contributed an encouraging proportion of the production value of industries, contributing to the annual budget of the country. Conditions for SME development have been paid attention to by state management agencies and somewhat improved, creating conditions for SMEs to be born and operate.

*In the period 2016-2022, SMEs in Vietnam have achieved many remarkable achievements:*

A great contribution to the economy: In particular, SMEs account for a large proportion of the Vietnamese business community, employ nearly half of the total number of workers and contribute significantly to about 40% of GDP annually. Playing an important role in the private sector, the SME sector has created jobs, mobilized domestic capital sources for production and business activities, and solved social issues promoting the transformation and growth of Vietnam's economy in recent years.

Enhancing competitiveness: Many SMEs have invested in research and development, technology improvement, production management, offering high-quality products and services, improving production and business capacity, creating more jobs, and improving incomes for workers. SMEs develop towards product diversification to meet the needs of domestic and foreign markets.

Strengthening foreign cooperation and investment: Many SMEs have sought opportunities for foreign cooperation and investment, established joint ventures, and cooperated with foreign partners to offer high-quality products and services.

*On the other hand, SMEs still have some drawbacks:*

SME development in Vietnam has not been associated with the common and long-term sustainable interests of the whole society; SMEs are small in terms of capital size, labor, and weak competitiveness; Qualifications and capacity of production and business management of business owners; the technical level, professional expertise and skills of workers in SMEs are still very limited; Machinery and equipment are mostly outdated, have not applied advanced science and technology to production and business activities as well as management; SMEs face capital difficulties and poor self-financing; Product competitiveness is still low, the product consumption market is small; SMEs' ability to link, cooperate and join associations is limited; SME development conditions have improved, but many limitations remain.

According to the statistics of the General Statistics Office, this is a fragile force in the market, especially when the event happened. From 2020 through 2022, due to the impact of the Covid-19 pandemic, an average of over 10,000 businesses withdraws from the market every month. In difficult times, government policies, especially fiscal policies, have a significant impact on SMEs.

## **2.2. Current status of tax policies applied to small and medium enterprises in Vietnam.**

In recent years, the Party and State have promulgated many mechanisms and policies to support SMEs to overcome difficulties and barriers to improve financial capacity, develop production, business and create jobs such as the Law on Enterprises (2014, 2020), Law on Investment (2014, 2020), Law on SME Support 2017, The Law on Value Added Tax, Corporate Income, Import, and Export Tax has had a positive impact on the development of SMEs in Vietnam, creating an open and equal environment for all types of enterprises.

However, small and medium-sized enterprises still face many difficulties, many policies are issued but slow to have guiding documents, leading to many small and medium-sized enterprises being confused in implementation; some policies are not strong enough to create motivate for small and medium-sized enterprises to operate and develop, Although there is no policy discrimination, in fact, compared to large-scale enterprises, SMEs are facing more difficulties and barriers in accessing existing tax incentives.

### **2.2.1. Corporate income tax policy for small and medium-sized enterprises**

Corporate income tax is one of the important sources of revenue of the state budget. Corporate income tax policies are stipulated by the Government in each specific period, to ensure adaptation and suitability corresponding to fluctuations of the business environment, economic cycles, difficulties of enterprises as well as the Government's expectations of policies. In the period from 2016 to 2021, the government has had many policies to support businesses in general and SMEs in particular on corporate income tax to promote national economic development.

Vietnam has gradually reduced the common corporate income tax rate through amendments and supplements to a number of articles of the Law on Corporate Income Tax in accordance with the set roadmap, for small and medium enterprises from January 1, 2016, up to now, the tax rate of 20% has been applied.

The reduction of the common corporate income tax rate has significantly reduced the contribution obligations of many businesses but has had an impact on encouraging business and creating favorable conditions for businesses to increase accumulation, increase investment, and promote growth.

In the period from the end of 2019 to the end of 2021, the outbreak of the Covid-19 epidemic affected the production and business situation of SMEs, so to support businesses, especially SMEs affected by the epidemic, the government has also launched many economic relief packages amounting to hundreds of trillions of VND. Notably, in addition to economic relief packages, in 2020, the Government implemented many flexible tax policy solutions such as tax exemptions, extensions, fees, land rent with nearly VND 124,000 billion, timely support for businesses and business households to overcome difficulties caused by the COVID-19 pandemic.

Specifically, in 09/2020, the Government issued Decree 114/2020/ND-CP detailing the implementation of Resolution No. 116/2020/QH14 of the National Assembly on reducing payable corporate income tax in 2020 for enterprises, cooperatives, non-business units, and other organizations. Accordingly, the Decree states that 30% of the payable corporate income tax amount of the 2020 corporate income tax period will be reduced in case the enterprise has a total revenue of not more than VND 200 billion.

The Government has also issued Decree No. 41/2019/ND-CP dated 08/4/2020 extending the tax payment deadline for the amount of corporate income tax still payable according to the finalization of the 2019 tax period and the provisional corporate income tax amount paid in the first and second quarters of the 2020 tax period of enterprises, organizations being corporate income taxpayers specified in Article 2 of this Decree. The grace period is 05 months from the end of the corporate income tax payment period following the law on tax administration. According to the General Department of Taxation, as of September 22, 2020, the total amount of corporate income tax extended was VND 30,563 billion, 2.75 times higher than the initial reduction estimate of the Ministry of Finance (VND 11,100 billion).

On April 19, 2021, the Government issued Decree 52/2021/ND-CP dated April 19, 2021 on extending the deadline for paying value-added tax, corporate income tax, personal income tax, and land rent in 2021. Specifically, for corporate income tax: Extend the tax payment deadline for the provisional corporate income tax amount of quarter 1 and quarter 2 of the corporate income tax period in 2021 of enterprises and organizations mentioned above. The grace period is 03 months from the end of the corporate income tax payment period by the law on tax administration.

**Paragraph 1: Situation of enterprises temporarily suspending business, waiting for dissolution procedures, completing dissolution procedures 10 months of 2021**

Source: GENERAL STATISTICS OFFICE

Thus, in the period 2016-2021, the Government of Vietnam has had many policies to exempt, reduce and extend the tax payment period to partly support the expenses that SMEs have to spend on corporate income tax in order to promote economic development and reduce the financial burden on SMEs.

Currently, the Ministry of Finance has submitted to the Government for promulgation 2 Decrees (license fees, registration fees) and issued more than 30 circulars to amend 34 types of fees and charges, current in the direction of exemption or reduction of the collection of many fees and charges or Decree 91/2022/ND-CP (effective from October 30, 2022), the temporary payment of corporate income tax in the quarter of 2023 to continue to make policy adjustments to suit the actual situation, as well as continue to the development of the whole business in general and SMEs in particular continue to grow and develop stably.

**2.2.2. Current status of value-added tax policy of small and medium-sized enterprises**

The current status of value-added tax (VAT) policies of small and medium enterprises in the period of 2016-2021 is reflected in specific data including tax rates and tax refund amounts and total state budget revenue from the value-added tax that SMEs have paid and enjoyed.

**Paragraph 2: Overview of value added tax for the period 2016-2020 (unit: Hundred billion dong)**

Source: GENERAL STATISTICS OFFICE

The VAT Law stipulates 25 groups of goods and services that are not subject to value-added tax. In addition to the tax rate of 0% applied to exported goods and services, the Law stipulates 14 groups of goods and services subject to the tax rate of 5%. The remaining goods and services are subject to a tax rate of 10%. The Law on Value Added Tax does not provide for tax exemption and reduction, so to show flexibility in administration as well as adaptation to fluctuations of the economic cycle or the impact of the COVID-19 epidemic, our state has issued policies on value-added tax to support the government. Enterprises, including SMEs, overcome difficulties such as:

In 2020, the Government issued a VAT extension policy under Decree No. 41/2020/ND-CP, which has created many positive effects in supporting businesses affected by the COVID-19 pandemic. This policy allows businesses to extend the VAT payment deadline for up to 5 months without incurring any fees. This gives businesses more peace of mind in managing cash flow and alleviates financial pressure due to difficulties during this time. This policy has contributed to supporting and promoting economic development because it has encouraged businesses to continue operating and investing in its development. According to the General Department of Taxation, the total amount of value-added tax and personal income

tax of households and business individuals extended as of September 22, 2020, is VND 827.8 billion, only 1.34% compared to the initial state budget revenue reduction estimate of the Ministry of Finance (estimated initial reduction of about VND 61,600 billion). This number is too small compared to the estimate, which will affect the operation of enterprises in general, especially the group of SMEs - the most vulnerable group of businesses.

In 2021, the Government also issued Decree 52/2021/ND-CP dated April 19, 2021, extending the deadline for paying value-added tax, corporate income tax, personal income tax, and land rent in 2021. The Decree states and extends the tax payment deadline for the amount of value-added tax incurred to be paid (including the amount of tax allocated to other provinces where the taxpayer is headquartered, the amount of tax paid according to each occurrence) of the tax period from March to August 2021 (for the case of declaring value-added tax by month) and tax period Q1 and Q2, 2021 (for the case of quarterly value-added tax declaration) of enterprises and organizations. The grace period is 05 months for the value-added tax amount from March to June 2021 and Q1, Q2 2021, the grace period is 04 months for the value-added tax amount of July 2021, and the grace period is 03 months for the value-added tax amount of August 2021... Unlike Decree No. 41/2020/ND-CP, Decree 52/2021/ND-CP is said to be more effective and detailed for enterprises, especially SMEs when the group of businesses has been greatly affected by the complicated developments of Covid-19.

In addition, in 2022, to support businesses and people in recovering from the Covid-19 epidemic, the Government has also submitted to the National Assembly for approval Resolution No. 43/2022/QH15 on fiscal and monetary policies to support the Socio-Economic Recovery and Development Program (including regulations on reducing the VAT rate for most items that are subject to a tax rate of 10% down to 8%; At the same time, continue to implement solutions on extension, exemption, and reduction of taxes, fees, charges, and land rent and in the face of fluctuations in gasoline and oil prices affecting production and business and the lives of people and enterprises.

It can be seen that the special attention of the State to businesses in general, including SMEs to stabilize the economy to help businesses overcome difficulties, besides the positive aspects, there are some limitations such as VAT costs are still high for some goods and services, along with the delayed and complicated implementation of the VAT refund policy of state agencies. Therefore, the government needs to make adjustments and improvements in VAT policy to ensure stable development for SMEs and help create motivation for business activities.

### **3. ASSESSING THE CURRENT SITUATION OF TAX POLICIES FOR SMALL AND MEDIUM ENTERPRISES IN VIETNAM.**

#### ***Results***

##### *Corporate Income Tax Incentives*

The results of the implementation of corporate income tax policy for SMEs show that solutions to support SMEs to exempt and reduce taxes in the period of 2016 - 2021 have supported SMEs to enjoy many incentives, save costs, and turn over capital quickly to stabilize production, and business.

In 2020, in order to share difficulties with the business community, economic organizations, households, and business individuals affected by the Covid-19 epidemic, the solution to extend the deadline for paying corporate income tax according to Decree No. 41/2020/ND-CP also helps SMEs use the corresponding money for 5 months with 0% interest rate; At the same time, reducing corporate income tax by 30% for SMEs with revenue of less than 200 billion VND/year helps SMEs have more financial resources to recover production - business when the Covid-19 epidemic is still complicated on a global scale.

In addition, the corporate income tax policy has contributed to the implementation of the development orientations of the Party and the State. Corporate income tax policies contribute to the redistribution of income, ensure social justice and ensure revenue for the state budget. the corporate income tax has created a large, concentrated, and increasingly stable source of revenue for the state budget; contributing to eliminating discrimination between economic sectors and between types of businesses, thereby contributing to creating a healthy competitive environment between economic sectors. The addition of the principle of corporate income tax collection for enterprises investing abroad has helped to reasonably encourage overseas investment to transfer income to Vietnam.

#### *Value-Added Tax Relief Policies*

The regulation of tax rates at 3 levels has ensured compliance with Vietnamese conditions, creating favorable conditions for SMEs to apply as well as gradually approach tax rates in the region and the world.

The law also stipulates a tax refund period after at least 12 months with the tax amount not fully deducted and the minimum tax rate to be refunded for investment and export is VND 300 million (formerly VND 200 million), contributing to overcoming current shortcomings, reducing difficulties for the tax refund fund; contributing to preventing fraud in tax refunds, and at the same time promoting domestic manufacturing enterprises to accelerate the introduction of projects into operation and promote the circulation of goods for enterprises, especially SMEs.

Extending value-added tax in the Covid-19 period according to Decree No. 41/2020/ND-CP has been creating positive effects for SMEs to stabilize and gradually strengthen production and business in 2020, creating a premise for development in the following years, contributing to sharing difficulties mainly for SMEs.

The reduction of value-added tax will contribute to reducing production costs, lowering product costs, thereby helping businesses increase their resilience and expand production and business, creating more jobs for workers. At the same time, it helps businesses reduce costs, remove difficulties for businesses, create conditions for businesses to maintain and stabilize production and business activities in difficult economic conditions, and at the same time encourage morale and create confidence for businesses.

#### *Backward and shortcomings*

In recent years, the Government has issued policies to support the development of SMEs, but the implementation of policies is still limited, and SMEs still face many difficulties in the development process.

#### *Corporate Income Tax Incentives*

The attention to the policies of enterprises is still limited, with many backlogs of corporate income tax fraud. This leads to a loss of state budget revenue, especially in the non-state sector, which focuses on areas such as basic construction, resource exploitation, minerals, private transport business, construction materials business, e-commerce business online sales...

The problem of inconsistent, cumbersome administrative procedures, slow implementation, or enforcement officers causes difficulties for businesses, which can cause businesses to miss the opportunity to take advantage of capital for production and business.

Some enterprises are still confused when applying criteria to identify beneficiaries of incentives according to the provisions of tax exemption and reduction policies issued during this period on the development of supporting industries. Accordingly, the beneficiaries are supporting industry products including new investment projects, technology expansion and innovation projects with the application of new technology equipment and new production processes, with a production capacity increase of at least 20% of enterprises that do not know which criteria will be used to qualify for the support.

The maintenance of two forms of corporate income tax (CIT) incentives is the priority of tax rates and the period of tax exemption and reduction. This, on the one hand, can lead to the risk that businesses “circumvent the law” in the form that after the tax exemption and reduction period, the end of the enterprise will seek to declare losses or make price transfers, evade taxes, or also proceed to dissolve to establish a new business; On the other hand, it will lead to an overlap between the tax rate incentive mechanism.

The extension of corporate income tax under Decree No. 41/2020/ND-CP for small and medium enterprises affected by the Covid-19 pandemic is not large (VND 30,563 billion)/the total number of enterprises affected according to the statistics at the end of 2020 (more than 700 thousand enterprises), leading to low support efficiency. In addition, with the exemption policy of 30% of corporate income tax for enterprises with revenue in 2020 of less than VND 200 billion, enterprises can only use this exemption source in 2021, which cannot be used immediately because they have to wait until the 2020 settlement period.

#### *Value-Added Tax Relief Policies*

Some SMEs take advantage of loopholes in the policy to cheat on VAT for businesses, which has remained a problem throughout the years in sophisticated forms, causing difficulties for businesses and tax management such as:

*Firstly*, enterprises that reduce the output value-added tax payable, increase the deductible input value-added tax.

*Second*, fraud by adjusting the input and output value-added tax not according to regulations.

*Third*, enterprises deliberately misidentify tax rates for services and goods.

Although the policies to remove difficulties for the market to support production and business such as Decree No. 52/2021/ND-CP, Resolution 406/NQ-UBTVQH 15, Decree No. 57/2020/ND-CP, Decree No. 41/2020/ND-CP have supported small and medium enterprises to overcome difficulties, however, SMEs still have to fulfill many tax obligations when their obligations are due, leading to cash flow insecurity to pay tax obligations.

The extension amount according to Decree No. 41/2020/ND-CP is low, the reason is in addition to the value-added tax in the first and second quarters of 2020. In addition, the cumbersome procedure makes it difficult to access. According to a survey on the situation of receiving the first support packages published by the National Economics University, about 80% of surveyed enterprises did not receive the first support package according to Decree No. 41/2020/ND-CP. The reason is that the business does not meet the conditions and/or does not have information about the support policy.

In some cases, it is easy to cause misunderstanding in the issue of applying value-added tax rates on input materials and output products at manufacturing enterprises. In particular, the accounting team of coal enterprises is having difficulty in the process of applying value-added tax exemption, reduction, and extension policies.

#### **4. ORIENTATION TO IMPROVE TAX POLICY FOR SMES IN VIETNAM**

Facing the limitations and difficulties of the business sector in general - SMEs in particular, it is required that the Government synchronously perfect the tax policy system of Vietnam in accordance with the standards of a good tax system according to Circular No. international standards, and at the same time meet the resource requirements for the implementation of the 10-year socio-economic development strategy 2021-2030, including the following main taxes, fees and charges: Value-added tax increase; excise tax; export tax, import tax; Corporate income tax; personal income tax; resource tax; agricultural land use

tax; non-agricultural land use tax; environmental Protection tax; fees, charges and other revenues belonging to the government budget.

The institutional reform related to tax policy with the reform of tax administration institutions will have to be carried out synchronously, including restructuring the tax administration professional process and improving the efficiency of tax administration. Tax management based on risk management platforms, information technology applications and big data. Strengthen the building of tax database to better meet the requirements; research to establish a mechanism to collect information and link information related to taxpayers to identify tax avoidance and tax evasion activities.

### **Solutions to improve tax policy to support the development of SMEs**

#### **For corporate income tax**

Review to amend or abolish tax exemption and reduction preferential policies that are no longer suitable with development requirements and international integration requirements; minimize the integration of social policies with tax exemption and reduction policies, ensure tax neutrality for stable application in the medium and long term.

Implement corporate income tax incentives for small and micro enterprises, and at the same time, shift the focus of foreign investment attraction policies from quantity to quality, and encourage the participation of all economic sectors. in investment in key industries and trades and in areas that need to be encouraged for investment. Broaden the tax base to reflect the country's socio-economic environment and international practices; implementation of standards to prevent and combat transfer pricing - tax evasion, and prevention of income erosion in line with international practices.

Completing and appropriately amending corporate income tax policies depending on specific circumstances and periods:

Firstly, there is a preferential corporate income tax policy for SMEs in the industries that produce products with great added value such as high technology, science and technology; SME incubator, technical base, co-working area to support and invest in innovative start-up SMEs.

Secondly, reducing the tax rate for SMEs, although reducing the corporate income tax rate, will lead to a decrease in state budget revenue, but will stimulate investment, increase GDP, and ensure competitiveness and investment environment. attractive, selective investment attraction and improve investment quality of Vietnam with the region and the world (common at 10%, 15%, 17%, 19% and 20%).

Third, apply the form of the investment tax deduction for SMEs when investing and purchasing fixed assets for the business. One of the difficulties of SMEs is the lack of business capital, so the State can have policies to support businesses when they invest in purchasing fixed assets for production and business through the form of investment tax deduction.

Fourthly, to determine SMEs enjoying CIT incentives, the CIT rate should be based on income threshold instead of revenue. This regulation helps tax authorities reduce administrative costs, create fairness among enterprises of the same size, and contribute to generating stable revenue for the state budget.

Fifth, continue to review and simplify tax administrative procedures for SMEs such as micro-enterprises only submit CIT declarations once a year; The CIT declaration should be simpler in design, requiring only a few items (Revenue; expenses in the year; income in the year; adjustments without attachments or financial statements such as appendices or financial statements such as: Present) ...

Sixth, it is necessary to give strong incentives to income declaration, encourage the implementation of transparent and clear transactions across banks, and properly execute books, records, invoices, and

documents in accordance with the law. At the same time, tax authorities should give recommendations to SMEs about the risks of tax audit and inspection; prosecute before the law...

Seventh, to ensure the clarity, fairness, publicity and transparency of the CIT policy in order to encourage investment and contribute to the realization of the economic re-growth target.

**Regarding value-added tax:**

Expanding the tax base by reducing the group of goods and services not subject to value-added tax and the group of goods and services subject to the 5% tax rate; essentially apply a single rate of taxation.

Research to increase the value-added tax rate according to the roadmap; review and adjust the revenue threshold applying the deduction method to suit reality; research on uniform application of tax calculation method as a percentage of turnover for taxpayers whose turnover is below the threshold or are not eligible to apply the deduction method.

Completing regulations related to value-added tax on exported goods and services, ensuring that they reflect the true nature and international practices. Research to amend and supplement regulations on tax deduction and value-added tax refund in the direction of simplicity, transparency and synchronization with relevant laws./.

## GREEN CREDIT IN VIET NAM: SITUATION AND SOLUTIONS

Author: Phan Thi Nguyet, Tran Thi Huong<sup>1</sup>

*ABSTRACT: Apparently, green credit is a topic of great interest around the globe nowadays. The green credit model plays a vital role in providing countries with essential capital with a view to achieving their sustainable development goals, especially the environmental and climate ones. In Vietnam, green credit activities have also been implemented in recent years and achieved many encouraging results in a wide range of fields. However, the process of implementing this new growth model is still facing many disparities and challenges. After assessing the current status of green credit activities in Vietnam during past time, this study proposes some recommendations to boost the development of this activity in the coming time.*

*Keywords: green credit, Vietnam*

### 1. RATIONALE

In reality, Vietnam is known as one of the most vulnerable countries to climate change as well as a country with a large open and fast-growing economy. Boosting investment in green infrastructure is therefore very important for Vietnam to meet international commitments on climate and build the resilience to the impacts of climate change, thereby contributing to economic development. In reality, Vietnam has now identified green growth as a strategy for sustainable development, especially in the context of being heavily affected by natural disasters and climate change. In order to implement the green growth strategy, a large amount of capital is required to focus on green projects. Along with the banking system, the capital market in general and the bond market in particular are vital capital mobilization channels for green projects, thereby gradually forming a green credit system to serve national strategic goals on green growth.

Based on those requirements, with the desire for Vietnam's economy to grow in a green way, the expectation of each Vietnamese's more deeply understanding about the importance of green credit and the wishing to offer some valuable solutions to promote green credit, I decided to choose the topic "*Green credit in Vietnam: Current situation and solutions*" for this research paper. The paper provides readers with thorough understanding about the requirements, benefits and importance of green credit and suggests some solutions to promote green credit in Vietnam.

### 2. LITERATURE REVIEW

Prior researches at home and abroad have provided a theoretical foundation for green credit as well as an assessment of the impacts of green credit on economic and social fields, etc. Specifically, Aizawa and Yang (2010) presented that green credit is one of the solutions applied by the financial industry to handle the world's environmental and social challenges through financial instruments. Wang, E., Liu, X., Wu, J., & Cai, D. (2019) assessed the importance of green credit in China, according to which it is necessary to develop strategies, create markets and make room for green economy; to forecast, share and guide in green economic development. Moreover, the government should assist enterprises in developing green economy.

Nguyen Phuong Lien (2022) studied the current status of green credit in Vietnam in terms of implementation organization, capital sources, products, scale, structure and growth rate of green credit. From the results of

<sup>1</sup> Academy of Finance.

analysis and assessment of the current situation and the issues set out in the green credit development of Vietnamese commercial banks according to the characteristics of green credit, the authors of the article recommended useful solutions to commercial banks, to organizations and individuals investing in green projects, to the government and state management agencies to develop green credit, thereby contributing to the successful implementation of the National Action Plan under the 2030 Agenda for Sustainable Development.

In fact, the analysis and assessment of the impacts of green credit on the economy as well as on other fields such as environment, culture, society, etc., always play a crucial role in the development of each country, each region and each locality especially in the context of climate change and that natural disasters negatively affect the world. Based on the changing reality of green credit activities in different periods, the study will make appropriate assessments on promoting the development of green credit, thereby providing scientific evidence to help managers with policies towards the goal of promoting the development of green credit in the context of climate change and strong impact of natural disasters.

With the view to assessing the status of green credit in Vietnam, the study uses qualitative research methods to contribute to clarifying the topic. The qualitative research methods used in this study include: analytic method, method of document collection and comparative method. The above methods help assess the status of green credit development in Vietnam compared to other countries, thereby offering suitable solutions to promote green credit in Vietnam. Research data is collected from the General Statistics Office, the State Bank and Annual reports at a number of Vietnamese banks in the period 2016-2020.

## **2. CURRENT STATUS OF GREEN CREDIT IN VIETNAM**

### **2.1. Green credit for the Vietnamese economy**

Vietnam ranks the world's 42<sup>nd</sup> largest economy. Nevertheless, it is also one of the ten countries with the highest levels of air pollution in the world, according to the World Bank's Environmental Performance Ranking 2021. After Vietnam joined the World Trade Organization (WTO), the economy faced great pressure from member countries, the concern was that domestic goods could not compete with international products, which had set an urgent requirement to actively expand and improve the quality of domestic products.

However, improvements in quality need to closely related to transforming and upgrading operating models in order to meet environmental standards in the right direction of the economy's sustainable development in the new era. Currently, most domestic enterprises are in a state of capital shortage. A series of projects and sustainable development models cannot be implemented because of limited budget supply. Resources for green finance are becoming essential as:

*Firstly, Vietnam is aiming to achieve the goal of sustainable development, so green credit plays a vital role in this process.* In fact, the process of socio-economic development in Vietnam in recent years have not yet been given due attention. According to the World Bank (2017), Vietnam is one of the countries most affected by climate change. The impact of climate change in Vietnam seriously threatens the progress of poverty reduction, the implementation of the Millennium Development Goals and the country's sustainable development. Faced with the above issues, the government has implemented the National Strategy on Climate Change and updated the scenarios to respond to climate change and sea level rise, emphasized the link between climate change sustainable development, while recognizing climate change as a common challenge that requires the cooperation of the whole society.

*Secondly, this is a real fiscal space to which commercial banks need to pay attention, especially in the context of increasingly positive liquidity and capital input.* Experience from countries around the world indicates that green growth projects often had difficulties in mobilizing capital since the State could

only aid a small part, the rest would be self-financed from other sources. Therefore, this is the “land” that brings many sustainable benefits to credit institutions (profit, prestige, etc.) and provides businesses and the community with loans.

In Vietnam, according to Article 149 of the Law on Environmental Protection No. 72/2020/QH14 passed by the XIV National Assembly on November 17<sup>th</sup>, 2020, green credit is a credit granted to the following investment projects: (i) Using natural resources effectively; (ii) Response to climate change; (iii) Managing waste; (iv) Treating pollution, improving environmental quality; (v) Restoring natural ecosystems; (vi) Conserving nature and biodiversity; and (vii) Generating other environmental benefits.

## **2.2. Current status of green credit in Vietnam**

### **• *Green credit development policy***

In order to promote the development of green credit to implement the guidelines and strategies of the Party and State on green growth and sustainable development, over the years, the State Bank of Vietnam (SBV) has issued many mechanisms and policies to create a legal basis for this activity, which starts with Directive No. 03/CT-NHNN on promoting green credit and managing environmental and social risks in credit granting activities. Following that, the State Bank issued Decision No. 1552/QD-NHNN dated August 6, 2015 on the Action Plan of the Banking sector to implement the National Green Growth Strategy for the period 2015-2020; Decision No. 1604/QD-NHNN dated August 7, 2018 on approval of green banking development project in Vietnam; Decision No. 1731/QD-NHNN dated August 31, 2018 promulgating the Action Plan of the Banking sector to implement the 2030 Agenda for Sustainable Development.

In addition, in order to concretize the orientations and goals for green credit development and green banking, the SBV has issued many documents guiding lending and credit granting activities to ensure compliance with the Law on Environmental Protection, such as: Circular No. 27/2015/TT-NHNN dated December 15, 2015 of the Governor of the State Bank of Vietnam guiding the implementation of loans for production afforestation and livestock development in accordance with the provisions of Decree No. 75/2015 /ND-CP dated September 9, 2015 of the Government on mechanisms and policies for forest protection and development, associated with the policy of rapid and sustainable poverty reduction and support for ethnic minorities in the period 2015-2020 ; Circular No. 39/2016/TT-NHNN dated December 30, 2016 of the Governor of the State Bank regulating lending activities of credit institutions (CIs), foreign bank branches to customers.

In addition, the SBV also cooperated with a number of international organizations to develop guidelines for credit institutions to identify and make statistics on credit granting activities for 12 green areas, to issue a manual to guide credit institutions to conduct credit assessment environmental and social risks in credit granting activities to 15 economic sectors with high risks to the social environment.

Along with the issuance of the above documents, the SBV has researched and developed mechanisms, policies, schemes and projects in order to develop modern banking services using high technology, contributing to the green growth, such as: Completing the legal framework in the field of payment; Deploying the non-cash payment development project; The scheme to promote payment through banks for the collection of fees for public services; Developing payment facilities and services via the Internet, via mobile phones, via QR codes; submit to the Prime Minister a scheme on experimental management mechanism for financial technology (Fintech) activities in the banking sector; Research on the topic of Blockchain technology or distributed ledger technology to have an effective solution to perfect the legal framework, thereby creating a foundation for the development of the Fintech field...

Furthermore, the State Bank also actively participates in directing the implementation of green credit programs in some sectors and fields such as submitting to competent authorities for promulgation according to their competence preferential credit policies on interest rate support, and preferential collateral for customers implementing agricultural production projects along the value chain, hi-tech agriculture, and clean agriculture; Implementing loan programs for planting production forests according to Decree No. 75/2015/ND-CP dated September 9, 2015 of the Government; Implementing programs to support the poor in housing to prevent climate change such as loan program to build houses to prevent storms and floods in the Central region, to build houses in flooded areas of the Mekong Delta; credit programs that contribute to reducing greenhouse gas effects and reducing environmental pollution such as rural clean water and sanitation programs...

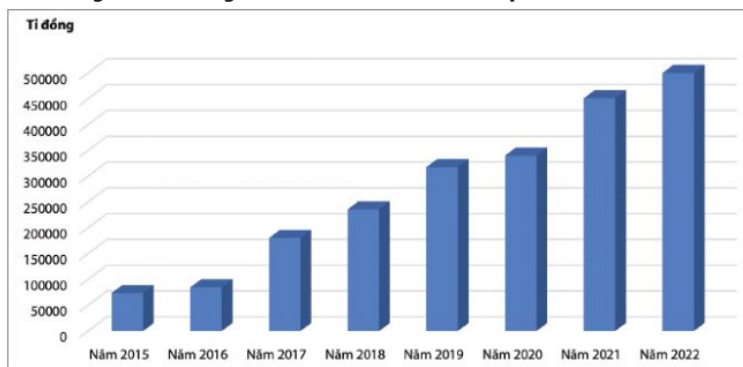

In order to strengthen the capacity of credit institutions in implementing green banking - green credit, the SBV has implemented many activities such as: Organizing programs and training courses to foster capacity for credit institutions and individuals participating in the development and implementation of mechanisms, policies, programs and products of green banking - green credit; Strengthening internal communication in the industry with diverse forms and rich content to raise awareness for officials, civil servants, public employees and employees of the Banking sector about the role and objectives of the national green growth strategy; Increasing resource mobilization from international financial institutions and bilateral and multilateral donors in order to diversify capital sources and improve financial capacity for credit institutions to implement green credit; Coming up with measures to encourage focusing on bank credit capital for projects, business production methods and investment in industries or fields to mitigate as well as adapt to climate change...

Under the drastic direction of the State Bank and appropriate organizational and implementation solutions, with the participation of credit institutions with a high sense of responsibility, the green credit policy has been implemented rapidly and is now put into effect.

- **Green credit development results**

By the end of 2022, credit balance for green projects (12 green projects built and issued by the State Bank of Vietnam since 2015) reached nearly VND 500,000 billion (accounting for about 4.2% of the total outstanding loans of the economy), focused on areas such as renewable energy, clean energy (accounting for the highest proportion 47%), followed by green agriculture (over 30%) (Figure 1). Credit institutions actively carry out assessing environmental and social risk in credit granting activities with outstanding loans of more than VND 2.2 million billion with more than 1.1 million loans.

**Figure 1. Total green credit balance for the period 2015-2022**

Source: Credit Department for Economic Sectors, SBV, 2022

Regarding interest rates, to support green projects of businesses and people, depending on the capital mobilization conditions and financial capacity of each bank and the nature of each field, credit institutions

have applied different interest rates, but the average rate is lower than normal lending rates in the market. Specifically, lending interest rates have been applied by credit institutions for short-term green fields from 5-8%/year, medium and long-term from 9-12%/year.

In terms of structure, green credit balances focus on two main areas which are renewable energy, clean energy and green agriculture. Specifically, the proportion of outstanding loans in the field of green agriculture in the total outstanding green credit in 2021 is 32% which decreases 8 percentage points compared to 2020 (40%); In contrast, the proportion of outstanding loans in the field of renewable energy and clean energy increased from more than 30% (2020) to 46% (2021). It can be seen that green credit for renewable energy, clean energy has had a breakthrough with total outstanding loans increasing by more than 100% (from nearly 100 trillion to more than 200 trillion) in 2021.

**Figure 2. Green credit structure in 2021**

*Source: Report on implementation results of green banking development project in Vietnam in 2021*

Up to December 31, 2021, there were 38 credit institutions with green credit balance, of which 24 credit institutions (63.16%) had green credit balance growth in 2021.

Interestingly, green credit balance is still highly concentrated in a few credit institutions. However, the concentration level has decreased compared to the previous year, which depicts that more and more credit institutions, especially small credit institutions, had focused on developing their green credit activities.

In respect to green credit balance scale, in general, credit institutions had had larger and larger green credit balances. By the end of 2021, there were 6 credit institutions with outstanding green credit of over VND 20,000 billion; 10 ones had green credit outstanding from 1000 to 10,000 billion dong; 12 ones had outstanding green credit from VND 100 billion to VND 1000 billion.

**Figure 3. Current status of green credit balance at credit institutions (according to the scale of outstanding loans)**

On the subject of the proportion of green credit outstanding on the total credit balance at each credit institution, the number of credit institutions with a high proportion of green credit outstanding tends to increase and the number of credit institutions with a low proportion of green credit outstanding tends to reduce. Up to December 31, 2021, there were 3 credit institutions with the proportion of green credit outstanding of from 10% - 20%; 3 credit institutions with green credit balance proportion of from 5% to 10%; 4 credit institutions had green credit balance from 3% to 5%; 14 credit institutions had a green credit balance proportion of less than 1%.

**Figure 4. Green credit balance to total credit balance at each credit institution**

Source: Report on exploiting the Green Bank development project in Vietnam in 2021

In general, in 2021, the goal of increasing the proportion of credit capital for green sectors and fields continued to be improved. The outstanding balance of green credit not only continued to increase, but also increased at a faster rate in the context of the economy being heavily affected by the Covid-19 pandemic. This reveals that credit institutions are increasingly focusing on providing green credit. In addition to the large group of credit institutions, small ones have also gradually increased the size and proportion of green credit, accounting for a larger proportion of the total green credit outstanding of the whole system.

- Limited and causes

Although many important results had been achieved, the green credit policy still had some shortcomings and limitations such as: lack of legal basis for green credit activities, lack of specialized guidance of specialized agencies on the list of green sectors and fields with specific criteria as the basis for state management agencies to develop mechanisms and incentives to encourage green activities and grant green credits; lack of an interdisciplinary cooperation mechanism to stimulate businesses to invest in green fields and to encourage banks to develop green credit.

On the side of credit institutions, the mechanism of mobilizing to create capital for green credit had not really been effective while accessing to preferential capital for green credit from international financial institutions (WB, ADB or funds for environmental companies, support funds...) with many difficulties. In reality, there are a wide range of credit institutions interested in and promulgating internal processes on green banking, green credit, appraisal process for green projects was not in large quantity. Furthermore, the capacity to assess environmental and social risks of many bankers was still weak, etc.

### 3. SOME RECOMMENDATIONS

#### Firstly, Measure and control criteria on green credit quality.

In general, the common problem of commercial banks in Vietnam is that they have only developed green credit from a macro perspective without specifically separating quantitative criteria such as measuring outstanding green credit, income from green credit, green credit market share, etc.

The figures given are still not clearly separated from green credit, income from green credit or outstanding green credit. Therefore, commercial banks in Vietnam need to develop tools to measure and

evaluate in detail the outstanding green credit and efficiency of green projects. Thus, commercial banks in Vietnam can control green credit and contribute to the development of green banking activities in Vietnam.

### **Secondly, Propagate and raise awareness about green credit**

Due to the lessons acquired from other nations, it is vital to take action to spread and broadly disseminate information in order to increase banks' awareness of the advantages and efficacy of providing green credit.

Besides, it is necessary to make banks believe that participating in and well implementing regulations on environmental risks will not only help the socio-economy in the direction of green development in general but also bring new business opportunities for banks, help the bank develop sustainably. At the same time, it is necessary to strengthen education and training on environmental awareness and responsibility of enterprises as well as help businesses understand the conditions for loans from green credit programs, so that they can actively adjust their operations and access loans from green credit programs.

In addition, after receiving green credit capital, enterprises need to use it responsibly and effectively, thereby gradually building trust between banks and enterprises in green credit development activities.

### **Thirdly, Developing a legal framework on green credit**

The prerequisite lesson of these three countries for Vietnam is that it is necessary to soon develop policies and operating mechanisms of green credit. The success of South Korea, China and the United States has a significant role of the government and regulators.

As a result, the Central Bank should release green credit guidelines shortly, as the majority of financial institutions currently lack any formal guidelines or strategies for managing customers' socio-environmental risks. Prior to directing the creation of green banks for credit institutions, the Central Bank must develop and issue guidelines.

In reality, the Central Bank shall provide instructions on how to create a report regarding green banks and green credits simultaneously, including the standards and reporting requirements to guarantee the following elements: governance and organizational structure, policy system and financial capacity, process management, internal controls and information disclosure; Out of the twenty-one economic sectors in total, the authors study and finish the Manual on Environmental and Social Risk Assessment for the sectors that have not yet offered instructions for loan-granting activities of credit institutions.; update the Green Project Portfolio on a regular basis.

### **Finally, Foster international co-operation**

Globalization has opened up various opportunities for people to implement green credit activities quickly and efficiently, so to take advantage of those opportunities. In order to help commercial banks have a foundation to gradually become more environmentally friendly, the Government and the Central Bank must work with international organizations and more developed nations to develop common environmental policies, facilitating the emergence of green banks in Vietnam.

Encourage international collaboration to exchange knowledge, conduct research, and gain experience in order to adapt green credit activities to the nation's current condition in a scientific and appropriate manner.

Promote international cooperation to build a legal corridor for green credit.

## ATTRACTING VENTURE CAPITAL TO INNOVATIVE START-UPS

**Authors: Vu Thi Phuong Thao<sup>1</sup>, Le Hai Ngoc<sup>2</sup>**

**Mentor: Ph.D Nguyen Dinh Dung<sup>1</sup>**

*ABSTRACT: Vietnam has thousands of innovative start-ups operating and funded by large domestic and foreign investment funds, however, ensuring working capital for operation and development is one of the great issues that startup businesses have been faced with. The study is conducted to point out the context as well as the achievements and limitations of attracting capital to Vietnamese innovative startups in the period 2018 - 2022. The results show that: the innovative start-up ecosystem in Vietnam still has a lot of barriers and is less competitive compared to other countries. The limitations are mainly due to the lack of facilities for research, limited financial support from the state budget and the scarcity in quantity and quality of high-tech human resources. Consequently, capital flowing into this kind of business becomes less and less, which calls for Governments' actions to address the situation.*

*Keywords: venture capital supply; legal corridor; technology; innovative startup ecosystem.*

### 1. INTRODUCTION

Up to now, Vietnam has hundreds of startup ideas that have been seeded, created and connected with the community and investment funds. With strong international economic integration, Vietnam is attracting more and more attention and capital from various businesses from different countries and regions such as the US, European Union, Japan, Korea, Taiwan, Loan, Singapore, China, etc. Some foreign investors even have the intention to establish a venture capital fund in Vietnam. Start-ups in general and innovative start-ups in particular have been contributing to economic growth, innovation and job creation for the domestic labor market. Despite the impressive growth rate, Vietnamese innovative startups are facing many barriers in the process. Securing capital for operation and development is one of the core issues that need attention of every startup business. It is clear that finance is an important cause that needs to be addressed quickly and promptly in the near future. The article analyzes the current situation encountered in the process of calling for investment capital for innovative start-ups and at the same time suggests some solutions to help enterprises open up capital in the period of industrial revolution 4.0 and become a vital driving force for national economic growth. Because of these opportunities and challenges, it is necessary to conduct research on the issue of "Attracting venture capital for innovative start-ups" to propose solutions.

### 2. THEORETICAL FRAMEWORK

#### 2.1. Theory 1: Venture capital

##### 2.1.1. Concepts and characteristics

###### 2.1.1.1. Concepts of venture capital

In terms of semantics, in English, the term "Venture" means in general an act of taking risks. Venture capital is a risky investment.

<sup>1</sup> Academy of Finance.

<sup>2</sup> Academy of Finance, CQ58.08.05.

In economic terms, venture capital is a general term to describe the investment in special technology or scientific projects that are in a state of “thirst for capital”, typically small and medium-sized companies, newly established ones or those in the start-up stage, having a good business idea or plan.

In addition, this term in each region has different interpretations.

In Asia, the term refers to equity investment in small and medium-sized enterprises, which are unlisted on the stock market and, to some extent, involve investors in the public management process.

In Europe, according to Natwest Bank - United Kingdom, the term means an activity managed by organizations or individuals making long-term investments with high financial risk for small and medium-sized enterprises, newly established or developed, not listed on the stock market but with growth potential. This is the common understanding of European countries about the term and is considered to be understood in a broad sense.

In the United States, according to the American Venture Capital Association, venture capital is capital investment in startups, young enterprises, those unlisted on the stock market but capable of rapid growth, innovation and technology-based. This is considered a narrow sense and is widely accepted.

*Overall, it can be given a general concept of venture capital: It is a combination of investment and financial activities, carrying high risk but also full of potential for profit. It includes not only investment in the high-tech sector, but also all other activities in the economy.*

#### 2.1.1.2. Characteristics of venture capital

Venture capital has two main characteristics:

(1) It is essentially a form of capital business. Venture capitalists provide capital primarily for startups, usually in the high-tech sectors with strong innovation and high growth potential.

The failure rate of businesses in the early stages can be very high, up to 80-90% - a high level of risk, but if successful, it will make great profits.

(2) The venture capital providers not only invest capital, but also use their accumulated experience, knowledge and networks to support enterprises to manage their business better. Instead of a return on capital and interest on the investment, the venture capital providers only require holding some shares, sometimes controlling the organization and business strategies of the companies receiving the capital.

*In essence, venture capital is a form of capital business, in which people have capital through experienced investors to invest in immature and highly profitable businesses.*

### **2.1.2. Venture capital fund and its models**

#### 2.1.2.1. Venture capital fund

A venture capital fund is a specialized investment fund. That is reflected in the fact that it specializes in providing capital by the method of venture capital in a number of fast-growing and mainly high-tech sectors. Therefore, it can also be considered a type of growth fund. In addition, some venture funds specialize in investing in a certain area or a certain country (country fund), or in another venture fund to split the risk which is called a fund of funds.

#### 2.1.2.2. Characteristics of venture capital fund

The fund is often associated with venture capital and its activities. Therefore, the characteristics of this fund are also inseparable and are derived from the characteristics of these activities.

(1) The risk of investments: Venture capital has a very high risk because the recipients of the capital are newly established private companies or active in newly formed fields.

(2) Duration of investments: most are medium to long term. The recipients of the capital are mainly private joint stock companies, unlisted on the stock market, even in the ideation stage.

(3) Investors: the investors are usually organized ones such as pension funds, university sponsorship funds, insurance companies, businesses or a few wealthy individuals.

#### 2.1.2.3. *Venture capital fund models*

- Limited partnership model
- Trust unit model
- Limited liability company model
- Joint stock company model

### **2.1.3. Factors forming and affecting the development of activities of investing and attracting venture capital**

#### 2.1.3.1. *Forming factors of venture capital*

According to Ronald J. Gibson and Bernard Black - Journal of Applied Corporate Finance (Pages 36 – 48, 1999), “Venture capital is an investment made by specialized organizations to fast-growing, high-risk and often high-tech companies in need of equity to finance product development or growth.”

Venture capital can be formed from a variety of sources, the most common of which is the issue of shares.

##### *\* Participants of venture capital activities*

- Investors: Wealthy individual capitalists (or angel capitalists), banks, insurance companies, pension funds, manufacturing corporations, etc. have large amounts of money ready to invest and accept high risk, hoping to achieve big profit.

- Self-investing individuals: The initiative of investors is very high. They have visions and seize opportunities by choosing the appropriate investment recipients, then receiving all the profits earned without sharing to any other parties.

- Investment organization: many investors contribute capital together to make investments towards a common goal.

- Venture capital managers: venture capital experts who have both technology knowledge and management capacity, and can also take on the function of raising capital from investors, searching and evaluating investment opportunities, conducting investments according to certain strategies to add value to the investee company, and then exiting capital to recover capital and profits, at the end, returning to investors.

#### 2.1.3.2. *Factors affecting the development of activities of investing and attracting venture capital*

##### *\* Structure of financial markets*

Conditions to be listed in the stock market should be changed to suit the needs of businesses, disclosure requirements should be maintained strictly to ensure investors' belief.

##### *\* Ability of human resources*

Venture capital markets can only prosper with an adequate supply of businesses. The ability of human resources also determines the development of new companies.

##### *\* Investment opportunities*

Availability of investment opportunities is related to a number of factors:

- The level of development of the research and technology environment.

- Channels between research and the venture capital industry.
- Ease of access for businesses to the domestic market.
- Ease of starting a company for the first time.
- The authority of the legal system to ensure business opportunities are not turned into opportunities for corruption by officials and other forces.

*\* Government policies*

Based on the mechanism, government policies can be classified into 3 types:

- Governments act as the market maker.
- Government policies and regulations of venture capital activities directly affect the industry.
- Laws and regulations of the federal pension fund, stock market, labor market and other areas indirectly affect the venture capital industry.

## **2.2. Theory 2: Innovative startup**

### **2.2.1. Startup ecosystem**

#### *2.2.1.1. Concepts*

Startup ecosystem is set up by a country or a city to promote local entrepreneurship. The innovation startup ecosystem consists of individuals, groups of individuals, innovative start-ups and entities supporting the development of start-ups, including state policies and laws; infrastructure for starting up; capital and finance; startup culture; startup support organizations, coaches and consultants; universities; training course for individuals or groups of individuals starting a business; startup investors; human resources for startup; domestic and international markets.

#### *2.2.1.2. The core and foundation part of startup ecosystem*

The core part includes the factors directly involved in the start, incubation of a startup idea and the realization of turning that idea into a real business activity in accordance with the right goals and startup blueprints, such as ideas, individual entrepreneurs, venture entrepreneurs, start-up groups, investment capital, startup coaches, various organizations and individuals involved in the process.

The foundation part is the factors in the outer circle, which makes up the macro foundation for start-up activities, including organizations supporting start-up incubators to provide office and coworking space; large companies acting as investors or customers; universities or research institutes acting as the biggest source of knowledge and startup ideas; funding institutions, service providers.

The core part of the startup ecosystem has a direct role in implementing, conducting start-up projects and determining the success of the startup movement. In the long term, the foundation part is the agents that create the macro environment for startups to flourish.

### **2.2.2. Concepts of innovative startups**

Startups are companies that are in the process of starting a business in general, associated with the pinnacle of science and technology, operating things that the world has never done. An innovative startup is an organization designed to deliver products and services under the most uncertain conditions and with the fastest growth opportunities, building a new market segment, creating distinctive; is the process of starting a business based on creative ideas, creating new products; or old products but have other outstanding and superior points compared to products and services that were already on the market and have rapid development.

### **2.2.3. Characteristics of innovative startups**

\* Breakthrough and creativity: Breakthrough and creativity are inevitable in business activities under the context of Industry 4.0. The value of intelligence and creativity greatly contributes to the breakthrough and determines the competitiveness of innovative start-ups. Innovation is a must to be able to create a better value than what is already available.

(2) Huge growth and profit potential: Innovative start-ups are passionate about fast growth and creating a business model with that pace and replicating it. An innovative start-up will not set limits on growth, and the owners have the ambition to develop it to the greatest extent possible. When the plan is successful, the financial returns can be huge.

(3) Hard start and high risk: The capital of innovative start-ups starts from the founder's own money, or donations from family and friends, in some cases, crowdfunding. However, most of these start-ups have to raise capital from Angel Investors and Venture Capital Funds.

Innovative start-ups have a unique startup idea or are different/better than competing solutions in the market. This makes the implementation uncertain and of course quite risky.

Innovative start-ups always lack resources (mainly time and money) because their target market is large, meanwhile, product development requires a lot of testing and re-implementation. The key is to find the right balance between development and implementation. The ultimate goal is to get to the growth stage of that business earns revenue as quickly and cost-effectively as possible.

## **3. RESEARCH METHOD**

The study uses some research methods: research, analysis and synthesis of relevant documents such as books, newspapers, domestic and foreign reports with clear verification to build a theoretical basis for the study of capital and venture capital activities, to discover common characteristics of research subjects and to save important information directly related to the research problem. Then linking and organizing documents and theoretical information that have been obtained to create a theoretical system on the topic of the research. Methods of data collection and information processing to collect data from scientific studies, articles and research papers related to venture capital activities and find research gaps, at the same time, inherit the scientific theory and build the theoretical basis of the research problem.

## **4. RESULTS AND DISCUSSION**

### **4.1. Results**

#### **4.1.1. The current state of innovative startups in Vietnam**

##### *4.1.1.1. Number of innovative start-ups in Vietnam*

According to the statistics of Echelon Magazine (Singapore), Vietnam as of September 2018 had about 3,000 innovative start-ups - an increase of nearly 2 times compared to the data at the end of 2017. This was a pioneering force of enterprises, with high growth to effectively contribute to the country's socio-economic development. Regarding financial activities, there were about 40 venture capital funds operating in Vietnam. Calculated in the two years 2018-2019, the total number of innovative start-ups accounted for the majority in terms of the number of new registrations. The growth rate of successful innovative start-ups is many times faster than that of large enterprises.

According to the assessment of the Vietnam Chamber of Commerce and Industry (VCCI), if calculated per capita, the number of innovative start-ups in Vietnam is higher than that of other countries such as China,

India or Indonesia. The comparison between the fields shows that information technology enterprises have superior numbers compared to those in other fields. This fact reflects the development trend in the context of the industrial revolution 4.0.

Although the number of innovative startup investors is not much, it has started to go up. Most of these are successful entrepreneurs who want to invest in the next generation of innovative start-ups. Some overseas Vietnamese and students have been returning to Vietnam to participate in innovative startup investment. The activities of angel investors in Vietnam have started to be more systematic through connecting and forming a number of clubs and investment networks for innovative start-ups such as VIC Impact, iAngel or VCNetwork.co.,...

#### *4.1.1.2. The scale, level of technology development and ability to raise capital*

The level of technology underpins innovation. The technological level of enterprises makes an important contribution to creating conditions for the spirit of starting up.

In Vietnam, published survey data in 2018 showed that, out of a total of 7,450 enterprises surveyed, only 464 enterprises confirmed to have research and development (R&D) activities, accounting for 6.23%. This means that the majority of businesses have not yet paid attention to the application of science and technology. However, in the period of 2018-2020, the fields selected by innovative start-ups focused on financial technology, travel technology, artificial intelligence/chatbot, Internet of things, care health and big data collection according to the development trend of the industrial revolution 4.0.

Investment in innovative start-ups in Vietnam mainly comes from investment funds, large corporations, business promotion organizations and individual investors from both domestic and international. In general, raising capital and calling for investment of innovative start-ups are taking place more and more actively. Large deals mainly come from foreign investors, while domestic ones have not yet boldly invested in start-ups. According to the research by Topica Founder Institute, the amount of foreign capital and venture capital funds poured into innovative start-up businesses in Vietnam has tripled in the period 2016 - 2020 (US\$205 million to nearly US\$900 million) with the number of brands nearly doubling (50 deals to 92 deals). In 2017-2018, many Vietnamese corporations invested in innovative start-ups such as FPT Investment Fund (FPT Ventures), Viettel Investment Fund (Viettel Ventures), CMC Innovation Fund. In the year 2018-2019, according to statistics of the Ministry of Science and Technology, only the 5 most successful capital raising deals have a total value of more than 50 million USD. Meanwhile, according to data from the National Program 844 (Ministry of Science and Technology), the total value of investment deals in Vietnamese start-ups from the beginning of 2020 up to now is 290.43 million USD; the number of investment deals is 56 deals, of which 34 investment deals are announced. The number of investment deals in Vietnam is increasing, but the number of deals under 1 million USD accounts for the majority. The number of deals receiving investment with a capital of more than 10 million USD is very small. The number of M&A deals is still very small. No innovative start-ups have yet to conduct an IPO.

#### *4.1.1.3. Growth potential*

The start-up and innovation network is developing strongly in localities across the country. Provinces and cities actively apply information technology in digital transformation, product traceability, intellectual property and sustainable socio-economic development solutions in industries and sectors. On the ranking of the Global Innovation Index (GII), for 12 consecutive years, Vietnam has always performed higher than the level of development. In addition, since 2017, Vietnam has used the Global Innovation Index, published annually by the World Intellectual Property Organization (WIPO), to recognize the pace of innovation.

Start-up enterprises have created many new jobs applying science and technology for employees, at the same time, promoted economic growth and contributed to the formation of a market economy. For Vietnam, innovative start-ups contribute to deepening international economic integration on many levels, diversifying forms, and gradually adapting to the principles and standards of the global market.

#### **4.1.2. The current situation of attracting venture capital for innovative startups in Vietnam**

In the context that the industrial revolution 4.0 has been taking place strongly, Vietnam has steadfastly adhered to the policies of innovation, reform and development, proactively and actively restructured the economy to innovate the growth model, to consider science, technology and innovation to be important driving forces and the key to rapid growth as well as sustainable development. Vietnam is also likened to a peak of Southeast Asia's "golden triangle" in startup development - a bright spot in attracting investment when it is a "good land" for high-quality foreign direct investment inflows. Because of that, the COVID-19 pandemic has again become a catalyst for innovation and digital transformation in Vietnam. The domestic innovation and startup ecosystem has recovered and reached new heights in the last two years. Venture capital for start-ups in Vietnam reached a record high in 2021 with a total investment of \$1.4 billion - up 1.5 times from the record \$874 million in 2019. Thanks to the convenience of online webinar applications, travel restrictions are no longer a barrier in the investment decision-making process. The total investment capital in innovation in 2021 has surpassed a record number \$874 million in 2019 and far ahead of \$451 million in 2020. Also in this year, the taste of investors also changed rapidly to focusing on fields that were not strongly affected by the pandemic. Vietnam has welcomed the arrival of two new tech unicorns - Momo and Sky Mavis (valued at \$2 billion and \$3 billion) during the pandemic.

In the first nine months of 2022, investment in technology in Vietnam witnessed a slight decrease compared to 2021. Total investment capital poured fell by 17.9%, while the number of deals decreased by 13%. However, in the face of the ups and downs of the world economy, the picture of technology investment in Vietnam in the first 9 months of 2022 still shows persistence. The capital inflow to companies in the later stages is maintained at the same level as in 2021, in which the series B round recorded a record level in both investment value and number of deals. Vietnam also hit a record in the number of transactions with the capital raising scale reaching 10-50 million USD. That shows companies that raised Series A (Pre-A) and Series A pre-round funding in 2021 have grown into the next stage. The number of deals worth 3 - 10 million USD and more than 50 million USD are equal.

Among the industries selected for investment, the retail industry continues to be the leading group in terms of the amount of investment capital poured in, followed by the financial services (fintech), health sector, education sector. It can be said that, in general, Vietnam's digital economy is still at a stage of rapid development in the region, still has a lot of potential to receive venture capital from investors.

#### **4.1.3. The current situation of venture capital supply**

The field of venture capital investment in Vietnam has grown since 2004 with the establishment of International Data Group Ventures Vietnam (IDGVV), founded by Patrick McGovern - Founder and Chairman of IDG. From 2004 to 2013, IDGVV invested in 42 companies, developing into multiple industries - both in technology and non-tech. Another investment fund in this industry is CyberAgent Ventures (CAV) - a venture capital fund in Japan that entered the Vietnamese market in 2008, has invested in more than 25 companies in Vietnam. There is also DFJ VinaCapital - a joint venture between VinaCapital - one of Vietnam's largest private equity funds and Draper Fisher Jurvetson (DFJ) - an American venture capital firm focused on early-stage and growth investments.

Founded in 2014, the Startup Vietnam Foundation (SVF) is the first and only socialized, non-profit fund in Vietnam to support the open innovation ecosystem. Continuously for 5 years, SVF has contributed to building the ecosystem throughout the territory through activities to improve local core competencies, training the leadership team of businesses/startups.

However, due to the wave of COVID-19 pandemic and the global economy experiencing many significant changes, the issue of lack of investment capital for innovation has become even more urgent. Alternative sources of funding such as venture capital funds are considered to have a vital role in encouraging entrepreneurship, promoting innovation and thereby promoting economic growth under the new normal.

It can be said that the financial resources for investment in technological innovation in Vietnam are still very limited. Barriers from loan guarantees by credit institutions have limited enterprises to borrow medium and long-term capital for innovation investment. The activities of the Development Assistance fund are similar, but with more favorable interest rates and only limited to those who have needs in a number of areas regulated on the State's development investment credit. Other sources of capital mainly come from international organizations such as ADB, WB... and bilateral trade agreements.

#### **4.1.4. Achievements**

According to statistics of the Ministry of Science and Technology (2021), Vietnam currently has more than 1,400 organizations capable of supporting startups, of which 196 coworking zones, 69 business incubators and 28 organizations promoting business activity have been established. The number of Venture Capital Funds considering Vietnam as a target market has 108 funds operating in Vietnam, of which 23 have Vietnamese legal entities and 23 are pure Vietnamese funds.

In 2021, the market recorded 165 investments in startups, attracting more than 1.44 billion USD. The Vietnamese startup investment market is forecast to reach \$2 billion by 2022. By the end of the first quarter of 2022, the Vietnamese startup market has marked a potential start with outstanding deals in the financial technology and e-commerce segment such as Square Peg's investment in Timo digital bank, VNG's and Do Ventures' investment in digital software solutions company Open Commerce Group.

Besides, the value of deals is increasing. In the 5 years from 2016 to 2021, many venture capital deals worth more than 10 million USD were made. According to a report by the National Innovation Center (Ministry of Planning and Investment) and Do Ventures, Vietnam is assessed as one of the most promising venture capital markets in ASEAN. Specifically, Vietnam currently leads Southeast Asia in the growth rate of venture capital transactions. Compared to 2020, the number of venture capital transactions in Vietnam in 2021 has increased by 57%. Investment growth rate in Vietnamese startups is higher than that of Singapore, Philippines, Indonesia, Thailand and Malaysia. In terms of investment capital, Vietnam is currently ranked 3rd in ASEAN in terms of capital growth rate for start-up investment.

Technological unicorns and typical businesses such as MOMO, VNPay, or TIKI are such achievements in efforts to promote innovation activities in Vietnam. At the same time, the statistics show the important role of the venture capital fund market in the development of the startup ecosystem in Vietnam, realizing innovative ideas in enterprises and providing abundant financial resources for the startup investment market. Thus, the venture capital fund in Vietnam is an important intermediary with venture capital tools to help form and develop startup ideas as well as promote innovation activities.

## **4.2. Discussion**

### **4.2.1. Challenges**

Firstly, regarding the legal corridor, there are currently no legal documents directly referring to the form of venture capital, but only a few regulations related to this activity. The Enterprise Law already stipulates that

members of a limited partnership can only be individuals. Meanwhile, according to other countries, capital contributors are mostly organizations such as banks, pension funds, research institutes, universities, etc. and partners can also be fund management companies. Therefore, there is no appropriate legal regulation for the venture capital fund to operate in Vietnam in the form of a limited partnership company.

Second, the protection of intellectual property rights in Vietnam still has many shortcomings. Infringement of intellectual property rights and counterfeit goods are rampant. In particular, the most alarming is in the field of software - one of the potential areas to attract the attention of investors.

Third, the business environment in Vietnam currently does not encourage transparency in business activities and is “snappy”. The tax regulations are not clear and the income tax rate is quite high, forcing many domestic enterprises to follow a non-transparent accounting regime.

Fourth, Vietnam’s high-tech industries are currently in the launching stage, especially compared to other countries. This industry is currently facing many difficulties in the process of competing with other countries in terms of human resources, grasping and accessing markets.

Fifth, the Vietnamese human resources suitable for the development of venture capital investment are currently not available. It is quite a new and unpopular term in Vietnam, so human resources knowledge and having the necessary skills for this type of business are limited.

#### **4.2.2. Opportunities**

Firstly, the stock market in Vietnam officially came into operation in July 2000. So far, although it has not played a big role in mobilizing capital in the economy, its initial steps have promised to create a potential capital withdrawal channel for the venture capital funds in the near future.

Second, the private business sector and entrepreneur spirit are encouraged and growing stronger. One of the important milestones was the introduction of the Enterprise Law in 2000, which cleared legal barriers for the private sector, created a favorable legal environment and increased the number of non-state enterprises in Vietnam. In addition, many guidelines, policies and measures from the Government to encourage and support the development of the private sector have clearly demonstrated its commitment to the development of this sector, thereby encouraging entrepreneurship among the population and promising attractive projects for the venture capitalists.

Third, Vietnam’s economy in recent years has witnessed a high and stable growth rate in the region. A stable, high-growth economy promises a good market for business activities.

#### **4.2.3. Solutions**

(1) Support from the Government in promoting the attraction of venture capital and venture capital activities.

Firstly, the preferential mechanism for angel investors and venture funds in Vietnam. These issues are up to now unclear and lack legal frameworks. In order to attract attention to domestic and foreign investors, the Government can actively invest in the venture capital fund.

Second, the capital degradation mechanism is more favorable for investors. Notably, strict foreign exchange management has caused difficulties in receiving investment capital and divesting capital.

Third, building the startup ecosystem as soon as possible and the ecosystem to create capital for startups is extremely important. There should be studies on angel investment funds, venture capital funds and creating incentive mechanisms to help startups always have capital ready to operate.

(2) Increasing the provision of information and disseminating knowledge.

To improve the community's understanding of entrepreneurship, venture capital and its investment, it is necessary to: Inspire, share and devote the knowledge from experts through the formation and operation of classes, workshops and seminars and in all provinces and cities. Enhance the creation of more favorable conditions for organizations to support start-up activities, especially non-profit organizations. Strengthening the dissemination of information on national television and newspapers.

(3) Promoting and improving the quality of venture capital activities in Vietnam.

Firstly, extending the connection with foreign investors or those abroad. Most of the venture capital funds with large capital and experience are located in foreign countries, therefore, innovative start-ups need to have the right orientation towards innovations that the whole world can apply.

Second, it is urgent to improve the quality of venture capital activities in the country, increase the number and expand the technology incubators, especially those with support from foreign entities. The incubator has a strong connection between those who need capital and those who have excess capital, which is an effective service model for start-ups, attracting venture capital and its investment.

Third, it is important to limit monopolies and create a healthy competitive business environment.

(4) Developing human resources for startups and venture capital in Vietnam

*\* For students at schools and universities/colleges*

Starting up should be considered as a support and career-oriented activity for students from the second year onwards. It is necessary to form a training network for lecturers at the national level and support them to participate in planned, thematic and certified training courses; at the same time, the startup system needs to soon form a website and connect with each other to provide databases and information of training institutions, lecturer system and various start-up programs/training courses to meet the online training needs of learners and students. In addition, focusing on connecting resources between universities, experts, investors or large enterprises to support, accompany a number of start-up projects and towards future success to promote the company and other partners.

*\* For individuals, business organizations*

Individuals and organizations need to improve their creative capacity by participating in startup ecosystems, technology incubators, actively learning directly from seminars, workshops, events on startup activities and innovation at home or abroad or participating in competitions related to innovation, creativity or startup or even reality TV shows about startups and raising capital from investors in order to have experience, connect and promote their achievements more effectively. In addition to ideas, individuals and businesses improve their knowledge of management, finance, accounting and foreign languages through classes or online courses for their solid development.

## 5. CONCLUSIONS

Startup activities in Vietnam are growing and getting more attention, so the potential to attract venture capital and develop venture capital activities is increasing. Through the results of this research, it is also possible to partially assess the current state of startup and venture capital investment at that time. The development of venture capital activities will provide an effective funding channel for start-ups in particular and the Vietnamese economy in general. Lessons from the experience of starting a business on venture capital activities from countries around the world will help Vietnam learn and shorten the time in the country's economic development roadmap. Although there are still many barriers such as legal issues, limited level of resources, more and more attention, recognition of problems, finding solutions and

innovation from the community and the Government are promising to witness a tremendous growth of startups and venture capital investment in the future.

## DEVELOPING E-TAX IN VIETNAM

**Author: Nguyen Thi Anh<sup>1</sup>**

**Mentor: Le Xuan Truong<sup>1</sup>**

*ABSTRACT: The development of e-tax is an inevitable trend in the digital economy. This paper systematizes theoretical issues on e-tax and its development, assesses the current state of e-tax development in Vietnam, through that, pointing out the achieved results and limitations in e-tax development in Vietnam; assess the current situation of factors affecting the development of e-tax in Vietnam. On that basis, this paper proposes solutions to promote the development of e-tax in Vietnam in the coming time.*

*Keywords: Development, E-taxation, Vietnam.*

### 1. INTRODUCTION

E-tax has its own distinctive features, is a constituent part of e-Government, developing along with the general development of e-Government, tax public services. E-tax is provided entirely on online platforms and it is a product of the industrial revolution 4.0.

Basically, e-tax provides a lot of utilities related to public tax services, but it can be generalized the basic functions such as: Account registration, e-tax declaration, e-tax payment, e-tax refund, e-invoices, business management, lookup, FAQs etc.

The e-tax system brings benefits not only to taxpayers, tax authorities but also to commercial banks and service providers related to e-tax. Thanks to e-tax, procedures are simplified, and human resources, time, travel costs and paperwork costs are saved.

Up to now, there have been many research works both at domestic and abroad in the subject of e-tax such as: The work “Electronic Tax Filing in the United States: An Analysis of Possible Success factors” summarized and analyzed the demographic, socio-economic and geographic factors affecting e-filing in the United States in 1999, and 2004–2007 and an increase in e-filing between 1999 and 2007. (Sonja E.Pippin and Mehmet S.Tosun, 2014). The study titled “Determinants of user acceptance of the e-Government services: The case of online tax filing and payment system” by Shin-Yuan, Hung Chia-Ming Chang and Ting-Jing Yu offers that in addition to the obvious academic value, the management implications of this study will also benefit government policymakers. Government agencies and system designers. (Shin-Yuan, HungChia-MingChang and Ting-JingYu, 2006). Scientific article “Strengthening the role of e-tax in e-government development in Vietnam: Current situation and recommendations” by Nguyen Thi Le Thuy - National Economics University. This paper analyzes the situation of e-government and e-tax in Vietnam, analyzes issues that need to be solved in e-tax implementation. The paper proposes 3 groups of solutions to strengthen the role of e-tax in e-Government development in Vietnam in the coming period. (Thuy, N. T. L. 2018)

## 2. THEORETICAL FRAMEWORK

### 2.1. Criteria for assessing the development of e-taxation

E-tax development is developed in two main aspects: *expansion, increase in quantity* and *improve quality*. The increase in quantity is reflected in the increase in the number of users, the increase and diversification of the utilities of e-taxation, the increase in the types of tax procedures applied, the increase in the number of operational functions and tax administration operations are electronicized, the rapid increase in processing speed etc. The improvement in quality represents better and better satisfaction of the needs of e-tax users, both from the part of taxpayers and tax authorities. Only when e-tax develops comprehensively in all aspects and all the criteria mentioned above, will e-tax development really expand in scale (horizontally) and go into quality (in depth) towards more and more perfection at a higher and higher level. From the above concept, it can be seen that quantitative and qualitative criteria assessing the development of e-taxation are as follows:

**Quantitative indicators:** The rate of increase in the proportion of tax public services applying e-tax to the total number of tax public services; The rate of increase in the ratio of public service levels on e-tax to the total number of public services on e-tax; The rate of increase in the ratio of taxpayers using e-taxes to the total number of taxpayers; The speed of increase in the number of taxpayers using e-tax services for each specific type of tax procedure; The change in the processing time of electronic tax procedures.

**Qualitative criteria:** Taxpayer satisfaction when applying e-tax; utility of e-tax in tax administration of tax authorities; ability to preserve and secure the e-tax system.

### 2.2. Factors affecting the development of e-taxation

**Factors from tax authorities:** The Government's e-tax development policy; the quantity and quality of human resources of tax authorities; the scale and orientation of investment in e-tax development of tax authorities.

**Factors outside tax authorities:** Legal corridor for e-tax development; level of development of technological infrastructure of the economy; human resources for receiving and using e-tax; development of e-public services of relevant state agencies; coordination of relevant state agencies.

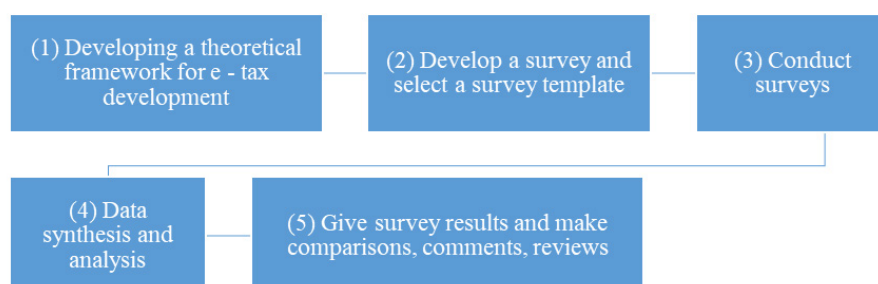

## 3. METHODOLOGY

*The author of this paper uses the following main research methods:* Using dialectical materialist methodologies, historical materialism, meta-analysis methods, statistical methods, comparative methods, evaluations, comments.

*Data collection method:* The topic using secondary data which is reported by the General Department of Taxation and official statistics of state agencies.

The author uses the questionnaire survey method to collect data on “The efficiency and quality of e-tax through the actual survey of taxpayers’ use when using the e-tax system provided by the domestic tax authority” with the research sequence according to the following model:

**Diagram 1: Survey methodology diagram**

**4. RESULTS AND DISCUSSION**

**4.1. Results**

**a) Current situation of e-tax development in Vietnam quantitatively**

- *Current status and growth rate in the proportion of tax public services applying e-tax to the total number of tax public services*

By the end of 2022, according to the report, the tax industry has actively deployed and provided online public service provision with 304 administrative procedures in the field of taxation with the rate of tax on tax public services applying e-tax to the total number of tax public services is very high and all at level 2 or higher. Meanwhile, the number of public services integrated into the National Public Service Portal also reached about 82.42%.

- *Current status and speed of increase in the ratio of public service levels on e-tax to the total number of public services on e-tax;*

In 2022, based on the Decision to announce administrative procedures, the General Department of Taxation has completed the deployment of 103/234 online public services level 3 and 4 and integrated 97/103 online public services level 3 and level 4 to the National Public Service Portal.

- *The current situation of the increase in the proportion of taxpayers using e-tax compared to the total number of taxpayers*

By the end of October 2022, according to statistics, the General Department of Taxation had received 1,939 first-time tax registration applications and 1,832 applications for changing tax registration information of individuals who do not do business through the National Public Service Portal. In addition, in terms of deploying e-Tax Mobile service, by May 4, 2022, there have been 129.4 thousand downloads and installed, used the e-Tax Mobile application, 45,866 accounts registered for transactions. In addition, immediately after the launch of the Portal for Foreign Suppliers, by 2022, 38 foreign suppliers had successfully registered and declared taxes.

- *The current situation of the increase of taxpayers using e-tax services for each specific type of tax procedure*

- *E-filing*

**Figure 2: The chart shows the number of enterprises filing tax online, 2018 – 2022**

(Source: the NEAC and figures from the Ministry of Finance)

In the period of 2018 – 2022, the number of businesses filing taxes online is increasing and has a fairly fast speed. From 2018 to 2022, the number of businesses filling online tax declaration increased by 189,769 businesses, or 1.27 times (increased to 127%).

- *Electronic tax payment***Table 3: Statistics table on e-tax payment in the period 2018-2022**

(Source: Annual Report - Ministry of Finance)

Target	2018	2019	2020	2021	2022
Electronic tax payment transaction number (Transaction)	3,100,000	3,236,477	3,224,392	3,123,854	3,346,667
Proceeds from electronic tax payment	VND 656,824 billion	VND 654,516 billion and USD 23,669,146	732,858 billion VND and 36,683,130 USD	VND 731,872 billion and USD 40,356,595	VND 765,817 billion and USD 55,853,591

The table above shows that, in the period from 2018 to 2022, the number of e-tax payment transactions and the amount collected through e-tax payment increased steadily over the years.

- *E-tax refund*

The State has strengthened tax administration, strictly and thoroughly controlled VAT refund payments, improved the efficiency of tax refunds, and facilitated capital turnover for enterprises.

**Table 4: Statistics of e-tax refund in 2018-2022**

(Source: Annual Report - Ministry of Finance)

Target	2018	2019	2020	2021	2022
Number of enterprises applying for electronic tax refund (Enterprise)	7,340	8,424	8,915	8,856	7,938

- *E-invoices*

The whole tax industry has successfully implemented e-invoices in accordance with the provisions of the Law on Tax Administration No. 38/2019/QH14. Accordingly, except for special cases where printing invoices of tax authorities are used, from 01/7/2022, all organizations, businesses and individuals using invoices nationwide have registered to convert to using electronic invoices. As of the end of 2022, there had been more than 2.1 billion e-invoices issued.

- **Current situation of changes in the processing time of e-tax procedures**

Most e-tax procedures are processed within 24 hours of receiving the request, this time is much faster than e-taxes in the past and is a great level of disruption compared to the time when working with traditional tax procedures when it did not consume printing time press, travel, search for information.

**b) The current situation of e-tax development in Vietnam in qualitative terms**

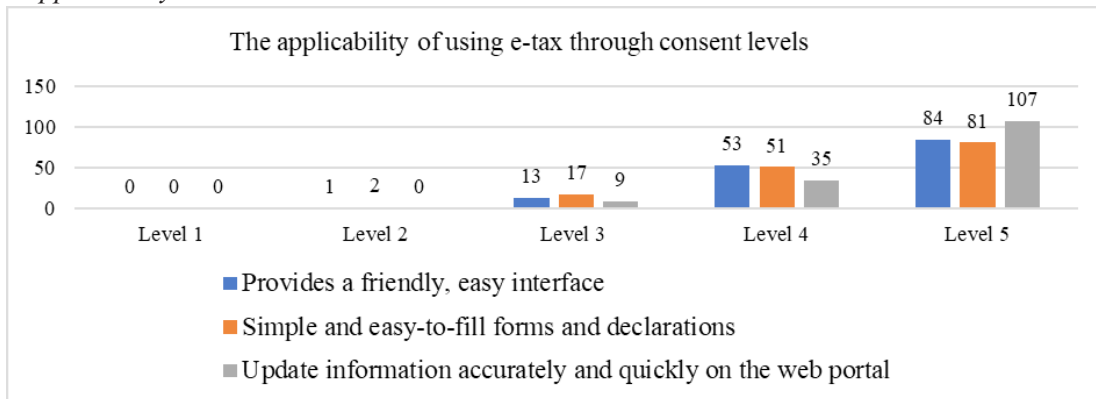

- **Current status of taxpayer satisfaction when applying e-tax**

- *Efficiency***Figure 5: Chart showing benefits of using e-tax through consent levels**

(Data: Survey results of the topic author)

From the chart, we see that level 5 (Totally agree) chosen by the majority of survey participants shows the effectiveness and convenience of using the electronic tax system.

- *Applicability*

**Figure 6: Chart showing the applicability of using e-tax through consent levels**

(Data: Survey results of the topic author)

From the chart, we see that level 5 (Strongly agreed) chosen by the majority of survey participants shows the applicability of the e-tax system through 3 criteria.

- *Security*

**Figure 7: Chart showing security when using e-tax through consent levels**

(Data: Survey results of the topic author)

Through statistics and data analysis, the majority of survey participants agree on the criteria that information is stored safely and securely at level 3 (Normal) and level 4 (Agree); in which, the majority of survey participants chose level 4 (Agree) with the criterion that information is not stolen and level 5 (Completely agree) with the criteria of authenticating the account when logging in fully and securely.

- *Transmission line*

Level	Level 1	Level 2	Level 3	Level 4	Level 5
Number of people	27	80	18	21	5
Proportion (%)	17.9%	53%	11.9%	13.9%	3.3%

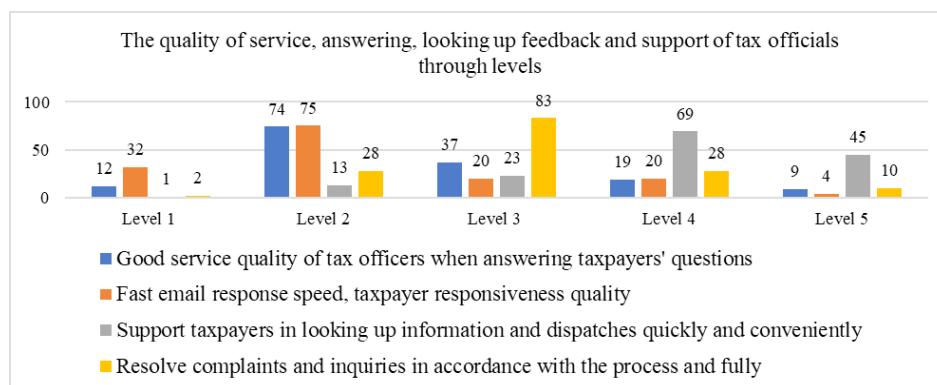

**Table 8: Table showing agreement on transmission lines when using e-tax through the following levels**

(Data: Survey results of the topic author)

From the chart, we see that level 2 (Disagree) is chosen by the majority of survey participants for the criterion of stable transmission with little interruption.

- *Lookup, Q&A, feedback, business support*

**Figure 9: The chart shows the quality of service, answering, looking up feedback and support of tax officials through levels**

(Data: Survey results of the topic author)

Through statistics and data analysis, the majority of survey participants agree on the following criteria:

- The quality of service of tax officers when answering taxpayers' questions is good: The majority of respondents agreed at level 2 (Disagree).

- Fast email response speed, taxpayer response quality: Majority of respondents agree at level 2 (Disagree).

- Support taxpayers in looking up information and dispatches quickly and conveniently: The majority of respondents agreed at level 3 (Normal).

- Resolve complaints and questions in accordance with the process and fully: The majority of respondents agreed at level 4 (Agree).

- ***Current status of utility of e-tax in tax administration of tax authorities***

Currently, the basic electronic tax system has met the following utilities in tax administration of tax authorities such as: Collection, statistics, synthesis, information and data of taxpayers; Processing documents submitted by taxpayers through the Web Portal; Collate, check data, review data in cases of professional re-examination, tax refund, inspection and inspection; Information storage, data management; Report, summarize; Control of tax-related operations of enterprises.

- ***Current status, security and preservation of the e-tax system***

- Regarding ensuring data sources and electronic information: The tax industry orients to partition the server system according to basic functional groups, apply methods to enhance backup to many different places to limit risks, use a decentralized user resource management system, Apply informatics antivirus system on all server systems, networked computers and single machines with regularly updated antivirus software from the providers.

- On the side of transaction and taxpayer account security: The accounts provided to taxpayers are secured through login passwords, transaction PINs and digital identifiers for taxpayers. There are legal provisions on specific responsibilities for enterprises participating in providing T-VAN services in information security.

**c) Assessing the current situation of factors affecting the development of e-tax**

- ***Factors from the tax authorities***

- *The Government's e-tax development policy*

The Government has instructed state agencies to implement the policy of e-government and digital government. Since then, the tax sector has concretized into action programs to develop e-tax with practical activities such as: Scaling up the model of smart operation centers; programs to encourage people to

use electronic invoices such as: “Lucky invoice” of the General Department of Taxation directed to tax departments of 63 provinces and cities to report to competent authorities to organize; commend individuals, organizations and enterprises for fulfilling tax obligations, especially using e-tax platforms...

*- The quantity and quality of human resources of tax authorities*

+ In terms of quantity: Compared to 2015, in 2022, payroll has decreased by 16.8%. In the 5 years from 2016 to 2022, the number of payrolls decreased by 9,696 people (i.e. 22.72% of the payroll assigned by the General Department of Taxation in 2016), this number included retirees, quitters and downsizing. Implementation of Decision No. 520/Decision-Ministry of Finance dated 13/4/2018 of the Ministry of Finance on approving the plan to arrange and merge Tax Departments of districts, towns and cities into Regional Tax Departments under the Tax Department of provinces and centrally-run cities. From the end of 2018 to 2020, the tax department arranged and consolidated 565 tax departments to establish 267 regional tax departments, reducing 296 tax departments. Accordingly, the number of tax departments in the country have been cut from 711 to 415.

+ In terms of quality: Tax officers are now fully equipped with skills and skills, meeting standards for people’s development as well as operating the e-tax system; The leadership department has improved management ability, spirit and responsibility to work. However, the situation reflects, a part of tax officers is still not really equal in capacity and ethics.

*- Scale and orientation of investment in e-tax development of tax authorities*

The tax authorities have been focusing on investment orientation to develop e-tax comprehensively not only in quantity but also in quality, focusing on investing in the main human factor - taking taxpayers as the center of development. The General Department of Taxation has oriented investment in the development of e-tax in the direction of digital transformation: (1) Reforming of synchronous administrative procedures through the application of Information Technology; (2) Developing and implement an integrated and centralized tax management system; (3) Building a data platform for tax administration and smart tax services; (4) Deploying technical infrastructure to ensure safety and security for IT systems in the tax industry in the direction of digital transformation.

• ***Factors outside the tax authority***

*- Legal corridor for e-tax development*

In the period of 2018-2022, on the basis of existing laws in the past along with actual monitoring of issues surrounding e-taxation, the National Assembly, the Government and other competent agencies have promptly promulgated new and amended and supplemented legal documents as a foundation for e-tax development.

*- The level of technological infrastructure development of the economy*

According to statistics of the Vietnam Internet Center, as of the beginning of 2021, Vietnam currently has 68.72 million Internet users, accounting for 70.3% of the total population, Vietnam’s Internet speed and ranking have both increased (Vietnam Internet Center, 2021). Since the start of the COVID-19 pandemic until the first 6 months of 2021, Vietnam has added about 8 million new digital consumers, 55% of whom are from non-urban areas (Google, Temasel and Bain & Company, 2021).

Equipment serving the administration of the e-tax system of State agencies and at the same time meeting the standards of use of taxpayers. Basically, State agencies as well as organizations and enterprises have equipped relatively modern computers, electrical systems, and network transmission equipment for

using and working on the e-tax platform. For enterprises, the use of e-invoices requires the unit to have a certain level of technical infrastructure in information technology, along with the qualifications and capacity of relevant individuals and departments.

*- Human resources receive and use e-taxes*

Currently, in large enterprises and organizations, there is a separate department that handles direct tax jobs and operations with high qualifications, flexible working, proficiency in information technology, adaptation to policies, agile information sources and constantly learning, self developed in order to meet the pace of e-taxation. However, there have been still less developed areas such as those in rural, mountainous and island areas where taxpayers are far to meet the demand of e-tax. In these areas, human resources to develop e-tax of enterprises are not good enough for e-tax application.

*- The development of e-public services by relevant state agencies*

The current e-tax system in Vietnam has links with other public administrative services of relevant state agencies serving organizations and enterprises to provide information on administrative procedures and related public services, helping citizens to be convenient, enterprises access online public services and support information queries.

*- The coordination of relevant state agencies*

The coordination between tax authorities and other relevant state agencies is also an important factor to develop e-tax, currently the tax sector mainly coordinates with units: Ministry of Information and Communications, Ministry of Science and Technology, Ministry of Public Security - Department of Security and Prevention, fight crime using high technology. In addition, the Tax Department with the coordination of many other departments such as the Propaganda Department, the Fatherland Front,.. has greatly supported the overall development of e-taxation.

## **4.2. Discussion**

### **4.2.1. Advantages in the development of e-tax in Vietnam**

*- Comprehensively reforming the e-tax system*, deploying the use of e-tax services has **grown strongly in number**. The Ministry of Finance officially closed two old platforms, iHTKK and e-tax declaration, launched the e-Tax Mobile application and the Web Portal for foreign suppliers; Promptly amend and reform to bring a close, easy-to-use experience, integrating many functions and the smoothness and stability of the e-tax system with higher information security, bringing a comprehensive and convenient system for both users and managers. The e-tax system is implemented in 63/63 provinces and cities; covering up to 100% of tax departments deploying, expanding the scale and approaching almost the absolute number of operating businesses.

- Having built and perfected the legal system to **create a solid legal foundation**, recognizing the legality of e-tax; supplementing, amending and issuing new circulars and decrees, in order to resolve outstanding contradictions in the laws, guide people to follow legal documents and officials to handle situations, work in certain cases.

*- Service providers on online platforms* to tax payers have participated more and more so far: Seizing the development opportunities in the digital economy, business units of e-tax-related services have increased dramatically in number. If only at the beginning of 2018, there were about 40 commercial banks participating in the e-tax collection service, by 2022, there had been 55 commercial banks participating in this activity. The service quality of banks is increasingly fast, convenient, easy to transact anytime, anywhere, not only

that, but also supports the provision of other services for businesses registered with dense transaction offices to support taxpayers in the most convenient and fastest way. Not only that, the General Department of Taxation also have approved 8 units providing T-VAN services as value-added services for electronic transactions in the field of taxation and approved 17 units providing digital signatures.

#### **4.2.2. Limitations in the development of e-tax in Vietnam**

- Although it has grown quite strongly in quantity, e-taxes **have not met practical requirements for scale and diversity**. There are still many tax procedures and stages that have not been electronicized, and many types of tax professional jobs both use electronic systems and paper document systems.

- **The quality of** e-tax services is still **not high**. When taxpayers encounter problems, in addition to the most common and common problems answered directly by the General Department of Taxation on the Portal, there are still many difficulties in contacting to receive direct assistance from tax officials in special cases, as a result, taxpayers have to go directly to the tax office to work with tax officials. In addition, the quality of services working with tax officers when supporting the use of the e-tax system has not received the satisfaction of the people when there are negatives in the quality of service, ethics and lifestyle of the staff are still reflected a lot.

- **Information security** remains a concern of authorities and users. Currently, it is not possible to claim with complete certainty that taxpayers' own information, transaction activities, electronic invoices etc. will be absolutely safe. In case the tax system is attacked or terrorized, it is easy for the above information to leak to the outside. This causes enormous damage to taxpayers as well as the reputation of the e-tax system.

- Uneven and **weak facilities and technological infrastructure**. In mountainous and island areas, it is still difficult to access the internet, not to mention that the equipment for accessing and working on the e-tax system still has many limitations or even in developed areas, congestion and collapse of transmission lines still often occur, causing access disruption, working and transacting on the electronic tax system. The young and weak information technology system has led to worrying gaps and along with that, the efficiency of e-tax has not been optimal.

- **Intermediate costs** when using electronic taxes have been on the trend of **increasing**. In addition to fixed expenses for Information Technology, machinery, software costs, periodic maintenance, repairs or upgrade costs; Taxpayers have to pay additional costs to the digital signature management unit or in case of paying taxes through banks, fees may be charged. According to calculations with the money transfer fee in the current Vietnamese banking system, if an enterprise pays a tax of VND 10 billion, when paying tax electronically, the enterprise will spend an additional VND 3-4 million in fees to the bank while if paying in cash, there is no cost for this cost.

- **Adequate investment has not been made in the development of human resources and facilities**. Old facilities, not enough basic office materials such as printers, computers,... for employees is a problem of small businesses, small business households, not to mention the shortage of high-quality labor to work professionally in the field of taxation is also because financial and human resources are weak, not enough to invest to serve tax operations.

## **5. CONCLUSION**

This period of 2023-2030 will be a golden time for Vietnam's e-tax to continue inheriting the foundation of the 2018-2022 period and at the same time develop strongly, bringing the e-tax system to develop more comprehensively. In order to keep up with development needs, we need to set specific goals and roadmaps so that future steps can achieve successes and minimize risks encountered on the path of e-tax development

in Vietnam. Here, the author proposes solutions to overcome the backlog limitation and help promote the development of e-tax in Vietnam in the coming time as follows:

- **Complete a uniform legal corridor in** a timely manner, in line with the actual development of e-taxation in the process of reforming tax administration institutions and reforming the organization of the tax sector. Laws and institutions need to be constantly upgraded, amended, supplemented and perfected for the purpose of improving tax administration productivity while promoting voluntary compliance with the law and limiting legal risks, which is also the desire for results achieved when offering this solution: (1) Continuing to improve the laws and legal documents revolving around the field of e-taxation; (2) Simplifying the administrative procedures; (3) Continuing to improve the organizational model of tax authorities at all levels in the direction of streamlining; (4) Resolving conflicts between laws; (5) Amending and supplementing the documents detailing and guiding the implementation of the law to promptly handle current problems in the process of using e-tax; (6) Perfecting the regulations on e-invoices, e-invoices with authentication codes of tax authorities.

- **Upgrade facilities and technology infrastructure.** *Firstly*, increase the State's investment in offices and procurement of assets for tax authorities' operations, meet the requirements of modernizing the working environment of the tax sector, develop home and remote working systems for tax officials. Governments should propose investment from countries around the world through official development assistance funds and cooperate in technology exchange. *Second*, favorable conditions for technology enterprises to develop for the e-tax system should be created. *Third*, specific investment policies for disadvantaged areas such as rural, mountainous and island areas should be implemented. The Government should invest in equipment concentration areas such as installing computer systems in cultural houses of villages, villages and communes so that people gradually have access to technological equipment, consider installing mobile broadcasting systems and providing mobile networks in Vietnam.

- **Strengthen propaganda, encouragement and support for taxpayers to use e-taxes.** *Firstly*, programs to encourage people to use e-tax with service cost incentives, lucky draw programs, praising typical taxpayers in converting the use of e-tax, setting emulation targets among businesses to improve morale, responsibility for the use of electronic taxes should be conducted. *Secondly*, the tax authorities should implement programs to answer and support taxpayers online via the website of tax authorities (system of 479 information channels to support taxpayers), support taxpayers according to taxpayer subgroups and fields of operation arising from tax obligations, provide automatic information (artificial intelligence-AI, Chabot) for a number of topics/contents that the majority of taxpayers are interested in and need support, continue to maintain other forms to support taxpayers in areas and groups of taxpayers with limitations in using information technology applications. *Third*, depending on the access area, there are different communication options with the goal of disseminating e-tax and increasing people's trust in e-tax in the country through media, meetings and training. More tax law propaganda programs through multimedia channels, organize programs should be organized to increase people's understanding of e-tax in various forms from theoretical tests to the application in reality.

- **Solutions to improve the quality of human resources to meet the requirements of e-tax development**

*First*, the quality of human resources of tax authorities should be improved including: Renovating the recruitment of civil servants, promoting the training and fostering of in-depth knowledge and skills according to each tax administration function in order to meet the requirements of modern tax administration, building professional style, especially clean thinking and practice ethics. *Second*, the quality of human resources for taxpayers should be improved. Organizations and businesses should have policies to attract talents

such as: salary increase, bonus for excellent employees with advanced degrees; building a healthy working environment, healthy competition, investing in professional skills development for employees; encourage employees to actively learn, improve personal skills. **Third**, solutions to develop human resources in disadvantaged areas such as rural, mountainous and island areas should be implemented. High quality tax officers should be arranged to organize direct training, disseminate new policies, information as well as specific instructions on the use of e-tax. Well-trained and skilled tax officers should be attracted to work in this area to work with many opportunities such as: experiencing a new environment, improving promotion opportunities, enjoying special compensation regimes,...

**- Continue to improve, upgrade and modernize the e-tax system**

**First**, the e-tax system in Vietnam should be improved in a way that is integrated, simple and modern; highly consistent with the e-Government in general. **Second**, database of user information for search and management should be built; the automatic tax management information connection should be applied. **Third**, the application software systems, information technology systems of the tax industry should be built and improved. **Fourth**, the information protection barriers and confidentiality of the e-tax system should be strengthened. In terms of technical infrastructure, regular operation of the e-tax technical infrastructure system and transform and deploy the information technology infrastructure of the tax industry operating on cloud computing in the direction of providing platform-level services should be maintained. Regarding the information security system, the information security system for the deployment of existing applications of the tax industry should be maintained. Smart information security with the application of new technologies solutions should be soon applied. **Fifth**, a plan to maintain and upgrade the system to avoid interruptions to user access should be applied. **Sixth**, the e-tax improvement process with the proposed roadmap should be planned as follows: (1) Identifying inadequacies in e-tax. (2) Defining goals. (3) Selecting options to solve the problem of inadequacies. (4) Assessing the impact of the alternatives. (5) Collecting feedback. (6) Continuing, apply the new method into practice and rotate the assessment.

## FINANCIAL POLICIES TO PROMOTE THE DEVELOPMENT OF THE LOGISTICS INDUSTRY

**Authors: Do Duc Binh, Nguyen Van Nam<sup>1</sup>**

**Mentor: Assoc. Prof., Dr. Vuong Thi Thu Hien<sup>1</sup>**

**ABSTRACT:** *This research presents and analyzes the specific financial policies that Vietnam has implemented to promote the development of the logistics industry, including fiscal policies, credit policies, insurance policies, and tax policies. Additionally, through the use of analytical methods such as comparative statistical analysis and synthesis, the study also addresses the benefits and challenges of these policies, providing recommendations to improve the effectiveness of financial policies in supporting the development of the logistics industry. The research results will provide a comprehensive understanding of the relationship between financial policies and the logistics industry, while contributing to shaping future policies in this field.*

**Keywords:** *financial policies, logistics industry development*

### 1. INTRODUCTION

Financial policies encompass a set of decisions and actions implemented by governments or financial institutions to manage the financial resources of a country or organization. Financial policies have significant impacts on the economy and society, including economic growth, employment, prices, income, health, and education. Financial policies often involve tax regulation, public expenditure, public debt management, and financial market regulation. Choosing appropriate financial policies requires in-depth knowledge of the economy and financial issues, along with careful assessment of their impacts on the economy and society. Currently, Vietnam is considered to have many opportunities to promote the development of the logistics services sector. Therefore, the development of logistics services in Vietnam requires appropriate financial policies to meet the requirements of current rapid integration and development trends. By understanding the impacts of financial policies and proposing suitable policies, the government and relevant agencies can create favorable conditions for the development of the logistics industry, while supporting economic growth and improving the country's competitive position in this field.

### 2. OVERVIEW OF THE RESEARCH

Numerous empirical studies have been conducted to examine all aspects of logistics activities, including supply chain management, transportation management, warehouse management, human resource management, and financial management. Some notable studies include “The Effect of Financial Policies on the Logistics Sector of Nigeria” (2021) by Michael Chijioke Ugochukwu and Nwachukwu Prince Olumide; “The Impact of Financial Policies on Logistics Service Providers in the European Union” (2019) by Mihaela-Simona Suba. Other studies include “Application of Financial Policies in the Development of Logistics Services in Vietnam” (2019) by Nguyen Thi Lan Huong, and “Financial Policies and their Impacts on Logistics Activities in Vietnam” (2020) by Nguyen Thi Minh Phuong and Dao Xuan Thanh.

However, these works were carried out in specific economic, cultural, political, and institutional environments during the respective research periods. Due to the lack of uniformity in the environment and historical context across different countries and historical periods, it is challenging to achieve a consistent understanding. Moreover,

---

<sup>1</sup> Academy of Finance..

there are differences in political systems, cultures, economies, and educational levels, so the authors believe that studying financial policies for logistics development in a specific country, during a specific period, is necessary to align with the characteristics of each country in its respective era. Theoretical issues related to financial policies for logistics development need to be further developed and refined to align with practical situations. Therefore, continuous research and proposals of specific solutions with tangible results are required.

### **3. RESEARCH METHOD AND CONTENT**

#### **3.1. Research method**

This study employs the dialectical materialist approach, synthesis method, statistical and comparative method, and analytical method.

#### **3.2. Research Content**

In recent times, the Vietnamese government has implemented various financial policies to develop the logistics industry in Vietnam. Specifically, these policies include:

*Firstly, the state budget expenditure policy.* The investment in infrastructure construction is carried out in accordance with the resolutions of the National Assembly, aligning with the set objectives and orientations. It addresses the capital needs for infrastructure development, contributes significantly to the construction and upgrade of a synchronized, standardized, modern, and nationally and internationally connected infrastructure system. It also enhances the capacity of state assets and infrastructure to provide public services, ensures national energy security, and improves urban infrastructure, especially in major cities. These efforts aim to better meet the demands of socio-economic development with higher quality services and more favorable accessibility, thus creating a foundation to drive the development of the logistics sector.

In addition, the government has shown interest in and implemented policies to enhance the competitive capacity of the logistics industry through multiple support channels. These include developing training programs and enhancing the skills of logistics personnel, creating favorable conditions for universities, colleges, and vocational schools to offer logistics specialization programs, providing financial support for logistics workforce training, promoting cooperation between businesses and educational institutions, and establishing supportive policies for human resource development.

*Secondly, credit policies.* In order to support capital for the logistics industry in Vietnam, the Government has implemented credit policies, including providing loan packages with preferential or zero interest rates, sponsorship from government development support programs, and credit guarantees.

*Thirdly, credit policies.* In order to support capital for the logistics industry in Vietnam, the Government has implemented credit policies, including providing loan packages with preferential or zero interest rates, sponsoring from government development support programs, and credit guarantees.

*Fourthly, tax policies.* According to current regulations, imported goods are subject to import taxes based on the classification of goods. Goods such as machinery, equipment, vehicle parts, and production materials in the logistics industry still have to bear high import taxes, which increase the production costs and competitiveness of logistics enterprises. Imported goods used in logistics activities in Vietnam are subject to import taxes according to legal provisions. However, logistics enterprises may be exempted from import taxes for equipment, machinery, transportation vehicles, and tools used in their operations. Currently, logistics services fall under the category of commercial services and are subject to a 10% value-added tax (VAT). However, implementing this tax requires a clear distinction between logistics services and other business activities.

### **4. RESULTS AND DISCUSSION**

#### **4.1. Results of the Financial Policy's Impact on the Development of the Logistics Industry in Vietnam**

*Firstly, the government has paid attention to improving the legal framework for financial policies in the logistics sector*

The Prime Minister issued Decision No. 200/QĐ-TTg on February 14, 2017, approving the Action Plan to enhance the competitiveness and development of the logistics service industry in Vietnam until 2025. This plan sets out six objectives, 60 specific tasks, and comprehensive solutions to help the industry overcome difficulties and challenges, achieve advanced levels within the region and the world, and meet the country's economic development requirements.

*Secondly, the financial policies have had a positive impact on the revenue growth of logistics service providers*

According to the Vietnam Logistics Business Association, the logistics industry in Vietnam has been growing at a rate of about 14% - 16% in recent years, with a scale of 20 - 22 billion USD per year, accounting for nearly 20.9% of the country's GDP. The total revenue of the logistics industry in Vietnam has significantly increased in recent years. Specifically, the revenue increased from around 20 billion USD in 2015 to over 40 billion USD in 2019. Among them, freight transportation services account for the largest proportion, representing about 40% of the total revenue of the logistics industry.

*Thirdly, the financial policies have contributed to strong improvements in logistics infrastructure*

Vietnam has made strong investments in improving transportation infrastructure to enhance the capacity of goods transportation. The North-South Expressway and the high-speed railway from Ho Chi Minh City to Hanoi have been initiated, constructed, and completed in recent years. In addition, ports and airports in Vietnam have also been upgraded, expanded, and invested in. This has made freight transportation faster and more efficient.

*Fourthly, financial policies have emphasized investment in technology to promote the development of the logistics industry in Vietnam*

Investment in technology has been one of the important factors contributing to the development of the logistics industry in Vietnam in recent years. New technologies applied in the logistics industry aim to enhance efficiency, reduce costs, improve warehouse management, order management, and shipment tracking. These technologies include IoT (Internet of Things), Blockchain, AI (Artificial Intelligence), and robotic assistance.

*Fifthly, there has been an increase in international cooperation*

Vietnam has signed many free trade agreements with countries around the world, creating favorable conditions for the development of the logistics industry in Vietnam. This helps Vietnamese logistics companies easily access international markets and expand their businesses. These agreements include the ASEAN Smart Logistics Network and cooperation with international logistics companies and trade agreements.

#### **4.2. Discussion**

The logistics industry is currently one of the rapidly developing sectors in Vietnam. However, the promotion of its development still faces many limitations from the country's financial policies. Below are some constraints of the financial policies in promoting the development of the logistics industry in Vietnam in recent years.

*Firstly, the state budget expenditure policy*

- Restrictions on finance and investment: The financial and investment policies have not been optimized to support the development of logistics businesses.
- Limitations on legal regulations: The regulations regarding logistics are not comprehensive, clear, and consistent among ministries, sectors, and localities, making it difficult to implement logistics services. Registering and obtaining operating licenses in the logistics industry in Vietnam require businesses to meet

strict requirements regarding customs regulations, taxes, and labor laws. The collection of logistics service fees in Vietnam is also challenging due to unclear regulations on pricing and taxes. Some companies may charge higher service fees than others, leading to unfair competition. The lack of coordination among management agencies and the lack of cooperation between ministries and sectors in making financial support policies for the logistics industry still exist.

- State budget expenditure policies for training, technology investment, and transportation infrastructure are limited. There is insufficient close cooperation among relevant ministries, sectors, businesses, and training institutions to address issues related to finance, legal matters, human resources, infrastructure, and technology in the logistics industry.

*Secondly, concerning tax policies.* The awareness of the importance of the logistics industry is slower compared to practical demands, resulting in delayed and inadequate incentive policies. The tax incentive policies have not fully calculated the comparative advantages of Vietnam to encourage businesses to participate in global supply chains effectively. The tax incentives for logistics companies have not sufficiently considered the business environment and scale of Vietnamese companies. The enforcement of tax incentive policies is quite complex and involves multiple administrative procedures.

*Thirdly, regarding credit policies.* There are limitations in accessing loan capital from credit institutions and difficulties in implementing lending. The fulfillment of guarantee obligations is slow and faces many obstacles. Many cases involve banks being denied by guaranteeing organizations to fulfill their guarantee obligations. Due to the characteristics of logistics services and the low starting point of Vietnamese businesses, such as insufficient assets for collateral, financially infeasible financial statements due to excessive initial investments, and difficulties in persuading credit institutions with loan applications, logistics companies face significant challenges in accessing credit sources.

*Fourthly, insurance policies.* Vietnam still lacks product diversification in insurance, and insurance policies are lacking transparency and uniformity in insuring transportation vehicles, cargo, liability, and personnel. This creates difficulties for logistics businesses.

## **5. CONCLUSION AND PROPOSED SOLUTIONS**

### **5.1. Conclusion**

The development of logistics in Vietnam has many advantages, such as its strategic position in the Asian region, a large consumer market, and the growing trend of e-commerce. However, to turn this potential into reality, a comprehensive development policy is needed, from attracting investment to improving infrastructure and administrative procedures. The role of financial policies in the development of logistics in Vietnam in the coming time cannot be denied. Therefore, multiple synchronized solutions need to be implemented, with financial solutions playing an important role. Some solutions to improve financial policies for the development of the logistics industry include state budget expenditure policies, credit policies, tax policies, and insurance policies. Additionally, coordination among relevant authorities and agencies is necessary to ensure the effectiveness of financial policies.

### **5.2. Proposed solutions**

*Firstly,* to improve the state budget expenditure policies: Invest in logistics infrastructure by constructing and upgrading transportation infrastructure, port and airport infrastructure, railway infrastructure, inland waterway infrastructure, and logistics centers; Enhance the efficiency of managing and utilizing state budget funds by implementing supportive policies for enterprises operating in the logistics sector and improving the effectiveness of managing and supervising the use of state budget funds in the logistics field; Promote the development of logistics enterprises by encouraging cooperation in training between businesses and universities, vocational schools, providing scholarships and specialized

training programs, and establishing vocational training programs and certifications, creating conditions for companies to provide in-house training.

*Secondly*, to enhance credit policies: Build a credit information system; Provide financial support to small and medium-sized enterprises through preferential credit and funding from investment organizations, create a favorable financial market environment, and develop diverse financial products; Strengthen credit risk control by developing credit risk policies and procedures, evaluating the financial capacity of customers, valuing collateral assets, utilizing technology for credit risk control, and training and improving the capacity of staff. Support training and capacity building for management; Promote cooperation among enterprises in the industry.

*Thirdly*, to improve insurance policies: Introduce policies to encourage logistics companies to participate in civil liability insurance; Provide financial support policies for logistics companies to participate in civil liability insurance; Implement risk assessment policies in cargo transportation activities; Enhance training and raise awareness about insurance.

*Fourthly*, to improve tax policies: Reduce import taxes on necessary equipment and devices in logistics operations; Apply value-added tax with a mechanism for reimbursement to logistics companies; Implement tax policies for logistics services, aiming to reduce or exempt taxes; Adjust tax policies related to the importation of goods through border gates, ports, and airports; Provide tax support policies for logistics companies carrying out research and development projects in the industry; Strengthen control, supervision, and anti-tax evasion measures in the logistics sector.

In addition to specific financial policy solutions, the government can implement parallel measures to further optimize logistics costs and address other industry limitations, including: Improving institutional frameworks; Accelerating digital transformation; Enhancing international cooperation in the logistics sector.

## FACTORS AFFECTING THE CAPITAL STRUCTURE OF CONSTRUCTION COMPANIES LISTED IN VIETNAM

**Author: Nguyen Ha Linh<sup>1</sup>, Nguyen Linh Giang<sup>1</sup>, Nguyen Lam Anh<sup>1</sup>, Nguyen Thi Hoai<sup>1</sup>, Phung Thanh Thao<sup>1</sup>**

**Mentor: Bach Thi Thu Huong<sup>2</sup>**

**ABSTRACT:** *The research examines the determinants of the capital structure of construction enterprises in Vietnam from 2015 to 2021. The research sample comprises 30 listed construction companies. Empirical results indicate that company size, profitability, and solvency have significant impacts on the capital structure of enterprises in Vietnam's construction sector. Findings of the research will assist shelter building enterprises in Vietnam in determining the ideal financing structure for their operations.*

**Key words:** *Capital structure, factors, listed companies, construction sector, Vietnam*

### 1. INTRODUCTION

One of the most important duties for business managers is to choose the best financing plan for their company. Managers must consider not only the allocation and use of capital but also the proper method of acquiring capital when creating business financial policies. The average cost of capital is then reduced to the lowest possible level, maximizing the value of the enterprise.

Construction firms with features that demand an enormous amount of capital have to set up a suitable capital structure, assuring an appropriate ratio of equity to loan capital. Most listed construction companies conduct services such as directly participating in project construction, setting up the material supply chain, and supervising construction teams and subcontractor's project.

Understanding the importance of assessing the factors affecting capital structure in order to aid construction enterprises in establishing a reasonable capital structure and improving their competitiveness, the authors decided to carry out a study of the factors affecting the capital structure of listed construction companies in Vietnam. The outcomes of the study could help business managers in orienting themselves and choosing the appropriate financial structure for their company.

### 2. THEORETICAL FRAMEWORK

An enterprise's capital structure includes the arrangement and combination of equity, including preferred stock and common stock, and liabilities, including current short-term debt and long-term debt, to form the enterprise's business capital. Furthermore, capital structure affects profitability and business hazards that the organization may confront (Frank and Goyal, 2009). As a result, capital structure is frequently employed to finance a business's investment decisions.

Capital structure is a well-researched study from many different countries, here are some outstanding researches in the world and in Vietnam.

#### 2.1. Research on capital structure in the world

Jean. J. Chen (2003) used data from 77 companies listed in Shanghai for her research and found that factors affecting the capital structure of those companies included: profit, the ability to growth, tangible

<sup>1</sup> Academy of Finance, - CQ 58/09.02 CLC.

<sup>2</sup> Academy of Finance.

fixed assets, financial distress costs and tax-shield. This study was also based on the trade-off theory and pecking order theory. According to the results of this study, firm size and profitability have a negative relation to capital structure, although tangible fixed assets and growth rate are directly proportionate to the debt ratio.

Huang and Song (2006) stated that the tax shield, firm size, and fixed assets have a positive association with the enterprise's debt ratio, however the company industry and profit have an inverse link with the debt ratio. The conclusion was established after they carried out a research on 1000 listed companies in China during 1994 – 2003 period, in order to find the factors affecting the capital structure of Chinese companies. Besides, they also found that Chinese companies' capital structure was affected by the ownership structure of the firms

Wahab and Ramli (2014) did research of 13 out of 33 state-owned companies listed in Malaysia during 1997-2009 period. According to the outcomes of the research, while liquidity, size, and profitability are all negatively associated to debt ratio, tangible assets are positively related to debt ratio. Furthermore, the study suggests that the rate of economic growth and interest rate - these macro parameters - are negatively linked to the debt ratio of state-owned firms listed on the Malaysian stock exchange.

Wanrapee Banchuenvijit (2009) found that firm size is associated to debt ratio favorably, while profitability ratio and fixed assets are related to debt ratio adversely after conducted research on 81 companies listed on the Stock exchange of Thailand.

## **2.2. Research on capital structure in Vietnam**

Nguyen Thi Thuy Hanh (2019) analyzed secondary data from the financial statements of 38 commercial manufacturing business listed on HOSE and HNX, from 2009 to 2016 in order to understand the factors influencing the capital structure of commercial production organizations in Vietnam. According to the findings of the study, liquidity and state ownership have a negative impact on capital structure, whereas fixed assets and size have a favorable impact on capital structure.

Dang Thi Quynh Anh and Quach Thi Hai Yen (2014) stated that three main factors influencing the capital structure of firms are profitability, size and tax. The study was conducted by using FEM (Fixed Effect Model) method and the number of firms on the sample was 180 non-profit companies. According to the research, the association between size and profitability is positive, however, the relationship between tax and debt ratio of firms is negative.

Le Thi Minh Nguyen (2016) examined the factors influencing the capital structure of cement firms between 2007 and 2013. Based on the results of the study, profitability, firm age, and state ownership are all negatively connected with debt ratio. Meanwhile, the higher the debt-to-total-assets ratio, the larger the organization.

The study of Le Dat Chi (2013) identified six significant elements for assessing the factors that play an essential role in determining the capital structure of firms listed on the Vietnam stock exchange between 2007 and 2010. Taxes, inflation, market-to-book ratio, industry leverage, ROA, and management conduct are the actual repercussions. Furthermore, the study demonstrates that, based on the two traditional theoretical foundations of capital structure, namely the trade-off theory and the pecking order theory, capital structure planning of companies during the Research period is contrarian (strongly correlated with pecking order theory and not significantly with trade-off theory).

The authors continue to study, absorb, inherit, and create based on prior studies' theory and practice to assure scientific and practicality. As a result, the writers employ the following hypotheses:

- H1: The firm’s size has a positive impact on the debt ratio.
- H2: The enterprise’s solvency has a negative impact on the debt ratio.
- H3: The business’s profitability has a positive/negative impact on the debt ratio.
- H4: The enterprise’s asset structure has a negative impact on the debt ratio.
- H5: The enterprise’s growth rate has a positive/negative influence on the debt ratio.
- H6: Economic growth has a positive impact on the debt ratio.

### 3. DATA AND METHODOLOGY

#### 3.1. Data collection

Research subject: Factors influencing the capital structure of listed construction businesses in Vietnam. The study makes use of data obtained from the balance sheets and yearly audited financial statements of 30 Vietnam-listed construction businesses from 2015 to 2021.

#### 3.2. Analyzing data

Based on dialectical and historical materialist methodology, the study employed a combination of classic research methodologies such as comparison, analysis, statistics, and synthesis. Furthermore, the research uses econometric models to examine the influence of determinants on the capital structure of Vietnam’s listed construction businesses.

To aid the research process, the authors employed STATA software with panel data and a regression model to examine the determinants influencing enterprise capital structure. The original regression model (Pooled OLS), the random effect model (REM), and the fixed effect model (FEM) are all used in this thesis. The research team characterized the variable based on the gathered data for the minimum, maximum, mean, and standard deviation. Finally, to assess the relevance of independent variables, the group used multicollinearity tests, autocorrelation tests, and heteroscedasticity tests.

#### 3.3. Variables

##### 3.3.1. Dependent variables

We used the debt ratio variable (LEV) to describe the enterprise’s capital structure. The indicator reflects how much of the enterprise’s total capital is due. The LEV is calculated as follows:

$$LEV = \text{Total Liabilities} / \text{Total Assets}$$

##### 3.3.2. Independent variables

Based on the features of capital structure of listed construction businesses, real data, and performed investigations, the authors chose six factors to be used as independent variables in the model.

**Table 1: Independent variables**

Variables		Formula	Expectation
Company size	SIZE	SIZE = Log (Total Assets)	(+)
Liquidity	LIQ	LIQ = Short-term assets/ Short-term debt	(-)
Basic Earning Power	BEP	BEP = EBIT/Cost of borrowings	(+/-)
Assets structure	TANG	TANG = Tangible fixed assets/ Total assets	(-)
Company’s growth rate	GWLN	GWLN = (Net profit this period – Net profit previous period)/Net profit previous period	(+/-)
Economic growth rate	GDP	GDP growth rate	(+)

### 3.4. Research model

To examine factors affecting the capital structure of construction companies, we used the following model:

$$LEV_{it} = \alpha + \beta_1 * SIZE_{it} + \beta_2 * LIQ_{it} + \beta_3 * BEP_{it} + \beta_4 * TANG_{it} + \beta_5 * GWLN_{it} + \beta_6 * GDP_{it} + \epsilon_1$$

## 4. RESULTS

### 4.1. Data describing variables

**Table 2: Descriptive statistics of the variables in the model**

Variable	Obs	Mean	Std. Dev.	Min	Max
lev	210	.6878852	.1730621	.1727	.9924
size	210	6.144637	.3875734	5.5213	7.2493
liq	210	1.356243	.4902456	.5715	3.8699
bep	210	4.298472	6.236902	-9.1521	71.5215
tang	210	.057449	.0590105	.002	.428
gwn	210	.3155524	4.107857	-23.999	41.285
gdp	210	5.857143	1.98814	2.6	7.5

Source: The data was calculated on Stata

Table 5 displays descriptive data for the entire sample. In the period 2015-2021, the average debt ratio of listed construction businesses is 68.79%, while the average company size is 6.14, indicating that a company's average debt is somewhat more than shareholder equity. However, the degree of debt in certain businesses is quite high, with the highest being 0.99. The average solvency is 1.35, indicating that the average business can use short-term assets to pay off short-term creditors. Profitability has increased by 4.30% for businesses. Furthermore, the tangible fixed asset to total asset ratio is 5.75%. The influence of macroeconomic conditions on business success is shown through a dummy variable. It may be determined that firms must deal with economic changes during more than half of the research period (2012-2022). Inflation, interest rates, and the economic crisis all have a significant impact on business success.

**Table 3: Examine the correlation coefficient between the variables.**

	lev	size	liq	bep	tang	gwn	gdp
lev	1.0000						
size	-0.0601 0.3863	1.0000					
liq	-0.7637 0.0000	-0.0644 0.3531	1.0000				
bep	-0.3383 0.0000	-0.1148 0.0970	0.4775 0.0000	1.0000			
tang	0.1618 0.0190	-0.0143 0.8369	-0.2393 0.0005	0.0172 0.8042	1.0000		
gwn	0.0103 0.8821	0.0250 0.7186	-0.0488 0.4814	0.0412 0.5531	0.0153 0.8260	1.0000	
gdp	0.0939 0.1753	-0.0338 0.6258	-0.1050 0.1294	-0.0101 0.8843	0.0550 0.4279	-0.0686 0.3226	1.0000

Source: The data was calculated on Stata

The table depicts the correlation link between the variables in the model, which is used to forecast the direction of the influence of the components. At the 5% significance level, it can be observed that the variables in the model, LIQ, BEP, and TANG, are all tightly associated to LEV. At the 5% level of significance, the variables SIZE, GWLN, and GDP have no connection with LEV. Furthermore, several variables in the model are associated with one another. The authors will apply the test after generating the regression model to confirm whether or not there is multicollinearity.

#### 4.2. Regression models

The F-test has a p-value of  $0.0000 < 0.05$  after applying the FEM model, showing that the Pooled OLS model is not appropriate. As a result, the authors estimate the size by comparing the FEM model to REM to conduct and control for certain enterprise aspects. The author used the Hausman test to determine whether to use the FEM or REM model for regression. The Hausman test findings for the model in Table 5 reveal that  $\text{Prob}(\chi^2) = 0.0000 < 0.05$ , thus we may reject hypothesis  $H_0$  or the FEM model as the better appropriate model to do regression analysis scale for the research model.

To find out the influence of factors on the capital structure of listed construction businesses in Vietnam, the authors employ multivariate regression using the FEM model, using SIZE, LIQ, TANG, BEP, GWLN, and GDP as independent variables to determine whether capital structure is impacted by this factor. However, to have a stronger foundation for selecting a research model, the author's team tests and fixes any flaws in the model.

In practice, various approaches may be used to determine if the model contains multicollinearity problems, one of which is the measure of variance inflation factor (VIF). Because the VIF value is 1.15, the likelihood of multicollinearity is quite low.

In this research, the Wald test and the Wooldridge test were employed to investigate the phenomenon of heteroscedasticity and autocorrelation. The data are characterized by fluctuating variance and autocorrelation, as seen in Tables 4 and 5.

**Table 4: Result of Wald test**

```
Modified Wald test for groupwise heteroskedasticity
in fixed effect regression model

H0: sigma(i)^2 = sigma^2 for all i

chi2 (30) =      5456.28
Prob>chi2 =      0.0000
```

**Table 5: Result of Wooldridge test**

```
Wooldridge test for autocorrelation in panel data
H0: no first-order autocorrelation

F( 1,      29) =      237.506
Prob > F =      0.0000
```

*Source: The data was calculated on Stata*

To reduce the impacts of variance and autocorrelation, we utilized Stata's Robust option. Table 6 shows the regression findings for 30 Vietnam-listed construction businesses.

**Table 6: Regression results for Robust model**

Fixed-effects (within) regression		Number of obs	=	210

Source: The data was calculated on Stata

The table above shows the regression findings for 30 Vietnam-listed construction businesses. The model's explanatory level is: At the 1% significance level, the SIZE and LIQ variables are statistically substantially linked with the LEV variable. At the 5% significance level, the BEP variable exhibits a statistically significant connection with the LEV variable. At the 10% significance level, the GDP variable shows a statistically significant association with the LEV variable. Variables TANG and GWLN were not statistically significant when linked with variable LEV. Furthermore, the factors included in the model explain 61.16% of the change in capital structure. Specifically:

- Firm size (SIZE): According to the model results, the correlation coefficient of firm size (SIZE) is 0.2213, indicating that this variable has the greatest influence on the capital structure of publicly traded enterprises. At a 1% importance level, the construction industry. Specifically, when the company's size rises by one unit and all other elements remain constant, the debt ratio increases by 0.2213. According to the positive correlation coefficient, business size has a beneficial influence on LEV. This finding indicates that larger enterprises in the sample borrow more and raise less equity. This finding is entirely compatible with pecking order theory and others, such as Jean. J. Chen (2003), Frank and Goyal (2009), Dang Thi Quynh Anh and Quach Thi Hai Yen (2014),...

- Liquidity (LIQ): The cash flow correlation coefficient is -0.1854, indicating a negative association between cash flow and LEV at the 1% significance level. When the company's solvency grows by one unit and all other elements remain unchanged, the debt ratio reduces by 0.1854. The results reveal that firms with strong solvency tend to issue more stock and less debt. This outcome is entirely compatible with the idea of pecking order theory, Nguyen Thi Thuy Hanh (2019), Wahab and Ramli (2014),...

- Profitability (BEP): Affects LEV at a 5% level of relevance. In this case, the correlation coefficient of the positive variable BEP is positively related to LEV. This conclusion is consistent with pecking order theory; firms do not need to mobilize much debt when they are profitable and have a large amount of accumulated earnings. This finding is consistent with the findings of Le Chi Dat (2013).

- Economic growth rate (GDP): At the 10% significance level, GDP has a positive influence on LEV. The pace of growth reflects the economic cycle. During times of sustained economic development, firms prefer to employ more debt to enhance financial leverage, hence boosting the profitability of the enterprise's equity. Specifically, the period 2015-2019 sees Vietnam's GDP develop at a reasonably high pace (about 7%). This phase helps to encourage publicly traded construction firms to rapidly grow their capital scale and raise the value of construction production. On the contrary, the economic growth rate decreases in the year 2020-2021 owing to the protracted impacts of the pandemic, listed construction businesses seek to reduce debt to maintain solvency, other obligations and other factors.

According to the model's results, the parameters TANG and GWLN have no statistically meaningful relationship with the capital structure of the sample's companies.

## 5. CONCLUSION

The study found that the factors influencing the capital structure of listed construction businesses in Vietnam are similar to other studies conducted both globally and locally. Company size, solvency, profitability, and economic growth rate all have a significant impact on the capital structure of Vietnam's listed construction businesses. However, in addition to the aforementioned criteria, there are numerous additional factors that affect the capital structure of the firm that are not addressed in the model, such as ownership structure, inflation, interest rates, and so on. As a result, the above model's results are simply one of the foundations for assisting construction firms in listing research and offering solutions according to the actual situations of enterprises.

The study of factors affecting the capital structure of listed construction businesses in Vietnam is regarded as particularly essential in the socioeconomic backdrop, as well as the challenges that the construction industry faces. with many current difficulties. According to the research findings, the capital structure of firms is greatly influenced by the size of the enterprise, its profitability, and its solvency.

Aside from the benefits that capital structure provides to listed construction companies in Vietnam, the study also highlights the fact that there are not really appropriate points in the capital structure in these enterprises, resulting in a capital structure that is not really optimal, causing limitations in the operation process. The preceding approach necessitates that enterprises perfect their capital structure. The above-mentioned listed construction firms' research data and model findings serve as the foundation for listed construction companies to offer beneficial to businesses solutions.

## FACTORS AFFECTING THE PERSONAL FINANCIAL MANAGEMENT

**Author: Nguyen Pham Ngoc Nam<sup>1</sup>, Bui Linh Nga<sup>2</sup>, Dinh Hoang Nam, Bui Tien Dung**

**Mentor: Le Hai Anh<sup>3</sup>**

**ABSTRACT:** *The study identifies factors affecting personal financial management behaviors of young adults in Vietnam by examining the relationships among five factors including personal financial attitude, financial knowledge, locus of control, financial self-efficacy and personal financial management behaviors. The study's findings could be useful for organizations, government and other institutions to develop more projects in developing personal financial management.*

*Keywords: personal financial management behavior, financial attitude, financial knowledge, locus of control, financial self-efficacy.*

### 1. INTRODUCTION

In recent years, personal financial management practices in particular to youth has been contemporary issues for the society as a whole, which is considered as the huge challenges for youth globally (OECD, 2014). In the today's modernized age under the rapid globally economic developments, younger generations are growing up with higher living standards, non-stoppable growing in personal demands, especially in a culture of debt facilitated by a wide ranges of complexity financial products, credit choices and many different digital financial services. Therefore, it is alert for a surge in financial risks that youth have to confront with. In fact, it is pointed out that the financial and economic developments are not always matched by an increase in financial management skills of youth. According to OECD surveys conducted in 2014, young people tend to have lower levels of financial knowledge as well as attentions on personal finance compared with those of later generations. In Vietnam, an emerging economy, with relative low level of income, third of students in higher education always face up with problem of budget deficit because of spending most of received allowances from parents on personal interests like clothing, cosmetics, traveling, cinema tickets. These evidences prove that the young generation around the world do not have adequate essential abilities to manage their own finance. A failure in managing personal finances not only affects to each individual's current financial welling-being, but also accumulatively impacts on future saving goals and then leads to negative profound long-term influences in the financial systems as well as the comprehensive economic, financial and social stability and developments of a nation and even global scale (Faboyede et al., 2015). Hence, it is imperative for young adults to have sufficient financial management behaviors.

In general, Personal Financial Management Behavior (PFMB) is the subject of the financial discipline, regarding to all facet of behaviors related to process of planning, implementing and evaluating the cash flow, investments, risk management, retirement planning, tax planning, and estate planning. Another way, PFMB considers to all financial decisions and activities of each individual. Therefore, having solid PFMB enable individuals to be secured, have financial well-being, eventually obtain financial freedom and vice versa, the weak PFMB can lead to poor consequences like debt burdening, poor quality of life, mental health problems.

<sup>1</sup> Academy of Finance - CQ 57/09.01 CLC.

<sup>2</sup> Academy of Finance- CQ 59/09.01 CLC

<sup>3</sup> Academy of Finance.

Hence, in order to establish and enhance PFMB for young generation, it is necessary to determine factors affecting to PFMB, then propose suggestions and solutions to improve individual's PFMB.

In the global context, the term of PFMB is not innovative, there are many researchers attempting to determine and examine various factors impacted in PFMB under many different approaches in a wide range of sectors like psychology, sociology, finance, economics and event information technology (Ibrahim and Alqaydi, 2013; Robb and Sharpe, 2009). However, the differences in cultures, regions, levels of education, levels of economic and social development could have significant impacts on factors affecting PFMB. Besides that, such studies are still limited in the Vietnam context, especially studies considering young generations. Therefore, the purpose of this paper is determining and examining the factors affecting PFMB of Vietnamese young adults in the age of 18 to 30.

The paper comprises 5 sections. Section 2 refers to previous literatures regarding to PFMB and relevant factors. The following sections is selected methodology. Section 4 relates to results and discussions and final sections is conclusions and recommendations.

## **2. LITERATURE REVIEW**

### **2.1 Theoretical review**

#### **2.1.1. Theory of planned behavior**

As an extension of the original theory of reasoned action, in 1991 Ajzen continued to develop the theory of planned behavior which emphasizes the individual's intention which refers to three key elements including attitude, subjective norm, perceived behavioral control to perform a given behavior. This theory refers to general attitudes toward the behavior to the degree to which a person has favorable or unfavorable appraisal of the behavior. This evaluation is based on a person's beliefs on the expected outcome of his/her behavior. Experiments indicated that people tend to behave favorably if they believe their actions will have largely desirable consequences and vice versa, they form unfavorable attitudes towards the situations they expect and undesirable consequences. The second determinant of intention is subjective norm which is one of the social factors. This element is defined as the pressures perceived from society influences on the decision of performing or not performing the behavior. So, the subjective norm is the expected behaviors of individuals or groups that people believe. Another antecedent of intention is the degree of perceived behavioral control, which refers to a person's perception about whether performing the behavior is easy or difficult. Perceived behavioral control is supposed to reflect past experiences and forecasted impediments and obstacles. In other words, the perceived behavioral control is the people's level of confidence in their ability to control and monitor their actions. Overall, the theory of planned behavior affirms intention, perception of behavioral control, attitude toward the behavior and subjective norm present for each aspect of the behavior and can account for considerable changes in behavior. The more favorable the attitude and subjective norm, the higher level of perceived behavioral control, the stronger an individual's intention to perform the behavior under consideration. Based on the nature of each referred element, in the context of personal financial management, attitude towards the behavior could be linked to financial attitudes, subjective norm is relevant to financial self-efficacy and perceived control behavior may be similar to locus of control. Therefore, the theory gives a general view on the relationship between financial behavior and financial attitude, self-efficacy and locus of control.

#### **2.1.2. Social Cognitive Theory**

Social Cognitive Theory was introduced by Bandura in 1986, which is developed under the perspectives that learning is influenced by cognitive, behavioral and environmental factors. The theory proposes the

observation that others interact with one's own behavior and one's cognitive process to influence that individual's behavior. The theory emphasizes on the terms of "perceived self-efficacy" which is defined as people's judgments of their capabilities to organize and execute courses of action required to achieve targeted performances. It concerns an appraisal of what one can do with his or her possessed skills rather than skills one has. This theory also clearly distinguishes personal efficacy from the response to outcome expectations in which an individual's behaviors are influenced by expected consequences of an act. In more detail, people can believe that a course of actions will lead to certain outcomes, however they do not act based on such outcome beliefs since they are concerned about their abilities to execute necessary courses of action. Hence, it can be seen that the social cognitive theory could be used to explain how an individual's recognition of financial self-efficacy impacts financial management behaviors.

### **2.1.3. Social learning theory**

Social learning theory was introduced by Rotter in 1954. Different from traditional theories of learning, the theory indicates that behavior is not only the product of directly experienced response consequences, but also resulted from observation of other people's behavior and its consequences for them. An individual can learn by observing what is happening around and then learn them and learning rate a course of behaviors. For example, fearful and defensive behavior can be extinguished by observing others implementing the feared activities without any adverse consequences. The theory was constructed based on four main concepts including potential behavior, expectancy, reinforcement value and psychological situation. The potential behavior is defined as the possibility of doing a course of actions in a specific environment. Its possibility depends on perception or interpretation of the situation. Besides that, expectation refers to the perceived possibility that a particular activity can lead to an expected outcome. These expectations are formed based on previous experience and can be quantified. Actions are therefore regulated by anticipated consequences. However, an individual's cognitive capacity is not only affected by his or her experiences, but conditions of reinforcement. Furthermore, reinforcement value is related to the desirability of outcomes resulting from an individual's behavior. It depends on the learning one acquired and one's expectations. In fact, responses leading to unrewarding or punishing effects tend to be avoided or discarded whereas those that provide rewarding outcomes are retained and strengthened. Final component is the psychological situation, which is the combination of internal and external factors. An individual processes information from the environment then decides his or her behavioral response. This element refers to self-regulation which is the one's ability to arrange environmental incentives and apply consequences for specific situations. This psychological construct leads to important term of "Locus of control", which means that people with internal control expectation will receive situations, challenges in their life as contingent up on their characteristics and in contrast to those who are external control expectancies will more likely to perceive their challenges as contingent up on the luck and chance...

### **2.1.4. Family resource management theory**

Family resource management theory was introduced by Deacon and Firebaugh in 1988, which refers to the ability of a family in managing their resources to satisfy their needs and attain predetermined goals. The theory indicates a process of decision making starting from the inputs, followed by throughput and then obtaining output and then getting the feedback to reflect on inputs. This theory then has been applied in many latter studies, like Parrotta and Johnson (1996) describe the financial management systems as process starting from input which is financial knowledge and the following throughput including financial attitude, then resulting financial management behavior. Accordingly, this financial management conceptual framework proposes that financial attitude and financial knowledge are two critical factors to determine the personal financial management behaviors.

## 2.2. Empirical Review and Hypothesis Development

The previous literatures have identified various factors affecting PFMB under different perspectives. However, based on studies and characteristics of young Vietnamese as well as Vietnamese culture and region, the paper emphasis on testing the relationship between financial behavior and financial attitude, financial knowledge, locus of control and financial self-efficacy.

***Hypothesis 1 (H1): The relationship between financial attitudes and Personal Financial Management Behaviors is a positive correlation.***

Parrota and Johnson (1998) defined financial attitude as the psychological inclinations expressed under judgements of financial management practices. It refers to the ability to plan ahead, control and maintain a saving amount for financial issues. There are several studies advocated the positive relation between financial attitudes and personal financial management behaviors (Dwiastani, 2017; Ameliawati and Setiyani, 2018). They all agreed that the attitudes toward financial matters play as a key element to decide how a person manage his/her financial resources.

***Hypothesis 2 (H2): Financial knowledge and Personal Financial Management Behaviors are positively correlated.***

According to Chowa, Despard, and Akoto (2012), financial knowledge refers to the individual's competence in applying his/her knowledge into making appropriate financial decisions. It is clearly, financial knowledge plays an essential role to explain the variations in individuals' behaviors and their financial outcomes. A positive association between financial knowledges and PFMB is concluded by various studies. Robb and Woodyard (2011) and Zakaria et al. (2012) found that people possessing high level of financial knowledge tend to make financial decisions responsibly and manage their money efficiently and effectively. Van Rooij et al. (2011) determined the level of financial knowledge impact significantly on retirement planning, which means that financial knowledgeable people are able to better prepare for their future. Especially, in the context of digital transformation and the appearances of wide ranges of digital financial services, financial knowledge affects positively to the adoption of online services for making saving or investments or using debit and credit cards for daily payments (Sharma and Joshi, 2015; Roy and Jain, 2018).

***Hypothesis 3 (H3): Financial knowledge moderates the relationship between financial attitudes and financial management.***

Eagly and Chaiken (1993) supposed that the relationship between financial attitudes and PFMB could be affected by other correlated factors such as competence in finance. In research conducted by Bhushan and Medury in 2014, the good and reasonable educational programs or trainings are able to enhance personal financial attitude toward financial decision making such as lessening frequency of using credit cards. Joo and Grable (2004) found the interconnection between financial knowledge, financial attitude and financial behaviors. They indicate high level of perceptions on what people are considering are able to derive their attitudes on decision-making.

***Hypothesis 4 (H4): There is a negative relationship between external locus of control and Personal Financial Management Behavior***

According to Hellrigel et al. (2010), locus of control relates to an individual's belief that they are able to control over events that impact them. Internal control and external control were two aspects of the locus of control. Those with an internal center of control are more likely to be goal-oriented. External control refers to occurrences that were under the control of others, such as luck, chance, and fate (Hoffman et al., 2000). According to Mien & Thao (2015), the external locus of control negatively affects the Personal

Financial Management Behavior of young adults: people who have a stronger sense of external control exhibit poorer financial management skills.

**Hypothesis 5 (H5): Locus of control plays a mediating role in relation between financial knowledge and personal financial management behaviors**

Many literatures found a consideration impact of locus of control on the association between financial knowledge and personal financial management (Hayes, 2006; Zakaria et al., 2012; Perry and Morris, 2005; Mien & Thao, 2015). They identified that financial knowledge cannot be applied into practices if individuals do not have ability to control and monitor their financial decisions.

**Hypothesis 6 (H6): Financial self-efficacy and financial management behavior are positively correlated.**

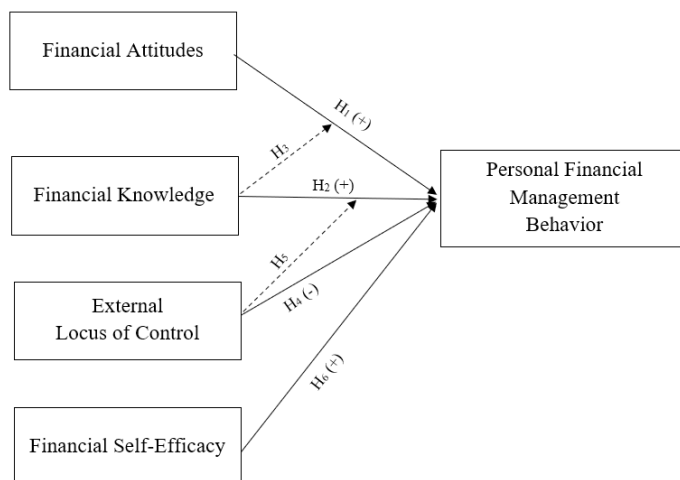

**Hypothesis 7 (H7): Financial self-efficacy impacts positively on the relation between financial attitudes and personal financial management behavior.**

Self-efficacy refers to a person’s belief in their ability to perform at a certain level and exercise control over events in their life (Bandura, 1994). Therefore, under perspective of financial management behavior, a person who has strong self -efficacy tends to consider financial difficulties in their life as challenges to be overcome rather than threats to be avoided. In the later studies, Qamar, Khemta, and Jamil (2016); Farrell et al., (2016); Asandhimitra & Kautsar (2020) asserted that the higher level of self-efficacy the more responsible individuals will be in making their financial decisions.

Besides that, Qamar, Khemta, and Jamil (2016) found a positive moderating role of financial self-efficacy affects to the association between financial attitudes and personal financial management.

**2.3. Conceptual model**

A conceptual model is suggested based on the findings mentioned above. Following are specifics on the conceptual model and related hypotheses:

**Figure 1. Conceptual framework for the research**

Source: the figure was synergized by authors

**3. RESEARCH METHOD**

**3.1. Research design**

To examine the relations between factors and personal financial management behaviors, the study adopts a mixed method, using both qualitative and quantitative approach. In this paper, there are 05 constructs examined

including personal financial management behavior (PFMB), financial attitude (FA), financial knowledge (FK), locus of control (LC) and financial self-efficacy (FSE). In order to measure these constructs, a questionnaire has been made based on previous studies and has been moderated to be suitable with Vietnamese cultures and life styles as well as younger generation. Personal financial management behavior was measured by 11 items. 15 items were used to estimate financial attitudes. Financial knowledge was measured by 6 items in terms of individual's self-assessment of knowledge of financial issues, financial self-efficacy was measured by 4 items and there are 6 items used to measure external locus of control. Five-point Likert-type scale was used for all items in this study. The questionnaire was firstly made in English, then was translated into Vietnamese to ensure respondents in Vietnam can understand. The questionnaire comprises 2 parts: first part refers to respondents' information and characteristics and second part contains items to measure five constructs in the proposed model.

### **3.2. Sample**

The study population includes the adult youth studying or working in Vietnam from 18 to 30 years old. Total 230 questionnaires have been sent to respondents. After the collection, 218 questionnaires are acceptable.

### **3.3. Research method**

The first step of testing collected data is using Cronbach's alpha to test the reliability of data. After that, exploratory factor analysis (EFA) and confirmatory factor analysis (CFA) were adopted to test the validity of measurement scales. Convergent validity and discriminant validity of data is assessed through Average Variance Extracted (AVE). The discriminant validity is assessed through Fornell - Lacker Criterion. Then the structural equation model (SEM) was applied to analyze the research model to test the hypotheses. The data was analyzed by both SPSS and AMOS package.

## **4. RESEARCH AND DISCUSSION**

### **4.1. Respondents' characteristics**

Total 218 responds are gathered from 18- to 30-year-old. According to the collected data, in total of respondents, male and female achieved 46.8%, 53.2% respectively. Age ranged from 18 to 30 years old, in which 58.2% of respondents from 18 to 22 years old, 18.8% from 23 to 26 years old and 22.9% from 27 to 30 years old. Regarding marital status, 76.1% of respondents unmarried and 23.9% of respondents married. The academic levels of respondents are relatively low with 39.9% of respondents being under bachelor, 38.5% of respondents' education level in bachelor and only 21.6% of respondents being in master degree or above. The employment status was represented with 54.1% of respondents are students and 45.9% are working full-time. Regarding to educational background, 43.1% of respondents are working in non-finance and 56.9% of them having finance or related finance background. 33.5% of the respondents have the income under 2 million VND per month, 20.6% of respondents have the income ranging from 2 to 5 million VND per month, 11.5% of respondents earn amount of money from 5 to 10 million VND per month and 34,4% have income above 10 million VND. This could be matched by the percentages of employment status.

### **4.2. Results**

The reliability of all scales in the main survey was examined by using Cronbach's alpha. The results showed that, almost scales met requirement of reliability, however eight items gained low corrected item-total correlation (under 0.3). These eight items were deleted from the measurement scale, which results to a significant increase of Cronbach's alpha (all Cronbach's alpha is higher than 0.8 except financial self-efficacy, just achieving 0.697).

After testing Cronbach's alpha coefficient, all measures were analyzed by EFA. The KMO value (0.882) is higher than 0.5, indicating the presence of a strong partial correlation. The significant value of Bartlett's test is 0.000, less than 5%, which means that the correlation matrix is indeed not an identity matrix. As the result, the test's results confirm that the data is suitable for factor analysis. There were 7 factors gaining the eigenvalues greater than 1 and simultaneously the extraction sum of squared loading indicated that 7 factors were extracted; the information contained in the original variables could be explained by 64.612%. However, the result is not aligned with determined constructs in part of literature review, therefore seven variables were removed from measurement to enhance the significance of analysis. After that, extraction method of principle axis factoring analysis was continued to be used to identify factors. As the result, KMO value is 0.871, significant value of Bartlett's test is 0.000, confirming the data set is still suitable for factor analysis. There were 5 factors extracted and it could explain 60,337% the information contained in the original variables. These 5 factors are matched well by the determined constructs.

To establish convergent validity and discriminant validity, AVE and Fornell-lacker criterion has been used. In order to convergent validity were within the acceptable value, 5 items having CR less than 0.7 and AVE less than 0.5 were removed, including FA11, FSE4, PFMB1, FSE3, PFMB6.

The CFA result indicated that the measurement model of all five factors received an acceptable fit of data: Chi-square = 371.782 (p-value = 0,000<0,05), CMIN/df = 199, CFI = 0.923, TLI =0.911, RMSE = 0.063 and GFI = 0.858. The finding indicated that all scales measuring the components of all constructs are validity.

All proposed hypotheses are tested by the structural model. The chi-square divided by degree of freedom was 1.9715 less than 3, the RMSEA value is 0,067 less than 0.8, CFI and TLI indices were 0,914 and 0,9 respectively (both are greater than 0.8), GFI is 0,914, so the model was acceptable.

Hypothesis 1 assumed that, financial attitude has a positive relation with financial behavior, however the result shows a p-value =0.241 greater than 0,1. Therefore, it means that financial attitude does not have effect on personal financial management behavior.

Regression estimator of relationship between financial knowledge and financial behavior is 0.25 with p-value is 0.007, which means the higher level of financial knowledge, the more responsible in financial behavior. The impact of financial knowledge was confirmed to financial behavior. Besides that, financial knowledge has a direct impact on financial attitude with coefficient is 0.141. However, there are no relation between financial attitude and financial behavior, so the hypothesis 3 does not support. The coefficient of external locus of control is -0.438 less than 0 (p-value=0.003), which means external locus of control has a negative effect on personal financial management behavior. In addition, financial knowledge has significant negative impact on external locus of control with regression coefficient is -0.452. The result of Sobel test indicated locus of control was a mediator of the relationship between financial knowledge and personal financial management behavior (P-value = 0.004). Apart from that, financial self-efficacy affects positively to financial behavior. The coefficient represented for this relationship was 0.258 at the significant level 0.05.

4.3. Discussion

The descriptive analysis of the study revealed that the average respondents have good behaviors towards managing financial resources responsibly. Besides, they also have strong competences in financial knowledge as well as have good attitudes to financial management practices. However, the results showed that nowadays, average young adults in the sample are lack of confident to make important decisions related

to financial resources as well as dealing with financial challenges in their life. Apart from that young adults are more likely to be influenced on external factors in financial management practices.

The data analysis surprisingly revealed that Vietnamese young adults' attitude towards financial activities did not influence their personal financial management behavior, though many researches indicated the opposite: Abeyrathna (2020) discovered that financial attitude has a positive influence on personal financial management behavior; Dwiastani (2017) also claimed that a person's ideas, attitudes, and judgments about their financial status will influence the things they do.

The reason is that, through the study, Vietnamese young adults' financial attitude is shown to be affected by their financial knowledge – it means that in order for an individual to develop their attitude towards finance or financial activities, they must have enough understanding of finance or financial activities itself. The result can be seen to be the same in Harsha's (2013) study, indicating that financial literacy leads to controlled spending behavior and encourages saving behavior and also has a significant impact on investment decisions of investors; however, differs from Parrotta and Johnson's (1998) research, which refers that financial attitudes predict financial management better than financial knowledge. The analysis, therefore, emergently points out that young individuals in Vietnam need more proper financial literacy, which comes from the lack of financial knowledge being taught in Vietnam's education system.

Consequently, the study found that financial knowledge also has a significant positive relationship with personal financial management behavior. It means that financial knowledge is also a factor that impacts on financial management behavior of a person. It shows that people who have a great deal of knowledge about finance tend to make decisions about spending, investing and insurance wisely compared with less knowledgeable people. The current finding supports the findings from Chen and Volpe (1998), Lusardi (2008), Agung (2016).

The study also discovered a substantial negative link between external locus of control and personal financial management behavior. It signifies that a person's financial management conduct is influenced by his or her external locus of control. It also suggests that someone with an outside perspective does not manage their money wisely. The current conclusion is consistent with the findings of Perry and Morris (2005), Mien and Thao (2015), Bapat (2020), Sovitha and Thavakumar (2020), and Mutlu and Ozer (2021).

Besides that, different from previous studies conducted in Vietnam such as Mien and Thao (2015), the study also found that the relationship between financial knowledge and personal financial management behavior is mediated by external locus of control. It implies that an external factor can influence a person's psychology leading to the ability to apply financial knowledge. Therefore, when a person believes that he/she cannot control his/her fortune, it is too difficult for him/her to make financial decisions based on his/her financial knowledge because that person does not have enough motivation and confidence to take action. It might be true for young Vietnamese people as theory and practice are not always going together and behaviors in management are sometime more influenced by psychology factors and people's characteristics rather than their knowledge. The current finding again confirms the main ideas of social learning theory and other the previous empirical research from Hayes (2006), Grable et al. (2009) and Zakaria et al. (2012).

The study also discovered a substantial positive association between financial self-efficacy and personal financial management behavior. This suggests that financial self-efficacy is another aspect that determines a person's financial management behavior. It also means that a person who is confident in his or her ability to manage money manages his or her money properly. The current conclusion is consistent with the findings of Qamar, Khemta, and Jamil (2016), Farrell, Fry, and Risse (2016), Asandimitra and Kautsar

(2020), Asmin et al. (2021), and Chong et al (2021). Another study conclusion demonstrated a substantial positive association between self-control and personal financial management behavior. It means that a person with self-control may responsibly manage his or her finances. In other words, self-control has a good impact on a person's money management habit. The current findings corroborate those of Miotto and Parente (2015), Strömbäck et al. (2017), and Siswanti and Halida (2020). The positive relationship between financial self-efficacy and personal financial management behaviors found in this study is also in align with the social learning theory.

Overall, these findings suggest that for Vietnamese younger generation, being competence in finance, self-oriented approach in financial decision making and being confident in ability of handling financial complexity are main factors affecting their responsibly financial behaviors. The current study has attempted to fill a gap in Vietnamese literature and has practical implications for future studies in the context of Vietnam. The study will be beneficial to students, and financial counselors.

## 5. IMPLICATIONS

Firstly, for educational organizations, government agencies, the labor Union at companies, it is necessary to organize more and more financial seminars, workshops to emphasize the importance of responsible financial management behavior. The students and employees should be trained to take responsibility for their financial decisions.

Secondly, educational initiatives, educational organizations should pay more attentions on providing more lectures, training programs or even online courses to equip for young people basic financial knowledge enabling them to enhance the effectiveness and efficiency in using, allocating and managing their finance resources. Especially in context of rapid digital transformation, there are more and more innovative financial products and services, therefore to help young people avoid fall in the trap of financial risks, implementing programs to improve financial levels is urgent demands.

Thirdly, for parents who have children are in college-age, it is necessary to forecast their children financial management behaviors based on their locus of control, knowledge, self-efficacy. Then they are able to have reasonable monitor in their children's financial management behavior.

Finally, for individuals, young adults should have a positive attitude to acquire and cultivate financial knowledge. Through a number of methods such as: taking courses on financial information, or simply learning some basic information about finance to be able to manage finances well. In addition, for individuals who are using digital financial services such as online loans, credit cards, etc., they must pay more attention to improving their understanding of different types of financial services. This is because it contains many risks, if not knowledgeable enough, users will easily fall into a situation of losing money, or taking out loans beyond their ability to pay, these are typical examples for poor managing finances.

## SOLUTIONS TO IMPROVE BUSINESS EFFICIENCY OF LISTED SEAFOOD COMPANIES IN VIETNAM

**Author: Pham Duc Minh<sup>1</sup>, Nguyen Le Thao Nguyen<sup>1</sup>, Ngo Thu Phuong<sup>1</sup>, Duong Quynh Huong<sup>1</sup>**

**Mentor: Assoc.Prof. Doan Huong Quynh<sup>1</sup>**

*Abstract: The study examines factors affecting business efficiency of listed seafood enterprises in Vietnam; from there propose solutions to improve business efficiency of these companies. Specifically, the paper determines the direction and extent of influence on return on assets (ROA) and return on equity (ROE) of the following factors: ASSETS (enterprise size), GROWTH (business growth), LIABILITY (debt ratio), RECEIVE (receivable turnover), INVEN (inventory turnover). The study was conducted based on data collected from 10 listed seafood companies over the period from 2017 to 2021. The study also uses quantitative methods combined with multivariable regression models to examine the hypotheses. Findings indicate that variables of ASSET, INVEN, RECEIVE have positive impact with ROA; ASSET, INVEN, RECEIVE, LIABILITY have positive impact with ROE. In accordance with the research findings, the authors propose specific recommendations and solutions to improve the business performance of seafood companies listed in Vietnam.*

*Keyword: seafood enterprise, business efficiency, impacting factor, financial performance*

### I. INTRODUCTION

Fishery is one of the key economic sectors of the country. In recent years, the fishery industry has made a positive contribution to the transformation of agricultural and rural economic structure and has made a relatively large contribution to Vietnam's export turnover for many years. However, in the current period, under the influence of many factors, our seafood industry also has certain difficulties, making the production and business situation of seafood enterprises facing many challenges. This requires seafood enterprises in general and listed seafood companies in particular to improve business performance in order to increase the health of businesses as well as increase competitiveness in the market. .

In such conditions, how to maintain business efficiency, generate profits, and long-term and sustainable development direction for enterprises is an urgent question for each listed seafood enterprise in Vietnam in the current period. Understanding this as well as the fact that seafood enterprises have not yet optimized their business advantages, the authors chose to study Return on assets (ROA) and return on equity (ROE) - two factors that characterize the business performance of businesses. The study analyzes the influence of the basic factors affecting the business performance of seafood enterprises, finding solutions to improve business efficiency.

**Table 1: The sample of the study**

No.	Company's name	Code/Stock exchange
1	Minh Phu Seafood Corporation JSC	MPC/UPCOM
2	Vinh Hoan Joint Stock Company	VHC/HOSE
3	Multinational Development and Investment JSC - IDI	IDI/HOSE
4	Nam Viet Joint Stock Company	ANV/HOSE
5	Sao Ta Food Joint Stock Company	FMC/HOSE
6	Cuu Long An Giang Seafood Import-Export JSC	ACL/HOSE

<sup>1</sup> Academy of Finance.

7	Camimex Group Joint Stock Company	CMX/HOSE
8	Ben Tre Seafood Import Export JSC	ABT/HOSE
9	Kien Hung Joint Stock Company	KHS/HNX
10	Mekong Seafood Joint Stock Company	AAM/HOSE

The research team selected a sample of 10 representative seafood enterprises below on the basis of:

- Firstly, these are enterprises of different sizes in the seafood industry with capital from 100 billion to 8000 billion and stable operation in the period 2017 - 2021.
- Secondly, they are all listed on the stock market (on HOSE/HNX/UPCOM) and have full information on audited financial statements for research purposes.
- Thirdly, choose reputable leading enterprises and have a large market share in the seafood industry such as Minh Phu Joint Stock Company as the “*flagship*” of the enterprise sector in shrimp export or Vinh Hoan Joint Stock Company which is confirmed as Vietnam’s No. 1 catfish exporter

## 2. THEORETICAL FRAMEWORK

Business efficiency is the top concern of businesses, as it is the standard and measure of all activities. Business is the process of carrying out some or all of the stages from investment in production to consumption or providing services in the market for the purpose of profit. Therefore, business efficiency is a challenge that most businesses have to deal with and has become a topic of research in recent years, including:

(1) PhD thesis in Economics by Mai Thi Dieu Hang (Financial Academy, 2019) - “*Enhancing business efficiency of seafood companies in Vietnam*”. The thesis evaluated the business situation of listed seafood companies in the Vietnamese stock market, and proposed specific solutions and implementation conditions to improve their business efficiency.

(2) PhD thesis in Economics by Pham Thi Minh Hien (Financial Academy, 2011) - “*Using financial tools to enhance the competitiveness of Vietnam’s textile and garment industry in the context of WTO accession*”. The thesis evaluated the use of financial tools to enhance the competitiveness of Vietnam’s textile and garment industry and proposed solutions to use macro financial tools to improve the industry’s competitiveness in the context of Vietnam’s WTO accession.

(3) PhD thesis in Economics by Nguyen Phuong Anh (Financial Academy, 2021) - “*Business efficiency of member securities companies of stock exchanges in Vietnam*”. The thesis evaluated the business efficiency of member securities companies of stock exchanges in Vietnam and proposed solutions to improve their efficiency.

(4) Master’s thesis in Economics by Hoang Ha Mi (Hai Phong Private University, 2018) - “*Some solutions to improve business efficiency in Northern steel companies*”. The thesis evaluated the business efficiency of Northern steel companies and proposed solutions to improve their business efficiency in the future.

(5) Master’s thesis in Business Administration by Vo Thi Tuyet Hang (Da Nang University, 2015) - “*Factors affecting the business efficiency of construction companies listed on the Vietnamese stock market*”. The thesis studied the factors affecting the business efficiency of construction companies and proposed measures to improve their business efficiency.

(6) PhD thesis in Economics by Doan Thuc Quyen (Financial Academy, 2015) - “*Solutions to improve the business efficiency of listed manufacturing companies in the Vietnamese stock market*”. The thesis evaluated the business efficiency of listed manufacturing companies in the Vietnamese stock market and proposed solutions to improve their business efficiency.

Based on reports and studies which have the similar research topic, with a serious study of the theory and analysis of business efficiency of cement businesses, the article “BUSINESS PERFORMANCE OF LISTED SEAFOOD JOINT STOCK COMPANIES ON THE STOCK EXCHANGE IN VIETNAM” will contribute to clarifying some basic issues in the theory of business performance along with the current situation and proposing solutions to improve the business efficiency situation in general and all the ratio in particular at listed companies.

### 3. RESEARCH METHOD

The object of the study: Business efficiency of Vietnamese seafood industry enterprises

Research scope:

- Spatial scope: The topic is studied in 10 seafood industry enterprises listed on the Vietnamese stock market.

- Time scope: Studying the business efficiency of 10 seafood industry enterprises listed on the Vietnamese stock market during the period 2017 - 2021.

The authors use a variety of research methods such as:

- Qualitative method: collect empirical information and data over time (secondary data of stocks is obtained from websites such as: <https://vietstock.vn>; <https://cafef.vn>; <https://fireant.vn>).

- Method of calculation and comparison: select the appropriate criteria for calculation and set out in the article, from which it can be compared with other similar indicators.

- Forecasting method: based on the calculated and collected results, the authors make a forecast about the development trend in the next periods of the object being evaluated.

The combination and use of many different research methods is aimed at helping the process of studying the current situation of business efficiency of listed seafood companies in Vietnam with high reliability and achieving better quality.

### 4. RESULTS AND DISCUSSION

- Basis for building models of factors affecting business performance

**Table 2: Summary of factors and hypotheses in the study**

Factor	Variable	Hypothesis	Symbol
Business efficiency	Return on assets		ROA
	Return on equity		ROE
Enterprise size	Total assets	+	ASSETS
Business growth	Revenue growth rate	+	GROWTH
Capital structure	Debt ratio	+/-	LIABILITY
Inventory management	Inventory turnover	+/-	INVEN
Receivables administration	Receive turnover	+/-	RECEIVE

\* Data collection

The group compiles information on the production and commercial operations of 10 seafood companies listed on the stock market based on information from the audited financial statements of the enterprises in the sample. Securities for Vietnam from 2017 until 2021. The dependent variables ROA and ROE as well as the independent variables employed in the research model are then calculated using the financial statement.

\* Setting up a research model:

$$ROA_{it} = \beta_0 + \beta_1 \log(\text{ASSETS})_{it} + \beta_2 \text{GROWTH}_{it} + \beta_3 \text{LIABILITY}_{it} + \beta_4 \text{INVEN}_{it} + \beta_5 \text{RECEIVE}_{it} + \varepsilon_{it}$$

$$ROE_{it} = \beta_0 + \beta_1 \log(\text{ASSETS})_{it} + \beta_2 \text{GROWTH}_{it} + \beta_3 \text{LIABILITY}_{it} + \beta_4 \text{INVEN}_{it} + \beta_5 \text{RECEIVE}_{it} + \varepsilon_{it}$$

Include:

*ROA: Return on assets*

*ROE: Return on equity*

*ASSETS: Total assets*

*GROWTH: Revenue growth rate*

*LIABILITY: Debt ratio*

*INVEN: Inventory turnover*

*RECEIVE: Receive turnover*

*i: company i*

*t: year t*

**Table 3 : Descriptive statistics of ROA and ROE**

	ROA	ROE
Mean	0.0741766	0.1473183
Min	-0.0546031	-0.0590211
Max	0.3251844	0.5370391
Std.Dev.	0.0646194	0.1216853
Obs	50	50

(Calculated from Stata 17)

The descriptive statistics reveal that there are a total of 50 observations, corresponding to a sample of 10 seafood businesses from 2017-2021. The lowest ROA in the sample is -5.46%, while the highest is 32.52%. The average ROA is 7.42%, with a standard deviation of 6.46%, which is relatively close to the mean value. This indicates that there are some differences in the ROA of the businesses. Similarly, the lowest ROE value in the sample is -5.90%, while the highest is 53.70%. The average ROE is 14.73%, with a corresponding standard deviation of 12.17%, which also indicates that there are some differences in the ROE of the businesses.

**Table 4: Descriptive statistics of explanatory variables**

	ASSETS	GROWTH	LIABILITY	INVEN	RECEIVE
Mean	6.189387	-0.358723	0.4285656	28.19523	6.29687
Min	5.303384	-11.57104	0.0336223	0	0.4453479
Max	6.920503	0.97495	0.8507865	1068.747	15.91671
Std.Dev.	0.5120066	1.875422	0.1953017	151.2371	3.706958
Obs	50	50	50	50	50

(Calculated from Stata 17)

In terms of independent variables, the scale of company assets (ASSETS) showed a deviation with a standard deviation of 51.12%. As for the revenue growth rate (GROWTH), the values ranged from -1157.0% to 97.49%, with a standard deviation of 187.54% and an average of -35.87%. This indicates

strong differences and fluctuations, such as Camimex Joint Stock Company (CMX) with negative revenue growth rate during the period of 2019-2021.

Regarding capital structure (LIABILITY), the average value was 42.85% with a standard deviation of 9.53%. This suggests that companies have a debt-to-equity ratio of nearly 50% of the total capital, and the standard deviation also shows a certain difference between companies. For example, Cuu Long An Giang Seafood Import and Export Corporation (ACL) has a high capital structure ranging from 53% to 65%, whereas companies like Mekong Seafood Joint Stock Company (AAM) almost entirely use owner's equity with a capital structure below 10%.

The other two indicators, inventory management and accounts receivable management, also showed strong fluctuations, with standard deviations of 15123.71 rounds and 370.69 days respectively, due to CMX's restructuring of the entire company, leading to significant impacts on these indicators. Therefore, the practical group tested regression models to overcome these shortcomings and understand the impact of factors on business efficiency.

**Table 5: Results of regression models**

Model	ROA			ROE		
	Pooled OLS	FEM	REM	Pooled OLS	FEM	REM
ASSETS	0.0738658 (0.000)	-0.0240976 (0.828)	0.0709406 (0.009)	0.1093079 (0.003)	-0.2222778 (0.307)	0.1053999 (0.009)

INVEN	0.0000947 (0.145)	0.0000857 (0.193)	0.0000964 (0.104)	0.0002237 (0.066)	0.0002068 (0.110)	0.000227 (0.051)
RECEIVE	0.0074674 (0.005)	0.0087589 (0.115)	0.0082191 (0.012)	0.0142753 (0.004)	0.0120134 (0.263)	0.0144769 (0.006)
Số quan sát (N)	50	50	50	50	50	50
R-squared	32.68%	52.13%	32.32%	34.52%	48.63%	34.46%
F (Wald-Chi <sup>2</sup> )	4.27 (0.0030)	2.72 (0.0082)	12.76 (0.0257)	4.64 (0.0017)	2.37 (0.0195)	18.19 (0.0027)

(Calculated from Stata 17; P-values are enclosed in parentheses)

The study is conducted using three models: Pooled OLS, FEM, and REM. Then, the most suitable model is selected based on F-test, Hausman, and Breusch and Pagan LM tests.

**Table 6: Summary of selection tests between 3 models Pooled OLS, FEM and REM**

Accreditation	ROA			ROE		
	Pooled OLS & FEM	FEM & REM	Pooled OLS & REM	Pooled OLS & FEM	FEM & REM	Pooled OLS & REM
F test	F(9, 35) = 1.58 Prob > F = 0.1595			F(9, 35) = 1.07 Prob > F = 0.4097		
Hausman test		chi2(5) = 1.19 Prob > chi2 = 0.9460			chi2(5) = 2.89 Prob > chi2 = 0.7175	

LM test			chibar2(01) = 0.62 Prob > chibar2 = 0.2156			chibar2(01) = 0.33 Prob > chibar2 = 0.2818
Conclude	Choose OLS	Choose REM	Choose OLS	Choose OLS	Choose REM	Choose OLS

(Calculated from Stata 17)

Results show that both ROA and ROE regression functions are more suitable for the Pooled OLS model. The group performed tests for heteroscedasticity and autocorrelation for both ROA and ROE regression functions.

**Table 7: Variance and autocorrelation tests for regression ROA and ROE**

Accreditation	ROA . regression	ROE . regression
Variance of variable error	chi2 (1) = 3.17 Prob>chi2 = 0.0749 > 0.05	chi2 (1) = 1.79 Prob>chi2 = 0.1815 > 0.05
Autocorrelation	F(1, 9) = 6.503 Prob > F = 0.0312 < 0.05	F(1, 9) = 8.157 Prob > F = 0.0189 < 0.05

(Calculated from Stata 17; P-values are enclosed in parentheses)

The results show that both models do not have variable variance but have autocorrelation. To overcome the phenomenon of autocorrelation error, the team used the general least squares (GLS) estimation method to overcome. The results summarize the impact of factors on the two models as follows:

**Table 8: Summary of regression results according to GLS . model**

	ROA		ROE	
	Beta	P-value	Beta	P-value
ASSETS	0.0571348	0.005	0.0946256	0.004
GROWTH	-0.0005256	0.047	0.0022079	0.036
LIABILITY	-0.0126887	0.571	0.1018911	0.059
INVEN	0.0000786	0.034	0.000201	0.027
RECEIVE	0.0093274	0.002	0.0159293	0.001

(Calculated from Stata 17)

- Test the model’s estimated hypotheses:

The results of the research model have the following equation:

$$ROA = -0.3460704 + 0.0571348 \log(ASSETS) + 0.0000786INVEN + 0.0093274RECEIVE$$

The variable ASSETS has a positive effect of 0.0571348 to ROA and is statistically significant at the 5% level of significance

The variable INVEN has a positive effect of 0.0000786 to ROA and is statistically significant at the 5% level of significance

The variable RECEIVE has a positive effect of 0.0093274 to ROA and is statistically significant at the 5% level of significance

With the collected data set, the remaining variables are not statistically significant at the 5% significance levels.

The results of the research model have the following equation:

$$\text{ROE} = -0.6066743 + 0.0946256 \log(\text{ASSETS}) + 0.01018911\text{LIABILITY} + 0.000201\text{INVEN} + 0.0159293\text{RECEIVE}$$

The variable ASSETS has a positive effect of 0.0946256 to ROE and is statistically significant at the 5% level of significance

The variable LIABILITY has a positive effect of 0.1018911 to ROE and is statistically significant at the 10% level of significance

The variable INVEN has a positive effect of 0.000201 to ROE and is statistically significant at the 5% level of significance

The variable RECEIVE has a positive effect of 0.0159293 to ROE and is statistically significant at the 5% level of significance

With the collected data set, the remaining variables are not statistically significant at the 5% and 10% significance levels.

Out of the 5 variables included in the model, 4 variables explain the level of impact on business efficiency through the dependent variable ROA and 5 variables explain through the dependent variable ROE, specifically:

Impact of variable ASSETS - enterprise scale: The regression coefficient of ASSETS has a positive impact on ROA and ROE. When ASSETS increase by 1, the ROA and ROE of the enterprise increase by 0.0571348 and 0.0946256 respectively, given that other factors remain constant. The results show that enterprise scale can bring good signals to business efficiency, but the external impacts on this indicator have multi-dimensional effects on the benefits that enterprise scale brings. Therefore, enterprises should adopt appropriate policies to build a suitable scale and adapt to the impacts from the market.

Impact of variable GROWTH - enterprise growth rate: The original hypothesis was that GROWTH would have an impact on ROA and ROE, but the results of applying the regression model demonstrate that, in contrast to the original hypothesis, GROWTH had no impact on ROA and ROE. The analysis shows that during the period of 2017-2021, the seafood industry was affected by the EU's IUU yellow card as well as the impact from Covid-19, leading to a decrease in the business growth rate and a negative impact on business efficiency.

Impact of variable LIABILITY - debt ratio: The regression result shows that LIABILITY only affects ROE. When LIABILITY increases by 1, the ROE of the enterprise increases by 0.1018911, given that other factors remain constant. However, an increase in LIABILITY does not necessarily mean that ROE will increase accordingly, as when the debt ratio of the enterprise increases beyond the optimal level, it will have a negative impact on business efficiency.

Impact of variable INVEN - inventory turnover cycle: The regression coefficient of INVEN has a positive impact on ROA and ROE. When INVEN increases by 1, the ROA and ROE of the enterprise increase by 0.0000786 and 0.0159293 respectively, given that other factors remain constant. Although it has a positive impact on business efficiency, the level of impact is very small, which is suitable for the economic context of the period 2019-2021 when the global supply chain was disrupted due to the pandemic, and seafood enterprises were significantly affected as the costs associated with preservation and transportation of inventory increased, leading to a decrease in inventory turnover cycle and a decrease in business efficiency.

Impact of variable RECEIVE - accounts receivable turnover cycle: The regression coefficient of RECEIVE has a positive impact on ROA and ROE. When RECEIVE increases by 1, the ROA and ROE of the enterprise increase by 0.0093274 and 0.0143314 respectively, given that other factors remain constant. In other words, the better the enterprise manages its receivables, the higher its business efficiency. Enterprises that manage their customer receivables well and apply reasonable sales policies will reduce their average collection period, thereby avoiding a shortage of capital for production investment and improving their business efficiency.

**Table 9: Summary of hypotheses testing**

Factor	Variable	Hypothesis	Result	
			ROA	ROE
Enterprise size	ASSETS	+	+	+
Business growth	GROWTH	+	Meaningless	Meaningless
Capital structure	LIABILITY	+/-	Meaningless	+
Inventory management	INVEN	+/-	+	+
Receivables administration	RECEIVE	+/-	+	+

• **Solutions:**

Firstly, in order to ensure production and business efficiency of enterprises as well as improve their attractiveness to investors, a reasonable capital structure must be established. The study’s findings showed that there is a positive correlation between debt levels and firm performance, meaning that as debt levels rise, so do the performances. Therefore, it is necessary to create a fair capital structure in order to secure the production and business efficiency of firms as well as increase their investor appeal. Fishery companies need to have a specific plan in using their capital reasonably to avoid excessive debt (>50%) or abuse of leverage. To do that, they need to identify and find funding sources: seek funding from the government, use other capital mobilization channels such as raising capital from share issuance activities. stocks and bonds for existing shareholders, for strategic partners or for public issuance on the stock market. This is an effective form of capital mobilization because businesses can both raise capital in large quantities and increase the owner’s equity. Companies can also improve their operational efficiency by increasing labor productivity, optimizing production processes and saving production costs. This will help increase the competitiveness of businesses and also help improve their capital structure. In addition, businesses also need to use assets effectively: handle tasks such as recovering debts from other units, releasing unexpected inventory, etc.

Secondly, effective credit practices are essential for fishery companies to effectively manage their receivables. The following factors are needed to establish a customer’s credit profile: customer information, transaction time, financial capacity indicators for customers, details on due dates for timely and late payments, debt turnover, etc.; bolster debt collection by assigning people to keep track of receivables to ensure that payments are made on time and to inform clients of due dates for repayment, etc.; Use the following metrics to assess the success of periodic receivables management: average collection period of businesses in the same industry or industry average; average collection period in the past; In order to track debts swiftly and precisely, firms need to spend money on debt management software.

Thirdly, to reduce the risk to their business, fishery businesses must categorize their inventory in a logical and scientific way. Liquidate inventory with a low turnover rate, reduce inventory while facing

competition to save costs, resolve the oversupply scenario, and improve product competitiveness in a variety of ways. We should pay more attention to domestic markets and promote exports from multiple markets. For export enterprises, they need to comply with regulations and proactively respond to opportunities and challenges. Domestic enterprises need to engage in healthy competition through product quality, reduce production costs and costs by improving processes and technologies, improve labor levels, and actively enter the international market.

## 5. CONCLUSION

Thus, in general, through the above analysis, it can be seen that the business performance of fisheries enterprises in the period 2017 - 2021 is influenced by the following factors: ASSETS (enterprise size), GROWTH (business growth), LIABILITY (debt ratio), RECEIVE (receivable turnover), INVEN (inventory turnover). Research results indicate that variables of ASSET, INVEN, RECEIVE have positive impact with ROA; ASSETS, INVEN, RECEIVE, LIABILITY have positive impact with ROE. In accordance with the research findings, the authors propose specific recommendations and solutions to improve the business performance of seafood companies listed in Vietnam.

## THE IMPACT OF ASSET SIZE & STRUCTURE ON FINANCIAL PROFITABILITY OF THE LISTED SECURITIES COMPANIES IN VIETNAM

**Authors:** Dang Phuong Anh<sup>1</sup>, Le Phuong Thao<sup>2</sup>

**Mentor:** TS. Nguyen Huu Tan<sup>3</sup>

*ABSTRACT:* This study investigates the impact of asset size and structure on financial profitability of listed securities companies in Vietnam. The authors have modeled and evaluated the impact of asset size, asset structure factors and the relationship between asset size and structure with financial profitability of 25 securities companies listed in Vietnam in the period of 2017 – 2021. The article states that the size and structure of assets is shown through the phenomenon of the influence of the indicator asset size affecting the same direction as ROE and the long-term asset ratio has an opposite impact on ROE. Moreover, the study also shows that factors such as cost coefficient, growth rate, and inflation also have an impact on the ROE of securities companies.

**Keywords:** asset size, asset structure, long-term assets, ROE,...

### 1. INTRODUCTION

The stock market is one of the most important capital mobilization channels of the market economy in the Vietnam economic renovation. Acting as a financial intermediary to raise capital for businesses and the economy; being an enterprise segment operating in the field of financial investment with self-employed activities with high profitability, etc securities companies can be seen to play a vital role in the stock market. Therefore, improving the profitability of securities companies is a prerequisite for the development of securities companies in particular and the stock market in general. To ensure sustainable profitability for securities companies, management entities must develop an appropriate financial strategy, including the size and structure of assets.

Maximizing financial profitability and benefits of management entities has become the main objective of the establishment and business operation of a securities company. Establishing asset size and asset structure allocation should be taken into proper consideration. An inappropriate size and asset structure can result in financial problems and even lead to decline in the company's ability to operate and its profitability.

Asset size represents the financial capacity of the securities company. The size of assets will determine what business activities the securities company can and can not carry out. A securities company with a large asset size will have more favorable conditions than other securities companies to develop and improve its activities as well as improving its reputation and trust with its customers. The large scale of assets also helps securities companies to innovate, upgrade and apply the most modern equipment to serve their work, thereby helping securities companies to promote profitability in business activities.

Asset structure of securities companies shows the ratio of long-term assets and the ratio of short-term assets to total assets. There are notable differences between each securities company. Securities companies

<sup>1</sup> Academy of Finance – CQ58/09.01CL.

<sup>2</sup> Academy of Finance – CQ59/22.01.

<sup>3</sup> Academy of Finance.

that focus on investing in technology and fixed assets will have a higher ratio of long-term assets to total assets. Thereby, which will facilitate securities companies to exercise business activities easier, more convenient and safer. In general, the operation of securities companies requires a large amount of cash to stimulate such business activities as margin, proprietary trading or securities underwriting, thereby increasing short-term assets in securities companies. Besides, the items of short-term loans and receivables also accounted for a large proportion in the securities companies' assets. Loans include margin lending, lending activities to advance proceeds from the sale of customers' securities. Short-Term Notes Receivables include receivables from dividends and interest up to the date of receipt, receivables from services provided by securities companies and other receivables such as prepayments to sellers, investment trusts, etc. Thus, most of the securities companies have a higher ratio of short-term assets than long-term assets, which make the asset structure of securities companies mainly in favor of short-term assets. The change in the asset structure of the securities company will change the business activities of the securities company, thereby impacting on the financial profitability of the securities company.

This study will focus on examining the influence of asset size and structure on financial profitability of listed securities companies in Vietnam in the period 2017 - 2021. This may provide some managerial insights in directing the organizational structure of securities companies.

The remainder of this paper is organized as follows: Section 2 reviews the previous literature and develops hypotheses. Section 3 presents data and methodology, while Section 4 presents experimental results and discussion. Finally, conclusions are drawn in Section 5.

## **2. RESEARCH OVERVIEW AND THEORETICAL FRAMEWORK**

### **2.1. Study overview:**

In the world as well as in the country, there have been studies analyzing the impact of the size and structure of assets on the profitability of enterprises in general and enterprises in the securities industry in particular.

Sivathaasan and his associates (2013) conducted a study on the factors affecting the profitability of all manufacturing companies listed on the Colombian and Sri Lankan stock exchanges from 2008 to 2012. Influential factors include asset structure, capital structure, company size and growth rate; The dependent variables representing the profitability of the business are ROE and ROA. The study showed that the independent variables explained 76.6% and 84.7% for the level of influence of the factors on the growth of ROA and ROE of the enterprise. In which, only capital structure has a positive impact on profitability of companies, the variables of asset structure, company size and growth rate have no statistically significant relationship with ROE and ROA.

Bolek & Wiliński (2012) studied the impact of internal and external economic factors on the profitability of construction companies listed on the Warsaw Stock Exchange in the period from 2000 to 2010. Research results have shown that asset size and GDP growth rate have a positive impact on the profitability of enterprises, while asset structure, capital structure, collection period. Average and quick ratio have the opposite effect.

Hang and Linh (2020) research for 27 typical real estate companies listed on HOSE from 2010 to 2019. The obtained results show that asset structure has a negative impact on corporate profits. On the contrary, many factors such as financial leverage, business size have a positive impact on the profitability of real estate companies.

Ngoc and authors (2020) studied the factors affecting the profitability of 20 oil and gas companies listed in Vietnam from 2014 to 2018 and showed that the size and total asset turnover had a positive impact

on the profitability. profits of enterprises in Vietnam’s oil and gas industry. While financial leverage has the opposite effect on corporate profits; remaining, net profit, debt ratio and expense ratio are not significant.

**2.2. Theoretical basis**

Based on theories and empirical studies, the authors conduct an empirical investigation of the influence of size and asset structure on financial profitability of listed securities companies in Vietnam in the period of time. 2017 – 2021. Therefore, it is hypothesized that: size and structure of assets have a relationship with financial profitability of listed securities companies in Vietnam.

To analyze the impact of size and asset structure on the profitability of securities companies, the model is built as follows:

$$Model: ROE_{it} = \beta_0 + \beta_1(Hn)_i + \beta_2(Htsdh)_i + \beta_3(SZ)_i + \beta_4(Gro)_i + \beta_5(Hcp)_i + \beta_6(INF)_i + \beta_7(GDP)_i + e_i$$

**Table 1: The table of defining measurement variables and expected signs**

Variable name	Definition	Proxies	Expected sign
Dependent variable			
ROE	Return On Equity	Net income/Shareholders’ Equity	
Control variables			
SZ	Enterprise size	The Logarithm of Total Assets	+
Hn	Debt ratio	Total Debt/Total Asset	+
Htsdh	Long-term asset ratio	Total long-term asset/Total asset	+
GRO	Enterprise Revenue Growth rate	Increase in the total Revenues/Total Revenues from the prior year’s	+
Hcp	Cost ratio	Total cost/Total revenue	-
GDP	Gross domestic product	Growth in gross domestic in 2017 - 2022	+
INF	Inflation rate	The annual inflation rate in 2017 - 2022	-

*Source: The Author’s team*

**3. DATA AND METHODOLOGY**

**3.1. Data collection**

For this study, the authors will focus on the impact of size and asset structure on financial profitability of listed securities companies in Vietnam. This study includes data of 25 securities companies listed in Vietnam over a period of 5 years (from 2017 to 2021) collected from the company’s audited financial statements. The final sample includes 25 firms with 125 observations.

**3.2. Data analysis**

The authors used STATA 16.0 software to estimate the regression equation that the authors proposed above. First, the two-way relationship between the variables was found through the correlation test. Next, the authors use ordinary least squares (OLS) to test the influence of independent variables on financial profitability. Hausman’s test is then used to discover which model fits the dataset better between the Fixed Effects Model (FEM) and the Random Effects Model (REM). The results show that the REM is consistent with the characteristics of the data in this study. The study also considers some necessary tests for the regression assumption to ensure that the regression results are blue, such as first-order autocorrelation, multicollinearity and heteroscedasticity.

Finally, to validate the author’s research results, REM regression was performed to recalculate the standard errors in case the models violate the regression assumptions.

## 4. RESULTS AND DISCUSSION

### 4.1. Description of stats

**Table 2: Descriptive statistics table of variables**

Variable	Obs	Mean	Std. Dev.	Min	Max
Firm	125	13	7.240121	1	25
Year	125	2019	1.419905	2017	2021
ROS	125	.2297136	.6405785	-3.6302	4.1203
ROA	125	.0687704	.0895524	-.1315	.5561
ROE	125	.1178608	.1229283	-.17	.6216
Hn	125	.3296224	.2538388	.0034	.8457
Htsdh	125	.0861888	.1170152	.005	.6006
SZ	125	14.3374	1.299701	11.9005	17.5742
Gro	125	.6866567	1.725797	-.9964	15.4809
Hcp	125	.7702864	.6405785	-3.1203	4.6302
INF	125	.02986	.0063724	.0184	.0354
GDP	125	.052782	.0208275	.0258	.07076

From the statistics table, it can be seen that the dependent variable ROE has an average of 0.1179, the lowest is -0.17 and the highest is 0.6216, showing that the financial profitability of listed securities companies in Vietnam has a significant difference. big fluctuations. In general, from 2017 to 2021, these financial profitability statistics show that

*Source: Analysis results of the author's team using STATA 16.0*

securities companies are profitable and stable. This comes from the fact that in 2017, the stock market recorded a record increase of 48% over the same period. In the period of 2020 - 2021, overcoming difficulties caused by the impact of the Covid-19 epidemic, the stock market has set a record in terms of scores, liquidity, number of new accounts opened... scale and quality, with excellent business results of many securities companies, including VPS, VND,... Financial statements of 10 leading companies in brokerage market share on Ho Chi Minh Stock Exchange (HoSE) have one thing in common: both revenue and profit have set records since their inception. Stock brokerage and margin lending are still the two main pillars helping companies record double- or even triple-digit growth year-over-year.

The Asset Size variable (SZ) has an average value of 14.3347, the highest value is 17.5742, the lowest value is 11,9005. The distance between the maximum and minimum values is not too large. It can be seen that listed securities companies have quite large assets, by the end of 2021, the asset size of 25 securities companies reached 211,821 billion VND. Large scale of assets concentrated in a few securities companies such as SSI, VND, HCM,... It can be seen that there is an imbalance in asset size among Vietnamese securities companies, mainly small-scale securities companies. That is one of the limitations and also a disadvantage for Vietnamese securities companies in improving business performance. This will significantly affect the ability to generate profits and improve business performance of securities companies. Therefore, for small-scale securities companies, it is necessary to have measures to improve the operation scale by increasing their own capital, merging with large securities companies.

The variable Long-term Asset ratio (Htsdh) averaged 0.0862, the highest value was 0.6006, the lowest value was 0.005. This shows that the majority of securities companies do not invest much in Long-term Assets but invest more in Short-term Assets. It proves that the proportion of Short-term Assets tends to increase gradually over the years, in line with the business characteristics of the market, increasing the

liquidity for the assets of securities companies. According to the author’s calculation, companies such as SSI, BSI, etc. have a higher than average ratio of assets (7.84%). This shows that most securities companies focus on investing in Short-term Assets instead of Long-term Assets, the ratio of Long-term Assets to total assets is very low. Moreover, securities companies with small asset size have a higher ratio of Long-term Assets to total assets than securities companies with large assets.

**4.2. Check for multicollinearity**

**Table 3: The table of the correlation**

```
. pwcorr ROE Hn Htsdh SZ Gro Hcp INF GDP
```

	ROE	Hn	Htsdh	SZ	Gro	Hcp	INF
ROE	1.0000						
Hn	0.3307	1.0000					
Htsdh	-0.2598	-0.4082	1.0000				
SZ	0.4592	0.7337	-0.2813	1.0000			
Gro	0.2797	-0.0848	0.1470	-0.1432	1.0000		
Hcp	-0.6049	-0.0614	0.0133	-0.1834	-0.0943	1.0000	
INF	-0.2818	-0.1385	0.0393	-0.2354	-0.1891	-0.0153	1.0000
GDP	-0.2721	-0.1496	-0.0082	-0.2342	-0.0984	0.1205	0.6081

	GDP
GDP	1.0000

From the results of the correlation analysis, in general, most of the variables in the model have a low level of correlation with each other (less than 0.5). According to the above table, there are SZ and Hn; INF and GDP being correlated. So to cure disability, remove SZ and GDP from the model. However, to confirm

*Source: Analysis results of the author’s team using STATA 16.0*

that when removing the two SZ and GDP variables, there is no multicollinearity phenomenon, the authors will test the multicollinearity phenomenon through the variance inflation factor (VIF).

**Table 4: The VIF test table**

```
. vif
```

Variable	VIF	1/VIF
SZ	2.47	0.405370
Hn	2.45	0.407405
INF	1.73	0.578855
GDP	1.66	0.604014
Htsdh	1.23	0.813059
Gro	1.12	0.889080
Hcp	1.10	0.909167
Mean VIF	1.68	

Based on the table, it shows that the average VIF of the variables in the model is 1.68, less than 10 and there is no independent variable whose VIF index exceeds 10, so there is no strong multicollinearity in the model.

*Source: Analysis results of the author’s team using STATA 16.0*

*Conclusion:* With the standard variance inflation factor VIF, multicollinearity does not exist in the regression model.

4.3. Selecting a regression model

Source: Analysis results of the author's team using STATA 16.0

From the regression results of the OLS model, there are 5 statistically significant variables, including: Htsdh, SZ, Gro, Hcp, INF being significant at  $\alpha=10\%$  and Hn and GDP being not significant. In which, Htsdh, Hcp and INF have the opposite effect on ROE; specifically, when the variables Htsdh, Hcp, INF increase by 1 unit, the ROE decreases respectively by 3.32; 8.78; 1.9 units and vice versa. The variables SZ, Gro have a positive effect with ROE, that is, when asset size and revenue growth increase, ROE increases.

From the results of FEM model estimation, with 10% significance level ( $\text{Prob} > F = 0.096 < 0.1$ ), the FEM model is more suitable than POOL OLS and REM model estimation results. With 10% significance level ( $\text{Prob} > F = 0.0000 < 0.1$ ), the REM model is more suitable than POOL OLS.

Thus, according to the Hausman test results, with the significance level of 10%, with the hypothesis  $H_0$ : the difference between the coefficients of the REM and FEM models is not systematic, the REM model is more suitable. ( $\text{Prob} > \text{chi}^2 = 0.9561 > 0.1$ ). From the above test results, the authors choose the REM model to regress the variables.

4.4. Analysis of regression results according to REM model

For the study sample of the authors, the assumption was also the same as the formal test. The authors test for possible violations such as variable variance, autocorrelation,... Hypothesis  $H_0$  is that there is no first order autocorrelation and no phenomenon of variable variance. change, the tested REM model has no

first order autocorrelation and variable variance phenomenon. This proves that the REM estimation model is completely capable and suitable.

**Table 9: The regression results according to REM model**

rho	.12246911	(fraction of variance due to u_i)				

Source: Analysis results of the author's team using STATA 16.0

From the estimation results, the efficient regression model shows that the only two variables Hn and GDP are not statistically significant at the 10% significance level. The regression model measures the impact of factors on the financial return (ROE) of securities companies as follows:

$$ROE = - 0,1456 - 0,2116 * Htsdh + 0,3052 * SZ + 0,0197 * Gro - 0,0992 * Hcp - 2,703 * INF + e$$

Thus, it can be seen that while the variable SZ has a positive relationship with ROE, the variable Htsdh has a negative relationship with ROE. This result is consistent with the study Bolek & Wiliński (2012), Hang and Linh (2020),... With a good market development period like 2020 - 2021, it is appropriate to invest in long-term assets. However, until the market shows some signs of risks such as liquidity risk, risk from proprietary trading portfolio, risk from credit control implemented by the State Bank,... The redistribution of asset structure, especially long-term assets, will help the company avoid unnecessary expenses. Therefore, in order to increase ROE, securities companies must increase their asset size, but they need to pay attention to the ratio of long-term assets to total assets. Growth of the VN30 index also has a positive effect on ROE, that is, when the stock market operates effectively, the VN30 index grows well, and the ROE of securities companies also increases. This is completely appropriate because the growth of VN30 proves that the stock market operates effectively, including the contribution of securities companies.

**5. CONCLUSION AND RECOMMENDATIONS**

This study examines the impact of asset size and structure on financial profitability through a sample of 25 listed securities companies in Vietnam for the period 2017 - 2021. The study shows that the asset structure measured by the ratio of long-term assets to total assets has a strong negative impact on a firm's ROE. Furthermore, the asset size is shown to have a positive effect on ROE while cost coefficient and inflation rate negatively affect the ROE of the company. Some limitations of this study that should be commented on are as follows: the data set used in this analysis is not sufficient to generalize the results to all securities companies in Vietnam; various profitability ratios and size variables and long-term asset ratios can be used to confirm these findings; time delay is not considered..

Regarding the proposed solution, Vietnam's stock market is rapidly developing, and many new products have been launched into the market. Therefore, to be able to provide these products, securities companies need to increase the size of their assets to improve their financial potential. In addition, securities companies also need to carefully control the ratio of short-term assets, long-term assets in their asset structure according to market fluctuations and in accordance with the company's industry characteristics, creating efficiency. business activities, improve financial profitability for securities companies.

## THE IMPACT OF THE SILICON VALLEY BANK COLLAPSE AND LESSONS LEARNED FOR VIETNAMESE BANKING SYSTEM

**Authors: Quan Thi Thien Kim<sup>1</sup>, Phung Ha Tam<sup>1</sup>, Le Ngan Ha<sup>1</sup>**

**Mentor: TS. Nguyen Huu Tan<sup>1</sup>**

*ABSTRACT: A commercial bank is one of the financial institutions that plays a leading role in the national economy, undertaking important functions such as credit intermediary, payment intermediary, money creation and provision of banking services for economic entities. With that important role and position, the inefficiency of a bank leading to bankruptcy will have a huge impact on the entire national financial system, even global economic activity. From the bankruptcy of Silicon Valley Bank (SVB) in early 2023, we can see its negative impacts on the US economy as well as the world, and draw many valuable lessons for banks operating in Vietnam.*

**Keywords:** Silicon Valley Bank (SVB), bankrupts

### 1. INTRODUCTION

The banking system plays an important role in supporting the economic and financial development of a country. However, the collapse of a bank can create significant negative impacts on the global banking system and have far-reaching effects on the economy and society. A prominent example is the collapse of Silicon Valley Bank, a financial technology bank widely known for its global influence.

Silicon Valley Bank (SVB), the 16th largest bank in the US, suddenly went bankrupt after only 48 hours, causing the entire US banking industry to suffer, plunging the nation's financial foundations into a serious crisis since the collapse of Washington Mutual. The impact of the SVB collapse was not limited to the national level, but also caused instability in the global financial system.

Vietnam's banking sector has witnessed stability and growth in business activities. Vietnamese banks have improved the quality of risk management, improved capital capacity and improved the quality of financial services. This has created trust from domestic and international customers and investors. Along with the achievements are difficulties and challenges that Vietnam's banking industry needs to overcome.

This article will conduct an assessment of the impact of the collapse of the Bank of Silicon Valley, further analyzing the causes of the bank's collapse, its impact on the global banking system and the socio-economic consequences it has caused. From there, recognize weaknesses and challenges, and propose specific lessons learned and solutions to overcome for Vietnam's banking industry can enhance stability and reliability in business operations, from risk management to internal control and international cooperation.

This article is not only important for banking professionals and managers, but also contributes to building a strong and reliable banking system for Vietnam, while creating the basis for the sustainable development of the economy.

### 2.1. Silicon Valley Bank and its bankruptcy

#### 2.1.1. Overview of Silicon Valley Bank (SVB)

Silicon Valley Bank (SVB) is a privately held commercial bank and financial services company serving the technology, health sciences, and innovation industries. SVB was founded in 1983 and is headquartered in Santa Clara, California. SVB provides various banking and financial services to startups, venture capitalists, private equity firms, investors and high net worth individuals.

SVB has an important role to play in accelerating the growth of the technology industry and startups in Silicon Valley and globally. With many years of experience working with startups and intermediaries, SVB understands the needs well. finance and challenges that new businesses create, thereby becoming a bridge to help businesses access capital easily and quickly. The two main roles of SVB can be mentioned as:

**Firstly, providing financial services to technology companies, supporting startups and startups.**

SVB is one of the leading banks in the US providing financial services to technology businesses, including loans, payment services, deposit management and personal finance solutions. SVB has provided more than \$30 billion in loans to more than 5,000 startups since 1983. This makes it possible for start-up companies to grow and expand operations, create new products, services and create jobs. Not only that, SVB also provides special financial solutions for startups, helping them to start and grow their businesses. Looking at the chart, it can be seen that up to 29% of deposits in SVB are from early-stage technology companies, 20% from technology and from many other sources such as healthcare, international, private banks...

Source: <https://seekingalpha.com/>

**Secondly, SVB is a source of information, connection and investment consulting support for businesses in the field of start-up technology.**

Thanks to its deep understanding of the technology and startup industries, SVB can provide useful information and advice to investors when evaluating and managing their portfolio. In addition, SVB also regularly organizes events and seminars to connect startups with each other and with investors. Through providing market information and analysis, SVB has helped startups make smart business decisions, helping investors better understand the startup market and this will provide their clients with the most accurate and effective investment advice.

Thus, it can be seen that SVB plays an important role in the economy in general, especially in the fields of technology, start-ups and new investment. In addition, SVB is also one of the key banks in international trade and investment activities, contributing to economic development globally.

### **2.1.2. The collapse of Silicon Valley Bank**

SVB's collapse began on March 7, 2023 when SVB announced that it had sold off \$21 billion in bonds and was expected to sell another \$2.25 billion of shares to balance its balance sheet. This has caused panic among customers as well as investment companies, leading many parties to withdraw their investments from this bank.

On March 9, 2023, SVB's shares collapsed, seriously affecting the stocks of many other banks. Only one day later, SVB shares officially stopped trading, and the bank gave up efforts to contribute capital or find suitable investors. As a result, shares of some other banks such as First Republic, PacWest Bancorp, and Signature Bank were also suspended. Not only that, SVB also faced depositors massively withdrawing \$42 billion in one day (equivalent to  $\frac{1}{4}$  of total deposits at the bank), which rendered the bank illiquid.

As a result, on the morning of March 10, authorities in California closed SVB Bank and handed it over to the Federal Deposit Insurance Corporation (FDIC).

The rapid collapse of SVB was caused in a short time by various factors but stood out:

#### **Firstly, the FED raised interest rates to control skyrocketing inflation.**

When the FED raises interest rates, borrowing costs are more expensive, stock prices fall and the dollar strengthens, and at this time the cost of capital for banks also increases. This reduces the profitability of SVB as they need to pay more to borrow funds from the Fed or other banks.

In the period from 2020 to 2022, SVB has invested heavily in government bonds, corporate bonds and mortgage stocks through home loans in the hope that interest rates will remain low for a long time. However, when the FED raised interest rates quickly to cope with inflation from the beginning of 2022, the value of these investments dropped sharply, being discounted more and leading to losses. The rapid increase in interest rates also makes the investment cash flow into technology companies and startups gradually decrease, forcing them to use deposits at SVB to cover rising costs. SVB was forced to sell these bonds to have money to pay, but the more they sold, the more they lost, so they had to plan to issue more shares to compensate. The unusual increase in demand for equity capital raised concerns for venture capital funds and deposit businesses, so they pulled out in unison.

#### **Secondly, the bank lacks portfolio diversification.**

SVB mainly invests in buying Government bonds with almost zero interest rate and this will lead to interest rate risks, financial risks and liquidity risks. When the interest rate on government bonds is almost zero, the bank will not have a source of profit from this investment portfolio. This may affect the bank's growth and profitability in the future. Not only that, if the bank invests too much in Government bonds, it will become too dependent on the financial stability of the Government. If the Government is in financial difficulty or is unable to repay the loan, the bank can suffer a great financial loss. In addition, government bonds may have low liquidity, which means that banks may find it difficult to quickly convert these investments into cash. The low liquidity of government bonds can be attributed to many factors such as long maturities, low interest rates, or lack of interest from investors. When the liquidity of government bonds is low, banks may find it difficult to buy or sell these investments. This can result in the bank not being able to provide sufficient cash in the event that it is needed, like paying off a debt or responding to a customer's withdrawal request.

**Thirdly, the weakness in risk management along with the inability to predict adverse movements in financial markets.**

Weakness in management caused SVB to collapse because it affected the bank's ability to assess, adjust and manage the risks it was facing. The cause of SVB's bankruptcy is said to be due to its main business activities, which are bond trading and losses. As SVB did not have enough contingency programs, there was not enough profit to cover the losses caused by selling bond-related assets at a loss. Not only that, SVB has been operating for 8 months without a risk manager because Mr. Laura Izurieta resigned as Chief Risk Officer of SVB Financial Group (Silicon Valley Bank's parent company) in April 2022. It was not until January 2023 that SVB appointed a new person to the CRO position, Kim Olson. Silicon Valley Bank has been without a full-time chief risk officer during its tumultuous transition in the venture capital markets. At the beginning of 2022, as interest rates began to rise, venture capitalists retreated and reduced the speed of transactions, leaving the tech companies they backed out of liquidity. That directly affects the deposit at SVB.

**Fourth, Silicon Valley Bank's operating model focuses too much on some high-risk areas.**

Some high-risk sectors such as technology, innovation, and health services - the sectors with the highest concentration of Zombies businesses (those that cannot afford to pay off their debts, cannot stay in business and are tied to banks). Too much focus on such a risky area can reduce an organization's ability to adapt and withstand the unexpected or market changes. One of the characteristics of SVB is that it mainly receives deposits from technology businesses and venture capital funds. These capital sources are not stable, so when needed, businesses and investment funds withdraw to pay their maturing obligations.

**Fifth, the number of people withdrawing cash increased dramatically, causing the bank to become illiquid.**

To balance finance, on March 8, SVB announced to sell a series of bonds with huge losses, even selling \$2.25B of new shares. This caused venture capital firms to start worrying and advising clients to withdraw funds urgently. As a result, SVB faced massive customer withdrawals of \$42 billion in one day, equivalent to 25% of the bank's total deposits and this made the bank insolvent.

## **2.2. The impact of the Silicon Valley bank collapse**

### **2.2.1. For the US:**

**Firstly, the collapse of SVB signals the failure of the Fed to regulate the banking sector.**

In its report released on April 28, The Federal Reserve Board (Fed) acknowledged that it "did not fully appreciate the extent of the vulnerabilities as Silicon Valley Bank grew in size and complexity". Accordingly, SVB's management did not take appropriate risk management measures before the bank's rapid collapse. While Fed supervisors have also failed to see signs and signs of a slowdown in SVB operations, they "did not take sufficient steps" to prevent an eventual collapse.

The collapse of SVB raises questions about the Fed's ability to respond to and adapt to the rapid transformation and development of the technology and financial industries. It also points to the Fed's shortcomings in anticipating and preventing potential risks in the banking system. Wrong decisions cause gaps and risks to remain in the banking system, including: Liquidity risk, concentration risk, interest rate risk... aggravated. As a result, just 2 days later, Signature Bank (SB) declared bankruptcy. 2 months later, First Republic Bank became the next bank to declare bankruptcy in 2023 in the US. This can be considered as a serious failure of the Fed in regulating the banking industry.

**Secondly, the collapse of SVB bank created many negative effects on the US socio-economy**

As America's 16th largest bank with total assets of up to 209 billion USD, SVB's bankruptcy has created many negative impacts on the US socio-economy:

One of the most negative effects is the loss of confidence of people and investors in financial markets. With the successive collapses of a series of large banks such as Silicon Valley Bank (SVB), Signature Bank (SB), First Republic Bank, customers as well as investors are gradually more concerned about the stability of the banking system and the safety of investments in other banks. A Gallup survey, which followed the collapse of SVB and Signature Bank but predated the failure of First Republic, has found that: Of the 1,013 survey participants, up to 48% of adults were concerned about their money being in banks. It can be seen that the continuous bankruptcy of large banks and financial institutions is making the American people increasingly lose confidence in the banking industry, indirectly losing people’s confidence in the policies of the Fed and the State: Only 36% of people trust the Fed chairman’s leadership — the lowest number in 20 years (according to the most recent Gallup survey)

**The level of people worried about the safety of bank deposits**

**Source: Made by Author, data from Gallup**

Another negative effect of this case is that technology companies and startups lose credit and face many financial difficulties: For SVB-invested startups, bankruptcy means liquidating the fund’s remaining assets, which will include shares of many startups that SVB has invested in. If liquidated by investment funds holding high-value shares, this will have an adverse impact on the company’s capitalization and brand value. Worse, this will impact the private equity market, causing a negative impact on idle funds. Meanwhile, cash flows in the market will be backlogged without creating any surplus value for investors. On the other hand, SVB is also acting as one of the important banks for technology businesses and startups. Therefore, SVB’s bankruptcy has created many difficulties in accessing capital and financial services.

Deposits are also one of the aspects affected by SVB’s bankruptcy. Of SVB’s \$209 billion in assets, most of them are venture capital investments and many deposits are not insured by the Federal Deposit Insurance Corporation (FDIC). The collapse of SVB left billions of deposits of many companies and investors “trapped”. Deposits not covered by FDIC (over \$250,000) may be transferred to another bank or liquidated, and customers may have to pay back their debts according to a schedule set by the courts and legal regulations. In the worst case, depositors are likely to lose all of their money. This led to the presence of a domino effect on withdrawals and sell-offs in bank stocks.

From these effects came a serious social consequence: Increased unemployment. SVB is an important sponsor and job provider in the technology industry. However, the collapse of SVB caused the companies’ deposits to be frozen, which affects the company’s business activities. On the other hand, the salaries of tech

workers paid through SVB have problems paying. Many of them were either laid off by the company with the aim of downsizing costs, or agreed to quit, rather than wait until the money was paid. The bank's collapse could lead to job losses and increased unemployment in the tech industry, affecting the U.S. economy.

**Thirdly, the collapse of SVB has stunned the U.S. banking industry after years of trying to maintain stability.**

Earlier, to curb inflation, the Fed has continuously raised interest rates, most recently raising the rate to 4.5%-4.75%, expecting to raise the rate to 5.25%-5.5%. High prices cause the value of investments to fall while borrowing costs rise, making investors suspicious of bank loans and banks lose a group of potential customers.

After SVB Bank's bankruptcy and the continued bankruptcy of other large banks, many people are concerned about deposit safety, leading to a domino effect on withdrawals at banks, especially at small and medium-sized banks. According to Fed statistics, since SVB's bankruptcy announcement, deposits in small banks have decreased from \$119 billion to \$5.46 trillion as of March 15. Deposits in major banks such as JPMorgan Chase, Wells Fargo and Bank of America also fell at their lowest levels in a decade (down \$61 billion in the first quarter of 2023 and down \$521 billion same period last year).

The loss of potential customers as well as the domino effect of withdrawing deposits spread illiquidity in banks. Followed by the continuous "plunge" of bank stocks or financial institutions, typically such as: Wells Fargo & Co down 6%, JPMorgan Chase & Co down 5.4%, Bank of America Corp down 6% and Citigroup Inc down 4% (ending the trading session on March 10); Bank Of America shares fell more than 16% in March; Shares of PacWest Bank and Western Alliance fell as much as 50% and 38% (at the close of trading on 04/05). The plunge of stock prices, the slowdown of banks (reflected in a very small increase in total assets of banks) and the domino effect of withdrawals persist even after the SVB incident. Although the U.S. government has made many efforts, such as: the U.S. government has guaranteed full payment of deposits at SVB to depositors (including those not covered by the FDIC), it is not enough to control the situation.

### 2.2.2. For the global economy

The U.S. banking crisis has created a ripple effect, weighing on global bank stocks. Specifically: after the announcement of SVB's collapse, at the trading session on March 14, many banks around the world recorded a decline in share prices: ANZ (Australia) fell more than 2%; STOXX (Europe) closed 5.7% lower; Commerzbank (Germany) fell 12.7%...

Above all, investors are worried about whether a domino effect emanating from the US will appear, bringing down more banks, dragging many other organizations and corporations. Because, SVB is currently the investor of many large companies in the world such as Roblox Corporation, Vimeo, Etsy ... The collapse of SVB will create many negative impacts on many businesses, especially technology businesses and startups. Indeed, declining confidence has sent the crisis to Switzerland, pushing the country's second-largest bank, crisis-ridden Credit Suisse, to the brink of collapse and ending up with a takeover of UBS. In Israel, home to a vibrant high-tech industry, hundreds of tech companies are counting on government assistance to escape bankruptcy due to the SVB affair. Although at the present time, the crisis is gradually under control, investors' confidence has not been able to regain.

On the other hand, the banking crisis from the U.S is a warning to governments and banking systems in risk assessment and policymaking, especially Asian countries - which are considered not to be affected much by the SVB case, including Vietnam.

### **2.3. Reference to the banking system in Vietnam**

#### **2.3.1. Theory of bank's bankruptcy in Vietnam**

In section 4 (2) of the 2014 Law on Bankruptcy which is currently being applied in Vietnam, bankruptcy is understood as "the situation of an enterprise or cooperative becoming insolvent and being declared bankrupt by the People's Court". According to that, a bank can be considered bankrupt in case it falls into insolvency of its due debts and is unable to fulfill its financial obligations to customers.

In the history of Vietnam's banking industry since 1951, there has been no bank that actually fell into bankruptcy. In fact, to bankrupt a bank is not simple and easy, and the consequences of this can last for decades to come. The reason is that the banking system in Vietnam today is very large, holding a huge amount of assets of the whole society; it plays a strong role in promoting investment, developing production and business activities as well as export and import; it is the most important factor in the process of growth and development of the national economy. The banking system has both controlled inflation and stabilized the macroeconomy; while providing capital for the economy. Therefore, the ability of banks to dominate and influence the economy is very strong.

Banks themselves act as financial intermediaries, so they must build high credibility for customers depositing as well as borrowing money. If a bank goes bankrupt, the deposited assets of businesses as well as people cannot be fully recovered. It creates bewilderment, anxiety and fear of a similar scenario for customers depositing money in other banks; makes people lose faith in the system, the market and the management agencies. That will lead to people's sentiments fluctuating and they will simultaneously withdraw money ahead of time in all banks in the country, causing the entire banking system to be overwhelmed and paralyzed. This is the power of the domino effect that causes not only the entire nation's finances to be negatively affected, but also to cause enormous social unrest.

Therefore, in Vietnam, when a bank shows signs of poor performance and creates negative effects, the Central Bank will immediately direct the implementation of measures to save it. Bank bankruptcy is only a last resort, as the Central Bank's previous attempts at disposal were unsuccessful.

To save a bank that is not performing well, the first solution that can be used is to inject more money so that the banks can maintain operations and improve the situation. However, this is an expensive measure. It can cause inflation and is difficult to address the root of the problem. Another popular and commonly used method in Vietnam is bank consolidation, merger and acquisition. The purpose of this is to help weak banks overcome difficulties in bad debt liquidity as well as other limitations and shortcomings. At the same time,

it creates opportunities for big banks to promote and utilize their resources in terms of capital, technology, human resources and market share. The last method to deal with a failing bank is to nationalize the bank. However, this measure is only used when the bank is “too big to fail”, which means there are too many large and intertwined links in the financial system. The direct acquisition of shares of commercial banks will help the Central Bank to actively restructure, ensure deposit payment, and prevent the spread of this bank’s weaknesses to other credit institutions.

### **2.3.2. Bank’s bankruptcy risks drawn from SVB’s case**

Although bankruptcy is almost impossible in Vietnam, its risks do exist and could affect Vietnam’s banking industry at any time. The Silicon Valley Bank (SVB) incident is also an opportunity for the banking industry around the world in general and Vietnam in particular to clearly recognize the major risks that can cause bankruptcy for a bank as well as negatively impact the banking system of a country. It can be said that the collapse of Silicon Valley Bank (SVB) is the result of the resonance of many risk factors that banks always face.

**Firstly**, the bank is subject to macro risks when the government introduces policies to raise interest rates to reduce inflation continuously and inappropriately. The U.S. Federal Reserve (Fed) continuously raises interest rates to reduce inflation, causing not only SVB but also many other banks in the US to fall into a difficult situation.

Banks may have a concentration risk problem when their customers are primarily focused on a specific industry, geography or target group. In SVB’s case, the bank mainly focuses on serving startups and venture capital; focusing on exploiting the market in the Silicon Valley region. That’s like putting all your eggs in one basket, increasing the risk for banks when their main customers are struggling.

**Secondly**, liquidity risk when banks fail to take actions to hedge liquidity risks to overcome cash flow gaps that are often longer than interest rate gaps and allow banks to become insolvent of maturing contracts. The risk that banks can face also comes from the lack of diversification of their portfolios, whether they only buy government bonds at low interest rates or invest in a few key items and make wrong financial decisions.

**Thirdly**, banks may also face risks in their organizational structure. For SVB, the bank has been operating for 8 months from April 2022 to January 2023 without a Chief Risk Officer (CRO), making it difficult for the bank’s risk management capabilities to predict adverse fluctuations in the financial market. Structural risks also emerged in Vietnam’s banking industry in 2014 when Nguyen Duc Kien, former Vice Chairman of Asia Bank (ACB), was arrested for fraudulently misappropriating assets amounting to VND 264 billion and sentenced to 30 years in prison.

**Finally**, the main reason for the collapse of SVB was the sudden increase in the number of people withdrawing cash due to crowd psychology, customers withdrawing 42 billion USD – or 25% of the total deposits of the bank. In Vietnam, in 2022, a similar case occurred that caused Sai Gon Joint Stock Commercial Bank (SCB) to have a mass withdrawal due to the negative information impact from the case of Ms. Truong My Lan who was arrested for fraudulent acts in issuing, buying and selling bonds contrary to the provisions of law. However, thanks to the timely intervention and handling of the Central Bank, SCB then stabilized and operated normally.

## **2.4. Lessons learned for Vietnamese banking system**

### **2.4.1. For the Government of Vietnam**

The Government should have policies to monitor, predict and forecast banking risks such as: Synthesize, analyze and forecast the monetary and financial situation, and propose systematic risk prevention measures. in

the field of money and finance. At the same time, it is necessary to develop policies and measures to respond to the crisis; ensure the stability of the monetary, financial and banking systems. Vietnam has become a prime example of how to handle deposit crises. In October 2022, Sai Gon Joint Stock Commercial Bank (SCB) faced a wave of massive withdrawals. However, the Central Bank intervened and handled the situation, pledging to depositors that their savings would be secured and quickly restoring market order. This quick intervention proves that the Central Bank is well prepared to contain sudden waves of panic, providing much-needed reassurance to customers and investors. Currently, the government has many policies and measures to respond to the crisis and ensure the stability of the monetary system at banks, such as:

- Preferential credit policy: This policy is applied to enhance the borrowing capacity of businesses and individuals, and at the same time create growth momentum for the economy. Specifically, the government can reduce interest rates on capital loans to ease the financial burden of businesses.

- Policy to strengthen management and supervision of banks: The government sets out regulations and policies to strengthen management and supervision of activities of banks. At the same time, strengthen inspection, supervision and strictly handle violations in the activities of banks

The Central Bank needs to consider adjusting and setting reasonable interest rates. As interest rates rise, new loans will become more expensive and it can reduce the need for loans, make existing loans more difficult to repay and increase the risk of default. This may lead to banks having difficulty in finding capital to lend or meet the payment needs of customers. In reality, the Fed's high interest rate hikes can increase funding costs. and put pressure on banks, including SVB. In the case of SVB, this bank has many loans with low interest rates and the interest rate on their customers is not high enough, then the Fed's interest rate increase will reduce this bank's profit and lead to collapse because they did not have enough capital to meet their debts. Through the SVB incident, the government of Vietnam has come up with a number of options to control interest rates at a stable level, including:

- Adjusting interest rates by the Central Bank: The Central Bank can adjust interest rates to control interest rates in the economy. If inflation is high, the Central Bank may raise interest rates to limit price increases. In case of economic recession, the Central Bank may reduce interest rates to increase the borrowing capacity of enterprises.

- Control of the money supply: When the amount of money in the economy increases rapidly, the Central Bank can reduce the money supply to limit price increases. Conversely, if the economy is in recession, the Central Bank can increase the money supply to stimulate production and consumption.

- Good management of debt loans: The government needs to manage debt loans well to limit risks in banks and minimize the negative impact of bad debt on the operation of the economy.

The government needs to pay close attention to, supervise and closely monitor the activities of banks, especially small banks. Banking control is not only carried out in large banks with high risks, but it is necessary to control all banks, because any bank that has problems can also affect the system, and there are always risks that we cannot foresee. When customers feel that a small bank is not safe, they can withdraw money to another bank, but many people rushing to withdraw money can bring down the entire banking system. Therefore, it is important that when a small bank has a problem, the Government needs to quickly control the fire to avoid the fire spreading to the whole banking system.

Each country needs to learn from the experience of other countries in risk management and build a financial safety net, in which it is necessary to pay attention to systemic risks, inter-bank risks, securities securities, real estate and the real economy, it is necessary to have a crisis handling mechanism in place to be able to react quickly, methodically and effectively.

The government needs to take measures to strictly handle those who post false information, confuse people and affect the bank's operations. Posting false and misleading information can cause serious damage to a bank, ranging from loss of customer trust to business operations. The Government needs to ensure that banks operate in a fair, transparent and trustworthy environment. Not only that, posting fake news can also lead to instability, anxiety and panic in the consumer community, which not only affects people's health and spirits, but also directly affects people's health. affect bank operations. The common cause of the banking crisis that occurred at two banks, Sai Gon Joint Stock Commercial Bank and Silicon Valley Bank, was derived from people rushing to withdraw money because they were provoked by false information being spread on the Internet. Learning from the above incident, the government has set out a number of policies to prevent fake news, namely:

- Setting out legal regulations: The Government has promulgated legal regulations to handle acts of creating fake news and spreading false information. For example, the 2018 Law on Cyber Security and the 2016 Press Law contain laws related to the handling of fake news.

- Monitoring and controlling online content: The government has set up authorities to monitor and control online content, in order to detect and handle fake news. Websites and social media accounts that spread fake news will also be handled according to the law.

- Enhancing public education about the importance of preventing fake news, and calling on people to join hands to prevent fake news. Fake news can create confusion, conflict and anxiety in society. When people are taught how to recognize and, through knowledge, prevent fake news, we can reduce the spread of fake news and ensure security and social stability.

#### **2.4.2. For banks in Vietnam**

Banks need strict financial supervision to ensure the stability and reliability of the financial system. If a bank's finances are not properly managed, it can lead to risks such as loss of customers' money, loss of bank assets, and even the collapse of the entire financial system. In addition, financial supervision helps the bank ensure compliance with legal regulations and ethical standards in its operations. Not only that, strict financial supervision also helps banks make the right decisions, improve risk management capacity and ensure liquidity.

Banks should diversify their investment portfolios to minimize risk as much as possible. Diversifying investment portfolios will help banks reduce risk by allocating investments to different asset classes. In addition, portfolio diversification also helps the bank to take advantage of new investment opportunities in different fields, if only investing in a single field, the bank may miss opportunities. Other attractive investments. At the same time, the monitoring, inspection and self-assessment of the business activities of banks also need to take place regularly, so the possibility of a crisis spreading from the collapse of other banks should not be underestimated.

Banks need to verify the health of businesses before granting loans or investments to ensure that businesses are able to repay loans and generate profits, minimizing risks for banks and businesses. The situation of "high investment but fake profit and loss" occurs when a business is assessed beyond its financial capacity, production and management capacity, and then cannot meet its financial needs. investment and bank profits. This is a difficult and dangerous situation for both banks and businesses. Therefore, to avoid risks for both parties, the bank should clearly assess the health of the business

Banks must prepare necessary provisions for long-term investments in the event of bad market conditions. Bank risk can be managed through hedging and buying long-term bonds or other investment instruments that add value to offset losses from bond sales when policy changes.

Banks also need to come up with measures to improve customer confidence because this is a very important factor to maintain the credibility and development of the bank. From the fact that people withdrew their money in a short time and caused a banking crisis at two banks, SCB and Silicon Valley Bank, that confirmed the importance of customer trust to the bank. If banks can offer reasonable and effective customer care and consumer confidence policies, this will be the basis for building trust and also being able to regulate risks. Customers trust the bank, they are willing to trust, invest and cooperate with the bank, thereby helping the bank control risks. According to the evaluation report of the Vietnam Assessment Report Joint Stock Company (Vietnam Report), as of June 2022, Joint Stock Commercial Bank For Foreign Trade Of Vietnam (Vietcombank) is the leading bank in the “Top 10 prestigious commercial banks in Vietnam in 2022”. The fact that Vietcombank is at the top of the table shows that the bank’s efforts in improving customer experience and service have been creating positive effects, and at the same time creating solid trust for customers. products when choosing an investment.

Banks need to invest in technology to enhance customer experience, including updating equipment systems, developing mobile apps, and easy-to-use websites to help customers make transactions. easily and quickly. Besides, banks should build attractive promotions to attract new customers and retain old customers. Promotions may include incentives such as fee reductions, gifts, increased savings rates, lower lending rates, or free services such as Internet Banking, credit cards, and products. other. These promotions can help increase sales and increase customer loyalty, and help banks create better relationships with customers.

#### **2.4.3. For customers**

From the fact that customers rushed to withdraw money, causing a banking crisis, this is even one of the reasons why the 40-year-old bank SVB collapsed in just 48 hours. We can see that it is extremely important for customers to have the right understanding, trust in the bank and the Government’s policies. The common cause for customers of SCB and SVB to withdraw money was determined to be because of unfounded information sources and posts posted on social networking sites about the fact that the two banks are in a bad financial situation. unstable or in danger of bankruptcy. Congressman Patrick McHenry, chairman of the US House of Representatives Financial Services Committee, commented that the SVB riot was the “first Twitter-incited withdrawal surge” and similarly, the incident that sparked the mass withdrawal of money at SCB was also stemmed from false posts on Facebook. These false posts have hit the psychology of consumers and caused a “domino” effect of massive withdrawals of people. Through the incident with the two banks above, it can be seen that, to ensure their legitimate interests, customers need to equip themselves with basic knowledge and have confidence in the bank and the government policies. For example:

- Customers need to improve their own knowledge and awareness and constantly update new knowledge, avoiding believing in fabricated, fraudulent and untrue information. If customers do not have sufficient knowledge or have no confidence in the bank as well as the policies of the Government, they may become the target of fraudsters or will lose their rights. As in the case of SCB, in the face of people rushing to withdraw money, the Central Bank has applied necessary measures for SCB to operate normally and ensure liquidity. For people who are saving money at SCB, Governor Nguyen Thi Hong said that people’s deposits at banks, including SCB, are guaranteed by the Government in all cases. Thus, the fact that customers are constantly updating new knowledge and having trust in banks and the Government not only helps them withstand the “information storm” exploding on social networks but also ensures their rights.

- Customers need to thoroughly understand and understand the bank’s financial products or services, especially risks. This will help customers know the level of risk and understand asset protection policies, so

that consumers can avoid unwanted risks and at the same time make the right decisions for the protection of assets. invest.

- Customers need to closely monitor the activities of the bank they are sending money to to have appropriate solutions, avoid following the crowd to lose their benefits. Monitoring the bank's activities closely also helps clients ensure that their deposits are protected and safe. Depositors can monitor information about security systems, customer protection measures, and compensation mechanisms in the event of a failure.

### 3. CONCLUSION

From the case of Silicon Valley Bank (SVB), we can see its negative and serious impacts on the US economy as well as other organizations around the globe, thereby drawing specific lessons for the banking system in Vietnam. It can be said that commercial banks play a central role in the economic development process not only for Vietnam but also for every country in the world. With this important position, each bank needs to ensure that its operations are well maintained and take specific measures to prevent and prevent risks that may occur under the support of the government, thereby avoiding falling into the situation of weak operation, inefficiency; leading to the risk of bank bankruptcy; causing adverse effects on the banking system in particular and society in general.

## FINANCIAL SAFETY OF SECURITIES COMPANY IN VIETNAM

**Author: Nguyen Hai Yen<sup>1</sup>, Nguyen Thao Nguyen<sup>1</sup>, Nguyen Hoai Thu<sup>1</sup>, Nguyen Thanh Nhan<sup>1</sup>**

**Mentor: MA Tran Thi Phuong Lien<sup>1</sup>**

*Abstract: Through the turbulent years of the global economy, financial safety has become a threat to financial institutions around the world, and they are also an inadequacy for the economy and market fledgling financial school in Vietnam. In order to create opportunities for domestic and foreign investors, along with developing the financial system in general and creating opportunities to raise capital for businesses and the Vietnamese government in particular; securities companies have been established and developed a financial safety system in order to protect the interests of investors. The reason for the focus on financial safety at securities companies in Vietnam is to solve the risk management problem when there is a sudden increase in the number of investment accounts in the market, the interests of investors in particular and the race to increase capital and dominate the market of securities companies in Vietnam in general in the last 5 years (2017 - 2021). In this study, we try to overcome it by completing all the evaluation criteria based on collecting written data, business situation, and focusing on a few typical securities companies. this latest study. Our findings also indicate that the lack of leadership and management judgments, and the neglect of issues of sensitivity to market risk, greatly influence the determination of the level of risk financial safety at securities companies in Vietnam.*

*Keywords: financial safety; securities companies; risk management; Vietnam.*

### 1. INTRODUCTION

Ensuring financial safety at securities companies is a prerequisite issue in developing the financial market in Vietnam. The issue of financial safety is not entirely new, but after the financial crisis and economic recession, they have been recognized and given more attention by researchers to control unwanted risks that come from macro and micro issues. Especially, for a nascent stock market like in Vietnam, the Covid 19 pandemic has accelerated the race of corporate investors and individuals, the risk control at securities companies become more and more important, in order to protect the interests and interests of domestic and foreign investors. Based on previous studies, which usually only revolved around ensuring safety and reducing risks at banks, in this study, we focus on the issue of ensuring financial safety at companies securities - the driving force for the development of financial markets. On the contrary, when risk management is poor, the company's financial insecurity will cause business activities to decrease, lose confidence of investors, and the company will easily get entangled in legal problems. Effective financial safety control is the overall management of factors affecting the operation of an enterprise such as: capital norms, asset quality, manageability, profitability, liquidity account, market sensitivity (according to CAMELS model). In this study, we choose the CAMELS model to provide the criteria for assessing capacity, financial position, effectiveness and risk level, which are quantified and applied uniformly to all projects. Banks, financial institutions can carry out the ratings/reviews in many consecutive periods and with the same unified criteria. At the same time, this model helps financial institutions detect weak or ineffective indicators, thereby helping them focus on improving the overall rating/review and financial indicators. In the introductory theoretical part, we introduce the built models and clarify the importance of the processes to monitor and evaluate the financial security of securities companies during the financial crisis, recent global economy. In the next section, we focus on research processes, where we

---

<sup>1</sup> Academy of Finance.

describe in detail the research methodology and main research directions. The results of the analysis are in the third section, where research results on both quantitative and qualitative characteristics have been synthesized. In the summary and statistics of the indicators, we also point out the risks that exist in general in financial institutions in general and the problems that securities businesses are facing in particular. Closing the research paper, our suggestions partly assist in overcoming financial insecurity in current securities companies in Vietnam and generate some new ideas to inspire for further studies.

## II. THEORETICAL FRAMEWORK

Currently, there are 2 sets of Laws, 10 Decrees and 20 Government circulars guiding the determination of financial safety indicators, the reporting regime on financial adequacy ratio of securities trading organizations, handling measures and responsibilities of related parties for securities trading organizations that fail to meet financial safety criteria. The Circular does not apply to the determination of tax obligations of securities trading organizations to the State budget.

Pursuant to Decision No. 617/QĐ-UBCKNN dated October 9, 2013 of the State Securities Commission, securities companies will be evaluated and classified according to the CAMEL model including the following contents. Currently, the SSC also uses the capital adequacy factor C (Capital Adequacy); Asset Quality A (Asset Quality); Quality Management M (Management); Profitability E (Earnings) and Liquidity L (Liquidity Exposure) of CAMEL system applied to Vietnamese securities companies. The CAMEL set of indicators is divided into two groups of factors: financial indicators (C, A, E, L) and governance criteria (M). Groups of financial factors can be assessed according to data from financial statements, annual reports and other financial data that have been reviewed or controlled in accordance with the law. Governance criteria is a separate factor because this factor is difficult to quantify and mainly based on qualitative criteria. The total score values of the group of financial factors and the total score of the administrative factors are assigned a weight level showing the importance of this group of factors in the overall score of the securities company. In which, the group of financial factors has the weight of 70% and the management factor of 30%. Rating score of securities companies = Total score of financial factors x 70% + Total score of management factors x 30% After analysis, securities companies are ranked from A to E:

- Rating A: From 80 points – 100 points: Securities company whose overall rating is at the initial rating threshold of A and no factor score below 65
- Rating B: From 65 points to less than 80 points: Securities company overall rating is at the initial threshold the first is B and no factor score is less than 50 points; or initially graded A but has 1 factor score below 65 points
- Rating C from 50 points – less than 65 points: Securities company within the initial rating threshold is C and no factor score is less than 35 points; or has an initial rating of B but has 1 factor below 50 points; or have an initial rating of A but have 2 or more factors with a score of less than 65.
- D rating from 35 points to less than 50 points: the securities company is in the initial rating threshold of D; or initial rating of C but with 1 factor score below 35; or initially rated as B but with 2 or more factors with scores below 50.
- Rating E from 0 to less than 35 points: Securities companies fall into one of two cases: they can be scored but not in the above cases. or unable to score due to failure to perform reporting obligations as prescribed or at the request of the SSC.

Management - Ability to manage: There are 19 criteria to evaluate Management Quality, but most of them are qualitative and require information gathering from many sources other than financial statements

including internal data sources. For example, criteria 3 and 4 require the number of years of experience in the financial/business field of the Chairman and the Director/General Director, or criterion 3 refers to the modernity of the system. information technology, etc. These criteria are difficult to quantify and require a relatively large source of internal information. Some other indicators require information of all brokers in the industry such as criterion 12: Proportion of stock trading volume made through the company (on two exchanges) / Total trading turnover of market (total transaction turnover of the two departments).

### III. RESEARCH METHOD

The objective of studying the financial safety of securities companies in Vietnam is to ensure transparency, honesty, and reliability and to protect the interests of investors. Securities companies are in need of ensuring that their business activities comply with regulations, processes, and standards on risk management and risk mitigation to minimize risk to investors. Regarding the defined goal, we have established several commonly used indicators, including the ratio of available capital, and the set of CAMELS model indicators (capital adequacy - C, asset quality - A, management - M, earning - E, liquidity - L, and sensitivity - S).

After collecting statistical data on HOSE at the end of 2021, we have classified securities companies into four groups: group 1 (Charter capital over 1500 billion dongs), group 2 (Charter capital from 1000 billion dongs to 1500 billion dongs), group 3 (charter capital from 500 billion dongs to 1000 billion dongs) and group 4 (charter capital below 500 billion dongs). Using a mixed method, we analyzed the financial statements, prospectuses, annual reports, and management reports of the companies, and then selected 12 companies with good growth rates, the highest profit after tax, and equity over 1500 billion VND to carry out the research. The group of 12 securities companies we selected for our research analysis in the model is listed in the table below:

**Table 1: List of securities companies researched**

Abbreviated name	Company name	Charter capital (VND)
ACBS	ACB Securities Co., Ltd	3.000.000.000.000
AGRISECO	Agribank Securities Corporation	2.120.000.000.000
HSC	Ho Chi Minh City Securities Corporation	4.580.523.670.000
KIS	KIS Vietnam Securities Corporation	3.761.579.550.000
MAS	Mirae Asset Securities Corporation	6.590.500.000.000
MBS	MB Securities Corporation	2.676.183.240.000
MSVN	Maybank Securities Co., Ltd	2.200.000.000.000
SSI	SSI Securities Corporation	14.911.301.370.000
TVSI	Tan Viet Securities Corporation	2.639.000.000.000
VIX	VIX Securities Corporation	5.821.391.890.000
VNDS	VNDIRECT Securities Corporation	12.178.440.090.000
FPTS	FPT Securities Corporation	1.950.599.510.000

### III. RESULTS AND DISCUSSION

#### 1. Capital adequacy

##### a. Index C1 ( Equity/Total Asset)

In general, the autonomy of securities companies has been decreasing in recent years. 2018 is the year with the highest index, proving that securities companies have high financial autonomy and are less dependent on debt. Stock market.

**Table 2: Index C1 of 12 securities companies in the period 2017-2021**

Securities Company	Year 2017	Year 2018	Year 2019	Year 2020	Year 2021
ACBS	68%	66%	74%	50%	
AGRISECO	99%	98%	93%	92%	89%
HSC	42%	58%	57%	36%	30%
FPTS	86%	79%	83%	65%	32%
KIS	46%	74%	59%	47%	48%
MAS	84%	68%	62%	50%	41%
MBS	30%	39%	35%	29%	31%
MSVN	68%	76%	66%	61%	56%
SSI	46%	38%	35%	28%	28%
TVSI	50%	60%	60%	39%	53%
VIX	70%	72%	80%	83%	80%
VNDS	31%	28%	28%	26%	26%

*Source: Compiled from financial statements of securities companies*

The success of Vietnam's stock market in 2021 is like that despite many fluctuations due to the pandemic, the stock index still increased by 36% within a year. The business results of the large-cap stock market improved significantly, although it slowed down in the third quarter under the influence of the fourth Covid-19 pandemic, the corporate bond market continued. boom as of November, the issuance volume reached nearly 500 trillion to warn potential risks of corporate bonds to investors, the Government has issued documents to inspect and handle violations in this market; Foreign investors still had a record net selling but were absorbed by domestic investors. It seems that these securities companies have a slow growth rate of equity in the period from 2018 to 2021.

The most notable among the 12 securities companies is FPTS, the growth rate of equity and total assets in the 3 years of 2017 - 2019 increased sharply by 39%, leading to an increase in this indicator, in 2021 with total assets increasing by 2 times. but equity only increased by 7 trillion dong, making this indicator drop sharply, showing that the company is increasingly dependent on borrowed capital, thereby reducing financial autonomy. MBS, SSI, VNDS are the 3 securities companies with the lowest safety ratio in this group of securities companies below 51% in comparison with the law: Total assets increased rapidly and strongly but the equity increased slowly and accounted for ¼ in total assets which leads these companies to always remain low.

#### **b. Index C2 (equity/legal capital)**

In Vietnam, Decree 155/2020/ND-CP, based on Clause 1, Article 175, stipulates as follows “Minimum charter capital for business operations of securities companies in Vietnam is as follows:

- + Securities industry: 25 billion VND
- + Proprietary securities trading: 50 billion VND
- + Underwriting securities: 165 billion VND
- + Securities investment consulting: 10 billion VND”

In general, the equity of the companies all exceeded the regulation. regulations and this rate is high. Securities companies have always improved this index over the years. Especially in 2021, securities companies increase their equity, creating a premise for this index to grow strongly by 679% compared to 2020.

**Table 3: Index C2 of 12 securities companies in the period 2017-2021**

Securities Company	Year 2017	Year 2018	Year 2019	Year 2020	Year 2021
ACBS	620%	608%	628%	685%	1365%
AGRISECO	588%	623%	656%	699%	817%
HSC	930%	1020%	1435%	1480%	2442%
FPTS	518%	658%	704%	734%	994%
KIS	371%	655%	698%	997%	1568%
MAS	702%	1535%	2046%	2212%	2866%
MBS	428%	487%	557%	687%	1137%
MSVN	322%	420%	443%	478%	926%
SSI	2872%	3052%	3134%	3291%	4740%
TVSI	200%	399%	444%	519%	1178%
VIX	308%	368%	474%	583%	474%
VNDS	823%	991%	1083%	1273%	3274%

*Source: Compiled from financial statements of securities companies*

The most noteworthy aspect of this indicator is that SSI has been growing for many years, indicating that the company is striving to improve its position in top stocks. HSC and MAS achieved breakthroughs in 2018 and maintained steady growth for 4 years during the research period. It is worth noting that VIX must be mentioned because the company is growing, but VIX will grow and decline slowly in 2021, which explains this. We find that VCSH and TTS are both declining, and the company's VCSH has declined by more than 300 trillion Vietnamese đồng.

### c. Ratio C3 (Liquid Capital Ratio/Total Risk Value)\*100

It was found that in the period of 2017 - 2019, the indicators increased steadily, but in the period of 2020 - 2021, they decreased gradually. In 2020, with the outbreak of the pandemic leading to fear of investors withdrawing money from the market, the market fell while securities companies lowered the total value of market risk in that year. As of December 31, 2021, we see that all securities companies that meet the criteria of liquid capital ratio according to circular 91/2020 greater than 180% are considered healthy operations.

**Table 4: Total market risk of 12 securities companies (Unit: million VND)**

Securities Company	Year 2017	Year 2018	Year 2019	Year 2020	Year 2021
ACBS	28.725	50.459	36.215	31.691	59.777
AGRISECO	31.595	46.058	127.387	170.946	92.131
HSC	188.102	65.142	274.189	180.103	276.901
FPTS	7.940	27.731	29.874	54.899	63.181
KIS	2.080	5.344	10.555	68.311	131.822
MAS	25.813	31.238	80.686	93.315	183.563
MBS	189.905	194.422	236.916	249.049	243.038
MSVN	-	-	-	-	5
SSI	395.321	708.415	868.970	509.309	669.998
TVSI	16.946	113.010	99.745	82.934	275.477
VIX	228.038	284.635	278.059	245.047	365.531
VNDS	249.876	255.873	340.503	179.184	942.698

*Source: Report on the ratio of available capital of securities companies*

In 12 securities companies, we see that each year the companies will have different market risk value funds. It is worth mentioning that SSI has always had a high risk value over the years, showing that the company has appreciated the risks of the market, proving that if something goes wrong, the company can still meet some of the risks. with the market. VNDS Company in 2021, the company calculates a market risk value of nearly VND 950 trillion, but perhaps we can see it in the company when we appreciate the impact of the pandemic and the US-China trade war on the market. Vietnam stock market.

**Table 5: Total settlement risk value of 12 securities companies (Unit: million VND)**

Securities Company	Year 2017	Year 2018	Year 2019	Year 2020	Year 2021
ACBS	104.580	140.134	168.816	196.266	259.615
AGRISECO	504.088	546.114	552.469	552.347	500.425
HSC	106.755	119.623	185.836	50.802	360.063
FPTS	11.083	26.850	21.810	29.724	48.478
KIS	197.817	182.887	181.090	169.035	156.734
MAS	8.395	65.872	56.768	48.315	131.242
MBS	66.319	37.906	75.781	80.283	186.329
MSVN	9.152	13.700	7.881	10.224	3.139
SSI	601.194	1.263.873	1.265.528	1.528.813	1.541.739
TVSI	4.346	26.726	10.709	11.166	8.137.955
VIX	15.564	15.465	23.155	17.606	16.503
VNDS	197.223	437.540	291.227	338.836	697.281

*Source: Report on the ratio of available capital of securities companies*

It was found that Agriseco and SSI in the research period both assessed the value of payment risk higher than other companies. HSC, KIS, MBS, and VNDS, we see that the company has an evaluation but not as high as the above two companies, with an increase in value in 2021.

**Table 6: Total value of operational risk of 12 securities companies (Unit: million VND)**

Securities Company	Year 2017	Year 2018	Year 2019	Year 2020	Year 2021
ACBS	86.215	104.811	71.979	95.001	240.000
AGRISECO	60.000	60.000	60.000	50.000	93.629
HSC	202.940	378.148	257.578	379.561	582.254
FPTS	60.000	60.000	60.000	60.000	114.085
KIS	60.000	50.000	55.631	132.580	355.346
MAS	660.000	65.232	119.346	189.636	114.085
MBS	179.065	185.803	183.932	202.756	288.471
MSVN	60.000	60.000	50.694	60.309	160.000
SSI	317.490	438.581	462.977	615.676	536.233
TVSI	60.000	62.134	133.215	296.367	579.955
VIX	60.000	60.000	73.653	80.455	109.426
VNDS	98.312	249.403	247.802	289.296	535.281

*Source: Report on the ratio of available capital of securities companies*

In 2021, companies are all increasing the value of operational risk. We see that due to the high number of new securities accounts opening, the transaction volume will be higher, there may be technical errors, system and business process errors, human errors in the trading process, there may be a lack of money. business capital arising from expenses and losses from investment activities. We found that the following

companies with good network systems or good business management personnel all have the same operating risk value over the years such as: Agriseco, FPTS, KIS, TVSI, VIX, which we highly appreciate. these companies.

**Table 7: Available capital of 12 securities companies (Unit: million VND)**

Securities Company	Year 2017	Year 2018	Year 2019	Year 2020	Year 2021
ACBS	1.586.514	1.588.109	1.706.049	2.023.131	3.962.269
AGRISECO	1.893.648	2.354.846	2.680.321	2.808.131	2.960.712

FPTS	1.356.264	2.027.393	2.194.251	2.260.358	3.286.303
KIS	1.169.615	2.031.183	1.978.225	2.694.675	4.373.071
MAS	929.528	2.586.770	4.796.998	5.538.338	7.297.763
MBS	1.409.814	1.536.871	1.646.525	1.919.570	3.166.642
MSVN	932.820	1.215.803	1.271.782	1.382.465	2.715.854
SSI	6.553.196	7.866.329	8.248.448	8.200.484	10.263.130
TVSI	574.018	1.164.371	1.269.197	1.355.033	3.246.086
VIX	919.253	1.101.682	1.239.282	1.739.019	3.742.774
VNDS	2.305.078	2.758.422	2.936.111	3.321.157	9.003.546

*Source: Report on the ratio of available capital of securities companies*

The companies all maintain good working capital, we see 12 securities companies with healthy and good operations, meeting the safety thresholds according to current regulations. Shows that, if there is an event, the company can convert this available capital into cash in 90 days to respond to that event and handle it best.

## 2. ASSET QUALITY (A)

### a. Ratio A1 (Rate of Total Assets After Risk Adjustment/Total Assets)

In securities companies, the proportion of assets of securities companies is mostly financial investments and receivables. The average A1 ratio of 12 securities companies over the years is over 80%. This ratio has changed and increased in the last two years, much higher than the prescribed level of 60% or more, proving the quality of the products. secured assets. Most of the assets of 12 securities companies are safe assets with relatively low risk.

**Table 8: The average value of the A1 ratio and Converted average score of A1 of 12 securities companies in the period 2017-2021**

Year	The average value of the A1 ratio (%)	Converted average score of A1
2017	88,84	85,83
2018	88,26	83,33
2019	88,88	84,17
2020	90,84	94,17
2021	92,50	92,50

In the period from 2017-2019, the trends of the average value of the ratio and the average of the A1 ratio point increase and decrease are the same However, the trend of the A1 ratio average value and the average score after conversion There is a difference between 2020 and 2021, while the average ratio has a slight increase of 1.31%, the average rating score of securities companies has a slight decrease of 1.67 points from 94.17 to 92. ,50 points.

**b. Ratio A2 [Provision ratio/(Short-term investments + Long-term investments + Receivables)]**

To ensure the ability to compensate for risks when they occur, securities companies must make provision for risky assets, because most of the high proportion of securities companies' total assets are investments and other assets. accounts receivable have a high level of risk. As a rule, if the A2 ratio is below 8%, the property is considered safe. From 2017-2019, the number of securities companies in the group of 12 research companies accounted for 40%-50% of the companies that did not ensure the financial safety ratio. From 2019 to 2021, there is a huge change in this index in the group of 12 companies when this number is reduced to only 1 company that does not guarantee the financial safety ratio, which is Agribank Securities Joint Stock Company. This is also a company with a very high A2 ratio from 2017-2021, all over 90%, which is due to the company's very large provisions, including provision for impairment of financial and financial assets. mortgaged property. The A2 ratio maintained over the years at less than 3% is very good as in some companies such as MAS, SSI, TVSI, VIX, it proves that companies have effective investment strategies with little provision or KPT of companies is decreasing, there are less bad debts, leading to a decrease in the provision of KPTs. Especially in 2021, HSC and MAS will have the right rate of 0%.

**Table 9: The average value of the A2 ratio and Converted average score of A1 of 12 securities companies in the period 2017-2021**

Year	The average value of the A2 ratio (%)	Converted average score of A2
2017	29,04	40
2018	22,73	46,67
2019	16,83	46,67
2020	10,39	60,83
2021	11,93	76,67

The average A2 value of securities companies tends to increase over the years and there is a big fluctuation after year 5, increasing by 36.67 points. This reflects the larger A2 ratio, which reflects the larger value of provisions that the securities company has to make, showing that the company's management ability is not effective, leading to the evaluation score, so it will be gradually converted to a standard scale. short. But in the two years 2020-2021, the score increased significantly because most of the securities companies have had changes in management of provisions gradually decreasing. However, the score is still not high, the average value of the A2 ratio still does not ensure the financial safety threshold as prescribed.

**c. Ratio A3 (Receivables/Total Assets Ratio)**

To ensure financial safety, the ratio of Receivables/Total Assets currently applied to Vietnamese securities companies is 50%, the quality of assets of securities companies will be ensured, less dependent on accounts. Receivables. Because the higher the ratio of accounts receivable / total assets (A3), the higher the level of financial safety of the securities company will be dependent on the receivables. The average value of the ratio of Receivables/Total Assets of 12 securities companies is small, all reaching the allowable safety level of less than 50%. In most securities companies, receivables account for a relatively small proportion of total assets. This proves that the possibility of capital misappropriation of 12 securities companies is very low and should be promoted in the future.

**Table 10: The average value of the A3 ratio and Converted average score of A3 of 12 securities companies in the period 2017-2021**

Year	The average value of the A3 ratio (%)	Converted average score of A3
2017	3,57	100
2018	2,06	100
2019	2,28	100
2020	1,79	100
2021	2	100

Realizing that, mainly accounting for a large proportion of the receivables of securities companies is from margin lending transactions. In the case when the stock market is in trouble, investors with a high margin rate will have to bear many great risks and this greatly affects the business results of securities companies. Asset quality of securities companies depends greatly on the quality of receivables. In the period of 2017-2021, the average value of the A3 ratio fluctuates slightly over the years. This trend is consistent with the relationship between the ratio value A3 and the conversion target score A3 because the smaller the A3 value, the smaller the ratio of receivables to total assets. Thus, with the group of asset quality indicators in general, 12 securities companies only achieved an average level, not yet ensuring a solid level of safety.

### 3. MANAGEMENT CAPABILITIES (M)

When it comes to the management factors of financial institutions, our team’s goal is to investigate some subjective indicators in financial and other reports (such as prospectuses, governance reports, and annual reports) and draw objective conclusions. Through securities firms, we have established different components to most clearly evaluate the management, management, and control capabilities of operating institutions in identifying, measuring, monitoring, and controlling risks in credit cooperative activities, ensuring safe and healthy operations, and ensuring compliance with applicable laws and regulations. Regarding business strategy and financial efficiency, especially for countries like Vietnam, which are in the development stage and always have policies that contradict world trends, According to information provided by the government, securities companies are more cautious in regulating their business development.

In the three years since Covid outbreak, securities companies have achieved breakthrough growth in personnel scale, number of accounts opened and growth. The company maintains, develops and expands the online trading portal. The new functions enable customers to place orders, manage their accounts and other trading support functions. The human resource management of the company is relatively good, focusing on the team of brokers to meet the needs of the stock market. In addition, risk handling activities have been constructed and implemented by securities companies in five steps: identifying risks, measuring and evaluating risks, determining risk limits, monitoring risks and handling risks.

At present, all the companies listed in our research have guaranteed a common form of risk management. However, some companies still face many risks, such as: ACBS is a family limited liability company, and most of the power is in the hands of one leader, which may lead to human resource management risks. At the same time, the risks that may lead to property rights disputes conflict, and the company’s poor management makes it impossible to expand its business model. Some enterprises in the development stage have not fully established the risk management system, and the shortage of risk management and IT talents can easily make enterprises fall into the risk of cyberspace attacks and internal network security threats.

#### 4. PROFITABILITY (E)

The goal throughout the operation of securities companies is high and stable profitability. In particular, the rate of return on sales (ROS) plays a very important role in evaluating the business performance of companies. best. The ratio of profit to revenue of 12 securities companies in the period of 2017-2021 is shown in the following chart:

**Table 11: Average ROS of 12 securities companies in the period 2017-2021**

Year	ROS (%)
2017	28,4
2018	28,42
2019	27,83
2020	29,91
2021	32,81

Source: Compiled from financial statements of securities companies

In the whole industry, the securities Corporate group with a licensed capital of more than 150 billion Vietnamese đồng has been at a high level and remained stable for some time. In the case of ROS security level > 0%, the stock group has reached and exceeded this level. In 2017, only two companies had ROS below 5%, namely KIS and MBS. This is because these two companies have implemented less effective cost management policies in the past year, coupled with the additional appropriations and significant discounts that must be charged. However, after two years of development, the company's donations have significantly improved, increasing by 15-20 times compared to 2017. Overall, in terms of ROA and ROE, the business activities of the 12 companies are profitable (after tax profit > 0), However, in terms of the profitability of the enterprise (the comprehensive results of organizational ability, management level, execution results, and final business performance for each period), the overall level is not high.

**Table 12: Average ROA and ROE of 12 securities companies in the period 2017-2021**

Year	ROA (%)	ROE (%)
2017	4,98	9,04
2018	6,62	10,97
2019	4,48	8,52
2020	5,18	10,95
2021	7,46	16,45

Source: Compiled from financial statements of securities companies

In Vietnam market conditions, ROE reaches 0% or more, but for international practice of over 15%, the securities company's finances are considered safe. This is an indicator of interest to owners and investors, who expect to invest capital in businesses. ROE of companies is still quite low, although this is a group of large companies in the market, being assessed as having good risk management ability, it is expected that the profitability will always reach a high rate. Besides, the net profitability of the asset depends on the asset's turnover and the operating profit ratio, and these two factors exist as opposites, so it can be confirmed that the low ROA is low. Fast asset turnover. The reason is that some securities companies do not invest in assets. However, the capital of a securities business organization more or less depends on the type of assets to be financed. The company wants to do a securities underwriting business that requires a large amount of capital. Self-trading activities also maintain a large amount of capital to carry out buying and selling, other activities do not require much capital. In summary, the profitability of 12 securities companies is relatively low, there are still some companies that have not yet ensured the financial safety threshold according to the profitability criteria.

**5. LIQUIDITY (L)**

Analysis of this indicator aims to assess the solvency of the enterprise to help identify the financial risks that the business has to face. For the current ratio L1. Through studying most of the group of 12 securities companies according to international practices, the L1 coefficient must reach 200% or more to be considered safe. On average, this coefficient of a group of 12 securities companies has achieved the safety level according to international practices but still ensures safety according to Vietnam’s regulations. However, some companies have a relatively low ratio and some years are even lower than the safe threshold such as: VNDS and SSI. The reason explained by SSI is that they have not yet ensured the autonomy to pay short-term debts when they are due. Most of the company’s current assets are in the form of short-term investments, while the financial assets are available for sale. This, in turn, can lead to the company’s disadvantage when it comes to debt repayments when there is not enough cash to pay, forcing a decision to sell short-term financial investments or financial assets. willing to sell at a lower price than expected. The instant ratio L2 reflects the company’s ability to meet short-term liabilities in cash and cash equivalents. That is, with the amount of cash and cash equivalents available, the enterprise can ensure the ability to pay short-term debts immediately. On average, the instant ratio of the group of 12 securities companies over the years is higher than 15%, in 2017 - 2019 achieved the highest level of financial safety. However, during the period from 2017 to 2022, this rate decreased quite a lot.

**Table 13: Securities companies with an instant ratio of less than 15% in the period 2017-2021**

STT	Year 2017		Year 2018		Year 2020		Year 2021	
	Company	L2	Company	L2	Company	L2	Company	L2
1	HSC	5,06%	HSC	5,34%	ACBS	10,97%	ACBS	10,82%
2	KIS	6,83%	MAS	3,87%	HSC	2,57%	AGRISECO	9,77%
3	MAS	10,03%	SSI	4,55%	KIS	0,96%	KIS	5,92%
4	MBS	11,60%	VIX	1,28%	MAS	9,61%	MAS	11,71%
5	MSVN	11,70%	VNDS	12,98%	MBS	2,03%	MBS	1,74%
6	SSI	0,37%			SSI	1,41%	SSI	3,05%
7	VNDS	6,56%			VNDS	8,82%	VNDS	10,25%

The reason is that the amount of cash as well as cash equivalents in some highly liquid companies account for a very low proportion of current assets. This can lead to risks in payment activities of companies. Therefore, companies need to maintain this ratio at an appropriate level to both ensure liquidity and improve capital efficiency.

**Discussion**

These analyses show that CAMELS model is effective in comprehensively evaluating securities companies or financial institutions. However, the data of these 12 securities companies can’t fully represent 73 securities companies (according to statistics, by the end of 2022), because the companies facing financial security problems in Vietnam are all securities companies with a market value of less than 150 billion VND, such as Vietnam Securities United Securities Company (TVB) and Asia Pacific Securities United Securities Company (APS),...which limits the inclusiveness of our research. These companies are mainly caught in legal problems, and their organizational and management capabilities are weak, resulting in the loss of trillions of Vietnamese dong for the economy and investors. Basic companies have strong financial potential and relatively sustainable development, but there are still many shortcomings and limitations in enterprise risk management. Practice shows that the biggest risk of securities companies in the past and in the future is a terrible risk, that is, the risk of margin trading business. The financial safety supervision

index system has not covered all kinds of risks, and the supervision information system is not perfect and has not been updated regularly. Financial companies have not yet created risk management information for all employees, so that employees can consciously control their own activity risks. As a result, business risk management ability and market risk are limited.

## **6. CONCLUSION AND RECOMMENDATION**

### **6.1. Conclusion**

In general, Financial Safety plays an extremely important role for securities companies in the process of existence and development of companies. Through the process of studying the financial safety of 12 securities companies, we see their strengths and weaknesses. The indicators over the years have been improved and adapted to the market situation, we highly appreciate this issue in companies. However, there are still some limitations. In order to operate more sustainably and develop more in the coming time, we propose practical and comprehensive solutions to gradually improve Vietnam's stock market. general and securities companies in particular. The more a securities company ensures a high level of financial safety, the lower the level of risk in its operations. effective operation and competitiveness of securities companies in the market are increasingly improved. Therefore, it is extremely important to ensure financial safety at securities companies, especially in the group of large companies that have a certain position in the market and investors' confidence. and urgent.

### **6.1. Recommendation**

Securities companies are an important area of activity in a country's financial system. Therefore, to ensure financial safety for securities companies in Vietnam, it is necessary to implement a number of important solutions as follows:

In order to increase the profitability of assets of securities companies, it is necessary to use measures affecting 3 strategies (capital investment, capital management, operation management) to properly allocate capital and speed up rotation. moving capital, increasing profitability by reducing the cost-to-income ratio of each type of activity. In addition, to increase the profitability of equity, securities companies need to use major measures such as: Determining a policy to raise capital for reasonable financing; Determine a reasonable investment policy; To speed up the turnover of working capital on the basis of allocating and managing each type of capital, especially capital in cash and receivables and promoting business and services; Increase the ratio of net operating profit by monitoring the ratio of operating expenses to total net turnover, ensuring the business has managed each type of operating expenses in the best way.

Improving governance and supervision capacity of securities companies: Strengthening training and fostering management and supervision skills for officers and employees of securities companies. Ensure transparency and honesty in company operations: Securities companies should ensure transparency and honesty in their operations. This helps create trust for customers and investors, and makes it easier to monitor and administer the company's operations.

Strengthen information and technology security systems. The company needs to develop detailed and up-to-date privacy policies to ensure the information security of its systems. Use of security software: securities companies need to use security software to protect their systems from external network attacks.

Reduce risks from employees: Securities companies need to train employees so that they have a sense of information security and implement information security measures in their daily work. Upgrading the server system, strengthening the protection of customer data by using information encryption technologies, limiting access to customer data.

## DIGITAL TRANSFORMATION AND BUSINESS MODEL INNOVATION IN INTERNATIONAL BUSINESS ENTERPRISES IN VIETNAM: A RESOURCE-BASED APPROACH

**Author: Tran Thi Cam Nhung<sup>1</sup>, Tran Thi Diem Quynh<sup>2</sup>, Ngo Minh Thao<sup>2</sup>,  
Dang Thi Quynh Nga<sup>2</sup>, Doan Tran Ngoc Quynh<sup>2</sup>  
Mentor: Luu Tien Dung<sup>2</sup>**

*ABSTRACT : The overall objective of this study is to examine the correlation between digital transformation and business model innovation through enterprises' resources, including social networks, human capital, and dynamic capabilities. Our research results show the link between digital transformation and business model innovation, clarifying the role of human capital and social networks in helping businesses access and utilize specific resources for development, as well as the impact of dynamic capabilities on helping businesses maintain and develop sustainably in the current volatile economic situation. Some recommendations and suggestions have been made to help international business enterprises in Vietnam seize the opportunity to digitally transform, followed by innovating their business activities. The study also points out some remaining limitations and suggests directions for further research to improve.*

*Keywords: social networks, human capital, dynamic capabilities, business model innovation, digital transformation.*

### 1. INTRODUCTION

In recent years, the import and export activities of international business enterprises in Vietnam have made certain progress but still face many difficulties and challenges. The level of competition in production and services is not high because the level of technology is still low; most of the enterprises are still small and do not have much experience in management; resources are limited; and there is no specific direction in the process of participating in the global supply chain. Additionally, in the face of unexpected world fluctuations such as the economic downturn and cost-of-living crisis in China and the conflict between Russia and Ukraine, Pierre, O.G. - The Chief Economist of the International Monetary Fund (IMF) has forecast that the global economic situation in 2023 will be very difficult. Most of the major global economies will experience negative growth for two consecutive quarters, three of which include the US, the European Union, and China.

As Vietnamese international business enterprises largely participate in the global supply chain through exporting products and services, an important trend for businesses is the need to transform digitally to be able to participate more deeply in the global supply chain and adapt to changes in the world situation. However, their conversion speed is still slow, and not all businesses can successfully implement digital transformation. Under the negative impact of the economy and the challenges that Vietnamese businesses are facing, identifying the supporting factors for the success of digital transformation, which contributes to promoting business model innovation, is necessary and important.

It is obvious that many useful discoveries have given a better knowledge of digital transformation in recent years. However, in terms of resource application, there is almost no research paper assessing

<sup>1</sup> University of Economics and Law, Vietnam National University Ho Chi Minh City, Email: nhungttc204022c@st.uel.edu.vn

<sup>2</sup> University of Economics and Law, Vietnam National University Ho Chi Minh City.

the impact of enterprises' social networks on digital transformation implementation. Moreover, although there has been some micro-foundation on building dynamic capabilities for strategic changes, studying and examining how organizations build dynamic capabilities for digital transformation is still meager. In addition, some theories, such as human resource theory (Nwankpa et al., 2016), dynamic capabilities theory, and organizational capability theory (Li et al., 2018) have been applied to previous research to explain the internal forces of enterprises to support the digital transformation process. However, the theories of social networks, human capital, and dynamic capabilities have not been mentioned to explain the formation of external resources to promote digital transformation for international business enterprises, especially in a transition economy like Vietnam. Therefore, to learn more about the above factors, this research studies the role of digital transformation and business model innovation through considering the impacts based on resources: social networks, human capital, and dynamic capabilities, to help international businesses in Vietnam develop sustainably in the fluctuations of the economy.

Consequently, the current paper seeks to make the following contributions to the existing literature.

*First*, the research builds models to assess the relationship among digital transformation, business model innovation and the three factors consisting of social networks, human capital, and dynamic capabilities of international business enterprises in Vietnam.

*Second*, the research proves that social networks can help businesses access the resources needed for digitalization, while human capital and dynamic capabilities can actively support the implementation of digital transformation.

*Third*, the research proves that digital transformation will contribute to the creation of business model innovation.

*Fourth*, the research presents some management implications to help international business enterprises in Vietnam seize opportunities to digitally transform and innovate their business models through the mentioned resources.

## **2. THEORETICAL FRAMEWORK AND HYPOTHESIS DEVELOPMENT**

### **2.1. Theoretical framework**

#### **2.1.1. Business model innovation**

##### *a) Business model*

The advent of the Internet has dramatically increased research on business models, especially in the past decade (Zott et al., 2011). The business model is integrated with specific business aspects (Winter and Szulanski, 2001; Baden-Fuller and Haefliger, 2013; Baden-Fuller and Mangematin, 2013). There are three main aspects that explain a company's business model: value creation, value proposition, and value capture (Morris et al., 2005; Johnson et al., 2008; Baden-Fuller and Haefliger, 2013; Zott and Amit, 2013; Massa and Tucci, 2014; Spieth et al., 2014).

##### *b) Business model innovation*

Business model innovation is the enhancement of a business model from very basic and low-value models to more advanced and valuable models. While some researchers argue that business model innovation can occur even when only one of the elements or components of the business model is changed (Lindgardt et al., 2009; Demil and Lecocq, 2010; and Abdelkafi et al., 2013), some other researchers define business model innovation as an entirely different form of innovation than product or process innovation (Baden-Fuller and Mangematin, 2013; Björkdahl and Holmén, 2013; Massa and Tucci, 2014). In fact, business

model innovation often occurs as a result of external factors, such as globalization (Lee et al., 2012), changes in the competitive environment (De Reuver et al., 2013), opportunities from new technologies, or opportunities related to behavior (Wirtz et al., 2010). In such environments, previously successful and well-established business models may no longer be profitable (Chesbrough, 2007, 2010). Thus, the ability to innovate business models regularly and successfully can increase an organization's resilience to changes in the environment and form a sustainable competitive advantage (Mitchell and Coles, 2003).

### **2.2.2. Digital transformation**

Digital transformation is the use of new digital technologies to improve business such as by enhancing the customer experience, streamlining operations, or creating new business models (Fitzgerald et al., 2013). As such, digital transformation is not merely the digitization of resources but also the value and revenue generated from digital assets (McDonald and Rowsell-Jones, 2012). Digital technologies not only impact product transformation, business processes, or sales but also entire business models (Hess et al., 2016). Through digital transformation, organizations can integrate digital technology into many aspects of their operations to attract customers (Weill & Aral, 2007), increase market share, and reduce operating costs (Weill & Aral, 2007; Căpușeanu et al., 2021). A study by the Massachusetts Institute of Technology also found that digitally transformed businesses are 26% more profitable than conventional businesses (Schwertner, 2017).

### **2.2.3. Resource-based View**

The Resource-based View (RBV) is one of the most influential theories for explaining a firm's sustainable competitive advantage. The basic idea of this view is that firms can achieve a sustainable competitive advantage when they possess and control valuable and scarce resources that are not easily imitated or substituted (Barney, 1991, 1994, 2002). In RBV, resources are broadly defined as anything that can be considered the strength or weakness of a given enterprise (Wernerfelt, 1984), and all assets, capabilities, processes, attributes, information, knowledge, etc. controlled by the business allow the business to formulate and implement strategies, which improve performance and efficiency (Barney, 1991, 2002). As these definitions indicate, RBV recognizes different types of resources that are important to a business. In the research papers, both Barney (1991) and Grant (1991) argue that human capital and relationships with stakeholders, or in other words, social networks, are the intangible resources of enterprises. Due to their unique and difficult-to-imitate nature, it is suggested that intangible resources are the most important asset for a company (Drucker, 1992; Quinn, 1992). Therefore, the social network and human capital of enterprises can create sustainable competitive advantages if enterprises can control and effectively use these two resources in their business operations.

### **2.2.4. Theory of social networks**

A social network can be considered a relational model that links a defined group of people or social subjects (Seibert, Kraimer, & Liden, 2001) to achieve the goals of individuals and organizations (Granovetter, 1985; Powell et al., 2005), which enables collaboration and facilitates the sharing of ideas, information and knowledge and the mobilization of other resources (Fliaster & Spiess, 2008; Gulati, Nohria, & Zaheer, 2000; Hoang & Antoncic, 2003). Important structural features of social networks include the size and strength of relationships (Anderson, 2008; Cross & Cummings, 2004; Gabbay & Leenders, 2001). Thus, the larger the social network, the more effective the access to new information and knowledge will be (Burt, 1992). Managers with social networks outside the business often have a more comprehensive understanding of the fit between different strategic options in the business environment and tend to have a greater degree of

strategic flexibility in their organization. (Fernández-Pérez, Verdú-Jóver, & Benitez-Amado, 2013). When in a network, they not only receive benefits in the linking process, such as timely receiving information, successfully mobilizing resources, and accessing available resources, but also achieve benefits from the advantage of scale through collective business activities like building trust with partners and customers, promoting cooperation, and integrating into the overall value chain (Khayesi & George, 2011; Tokarczyk et al., 2007, Jasmine Tata & Sameer Prasad, 2015).

### **2.2.5. Theory of human capital**

According to McGregor et al. (2004), the definition of human capital covers a broader spectrum of the human resources of the workforce and requires more specific competencies in the form of knowledge, skills, and attributes of managers and the people they manage. In another aspect, Choudhury and Mishra (2010) defined human capital as knowledge, skills, expertise and the ability of employees to help the company operate and succeed. Along with that, Lien and her colleagues (2022) affirmed that human capital is an important factor contributing to the development of society and the growth of the economy quickly and sustainably. Human capital is also a contributing factor to the success of businesses, playing an important role in helping international businesses create competitive value. Mahlow and Hediger (2019) also stated that the concept of “education” must be developed appropriately to be able to face the digital transformation process. Therefore, enterprises can invest in human capital through education and training to improve the quality of their human resources.

### **2.2.6. Theory of dynamic capabilities**

According to Barreto (2010), dynamic capabilities are the potential of enterprises to solve problems systematically, formed by the tendency to identify opportunities and risks, make timely decisions according to market orientation and change their resource base. With this definition, dynamic capabilities is a multidimensional definition based on environmental analysis, making the right choice at the right time and fundamentally changing the resources of the enterprise. Capturing dynamic capabilities allows businesses to continuously integrate, restructure, renew, regenerate resources and, most importantly, upgrade and reinvent core competencies to respond to changing business environments and maintain competitive advantages. In this study, dynamic capabilities are analyzed in three dimensions from a process perspective, namely: strategic cognitive competencies (Neill, McKee, & Rose, 2007; Pandza & Thorpe, 2009; Weick, Sutcliffe & Obstfeld, 2005); timely decision-making competencies (Benjaafar, Morin, & Talavage, 1995; Shafman & Dean, 1997) and change-implementing competencies (Harrelld, O’Reilly, & Tushman, 2007; Noble, 1999).

## **2.3. Hypothesis development**

### **2.3.1. Effects of digital transformation on business model innovation**

In recent years, new digital technologies such as big data, artificial intelligence, and machine 4.0 have revolutionized the way companies do business (Rothberg & Erickson, 2017). The exploitation and integration of digital technology often affects the majority of companies beyond their limits by impacting products, business processes, sales channels, and supply chains. This influence can lead to many potential benefits, such as increased revenue or productivity, innovation in value creation and new forms of customer interaction. From there, the entire business model can be reshaped or replaced (Downes & Nunes, 2013). Similar to the above opinion, Schwertner (2017) also believes that new technologies can accelerate business model innovation and extend standard value chains in the provision of new products and services for consumers.

Today, it is no surprise to see more and more companies undertaking digital transformation to revolutionize their business models so that they can take advantage of the benefits of digitalization and new

forms of collaboration that it brings to companies, such as customers, employees, and suppliers (Kiel et al., 2017; Bresciani et al., 2018; Grandinetti et al., 2020 ). More specifically, according to Nowicka (2019), applying digital transformation helps to increase the level of process automation, thereby eliminating unnecessary operations. Besides, digital innovation will help reduce risks, redesign processes, reduce errors, increase sales (Menon & Kohli, 2013), as well as improve customer experience and market share.

**H1: Digital transformation has a positive impact on business model innovation.**

### ***2.3.2. Effects of social networks on digital transformation***

Based on the research of Chaolin Lyu (2022), companies in most industries that are developing digital technology or trying to digitally transform have to face many pressures including limited resources, difficult communication and a lack of innovation. Digital transformation requires a long cycle time, high risk and large investments, which increase the pressure on their resources. Under a lot of pressure, internal resources can no longer meet the innovation needs of enterprises. Therefore, making good use of the enterprise's social networks will be an advantage when accessing external resources. The relationship network can be seen as a foundation to help managers access resources from subjects in the horizontal network such as customers, suppliers, competitors... and subjects in the vertical network such as government levels, companies in the same group... (Landry et al., 2000; Jansen et al., 2011), including capital, information, advice, emotional support and endorsements (Coleman, 1988). These resources will create a strong driving force, promoting the digital transformation process for businesses.

**H2: Social networks have a positive impact on digital transformation.**

### ***2.3.3. Effects of human capital on digital transformation***

Research by Bontis, Dragonetti, Jacobsen & Roos (1999) has defined human capital to represent the human factor in the organization, which is a combination of intelligence, skills and experience. In the process of digital transformation, technology is supposed to be a means of support and people are the decisive factor. Because it is necessary that employees have enough knowledge, ability and qualifications to apply new technology in the business activities of enterprises. In order for people to meet the requirements of the digital transformation process, it is necessary to have skills in technology management (Kaivo-Oja, J., Roth, S., & Westerlund, L., 2017), leadership skills (Henderikx, M., & Stoffers, J., 2022), communication skills (Andriole, SJ, 2018) ... and new trends in skill development (Sousa, MJ, & Rocha, A., 2019). Human capital is also considered a treasure trove of skills that workers possess (Goldin, 2016).

**H3: Human capital has a positive impact on digital transformation.**

### ***2.3.4. Effects of dynamic capabilities on digital transformation***

In an ever-evolving technology age, when digital disruptions make current skills and resources held in a company obsolete, they need to focus on improving their technology skills to adapt to this change. Among them, dynamic capabilities can be an important factor during a company's digital transformation. Teece, Pisano, and Shuen (1997) have identified a dynamic capability that helps a company respond to rapidly changing circumstances in a timely manner. Therefore, using the usefulness of dynamic capabilities is necessary to maintain them in dynamic and constantly changing environments, such as those impacted by digital technology.

Conventional competencies allow a company to perform operational tasks such as accounting, human resource management, logistics and marketing, but they can be easily replicated in a digital environment and no longer support sustainable competitive advantage. In contrast, dynamic capabilities manage changes in a company's normal capabilities (Teece, 2007), are harder to replicate to help the company maintain a

competitive advantage (Teece, 2014) and support the development of the company towards stepping out of the “comfort zone”, (Helfat & Winter, 2011).

In literary strategic management, adaptation to changes in technology is often studied through Eisenhardt and Martin, 2000; Teece, 2007; Warner and Wager, 2019, dynamic capabilities provide a consistent approach to studying digital transformation and examining the powerful impact of digital technology on business (Warner and Wager, 2019). Therefore, to successfully participate in digital transformation, companies need a set of capabilities that facilitate changing their business models and organizations (Teece, 2007).

**H4: Dynamic capabilities have a positive impact on digital transformation.**

**Figure 1. Proposed research model**

**3. RESEARCH METHOD**

**3.1. Sample and data collection**

We use qualitative and quantitative methods to conduct the research by sending online forms through Google Forms by email and social media to employees of Vietnamese international business enterprises. After collecting a sufficient number of samples, the research team began to conduct preliminary analytical research to produce the final research results. With 193 sample sizes collected from September 2022 to April 2023 and no rejected votes, 100% of the survey questionnaires will be used in data analysis. Characteristics of the research sample include gender, age, business sector, and type of activity.

**Table 1. Sample demographic information**

Category		Frequence	Ratio (%)
<b>Gender</b>	Male	88	45.6%
	Female	105	54.4%
<b>Age</b>	20 – 30	117	60.6%
	31 – 40	63	32.6%
	41 and over	13	6.8%
<b>Business Sector</b>	Production	64	33.2%
	Commercial	89	46.1%
	Service	40	20.7%
<b>Business Type</b>	Private	65	33.7%
	Limited Liability	44	22.8%
	Shareholding	64	33.2%
	Others	20	10.3%

Source: Survey data analysis results until April 2023

### 3.2. Measurement scale

The questionnaire uses a 5-point Likert scale to measure variables. On this scale, 1 symbolizes strongly disagree, and 5 expresses strongly agree. The items are based on previous research, and we adjusted some items to be suitable for the Vietnamese business environment. The scale of business model innovation is measured by 9 observations adopted and adjusted following the study of Spieth & Schneider (2016). The scale of digital transformation was measured by 3 observations based on Weill and Aral's (2007) research. The social network scale was developed based on the synthesis of previous research and built by Nguyen Quang Thu et al (2020). However, the scale is not suitable because our research object is international business enterprises that have had a certain time of operation in the market, not just startups. For that reason, we removed variables related to startup factors from the scale and kept the remaining variables. The scale of human capital is based on the research of Rodchenko et al., (2021), which includes 6 observations, and the scale of dynamic capabilities is based on the research of Li & Liu (2014), which includes 15 observations.

**Table 2. Measurement Scale**

Construct	Measurement	References
Business Model Innovation (BMI)	BMI1: Target customers have changed	Spieth & Schneider (2016)
	BMI2: The products and services have changed	
	BMI3: The firm's position in the market has changed	
	BMI4: The firm's core competencies and resources have changed	
	BMI5: Internal value creation activities have changed	
	BMI6: Role and involvement of partners into the value creation process has changed	
	BMI7: Distribution has changed	
	BMI8: Revenue mechanisms have changed	
	BMI9: Cost mechanisms have changed.	
Digital Transformation (DT)	DT1: We are impulsing new business processes built on the foundation of technologies such as big data, analytics, cloud, mobile, and social media platforms	Weill & Aral (2007)
	DT2: We are integrating digital technologies such as social media, big data, cloud computing and mobile computing analysis to impulse changes	
	DT3: Our business is shifting to using digital technologies such as: big-data, cloud-computing, mobile-computing analysis, and social media platforms	
Social Networks (ML)	ML1: We have a good relationship with leaders of government at all levels	Nguyen Quang Thu et al. (2020)
	ML2: We have a good relationship with the staff of the Agency for Industrial Promotion	
	ML3: We have a good relationship with the staff of supporting organizations such as the General Department of Taxation, State Bank, Ministry of Industry and Trade, Ministry of Science and Technology, Social Insurance, Labor Confederation . . . , etc	
	ML4: We have a good relationship with our family, friends and colleagues	
	ML5: We have good relationships with universities and research institutes

### 3.3. Data analysis methodology

We use the SmartPLS version 4.0 program to evaluate the data. After conducting the above-described descriptive statistics on the samples that were collected, we moved on to assess measurement models, structural models, and test hypotheses with the following tests: Cronbach’s Alpha coefficient, composite reliability, convergent validity, discriminant validity Fornell & Larcker and Partial least squares structural equation modeling (PLS-SEM).

## 4. RESULTS AND DISCUSSION

### 4.1. Results

**Table 3. Reliability and convergent validity**

Construct	Item	Indicator Loadings	Cronbach’s Alpha	Composite Reliability (CR)	AVE
Business Model Innovation (BMI)	BMI1	0.869	0.953	0.960	0.727
	BMI2	0.893			
	BMI3	0.847			
	BMI4	0.841			
	BMI5	0.862			
	BMI6	0.850			

	BMI7	0.830			
	BMI8	0.814			
	BMI9	0.866			
Digital Transformation (DT)	DT1	0.877	0.856	0.912	0.776
	DT2	0.908			
	DT3	0.858			
Social Networks (ML)	ML1	0.790	0.939	0.949	0.674
	ML2	0.861			
	ML3	0.813			
	ML4	0.824			
	ML5	0.908			
	ML6	0.849			
	ML7	0.704			
	ML8	0.792			
	ML9	0.829			
Human Capital (HC)	HC1	0.848	0.926	0.941	0.728
	HC2	0.877			
	HC3	0.830			
	HC4	0.840			
	HC5	0.880			
	HC6	0.842			
Dynamic Capabilities (DC)	DC1	0.781	0.946	0.952	0.571
	DC2	0.834			
	DC3	0.764			
	DC4	0.765			
	DC5	0.717			
	DC6	0.767			
	DC7	0.791			
	DC8	0.701			
	DC9	0.775			
	DC10	0.733			
	DC11	0.708			
	DC12	0.731			
	DC13	0.753			
	DC14	0.792			
	DC15	0.708			

Source: Survey data analysis results until April 2023

Table 3 shows that the Cronbach’s Alpha coefficient of all variables is greater than 0.7, we accepted all constructs. AVE and CR are both greater than 0.5, which can prove the reliability and convergent validity of the scale. The results of CR and AVE show that all scales of the research meet the requirements of reliability and convergent validity. The results of data processing show that the loading coefficient of most of the observation variables is higher than 0.7 and none of the measured variables has a correlation smaller than 0.3. In addition, the scales in the research model all have convergent validity greater than 0.5, so the scales used in the research model can reach convergence and reliability standards.

**Table 4. Discriminant validity Fornell & Larcker**

	BMI	DC	DT	HC	ML
BMI	0.853				
DC	0.728	0.756			
DT	0.798	0.753	0.881		
HC	0.153	0.119	0.244	0.853	
ML	0.699	0.617	0.636	0.179	0.821

Source: Survey data analysis results until April 2023

Table 4 shows that the correlation coefficient of each variable with the remaining variables in the model is less than all the Square Roots of the AVE. Therefore, it can be concluded that all the scales of the research are suitable and have discriminant validity, according to Fornell and Larcker (1981).

**Table 5. Hypothesis testing results**

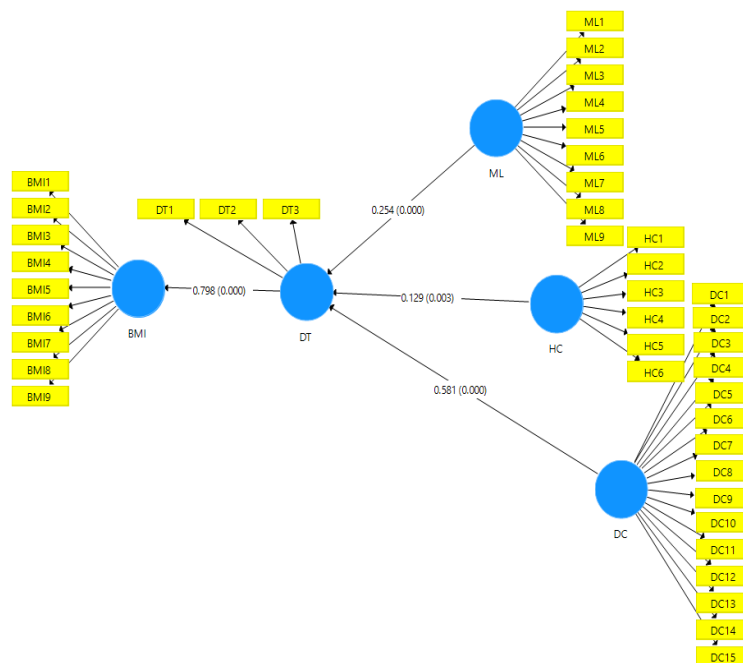

Hypothesis	Relationship	$\beta$	Standard Deviation	t value	p-value	VIF
H1	DT → BMI	0.798	0.042	18.980	0.000	1.000
H2	ML → DT	0.254	0.064	3.987	0.000	1.645
H3	HC → DT	0.129	0.043	2.983	0.003	1.033
H4	DC → DT	0.581	0.058	10.018	0.000	1.615
$R^2$		$R^2_{BMI} = 0.625; R^2_{DT} = 0.636$				
$f^2$		$f^2_{DT \rightarrow BMI} = 1.759; f^2_{DC \rightarrow DT} = 0.566$ $f^2_{ML \rightarrow DT} = 0.106; f^2_{HC \rightarrow DT} = 0.044$				
Stone- Geisser $Q^2$		$Q^2_{BMI} = 0.458; Q^2_{DT} = 0.480$				

Source: Survey data analysis results until April 2023

Table 5 shows that the VIF values of the variables are all under 3. Therefore, it can be concluded that the model does not have multicollinearity. The  $R^2_{BMI}$  value is 0.625 and the  $R^2_{DT}$  value is 0.636; both are greater than 0.25 and less than 0.75, which indicates that the BMI variable is related to the DT variable. Based on the value of  $f^2$ , it can be seen that the digital transformation (DT) factor has a great impact on business model innovation (BMI) with an  $f^2$  value of 1.759. The order of the degree of impact on the variable DT shows that the variable dynamic capabilities (DC) has the greatest influence and the strongest impact on the variable DT; otherwise, the social network (ML) variable and the human capital (HC) variable have weak impacts on the variable DT. The values of  $Q^2_{BMI}$  and  $Q^2_{DT}$  represent the predictive accuracy of business model innovation (BMI) and digital transformation (DT) at an average level.

After performing Bootstrapping with  $N = 5,000$  observations, the results show that the relationships between the factors of the research model are statistically significant due to  $p\text{-value} < 0.05$ . There are three variables respectively affecting the DT variable: the ML variable, the HC variable and the DC variable.

**Figure 2. The structural model after assessing the PLS-SEM**

*Source: Survey data analysis results until April 2023*

From the above results, all hypotheses proposed for the research model are accepted. That means that the digital transformation variable has a direct and positive impact on business model innovation. The three remaining variables, including social network, human capital and dynamic capabilities also have a direct and positive impact on the digital transformation variable.

#### 4.2. Discussion

In particular, digital transformation has a strong impact on business model innovation, contributing to increasing business performance through integration and transformation based on technology platforms such as big data, analytics, cloud, mobile and social media platforms,... Thanks to digital transformation, businesses can access convenient communication channels with customers, optimize their operating processes with technology, and build technology-based platforms to create new services such as sharing services, interactive experiences, etc.

The dynamic capabilities of businesses impact the success of digital transformation because digital transformation is not simply the application of new technologies, it is also related to how businesses use and leverage that technology to create value and innovate the business model. To be able to perform the digital transformation, enterprises must identify changes in the environment both inside and outside the business, predict risks and threats to be able to make timely strategies and decisions, have close coordination between departments, effectively manage information and quickly fix it in the customer care process.

For the social network of enterprises, having extensive relationships with authorities at all levels, such as leaders, local officials, state agencies, universities, friends, colleagues, or even suppliers and competitors, will give businesses a higher chance in the digital transformation process. Because social networks can create an environment of connection and interaction between individuals, organizations and resources in

an online community. Businesses can do business for their social network or share information and receive support from the community, etc. to help businesses improve and grow.

Although the human capital of the enterprise has a weaker influence than other factors, businesses also need to respect this factor. The company's employees must recognize the importance of digital transformation and have the skills to adapt to it, such as digital management skills, using technology skills, creativity and thinking.

From the contributions of the above inputs, the enterprise's ability to succeed in digital transformation will be improved, thereby changing its business model. Such changes may be present in the corporate governance process. To improve operational efficiency, businesses can change the way they operate, revenue, costs, partner roles, and core competencies, thereby changing the products and services provided to customers and target customers, leading to a change in the positioning of the business. The changes and adjustments of businesses, when supported by digital transformation, help businesses increase their competitiveness in the market.

Similar to Li & F. (2018); Bouwman, H., Nikou, S., & de Reuver, M. (2019); Pham Quang Hai, Phung Quang Phat, Do Hong Quan (2023); Nguyen Thi Nhu Quynh, Le Dinh Luan (2023); and many other related studies, this study also contributes to reaffirming that digital transformation is an inevitable trend in promoting business model innovation, contributing to increasing the competitiveness and operational efficiency of enterprises. In addition, the social network variable in the study has been proven to contribute to the success of digital transformation, so this will be useful data to contribute to the research on factors related to the digital transformation process, which very few domestic and foreign studies have done. Compared with the studies of Li, L., Su, F., Zhang, W., & Mao, J. Y. (2018), Tran, N. G., Nguyen, T. P. A., Nguyen, Q. T., & Ngo, Q. H. (2021), Santarelli, E., & Tran, H. T. (2013), Karimi, J., and Walter, Z. (2015), this study clarifies the impact of the firm's dynamic capabilities and human capital on efficiency of business operations, that is through the process of digital transformation in the business.

#### **4.3. Recommendations and policy implications**

After completing the research and drawing conclusions, the research team can come up with petitions to help businesses understand and make the right decisions in the future. Enterprises can invest in new technologies such as AI, IoT, blockchain, management software, sales websites... to increase productivity and work results. They can implement digital human resource training programs, improving programming skills, data mining and processing skills, information security, learning foreign languages... Moreover, they can enhance the quality of social networks on online platforms such as LinkedIn, Facebook... and actively take advantage of digital technology to increase competition, opportunities to access information, and support resources when needed. Lastly, enterprises can invest in dynamic capabilities to create business solutions, improve operational efficiency and secure solutions for business to adapt to markets and globalization around the world.

#### **4.4. Limitations and future developments**

In addition to its theoretical and practical contributions, the study still has certain limitations. The research sample space is limited and is not yet representative of the population, so the study can be improved by expanding the sample size to a larger range. Besides that, the data set of international business enterprises has not yet shown the specificity of each industry due to evaluation in many fields. Therefore, businesses need to do research in each specific field. In addition, this study only analyzes the impact of three factors, namely social networks, human capital, and dynamic capabilities, on digital transformation and business

model innovation. Therefore, the follow-up research can actively explore more resource-impacting factors. This not only improves the performance of international businesses but also enhances Vietnam's economic position in the global market.

## 5. CONCLUSION

The topic “Digital transformation and business model innovation in international business enterprises in Vietnam: A resource-based approach” is conducted with the main objective of researching digital transformation and business model innovation with an impact based on three resources: social networks, human capital, and dynamic capabilities. Our research team has demonstrated the importance of these resource factors. This serves to highlight how crucial it is to make the company's advantages known in order to coordinate the best resources, achieve sales targets, strengthen positions and take advantage of chances to engage more actively in the global supply chain. In the context of the world's economic and political fluctuations, businesses need to clearly define their goals and vision to ensure a balance between technology and business activities. Moreover, this improvement in the factors above will help businesses develop outstandingly and sustainably.

After more than six months of carrying out this scientific project, the research team has achieved important theoretical and practical values. The topic has overcome, tested, and shown the relationship among factors more clearly and intuitively than in previous studies. The research achieves the following objectives: analyzing the sample space and results of the evaluation scale; testing the model; and drawing conclusions and meanings for international business enterprises. Moreover, the study also presents solutions, analyzes the remaining limitations in order to achieve the goal of success in the process of argument change and business model innovation in particular, and contributes to the development of Vietnam's economy in the future.

## ANALYZING THE COMPETITIVENESS OF VIETNAM'S TUNA EXPORT INDUSTRY: FROM FOUR DETAILED INDUSTRY CODES TO THE WHOLE INDUSTRY

**Author: Nguyen Thi My Nga<sup>1</sup>, Le Vy Thuy Uyen<sup>1</sup>, Trinh Minh Nguyet<sup>1</sup>,  
Nguyen Van Anh<sup>1</sup>, Nguyen Dang Ngoc Minh<sup>1</sup>  
Mentor: Ph.D. Luu Tien Dung<sup>1</sup>**

**ABSTRACT:** *This study was conducted to determine the export competitiveness of Vietnam in tuna products compared to other competitors in the world's largest tuna-importing regions in the period 2007-2019. The analysis of 4 large tuna industry codes (0302, 0303, 0304 and 1604) to give an overall picture of the export tuna industry. From there, a number of solutions are proposed to promote the export competitiveness of this industry as a whole. To conduct the study, secondary data provided by ITC were used. In addition, to analyze competitive advantage, the study used the RCA (Revealed Comparative Advantage) and the CMS (Constant Market Share). After analyzing, it can be seen that in most markets, Vietnam holds a certain competitive advantage. Specifically, tuna code 0304 was the item more and more prior. However, there is still no stability in maintaining the RCA index. Meanwhile, although there has been an improvement in export quality and volume, the lack of allocation to high-demand markets explains why the CMS index in many periods remains negative. In conclusion, although there is a lot of potential in this field, Vietnam may have not really invested in exporting tuna.*

**Keywords:** *tuna, export competitiveness, RCA, CMS.*

### 1. INTRODUCTION

The tuna export industry is one of the key sectors in Vietnam's trade-oriented economy, accounting for 34% of around \$1 billion in total seafood exports in 2021 (VASEP). The tuna worldwide industry in 2022 reached a total export value of up to 13.9 billion USD (Trademap). Vietnam remained a positive tuna export value over the past 15 years. In 2007 the total value of Vietnam's exports to the world was only 1.7% and until 2022, Vietnam accounted for nearly 5% of the total value of export tuna to the world (Trademap). This is achieved through favorable geographical location, an abundant labor force with rich experience. Indeed, exports to major markets in the world such as the EU, Japan, have also been boosted thanks to the free trade agreements that Vietnam has signed in recent times, such as CPTPP, EVFTA. The tariff preferences as agreed in the Agreements have created a driving force to promote Vietnam's tuna exports to these markets. However, according to the evaluation of the Vietnam Association of Seafood Exporters (VASEP), Vietnam's seafood export industry has generally achieved results that do not correspond to the available potential.

To better compare the issue that Vietnam has not yet exploited its advantages and geographical potential, this study compares the data between Southeast Asia, fishing in the same sea. Based on an overview comparative study of competitive advantages and export products among 6 countries in Southeast Asia (Indonesia, Malaysia, Philippines, Singapore, Thailand and Vietnam) (Jayadi & Aziz, 2017), Indonesia, Vietnam and Thailand have similar advantages, but Vietnam's tuna export value is only about 35% of Thailand's and is still lower than Indonesia's (Trademap, 2021). In terms of the national economy such as tuna exports, the competitiveness of a country will play a huge role. "The competitiveness of a country is of great importance to the development of the national economy" (Ahasanul Haque, 2013). Therefore,

<sup>1</sup> University of Economics and Law, Vietnam National University of Ho Chi Minh City.

a proper assessment of competitiveness will be essential for Vietnam's tuna export industry, as previous scholars have assessed the competitiveness of the tuna export industry (Uyen Vo Thi Le, 2022).

Currently, the number of studies showing the competitiveness of the tuna industry in the world and in Vietnam is few and has not met the information needs commensurate with the billion-dollar industry. The number of research papers on world tuna exports is quite limited, since 2003 on the tuna industry in the world seafood market (Paquette, P. (2003)), development of the tuna industry as recently as 2010 (Miyake, 2010). Meanwhile, the number of research papers on the competitiveness of Vietnam's tuna industry is also less than that of Indonesia and Thailand. Thailand has many in-depth research papers on the tuna industry (G. J, 1987; Hudgins, L. L, 1987; Kalayanakupt, K, 2001). In Indonesia, research is also ongoing (Apridar, 2014; Hidayati & Masyhuri 2015; Suhana, Adrianto & Fahrudin, 2016). In Vietnam, a number of research papers have mentioned but not specified the whole tuna industry, only analyzed and compared the competitiveness of a few specific tuna species, such as yellowfin tuna (Le Thi et al, 2022), or yellowfin and bigeye tuna (NDH Thu, Cao Le, L.T.Minh, Nang Thu Tran & Lebailly, 2021). Besides, the research paper is recently outdated, such as the overview of Vietnam's tuna industry made since 2005 (A.D. Lewis, 2005). The lack of studies on the competitiveness of Vietnam's tuna industry will easily lead to errors in assessment such as overestimating or underestimating the ability of Vietnam's tuna industry, leading to not being able to effectively exploit its potential.

The first objective of the study is to compare the current position and competitiveness of Vietnam's tuna industry in major import markets such as the US, Japan, the EU, ASEAN, the Middle East to other players. Thereby helping to determine the position of Vietnam and others in the international tuna market. Thereby, it gives clearer predictions about the future competitiveness of Vietnam's tuna industry as well as untapped strengths and weaknesses that need to be overcome.

This study was conducted by using RCA, CMS measurement methods to assess the competitiveness of Vietnamese tuna with data from 2007-2019 by comparing these indicators with tuna exporting countries in the same segment as Vietnam. Competitors include Thailand, Indonesia, Ecuador, Taipei and markets include the US, Japan, the EU, ASEAN, the Middle East.

## **2. LITERATURE REVIEW**

This study analyzes four tuna products: frozen tuna, fresh or chilled tuna, prepared or preserved tuna and filets of tuna. The HS codes used to identify them are 0302; 0303; 0304; and 1604 respectively.

The competitiveness of a country facilitates economic growth, investment, industrial development and an improved quality of life. However, the definition of competitiveness is still a multidimensional concept. There are many studies that have addressed this approach. Among them, the most accepted definition is: "The degree to which a country can, under free and fair market conditions, produce goods and services that meet the test of international markets while simultaneously maintaining and expanding the real incomes of its people in the long term" (Stevanset et al, 2012).

### **2.1. Revealed Comparative Advantage (RCA)**

Traditional economic theory defines competitiveness based on the concepts of absolute advantage as defined by Adam Smith (1776) and comparative advantage as defined by David Ricardo (1817). This theory is measured by basic indicators such as productivity, price and value. However, Balassa (1965) recognized the limitations associated with the classical theory of comparative advantage. To address these limitations, he introduced the RCA, partly based on Liesner's Relative Export Performance Index (1958), designed to measure the impact of the removal of trade barriers. The RCA reveals a country's competitive advantage

through examination of trade data, demonstrating the impact of cost and non-price factors. There is much criticism and concern about the trade-distorting effects of government intervention and the inability to identify sources of comparative advantage. Despite this, scholars maintain that the RCA, when used with caution, is a useful measure of comparative advantage that can highlight patterns of specialization. Many researchers (Balassa, Citation 1989; Batra & Khan, Citation 2005; Hinloopen & Van, Citation 2001; Laursen, Citation 1998) used this index to estimate export competitiveness and comparative advantage for commodities with diverse datasets across countries. Kulapa Supongpan Kuldilok, P.J. Dawson, John Lingard (2013) examined the RCA indicators of the competitiveness of Thailand's tuna exports for the period 1996-2006. Fauzian Akmal Ramli, Rossanto Dwi Handoyo, Abdul Rahim Ridzuan & Mohamad I.Md Razak (2020) also used the RCA index and its variation to analyze the comparative advantage of the Indonesian tuna industry, thereby identifying factors in Indonesia's decision to export tuna. Zahra Saki and Marguerite Moore (2018) also examined the revealed comparative advantage for US textiles by analyzing the RCA.

## **2.2. Constant Market Share (CMS)**

Another commonly used method to explore the export potential of goods over a period of time for a given country is constant market share (CMS), which is an index widely used due to ease of application and visual appeal. This model is of enormous significance for examining component contributions to fluctuations in export turnover of a major product or set of commodities in export markets. The first idea of this approach was studied by Tyszynski (1951), who suggested that the export structure of a given country's goods affects its own global export performance even if other factors change.

In a study by Maheran and Muhammad (2008), the CMS approach was applied to study the level of competition in the Malaysian electrical and electronics industry over the period from 1990-2004. Tran et Al (2009) also used the CMS method to determine Vietnam's exports to the EU in the period 1997-2004. The results showed that the main causes behind Vietnam's competitive export performance were its relatively good universal trade as well as its good market posture. Hasanul Haque et Al (2013) also used the RCA and CMS indexes to identify the market prospects and challenges of exporting furniture from Malaysia. Muhammad Abdul Kamal (2020) analyzed Pakistan's export performance and trade potential in Central Asia based on CMS. In Vietnam, studies by Vo Thanh Danh (2008), Ngo Thi My (2017) applied the CMS model to analyze fluctuations in export turnover of agricultural products generally and some specific agricultural products in different regions markets.

Such studies provide valuable information on the competitive benefits and competitive positions of nations in specific export sectors. By using competitiveness measurement models (RCA and CMS), researchers can identify the sectors or products of a country that have a comparative advantage in exporting in the international market. Meanwhile, it examines the competitiveness of the products and helps to identify the components that affect export management and the competitiveness of that country. From these, the studies highlight the prospects and market challenges that industries and countries face in their export activities. In this way, policymakers can develop targeted policies and measures to enhance export competitiveness, promote industry growth and efficiently allocate resources.

## **3. RESEARCH METHOD**

### **3.1. Revealed Comparative Advantage (RCA)**

RCA is used to identify the shift in a particular country's exports with regard to its competitive advantage. However, a country's comparative advantage cannot be directly measured because such measures require relative prices before intangible transactions. Accordingly, the original Balassa (1965) RCA, which has

been adjusted for a range of measures, is the ratio of a country’s exports of a product to its total exports, to the ratio of world exports of that product to total world exports (Kulapa Supongpan Kuldilok, P.J. Dawson & John Lingard, 2013). The RCA of country i when exporting product j is:

$$RCA_{imj} = \frac{X_{ij}/X_i}{X_{mj}/X_m}$$

Where:

- $X_{ij}$  : Country i’s export of commodity j
- $X_i$  : Country i total commodities export to world
- $X_{mj}$  : Total import value/volume of commodity j in country m
- $X_m$  : Total import value/volume of country m.

Table 1: Evaluation the competitiveness of the export industry through RCA index

ID	Groups	Degree of comparative advantage
1	$0 \leq RCA \leq 1$	There is no comparative advantage
2	$1 \leq RCA \leq 2$	There is a low comparative advantage
3	$2 \leq RCA \leq 4$	There is an average comparative advantage
4	$RCA > 4$	There is a high comparative advantage

Source: Hinlopen, 2001

### 3.2. Constant Market Share (CMS)

A country’s exports can be classified by applying the CMS model by decomposing export growth into their respective parts (including Standard World Growth Effect, Commodity Composition Effect, Market Distribution Effect and Competition Effect). Thus, the overall CMS identifies a real change in the focus country’s exports between the two time periods. The CMS model is used to describe a country’s export growth. Here, the export performance of a particular country is compared with the “world average”. Currently, there is not an exact statement about the CMS formula and we have followed the “Export of furniture product from Malaysia: Market prospects and challenges” research paper formula. The CMS model used in this study can be performed as follows:

$$\sum_{i=1}^n (q_i^1 - q_i^0) = \underbrace{\sum_{i=1}^n r \cdot q_i^0}_{\text{World Demand Effect}} + \underbrace{\sum_{i=1}^n [r_i q_i^0 - r q_i^0]}_{\text{Commodity Composition Effect}} + \underbrace{\sum_{i=1}^n \sum_{j=1}^m r_{ij} q_{ij}^0 - \sum_{i=1}^n r_i q_i^0}_{\text{Market Distribution Effect}} + \underbrace{\sum_{i=1}^n (q_i^1 - q_i^0) - \sum_{i=1}^n \sum_{j=1}^m r_{ij} q_{ij}^0}_{\text{Competitiveness Effect}}$$

Where:

- $r$  : Proportionate change in total world exports in aggregate from initial time period (0) to terminal time period (1);
- $r_i$  : Proportionate change in world exports of the  $i^{th}$  commodity in aggregate from initial time period (0) to terminal time period (1);
- $r_{ij}$  : Proportionate change in world exports of commodity  $i$ , to market  $j$  in aggregate from initial time period (0) to terminal time period (1);
- $q_i^0$  : Total exports by the focus country of commodity  $i$  in the initial period;
- $q_{ij}^0$  : Total export by the focus country of commodity  $i$ , to the  $j^{th}$  market in the initial period;
- $q_i^1$  : Total export by the focus country of commodity  $i$ , in the terminal period.

### Data

First, we determined the HS codes of tuna that have been exported around the world. There are four major codes: 0302 (31, 32, 33, 34, 35, 35, 36, 39); 0303 (41, 42, 43, 44, 45, 46, 49); 0304 (87); 1604 (14) about tuna. Next, for the time frame, we chose the period from 2007-2019, because this is a stable period without incidents that seriously affect the global market like COVID-19. In addition, based on the statistics of the trade map, we selected five markets that were considered potential for exporting tuna, including the US, Japan, the EU, the Middle East and ASEAN. In these markets, we select the typical countries for each group of tuna export capacity. For example, in the EU, there will be exporting countries like Vietnam, Ecuador, Thailand and Indonesia. In each country, the data on HS codes will be determined from year to year based on continuously updated data on Trademap. We will rely on the above data to calculate the RCA, CMS for each country; each market is then combined with a number of factors for the conclusions.

## 4. RESULTS AND DISCUSSION

### 4.1. Results

#### 4.1.1. Total HS codes

##### RCA

The market share of Vietnamese tuna exports to the US during 2007-2019 had a positive average value of 9,91%. Vietnam was the second largest exporter to the US when compared to Thailand, Indonesia and Ecuador, which each had an average market share value in the US of 30,35%, 7,72% and 7,03%, respectively. Four exporting countries captured 55,01% of the US tuna export market share. This reflects that Vietnam was an important tuna exporting country for the US.

Figure 1. Percentage of market share of the four tuna exporting countries in US

The competitiveness of tuna exports to the US is determined using the RCA method. According to the results of RCA, Vietnam had export competitiveness to the US because of its RCA value during 2007-2019  $>1$ , with an average value of 3,59. Comparing the RCA value of Vietnam to Thailand, Indonesia and Ecuador which had an average RCA value of 13,77; 4,43 and 51,59 respectively, Vietnam is the lowest. Therefore, Vietnam had the lowest competitiveness level for tuna exports. However, Vietnam had the second highest export value to the US.

During 2007-2019, the RCA value of Vietnam fluctuated around 3-4. Whilst Ecuador increased sharply, Indonesia was quite stable and Thailand declined slightly; the value of tuna exports from them to the US rose. This indicates that the US market was opening up tuna imports from these countries. However, the RCA value of Vietnam did not increase rapidly. This may be explained that Vietnam focused on developing but had not mainly aimed to export tuna to the US.

*Table 2: RCA of total tuna export to the US market*

	HS	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	Total	4,36	3,44	3,04	4,05	4,01	4,14	3,99	3,79	3,57	3,33	3,08	2,80	3,08

In Japan, the RCA value of Vietnam fluctuated around 1 and even <1 after 2015. This reflects that the competitive advantage of Vietnam’s tuna exports to Japan was unstable. Besides, from 2015-2019, Vietnam did not have tuna export competitiveness. The RCA value of Vietnam in Japan was around 3 times smaller on average than in the US and so was that of Thailand. This indicates that Vietnam and Thailand were not focusing their tuna exports on Japan but on other countries and areas with more potential.

*Table 3: RCA of total tuna export to Japan market*

	HS	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	Total	1,05	0,96	0,79	1,16	1,19	1,19	1,28	1,15	0,92	0,77	0,76	0,78	0,80
Thailand	Total	3,75	5,08	3,84	3,94	4,54	3,96	4,56	4,18	3,25	2,87	2,79	3,19	3,11
Taipei, China	Total	0,91	1,45	0,97	1,09	1,33	1,26	1,24	1,14	0,89	0,85	0,93	0,99	0,94

In the EU, Vietnamese RCA value during 2007-2019 was >1 (average value of 4,08). This reflects that Vietnam had export competitiveness to the EU. Comparing the average RCA value of Vietnam to Thailand, Indonesia and Ecuador, which had an average value of 15,61; 4,96 and 57,27 respectively, Vietnam was the lowest. This reflects that Vietnam had a lower competitiveness level of tuna export to the EU than Thailand, Indonesia and Ecuador. Vietnam’s RCA value tended to decrease gradually from 2012, reached its bottom of 2,94 (2007-2019), then only recovered to 3,14 in 2019. This shows that the competitive advantage of Vietnam’s tuna exports was still unstable while Ecuador’s RCA value continuously increased and the RCA values of Indonesia and Thailand fluctuated slightly.

Interestingly, all above countries had RCA values during 2007-2019 in the EU higher than in the US. This reflects that they had a higher competitiveness level of tuna export to the EU than in the US. However, comparing export value annually during 2007-2019, the tuna export value of Vietnam to the EU lessened. This reflects that Vietnam owned less market share in the EU than in the US.

*Table 4: RCA of total tuna export to the EU market*

	HS	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	Total	5,09	3,86	3,57	5,35	4,66	5,36	4,28	4,15	3,89	3,66	3,13	2,94	3,14

Thailand	Total	18,18	20,36	17,34	18,19	17,81	17,76	15,23	15,09	13,79	13,61	11,51	11,99	12,14

The tuna value of Vietnam's exports to the Middle East was small, but the average RCA value (4,08) was higher than that of the US. This shows that Vietnam's value of competitive advantage was in the mid-high range in exporting tuna to the Middle East, similarly to its competitor, Thailand. However, Vietnam's RCA value in this market tended to decrease from 2013-2019. The RCA value in ASEAN was even smaller than in the Middle East, with an average value of 1,85. This shows that Vietnam has a low but stable competitive advantage in exporting tuna to the ASEAN market.

*Table 5: RCA of total tuna export to the Middle East market*

	HS	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	Total	5,57	3,99	3,16	3,92	3,89	4,60	4,63	4,18	3,94	2,94	3,38	2,61	2,62
Thailand	Total	19,89	21,05	15,34	13,32	14,86	15,24	16,45	15,20	13,95	10,95	12,42	10,63	10,12

*Table 6: RCA of total tuna export to the Asean market*

	HS	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	Total	1,75	1,21	1,46	1,96	1,74	2,05	2,03	2,34	2,55	1,75	1,62	1,62	1,91
Taipei, China	Total	1,52	1,82	1,78	1,84	1,95	2,17	1,96	2,32	2,48	1,92	1,99	2,04	2,23
Japan	Total	0,16	0,12	0,12	0,12	0,12	0,12	0,15	0,17	0,16	0,09	0,11	0,15	0,15

According to RCA value, in the EU, US and Middle East markets, Vietnam had a mid-high competitive advantage. Moreover, in general, Vietnam still had a low competitive advantage in the ASEAN and had no competitive advantage in Japan. In addition, in these markets, Vietnam had the highest competitive advantage in exporting tuna to the EU market. Concluding that, the above markets were all potential tuna export markets of Vietnam, especially the EU market, although there were still fluctuations.

### **CMS**

Using the CMS method to further examine Vietnam's tuna exports through markets around the world. The first 2 CMS elements, Standard World Growth Effect and Commodity Composition Effect, were the same in all markets and had positive value during 2007-2019. This reflects that the impact of global demand put direct pressure on Vietnam's tuna exports, causing a decline in tuna yield. This value declined from period I-II shows that the world tuna consumption continued to increase. That put pressure on Vietnam to produce more to meet world demand. However, from period II-III, this value increased by 4,6 times, showing that the value of influence of world demand increased strongly on Vietnam. The positive value of Commodity Composition Effect during 2007-2019 reflects the high market demand for this product. From period I-II, this value increased more than 2 times, showing that consumers were more interested in Vietnamese tuna exports. But after, this value decreased, illustrating that consumers' preference for Vietnamese tuna had decreased significantly.

**Table 7: Standard World Growth Effect and Commodity Composition Effect of tuna in total**

Period	Standard World Growth Effect	Commodity Composition Effect
2007-2010	6456,50	103,81
2011-2014	3410,60	21841,84
2015-2019	15938,24	13618,69

Another factor that strongly influences Actual Export Growth is Market Distribution Effect. This factor reflects Vietnam’s response to the increase in demand occurring in the importing country. During 2007-2019, its value was negative in 5 markets. This reflects that Vietnam had not properly allocated tuna exports to these markets. This may be because instead of allocating to markets with high import demand, Vietnam focused on low-potential countries. Moreover, in the US, Japan, EU and Middle East markets, Market Distribution Effect tended to decrease during 3 periods. Although from period II-III, in the ASEAN market, its value slightly increased. Therefore, it shows that Vietnam did not have an improvement in the allocation of tuna value to these markets.

Figure 2. Market Distribution effect of Vietnam’s tuna in five imported markets.

The last factor is the Competitiveness Effect. Its value was positive for 5 markets during 2007-2019. This shows that Vietnam focused on both increasing the value and quality of exported tuna. In addition, this value tended to increase sharply in periods I-II and decreased slightly after that. This proves Vietnam had improved its tuna quality to meet the needs of the importing countries.

Figure 3. Competitiveness effect of Vietnam’s tuna in five imported markets.

#### 4.1.2. Detailed HS codes

##### a) 0302

##### RCA

In the US, the RCA values of Vietnam, Indonesia, Ecuador and Thailand were 5,01; 0,00; 3,05; and 0.76 in 2007, respectively. Obviously, Vietnam had the highest competitive advantage. However, during 2008-2012, Ecuador moved to the top with an average RCA value of 7,71, while Vietnam dropped to the second rank with an average RCA value of 4,42. This shows that Vietnam had gradually lost its competitive

advantage over its rivals. Indeed, since 2012, Vietnam's RCA value showed a downward trend. Then, after 2015, the RCA value was <1. This reflects that Vietnam had no competitive advantage since 2015.

*Table 8: RCA of 0302 tuna export to the US market*

	HS	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	0302	5,01	2,79	4,02	4,87	5,01	5,44	2,08	1,10	0,48	0,09	0,14	0,12	0,10
Indonesia	0302	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00
Ecuador	0302	3,05	5,85	9,47	8,09	6,66	8,50	8,66	4,82	7,56	8,42	6,97	9,89	9,74
Thailand	0302	0,76	0,43	0,51	0,55	0,37	0,32	0,77	1,03	0,97	0,88	0,18	0,06	0,04

In general, the RCA value of 0302 Vietnamese tuna in the Japan market was smaller than in the US market. Moreover, only in 2007, 2011 and 2012, the RCA value of Vietnam was >1 while the RCA value of Thailand was <1 during 13 years. This shows that Vietnam and Thailand had almost no competitive advantage.

*Table 9: RCA of 0302 tuna export to Japan market*

	HS	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	0302	1,07	0,63	0,70	0,99	1,19	1,33	0,65	0,41	0,19	0,03	0,06	0,06	0,06
Thailand	0302	0,16	0,10	0,09	0,11	0,09	0,08	0,24	0,38	0,39	0,30	0,08	0,03	0,02
Tabei, China	0302	0,05	0,84	0,63	1,27	1,63	1,67	1,93	1,84	1,49	1,26	1,28	1,06	0,73

Vietnam's RCA value was higher in the EU than in the US. From 2007-2012, Vietnam had a high competitive advantage in exporting 0302 tuna with an average RCA value of 22,30. However, from 2013 onwards, Vietnam's RCA value decreased sharply and after 2016 this value <1. So, Vietnam had gradually lost its competitive advantage.

*Table 10: RCA of 0302 tuna export to the EU market*

	HS	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	0302	23,31	15,77	20,09	26,62	22,18	25,83	10,10	5,20	2,11	0,35	0,52	0,49	0,41
Indonesia	0302	29,28	37,77	30,16	33,56	18,33	15,97	16,40	14,41	9,45	9,37	4,84	3,27	2,77
Ecuador	0302	14,21	33,11	47,35	44,18	29,49	40,38	41,99	22,72	33,57	34,31	25,93	39,60	39,22
Thailand	0302	3,56	2,46	2,55	3,00	1,65	1,50	3,72	4,86	4,32	3,60	0,67	0,22	0,14

In the Middle East and ASEAN markets, in the period 2007-2012 with the average RCA values of 61,09 and 27,26 respectively, it shows that Vietnam had a higher competitive advantage than in the EU market. However, there was a downward trend after 2012. This shows that Vietnam had not focused on the 0302 tuna in these markets.

*Table 11: RCA of 0302 tuna Vietnam in Middle East and ASEAN*

	HS	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
The Middle East	0302	77,21	46,79	54,60	62,05	72,92	52,97	12,38	8,44	3,51	0,93	1,48	1,06	0,76
Asean	0302	37,10	25,47	24,21	20,56	28,57	27,68	16,73	7,15	2,01	0,43	0,64	0,90	0,63

In conclusion, the RCA values all tended to decrease strongly after 2012 and generally <1 from 2016-2019. This shows that Vietnam had no competitive advantage for the 0302 tuna from 2016-2019.

Especially in the Japanese and the US markets, Vietnam even lost the competitive advantage of this industry earlier, in 2013 and 2015 respectively.

Figure 4. RCA of 0302 tuna Viet Nam in five imported markets.

**CMS**

Standard World Growth Effect has positive value during 2007-2019. This reflects that the world demand may put direct pressure on Vietnam’s 0302 tuna exports. Moreover, this value declined significantly shows that the world’s 0302 tuna consumption continues to increase. The negative value of Commodity Composition Effect during 2007-2019 reflects that Vietnamese 0302 tuna exports are not favored by consumers around the world. From period I-II, this value decreased sharply. After that, although this value increased, it is still negative, indicating that consumer’s demand for Vietnam 0302 tuna is still poor.

Table 12: Standard World Growth Effect and Commodity Composition Effect of tuna HS 0302

Period	Standard World Growth Effect	Commodity Composition Effect
2007-2010	1554,30	-1490,15
2011-2014	665,88	-3644,96
2015-2019	338,62	-334,62

Market Distribution Effect of all 5 markets had positive values in period II, while period I and III were unstable. Indeed, Market Distribution Effect from period I-II tended to increase and then in II-III decreased. This shows that Vietnam had a proper distribution of 0302 tuna in these markets in period II.

Figure 5. Market distribution effect of 0302 tuna Viet Nam in five imported markets.

Competitiveness Effect, although having different values in each market, tended to remain the same. In period I, the positive value showed that Vietnam focused on both increasing the value as well as the quality of export 0302 tuna. Obviously, this effect decreased sharply from period I-II and increased slightly from period II-III. Although Vietnam had improved the quality of its 0302 tuna from period II-III, it had not yet focused much.

Figure 6. Competitiveness Effect of Vietnam tuna HS 0302 at five imported markets

b) 0303

RCA

In the US market, for tuna code 0303, Vietnam had RCA values >1 during 2007-2019 with an average value of 3,07. Whilst, Indonesia and Ecuador had higher average values, with 8,39 and 13,93 respectively. Vietnam’s export of tuna 0303 in general showed a downward trend, especially 2012-2014 and 2016-2019 and tended to fluctuate in other years. This shows that Vietnam was gradually no longer focusing on tuna 0303 in this market.

Table 13: RCA of 0303 tuna export to US market

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
<b>Vietnam</b>	1,90	1,64	1,89	6,15	5,90	4,61	2,12	1,28	2,22	1,73	1,56	1,04	7,83
<b>Indonesia</b>	4,27	4,75	4,15	4,76	6,13	10,75	9,55	7,37	5,89	5,19	8,71	4,89	32,71
<b>Ecuador</b>	4,03	11,11	20,05	20,11	22,11	7,20	10,47	14,39	8,30	5,69	15,50	18,44	23,72
<b>Thailand</b>	1,83	2,50	2,01	0,97	1,61	1,91	0,65	0,94	0,81	0,90	1,68	1,46	7,76

The RCA value in the EU market of tuna 0303 was higher than in the US market, with the average value being 3,78. This shows that Vietnam had an average competitive advantage. Meanwhile, Ecuador held an average RCA value of up to 18,40, much higher than Vietnam. Along with the instability in the export value of tuna 0303, Vietnam’s RCA value was also gradually decreasing, especially in 2015-2018. This reflects that Vietnam was no longer focused on exporting this code.

Table 14: RCA of 0303 tuna export to EU market

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
<b>Vietnam</b>	3,63	2,70	3,69	10,39	7,92	5,62	2,60	1,77	3,51	2,26	1,86	1,37	1,78
<b>Ecuador</b>	7,72	18,34	39,07	33,99	29,69	8,77	12,87	19,87	13,14	7,41	18,51	24,47	5,39

There were surprising similarities in the Japanese and ASEAN markets. Tuna 0303 to these markets from Vietnam lost its competitive advantage with the average RCA value of 0,21. However, the biggest rival in these markets, Taipei, also held an average RCA value at only 1,84 and 1,78, respectively. The RCA of Vietnam in the Japanese market increased slightly while decreasing in ASEAN. This can be concluded that in these markets, Vietnam had completely lost its competitive advantage without improving.

*Table 15: RCA of 0303 tuna export to Japan market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	0,15	0,13	0,15	0,44	0,43	0,37	0,23	0,12	0,21	0,15	0,14	0,11	0,14
Thailand	0,15	0,20	0,16	0,07	0,12	0,15	0,07	0,09	0,08	0,08	0,15	0,16	0,14
Taipei, China	1,42	2,07	1,35	1,25	1,56	2,21	2,36	1,92	1,69	1,58	1,87	2,31	2,36

*Table 16: RCA of 0303 tuna export to Asean market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	0,17	0,11	0,17	0,51	0,44	0,32	0,17	0,13	0,24	0,16	0,14	0,10	0,12
Taipei, China	1,56	1,69	1,57	1,44	1,61	1,93	1,68	2,10	1,90	1,65	1,89	2,05	2,11
Japan	0,14	0,10	0,09	0,10	0,10	0,09	0,13	0,14	0,10	0,05	0,08	0,11	0,09

In the Middle East, Vietnam’s RCA value during 2007-2019 was >1 with an average value of 3,59. Competitor Thailand had an average RCA value of 3,45. However, during 2013-2016, Thailand’s RCA index was <1. This shows that the potential of Vietnam in this market was quite large. However, export value from Vietnam seemed to decrease since 2012. This may be because Vietnam had started to focus on exporting other majors.

*Table 17: RCA of 0303 tuna export to The Middle East market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	3,59	3,90	3,03	5,66	6,97	7,14	2,73	1,17	2,61	1,54	1,71	1,54	1,61
Thailand	3,45	5,95	3,22	0,89	1,90	2,97	0,83	0,86	0,96	0,79	1,84	2,17	1,60

In short, RCA values tended to decrease in the US, EU and Middle East and even had <1 value in ASEAN and Japan. It can be seen that tuna code 0303 was no longer a priority export product of Vietnam.

### **CMS**

Analyzing tuna 0303, the Standard World Growth Effect value of Vietnam increased during 2007-2019. This shows that the demand for tuna 0303 decreased. While Commodity Composition Effect fluctuated. From period I-II, its value increased sharply, but when entering period III, it started to decrease. This reflects that consumers’ interest in tuna code 0303 of Vietnam had fluctuated.

*Table 18: Standard World Growth Effect and Commodity Composition Effect of tuna HS 0303*

Period	Standard World Growth Effect	Commodity Composition Effect
2007-2010	593,40	-217,39
2011-2014	790,35	4912,00
2015-2019	1591,92	1441,13

Market Distribution Effect fluctuates strongly. In the ASEAN market, it recorded a positive value in period I, then decreased in period II and increased again in period III. In the remaining markets, its value was negative during 2007-2018. This reflects that Vietnam was gradually losing its advantage due to improper output allocation when exporting tuna 0303.

Figure 7: Market Distribution Effect of Vietnam tuna HS 0303 in five imported markets

When analyzing Competitiveness Effect, there is a common trend during 3 periods in all markets: a positive value in period I, plummeting to a negative value in period II and slightly increasing in period III. This shows that the quality of tuna 0303 of Vietnam when exported to the US, Japan, EU, ASEAN and Middle East is given little attention.

Figure 8: Competitiveness Effect of Vietnam tuna HS 0303 at five imported markets

c) 0304

For tuna code 0304, in 2012 Vietnam started exporting to 5 markets. Therefore, this study analyzes the factors affecting the competitiveness of Vietnam in the two periods 2012-2014 and 2015-2019.

RCA

In the US, Vietnam had a competitive advantage when the RCA value was highest among exported countries. Only Vietnam and Ecuador had a competitive advantage with this industry code. In terms of value export, most countries tended to increase. Although Vietnam was the country with the largest increase, Vietnam’s RCA fluctuated. This shows that tuna 0304 from Vietnam in the US market lost interest.

Table 19: RCA of Vietnam tuna HS 0304 in US market

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	-	-	-	-	-	5,13	10,31	12,18	8,87	7,65	7,37	7,36	6,67
Indonesia	-	-	-	-	-	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00
Ecuador	-	-	-	-	-	-	2,59	5,09	7,50	9,67	7,90	5,68	6,37
Thailand	-	-	-	-	-	0,00	0,76	1,09	1,18	1,13	0,66	0,63	0,51

In the EU, for tuna code 0304, Vietnam’s RCA index was the highest with the average value 28,45. This reflects that Vietnam had a strong competitiveness in this market. Although the market share of Vietnam’s tuna 0304 in the EU gradually increased, the RCA value tended to decrease slightly. Thus, it is clear that Vietnam’s competitive advantage in this tuna code was not really stable.

*Table 20: RCA of Vietnam tuna HS 0304 in EU market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	-	-	-	-	-	25,45	40,46	42,92	31,30	23,57	20,97	21,09	21,87
Ecuador	-	-	-	-	-	0,00	10,15	17,94	26,49	29,77	22,45	16,28	20,87
Thailand	-	-	-	-	-	5,90	2,99	3,84	4,18	3,47	1,87	1,81	1,69
Indonesia	-	-	-	-	-	10,61	12,34	19,91	16,05	13,46	10,83	21,02	22,83

In the Japanese market, Vietnam still retained its competitive advantage, with an average RCA of 1,16. Meanwhile, Thailand and Taipei did not have a competitive advantage in this market, the average RCA index of these countries was very low (<1). Besides, with the increase in value, the RCA rose simultaneously. This means that Vietnam focused more on exporting this product.

*Table 21: RCA of Vietnam tuna HS 0304 in Japan market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	-	-	-	-	-	0,82	1,29	1,73	1,18	1,11	1,02	1,06	1,10
Thailand	-	-	-	-	-	0,19	0,10	0,15	0,16	0,16	0,09	0,09	0,08
Taipei, China	-	-	-	-	-	0,00	0,00	0,01	0,03	0,04	0,05	0,06	0,05

In the Middle East and ASEAN, Vietnam’s tuna 0304 tended to fluctuate strongly during 2012-2019 and achieved very high RCA values. Competitor countries also had RCA values >1, but export values fluctuated, even decreased, which means the competitive advantage of Vietnam in these markets was quite high and relatively stable.

*Table 22: RCA of Vietnam tuna HS 0304 in The Middle East market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	-	-	-	-	-	42,76	59,73	84,16	81,89	76,84	56,88	56,35	56,63
Thailand	-	-	-	-	-	9,92	4,41	7,54	10,94	11,32	-	4,85	4,37

*Table 23: RCA of Vietnam tuna HS 0304 in Asean market*

Asean	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	-	-	-	-	-	42,24	74,82	54,70	29,24	35,60	66,59	57,90	54,01
Taipei, China	-	-	-	-	-	0,00	0,01	0,47	0,68	1,18	3,44	3,29	2,49
Japan	-	-	-	-	-	1,66	1,32	0,73	0,49	0,56	1,27	1,03	1,28

In conclusion, with tuna 0304 in all 5 markets during 2012-2019, Vietnam always had the highest RCA index compared to rival countries on tuna code 0304. With the increase in RCA value, this product became a priority in Vietnam’s exporting chain.

When considering tuna 0304, we can see that the Standard World Growth Effect tends to increase strongly. This shows that the total demand in the markets decreased significantly and reduced negative pressure on exporters. Coming to Commodity Composition Effect, from stage II-III, this value dropped. This reflects that consumer interest in this code had reduced.

*Table 24: Standard World Growth Effect and Commodity Composition Effect of tuna HS 0304*

Period	Standard World Growth Effect	Commodity Composition Effect
2012-2014	966,20	21766,89
2015-2019	6729,49	14993,96

For the Market Distribution factor, except for the ASEAN market, there was a positive growth in resource allocation when exporting tuna 0304, reaching a positive value during 2015-2019 and recording a slight increase in the value of period III compared to period II, but in both periods still had negative values. Generally, Vietnam had not allocated value properly when exporting tuna 0304 to all 5 markets, but Vietnam made efforts to change it more positively.

*Figure 9: Market Distribution Effect of Vietnam tuna HS 0304 in five imported markets*

Next is the competitiveness impact on tuna 0304. While the ASEAN market decreased in 2 periods, the value increased slightly in other markets. This reflects the quality of this code of Vietnam when exporting to the ASEAN market tends to decrease, while when exporting to the other 4 markets, it increases slightly.

*Figure 10: Competitiveness Effect of Vietnam tuna HS 0304 at five imported markets*

**d) 1604**

**RCA**

In the US market, the RCA index of Vietnam was >1 with an average value of 3,34. Whilst, the RCA values of Ecuador and Thailand were 84,48 and 22,82 respectively. This means that Vietnam had a

competitive advantage but encountered strong competitors. In general, the export value of Vietnam's tuna 1604 tended to increase. However, the RCA value showed a downward trend, which means that despite being exported more, this product had not yet become a paramount product in Vietnam's export chain.

*Table 25: RCA of Vietnam tuna HS 1604 in US market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	5,03	4,11	3,09	3,36	3,35	3,54	3,69	3,34	3,19	3,29	2,89	2,42	2,17
Indonesia	3,82	3,14	3,28	2,45	2,99	3,50	4,06	3,89	5,00	5,17	5,24	5,08	5,56
Ecuador	68,63	69,85	48,43	38,27	55,01	66,14	81,83	85,73	98,29	118,25	136,25	123,22	108,29
Thailand	25,97	27,24	22,16	19,95	21,89	22,03	22,91	22,92	23,80	24,81	21,43	21,40	20,15

In the EU market, with tuna 1604, Vietnam still had a competitive advantage when the RCA was always >1. Whilst Ecuador, the strongest competitor, had an average value of 66,54. Besides, showing an upward trend in export value, only the RCA of Ecuador showed growth and Vietnam did not. This means although the export value rose, this product in the EU market lost focus.

*Table 26: RCA of Vietnam tuna HS 1604 in EU market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	4,15	3,54	2,75	3,60	3,24	3,48	2,95	2,62	2,23	2,32	1,96	1,70	1,65
Ecuador	56,62	60,06	43,17	41,05	53,29	65,04	65,40	67,40	68,61	83,22	92,71	86,30	82,14
Thailand	21,43	23,42	19,75	21,40	21,21	21,66	18,31	18,02	16,61	17,46	14,58	14,99	15,28
Indonesia	3,15	2,70	2,92	2,62	2,90	3,44	3,24	3,06	3,49	3,64	3,56	3,56	4,22

In the Japanese and The Middle East, for tuna 1604, Vietnam still retained competitive advantage, with an average RCA >1. Meanwhile, the competitor-Thailand, had a higher competitive advantage. The export value from Vietnam and Thailand had fluctuated, while the RCA of both countries had decreased. This shows that this product was gradually no longer receiving priority.

*Table 27: RCA of Vietnam tuna HS 1604 in Japan market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	5,40	4,40	3,55	4,94	4,31	4,52	4,58	4,16	3,00	2,49	2,27	2,03	1,88
Thailand	27,92	29,10	25,47	29,33	28,14	28,17	28,43	28,57	22,40	18,77	16,88	17,93	17,48
Taipei, China	0,00	0,00	0,00	0,01	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00	0,00

*Table 28: CMS of Vietnam tuna HS 1604 in The Middle East market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	4,42	3,43	2,38	2,69	2,59	2,70	3,15	2,74	2,23	1,74	2,00	1,34	1,24
Thailand	22,84	22,68	17,08	16,00	16,93	16,84	19,58	18,83	16,66	13,07	14,89	11,87	11,52

In the ASEAN market, Vietnam had the highest RCA for tuna 1604 when owned at an average value of 26,09. In terms of value, despite experiencing fluctuations, there had been periods of rapid increase. However, RCA value showed a downward trend. Therefore, despite having strength, Vietnam's competitiveness was unstable.

*Table 29: CMS of Vietnam tuna HS 1604 in Asean market*

	2007	2008	2009	2010	2011	2012	2013	2014	2015	2016	2017	2018	2019
Vietnam	39,27	19,78	21,00	25,49	14,38	12,76	15,01	14,15	9,80	8,20	11,32	8,21	6,60
Taipei, China	0,03	0,01	0,02	0,03	0,01	0,01	0,01	0,01	0,01	0,01	0,01	0,01	0,01
Japan	0,23	0,13	0,22	0,19	0,11	0,07	0,11	0,09	0,08	0,09	0,10	0,10	0,09

In all markets with tuna under HS 1604, Vietnam's export value seemed to increase. However, except for ASEAN, the RCA value seemed to decrease over the years. This can be concluded that, in these four countries, Vietnam was no longer focusing on this product. And for ASEAN, although exporting this product was highly prioritized in some periods, Vietnam couldn't maintain its strength.

### *CMS*

The Standard World Growth Effect of tuna with HS 1604 fluctuates erratically. In stages I-II, this value decreased, reflecting that pressure on exports increased. Whilst, during periods II-III, this value increased, showing that the opportunities for exporters rose. Similarly, with the Commodity Composition Effect, this value increased in I-II, illustrating that commodities from Vietnam were preferable. Conversely, when this value decreases in II-III, consumer interest in this product declines.

*Table 30: Standard World Growth Effect and Commodity Composition Effect of tuna HS 1604*

Period	Standard World Growth Effect	Commodity Composition Effect
2007-2010	4308,79	2204,82
2011-2014	1954,37	10192,44
2015-2019	7278,20	6869,49

Regarding Market Distribution, except for the ASEAN market, this value was negative in all markets in 3 periods. This shows that Vietnam had not yet allocated resources properly. While in ASEAN, in stages I and III, the Market Distribution value was positive. This reflects that Vietnam had more rational allocation of value to this market. However, this value had a negative value in phase II, which means Vietnam still has many limitations in this distribution.

*Figure 11: Market Distribution Effect of Vietnam tuna HS 1604 in five imported markets*

With the Competitiveness Effect factor of Vietnam's HS 1604 tuna, the trend in all 5 markets was up in phase I-II and down in phase II-III. Except for the ASEAN market, the value of Competition Effect in all countries was positive. Meaning that as well as value, the quality of this product improved

significantly. However, in the ASEAN market, the value in phase III showed that the quality at this stage significantly reduced.

Figure 12: Competitiveness Effect of Vietnam tuna HS 1604 at five imported markets

#### 4.2. Discussion

Our research results have some similarities with previous studies on the competitiveness of Vietnam’s tuna export industry, such as Uyen Vo Thi Le (2022). However, our study has provided a more comprehensive perspective than previous research. First, this study was conducted on a broader basis. We looked at the top 4 tuna exports from Vietnam. Meanwhile, Uyen Vo Thi Le (2022) inclined to consider one yellowfin tuna code. Overview of the tuna industry as a whole, there are few research papers on the competitiveness of the tuna export industry. Therefore, to a great extent, this analysis helps to provide an overview to maintain and improve the position of Vietnam’s tuna exports. Second, our study has used the CMS model to analyze the factors affecting the competitiveness of Vietnam’s tuna export industry. From there, it is possible to identify the strengths and weaknesses of Vietnam when exporting each of these tuna codes to foreign markets.

From the results, we can see that Vietnam had a competitive advantage in the US, EU and Middle East markets. The results of the CMS index also show the interest and preference of consumers for Vietnamese tuna. Otherwise, in the EU, US and Middle East markets, although they had competitive advantages, they still gradually declined. This shows that Vietnam only exported at a sustained level, but did not focus much on this industry. Besides, the transportation and storage cost issue in Japan was also a problem that Vietnam should take into consideration. This is a wake-up call for Vietnam to improve its policies to maintain its position on the world tuna map.

In 2012, when the code for tuna filets (0304) was first exported to the world market, the competitive advantage of tuna filet increased in all 5 markets, but it was accompanied by a gradual decline of fresh tuna (0302). In terms of export value, we can see Vietnam’s focus on tuna filets and a gradual decline in fresh tuna. The quality of the tuna filet group meets the standards of the markets, while the fresh tuna group does not. Due to the actual conditions in the process of handling these two types of fish, Vietnam is also limited by the handling and preservation of fresh fish. However, the competitiveness indicators and export value still show signs of decline of tuna filets on the world market.

For the prepared, preserved tuna product (1604), its competitive advantage in the US, Japan, EU and Middle East markets was average and tended to decrease. This was due to the fluctuating global demand for this industry and the improper allocation of export value in these markets. Only in the ASEAN market did Vietnam have a relatively high competitive advantage. Part of the reason is that Vietnam had made efforts to more rationally distribute canned tuna products. It showed that Vietnam focused more on exporting 1604 to

the ASEAN market compared to other markets. With that, this tuna product continued to receive significant attention from consumers worldwide.

On the contrary, frozen tuna (0303) had experienced significant fluctuations across different periods. Despite the positive shifts in consumer interest worldwide for this product, production volume and quality had not been ensured. Furthermore, only in the ASEAN market, Vietnam made efforts to improve the distribution of frozen tuna products, while the distribution was uneven.

In general, Vietnam has a competitive advantage in the tuna export industry to some major markets under consideration. However, similar to the research results of Hasanul Haque (2013), despite having a competitive advantage, in order to maintain and enhance its market position in this industry, Vietnam should take actions immediately. Specifically:

*For fishermen:* It is necessary to widen their understanding of advanced technologies in catching and preserving tuna. In addition, ship owners need to be more disciplined in keeping fishing logbooks to both avoid duplicate fishing in the same fishing ground and improve the product's reputation when exporting to countries with strict fishing requirements.

*For government agencies:* Firstly, Vietnam is one of the countries with the IUU yellow card. This negatively affects the competitiveness in export markets, especially the EU market. Therefore, the implementation of strong measures and policies improve the knowledge and skills of standard fishing for fishermen. Regarding the standard of fish caught for an average adult tuna, it should range from 40-50 kg. Fish that do not meet the standards of kilograms will be released back into the sea. Second, according to VASEP, because many fishing ports now stop issuing S/C certificates for tuna products caught for more than a month. Therefore, the government should invest technological equipment as well as patrol teams to support fishermen in case of emergency to ensure supply. Finally, the Vietnamese government needs to implement measures to optimize allocation of export value among markets like the US, EU and Middle East.

## 5. CONCLUSION

Vietnam's tuna industry has currently played an important role in the export value chain. It proves that the research conducted to vividly define Vietnam's position in the international arena is vital. Thanks to the results, the strengths and weaknesses of the tuna industry can be illustrated, thereby finding resolutions to foster the competitiveness of the whole industry. After analyzing RCA in the period 2007-2019, in the Japanese market, Vietnam did not have a competitive advantage. Meanwhile, in the other 4 markets, Vietnam held certain competitive advantages over time. However, these values showed a downward trend in all markets. In addition, when focusing specifically on the codes 0302, 0303, 0304, 1604, we clearly see the downtrend of the four codes. Especially, only tuna with 0304 was the product that became more precious. Then, based on CMS analysis for each detailed code and the whole tuna industry in 3 periods, it shows that Vietnam had improved the quality of exported tuna (especially 0304) to meet the needs of markets and Vietnam tuna was more popular with consumers around the world, especially in codes 0304 and 1604. However, Vietnam had not properly allocated both the tuna industry as well as specific groups of tuna. Finally, the study has recommended various measures such as changing from exploitation, processing, preservation and boosting product quality to distribution for each tuna industry code in particular and the whole tuna industry as well.

Despite efforts to better the study, some limitations still exist. The first is a methodological limitation. Since only two main models, RCA and CSM, are used, the study has not provided an in-depth analysis of the underlying reasons for the decline in Vietnam's competitive strength. Second, the study has not

considered other sectors that use the same resources as tuna. The priority of the research is on the group of event fish industries exported by Vietnam. Consequently, resources were transferred from the fishing industry to which sectors were not vividly analyzed. In order to gain a deeper insight into the assessment of Vietnam's seafood export industry, future studies may take advantage of the following suggestions. It may be the use of different supportive models to analyze the factors affecting the RCA, CMS models. For example, the FsQCA model analyzes the structures to determine results. Besides, it is possible to expand the research topic in this direction with other types of disciplines.

## EXPLORING FACTORS INFLUENCING JOB SATISFACTION OF EMPLOYEES DURING THE DIGITAL ERA: THE PRACTICAL CASE IN HO CHI MINH CITY

**Author: Bui Vo Anh Thu<sup>1</sup>, Nguyen Thi Khanh Ly<sup>2</sup>, Trinh Thao Minh<sup>2</sup>, Ha Thi Thu Thuy<sup>2</sup>**

**Mentor: MS. Vo Thi Le Uyen<sup>3</sup>**

*ABSTRACT: The digital workplace is a growing trend changing how businesses operate and how employees carry out their duties. But not everyone is happy or comfortable with this change. The study will examine the key elements influencing the job satisfaction of whom are working in Ho Chi Minh City, reach conclusions, and offer suggestions for enterprises and organizations. For managers, human resource directors, consultants, and policy scholars interested in this area, this study will be instructive. This study uses the Theory of Reasoned Action, Work Characteristics Model, Technology Acceptance Model, and Technology-to-task Fit Model to integrate into the overall model. Then test these models with Exploratory Factor Analysis, Cronbach Alpha, and Structural Equation Modeling and give the results by Bootstrapping method. From the research results, the authors advise organizations to enact suitable policies to enhance their employees' satisfaction and stimulate their well-being.*

### 1. INTRODUCTION

Ho Chi Minh City (HCMC) is a major economic hub in Vietnam, attracting numerous multinational corporations and diverse industries. The urban area has experienced rapid development in information technology and the digital industry. This can be seen through the presence of leading technology companies. HCMC is home to many top technology companies in software development, information technology, and the digital industry. Technology conglomerates like FPT, VNG, CMC, and numerous IT startups are actively operating thriving here. HCMC has created a favourable environment for the development of technology incubators and startups. Technology clusters and innovation centres such as District 2 (Thu Thiem District), District 9 (Phu My Hung New Urban Area), and the Dreamplex Technology Innovation Center are attracting creative individuals and companies in the field of information technology. HCMC is actively promoting the use of emerging technologies such as artificial intelligence (AI), blockchain, the Internet of Things (IoT), and deep learning. The application of these technologies in sectors such as transportation, healthcare, education, and business is driving the development of information technology and the digital industry in the city. Many multinational companies are investing in and expanding their business operations here. Multinational corporations such as Samsung, Intel, Unilever, Nestlé, and many others have offices and factories in HCMC. The presence of multinational businesses creates a multicultural working environment with diverse languages, cultures, and international regulations. HCMC has a concentration of diverse industries, including manufacturing, services, finance, real estate, education, healthcare, and many other fields.

The application of technology and the related developments in the digital age have brought about significant changes and impacts on the work environment. Conducting research on job satisfaction in this context can help us better understand the influence of information technology on employees and their

<sup>1</sup> University of Economics and Law, Vietnam National University Ho Chi Minh City Email: [thubva20413c@st.uel.edu.vn](mailto:thubva20413c@st.uel.edu.vn)

<sup>2</sup> University of Economics and Law, Vietnam National University Ho Chi Minh City

<sup>3</sup> Mentor: M.S. Vo Thi Le Uyen; Tel: +84 911 647272; Email: [uyenvtl@uel.edu.vn](mailto:uyenvtl@uel.edu.vn)

work. As business operations expand, manual processes are unable to meet the efficiency requirements of enterprises due to increased business complexities, changing and improving service products, growing workforce, and increasingly complex sales scenarios, leading to management difficulties. Many businesses face drawbacks in their management processes due to “patchwork” procedures, overlapping information, lack of synchronization, and lack of flexibility among departments. Therefore, the application of technology in daily operations is necessary for businesses to optimize operations and enhance competitiveness.

HCMC is the political and administrative centre of Vietnam, where developments related to work regulations and policies take place. Changes in the field of labour code, and regulations regarding wages, rights, and working conditions have occurred. For example, companies that do not pay equal wages or discriminate based on gender for workers performing equally valuable jobs will be fined from 5 to 10 million VND, as previously stipulated. There were no penalties specified for such behaviour before. The maximum working hours per shift are regulated as follows: For daily labour, the working hours should not exceed 8 hours per day and 48 hours per week. For weekly labour, the working hours should not exceed 10 hours per day and 48 hours per week. The government of HCMC has introduced various policies and regulations to promote the development of information technology and the digital industry. These policies include encouraging investment in information technology, providing favourable conditions for technology companies and startups, offering financial support, and facilitating the training of high-quality human resources. These changes can impact the job satisfaction of workers. Additionally, HCMC is a diverse cultural hub, attracting people from various regions within the country and from abroad. This multicultural environment creates a vibrant workplace with the intersection of different cultures and values.

In the era of economic integration and rapid digital development, competition has become increasingly fierce, and human resources play a crucial role in gaining a competitive advantage. Particularly for businesses in the midst of growth, rapid economic expansion, and a vibrant business environment with millions of people living and working there, it creates a competitive labour environment and work pressure. Seeking and asserting one’s position in the market requires careful attention to employee satisfaction. Therefore, this research is conducted to “Exploring factors influencing job satisfaction of employees during the digital era: the practical case in HCMC” human resource policies to satisfy the employees, thereby enhancing the individual performance of each employee and improving the overall business effectiveness of organizations in the digital age.

Previously, there have been studies on the impacts on the satisfaction of workers based on JDI such as the research of Tran Kim Dung (2005) in the *Journal of Science and Technology Development Magazine*, this study has launched an analysis to measure the level of satisfaction of work in Vietnam’s conditions. By applying Smith’s JDI scale, Kendall & Hulin (1969), the results showed that there were 7 variables affecting the satisfaction of the job, including: (1) The nature of the job, (2) income, (3) opportunities for promotion, (4) leaders, (5) colleagues, (6) welfare, (7) working conditions. Research by Ha Nam Khanh Giao and Vo Thi Mai Phuong (2011) produced similar results.

With the topic of measuring the level of satisfaction of employees of joint stock commercial banks in Dong Nai province - thesis from MS. Nguyen Hoang Diem Huong (2013) has shown a comparison of its results with research by author Do Ngoc Nhu Phuong (2011) and Le Hoang Trang (2012) at the research location in Ho Chi Minh City. Concluded the level of satisfaction of the study in Dong Nai for higher results than two studies in Ho Chi Minh City, the reason is that the author pointed out that in the provinces, the level of competition is not as fierce as banks in key cities like Ho Chi Minh City, the living standard in the province is lower and the number of employees has banking qualifications are also less because the human resources are mostly concentrated in big cities.

Reaching out to the world, research by Joerg Beechl, Ralf-Christian Härtinga, Mara Schrödera (2021) on the effects of digitalization on employees' satisfaction in small and medium enterprises that used the theory of data platforms, showing the relationship between staff satisfaction and digitization in small and medium enterprises. Resulting in digital technology, affecting employee satisfaction. Although qualitative research has some limitations: only 12 experts from small and medium-sized businesses are interviewed and the results are only meaningful to a limited level and in the context of interviews sometimes experts have been supported with the question.

Research by Nidhi S. Bisht, Clive Trusson, Juliana Siwale, M. N. N. Ravishankar (2021) named "Enhanced Job Satisfaction Under Tighter Technological Control: The Paradoxical Outcomes of Digitalization" concluded the satisfaction in the work of the penetrating insures. The research survey from the employees of the small-scale Indian corporation tends to increase, the same trend was the phenomenon of complaining of unnecessary issues of technology. Several other premise studies had discussed the benefits related to autonomy and flexibility to easily choose the time to work for employees but such benefits had not been proven in this study. But moreover, it brings very different results, the main reason is due to the reaction of each individual when experiencing a bad digital product and fear about the issue of identity defence and due to concern that the staff managers. Technology software can authorize the identity of employees to do other things. However, Nidhi S. Bisht and his colleagues (2021) still showed a positive reaction to the application of digital.

However, in Vietnam, especially with the current development of technology, it is almost impossible to find specific domestic research on the digital factor affecting the satisfaction of workers at work. Based on the latest development situation of our country these days and discovering the limitations of the above research articles, our research would fill those research gaps.

Since the workforce is the significant factor affecting performance and the development of the firm, measuring employee satisfaction is the core objective of human resource management. Therefore, it is necessary to verify that their personnel are content with their current jobs. It is the puzzle that must be solved at the outset to improve the efficiency and effectiveness of an employee's performance. Besides, the digital industry is increasingly inherent in the workplace, with the appearance of cutting-edge digital elements and fully automated processes. Through the considerations listed above, we see the need to unveil the aspects affecting job satisfaction in the digital workplace.

According to Hoppock, R. (1935) job satisfaction is an employee's job happiness, as a result of a mix of psychological, physiological, and other elements. Employee job satisfaction is influenced by other environmental elements. Aziri also describes job satisfaction as the emotional experiences when workers believe their jobs enable them to achieve their physical and psychological demands. Job satisfaction with digital tools reflects the overall affective perception of the experience of using such tools. For a business to grow sustainably, employee's satisfaction is a crucial factor. Still, quantifying job satisfaction is a challenging task because of the dynamic variations in the job satisfaction scale from one person to the next. This shift is primarily because employee behaviour is somewhat influenced by several variables such as technological traits, career advancement, employment structure, management style, and proactivity at work.

Digitalization is the process of converting information from analogue to digital form. It includes the use of measuring devices, decoders, computers, and software to convert data from physical form (such as paper, images, audio or video) into digital form. According to Legner et al. (2017), the term "digitalization" has been developed to refer to the numerous sociotechnical phenomena and occurrences that arise with the adoption and use of these technologies in larger settings within the individual, organizational, and societal levels.

In the context of the digitization workplace, Krauss, M. (2020), Cijan et al. (2019), Bolli and Pusterla (2022) are the authors applying the Work Demand-Resources Model (WD-R), Self-Determination Theory (SDT), Technology Acceptance Model (TAM), and Work Characteristic Model (WCM) to shed light on the intricate interrelationships between digital technology, job requirements and resources, employee behaviour and attitudes at work, and psychological needs of employees regarding autonomy, competence, and suitability for successful adoption and ongoing use of digital tools in the workplace. There are different and similar points of view between the articles, which is also the basis for us to refer to and hypothesize for the research paper.

This study then tested these models by EFA, Cronbach Alpha, PLS SEM, after that, gave the results by Bootstrapping method. From the research results, we also proposed solutions to improve employee satisfaction in the digital environment. These solutions may involve polishing up the work environment, training and developing employees' skills, optimizing work processes, and effectively utilizing digital technology. The findings of this study provide valuable information about social factors, professional skills, technological characteristics, the association between tasks and technology, physical conditions, awareness of the usefulness of digital tools, and employee satisfaction. These factors help businesses and organizations to elevate the quality of the work environment and meet the needs of employees in the rapidly evolving digital context, consequently, play a significant role in maintaining and enhancing competitiveness in the labour market.

## **2. THEORETICAL FRAMEWORK**

### **2.1. The theory of Reasoned Action (TRA)**

*The theory of Reasoned Action (TRA)* was created by Ajzen and Fishbein in 1967, and since then, it has been modified and refined further. The theory of reasoned action has been used successfully to predict and explain why people have (or have not) engaged in a wide variety of behaviors including smoking (Chassin et al., 1981; Fishbein, 1980). The primary goal of TRA is to comprehend a person's voluntary conduct by studying the person's concealed desire to carry out an activity. According to theory, an action's intention comes before its execution. Since behavioural intentions are "defined by attitudes towards behaviour and subjective standards", TRA can be used to elucidate the reasoning behind continuing to use digital equipment.

### **2.2. The Technology Acceptance Model (TAM)**

*The Technology Acceptance Model (TAM)* demonstrates how perceived usefulness and usability affect employees' acceptance of and use of digital technology in the workplace. The psychosocial theories of planned behaviour (TPB) and rational action (TRA) are the origins of TAM. TAM has been the focus of numerous study projects examining people's intents, beliefs, and usage of technology. The behavioural intention of the research object is determined by this model's usage of factors indicating ease of use and usefulness, which determine whether to accept or reject its use. For example, recent evidence has found ATCU (Attitude towards computer use) to be a significant predictor of the intention to use technology, especially in settings where the use of technology is voluntary (eg, Chau, 2001; Venkatesh, Morris, Davis & Davis, 2003).

### **2.3. Technology-to-task fit model (TTF)**

*Technology-to-task fit model (TTF)* is built to understand the results of technology investment for employees or users. This model specifies that the information technologies used in organizations must be suitable for the job characteristics, hence, task requirements and technology functions must match. The day-to-day operations of an organization are typically performed by employees (Torkzadeh, G., Koufteros, X., & Doll, W. J. (2005)). For this reason, employees' perception of task and technology fit is of significant value to user productivity, feasibility, and effectiveness (Moore, G. C., & Benbasat, I. 1991).

## **2.4. Self-Determination Theory (SDT)**

*Self-Determination Theory (SDT)* is a psychological theory that focuses on the motivation behind human behaviour. The three suggested fundamental psychological requirements are Autonomy, Competence, and Significance. Fulfilling these three demands consequently can increase intrinsic motivation, which is the drive to do something because of the intrinsic pleasure and fulfilment it brings.

## **2.5. The Work characteristics model (WCM)**

*The Work characteristics model (WCM)* is used in this study because it illustrates the connection between job features and employees' individual experiences in that position. Worker productivity, job satisfaction, energy level, and health are all impacted by this influence. The model is built upon the study conducted by Kwiotkowska, A., & Gębczyńska, M. (2022). The research paper explores different combinations of job characteristics that contribute to job satisfaction within the framework of Industry 4.0. Specifically, it focuses on small and medium-sized businesses that have implemented Industry 4.0 solutions.

### **2.5.1. Task Characteristics (TC)**

*Task Characteristics (TC)* is a theory in the field of management and work psychology, developed by psychologists Richard Hackman and Greg Oldham in 1976. According to this theory, five main characteristics affecting employee satisfaction and performance: Job Autonomy; Skill Variety; Significance; Task Identity; and Feedback from Job.

### **2.5.2. Contextual Characteristics (CC)**

*Contextual Characteristics (CC)* were proposed by American psychologist - Richard Snow in 1989 to explain how the surrounding environment affects human behaviour. including three elements: Physical Demands, reflecting the level of physical activity or physical exertion required on the job; Work Conditions, reflecting the environment in which a job is performed; and Equipment Use, reflecting the variety and complexity of tools used in a job.

### **2.5.3. Social characteristics (SC)**

*Social characteristics (SC)* include four scales related to the opportunities that work offers for social interaction with others. These scales include Social Support, Interdependence, Interaction Outside The Organization, and Feedback From Others.

### **2.5.4. Knowledge Characteristics (KC)**

*Knowledge Characteristics (KC)* reflect the types of knowledge, skills and ability requirements placed on an individual being assessed on the job, including 5 elements: Complexity Of Work, Information Processing, Problem-Solving, Skill Variety, and Specialization.

Integrating these models can help study the interaction between the factors affecting the behaviour of using technology in the work environment. Particularly, work characteristics can affect the sense of autonomy and users' effort, which in turn influences their attitudes towards technology. Users may be more willing to embrace and employ technology if they believe it is simple to use and essential to their work. Moreover, these elements may also influence users' motivation, making it simpler for them to use the technology. Depending on the particular work environment, these elements may interact and affect user behaviour in a variety of ways.

Broadly speaking, the merging of TRA, WCM, SDT and TAM models is the provision of an in-depth approach to research technology usage behaviour in the workplace.

### **3. RESEARCH METHOD**

The study is mainly focused on workers who have been or are working in a digital workplace in the Ho Chi Minh City, including those aged from 18 to over 51 years old.

#### **3.1. Statistical Methods**

##### **3.1.1. Qualitative research methods**

In this research, the questionnaire was made to explore employee satisfaction in the digital context. The survey-based data could provide initial information and support for quantitative research, thereby clarifying and explaining the causes of the results. quantitative research.

##### **3.1.2. Quantitative research methods**

The purpose of quantitative research is to measure and test the relationship between variables in statistical form. Following data collection, descriptive statistics on age, gender, and experience with exposure to the digital environment will be used to analyze the data and make inferences about the overall assessment.

To examine the data, the study employs a variety of models. Successively, Cronbach's alpha is used to analyse and use the EFA exploratory factor to evaluate the data and finally determine the weights by the PLS-SEM model. After that, those results are combined with the background theories to evaluate workers' job satisfaction.

#### **3.2. Overall study sample and questionnaire**

The sample size for the research was determined based on the factor analysis method guidelines. For this study, the authors determined the sample size to be 447, which exceeds the minimum requirement of 71 observed variables multiplied by 5, as suggested by Bollen.

The data collection method employed in this study involved the administration of a questionnaire survey with a specific focus on HCMC. Given the sample size of 447, the research team devised a questionnaire and distributed it to potential participants from our network. The distribution was conducted through various channels, including email, social networking platforms, and messaging.

#### **3.3. Evaluate the reliability of the scale**

In the quantitative study, the research team used Cronbach's Alpha test method before analyzing the EFA exploratory factor to eliminate inappropriate observed variables in the same factor.

Cronbach's Alpha helps to check whether the observed variables of a factor (in which, there are at least 3 observed variables) are reliable or not. It shows which observed variables of the factor contribute to the conceptual measure of the factor.

#### **3.4. Exploratory Factor Analysis (EFA)**

The model consists of six steps according to Hoang Trong and Chu Mong Ngoc (2010): defining the problem, building the correlation matrix, calculating the number of factors, rotating the factors, naming and explaining factors, and finally factor calculations.

Before performing this analysis, we need to test the conditions for performing EFA. Usually, studies using KMO coefficients (Kaiser-Meyer-Olkin) and Bartlett can be accepted if KMO coefficients is in the range from 0.5 to 1, and the significance level of Bartlett test is less than 0.05.

#### **3.5. Structural Equation Modeling (SEM)**

The research team used PLS-SEM due to the complex nature of the model. After building the path model, evaluate the reliability of the scale by the normalized load factor (greater than 0.7, the observed variable is significant in the model) and the scale convergence value by AVE (greater than 0.7, the observed variable is significant in the model) mean extracted variance. Hair et al (2021) said that the value of AVE reaching from 0.5

or more shows that the scale has good convergence. After testing the measurement model, conducting structural testing including evaluating multicollinearity between observations to ensure the coefficient of the path between observations and conducting bootstrapping to check the significance of the coefficient.

**4. RESULTS AND DISCUSSION**

**4.1. Results**

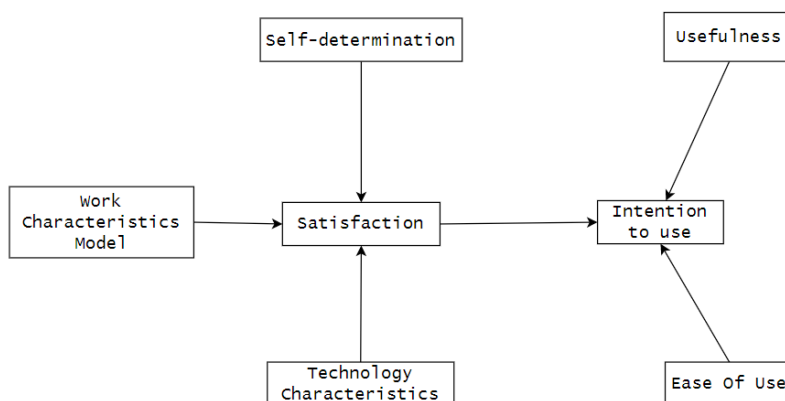

After 3 months, our research team received 479 responses, removed the non-quality samples, we kept 448 observations for research purposes. Using descriptive statistics for demographic variables, our research team presented the following pie chart and a brief model overview of the study below:

**Figure 1. Respondent Profile.**

Source: Research team

**Figure 2. Research Model**

Source: Research team

**4.1.1. Evaluate the reliability of the scale**

To analyze the reliability of the scales of the variables in the study, tests using Cronbach’s Alpha coefficients to remove unreliable observed variables before conducting factor analysis.

**Table 1. Cronbach’s Alpha coefficients.**

Variable	Cronbach’s-Alpha Coefficients	Variable	Cronbach’s-Alpha Coefficients
US	0.8336	SS	0.8184
SQ	0.8414	IN	0.8267
PTS	0.8787	FO	0.8618
JA	0.8384	CO	0.8183
SV	0.8090	IPS	0.8805
TS	0.8222	SP	0.9188
FJ	0.9567	SD	0.8860
PD	0.8132	UF	0.7703
WC	0.8998	BI	0.7725
EU	0.7836	SAT	0.8835

The results showed that the Cronbach alpha indexes are suitable and consistent to the next calculation steps.

**4.1.2. EFA Analysis Results**

The research team produced the results of running a number of criteria of the EFA analysis and the results from the Stata software including the Principal Components Analysis (PCA) test, eigenvalue, varimax rotation (added in the appendix), and the test. KMO determination and results of observed variables classified into 17 factors after data adjustment.

The eigenvalue test shows that there are 17 factors created (due to the threshold Eigenvalues > 1).

The results of the matrix rotation show that the independent variable is classified into 17 factors, all the observed variables have loading coefficients greater than 0.6 and there are no unusable bad variables.

After adjusting, removing outliers and deleting variables that do not fit the model, the remaining observation data is 447 suitable observations. After that, the research team performed Cronbach’s Alpha test and KMO test again, the authors have the result from Stata software equal to 0.532 (greater than 0.5) and conclude that Factor Analysis is consistent with the research data set.

Thus, the EFA exploratory factor analysis for the independent variables was performed within two-times. In the first time, 65 observed variables were included in the analysis, 32 observations in the data set that did not meet the conditions were removed for re-analysis. In the second (last) analysis, 65 observed variables converged and differentiated into 17 factors.

**Table 2. Goodness of fit test.**

	R-square adjusted		R-square adjusted
BI	0.539	TC	0.525
CC	0.688	TTF	0.678
KC	0.679	UF	0.767
SAT	0.690	US	0.614
SC	0.757		

This table 3 shows that R-squared adjusted of BI is 0.54, so the independent variables explain 54% of the variation (variance) of the BI variable, the remaining 46% is from systematic error and from other

factors outside the model. image.

The R-squared adjusted of SAT is 0.691, so the independent variables explained 69.1% of the variation (variance) of the SAT variable, the remaining 30.9% was from systematic error and from other factors outside the model.

In addition, the R-squared adjusted of CC, KC, SC, UF, TTF and US all reach approximately 0.7 and TC is greater than 0.5, so the independent variables included in the model can all explain these variables.

4.1.3. Path Coefficients

Table 3. Path Coefficients.

	Original sample (O)	Sample mean (M)	Standard deviation (STDEV)	T statistics ( O/STDEV )	P values
CC -> SAT	-0.043	0.000	0.065	0.000	0.000
KC -> SAT	0.151	0.182	0.055	3.330	0.001
SAT -> BI	0.210	0.213	0.052	4.025	0.000
SC -> SAT	0.167	0.090	0.095	0.962	0.000
SD -> SAT	0.081	0.105	0.064	1.574	0.000
TC -> SAT	0.114	0.108	0.046	2.394	0.000
TC -> TTF	0.373	0.381	0.051	7.301	0.000
TTF -> SAT	0.106	0.091	0.078	1.220	0.025
UF -> BI	0.426	0.430	0.056	7.626	0.000
US -> BI	0.106	0.124	0.070	1.522	0.128
US -> TTF	0.482	0.475	0.047	10.280	0.000

Considering p-value, we see the impact from Contextual Characteristics (CC) on satisfaction (SAT) < 0.05. Similarly, there are impacts from social characteristics (SC) to satisfaction (SAT), self-determination (SD) to satisfaction (SAT), and knowledge characteristics (KC) to satisfaction (SAT). SAT), task and technology fit model (TTF) to satisfaction (SAT) all have similar results < 0.05. This shows that these effects are statistically significant.

The experimental results are shown in the following figure 2:

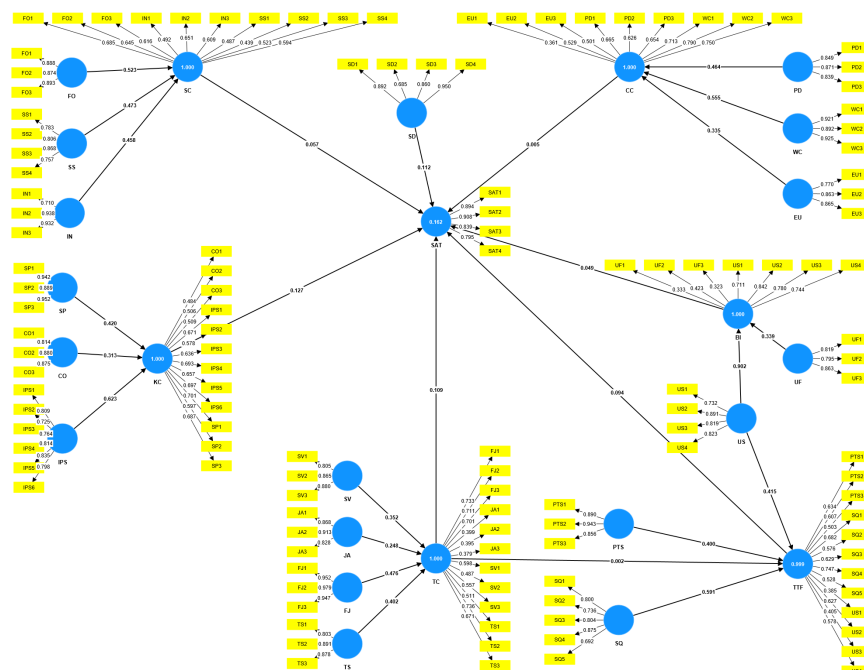

Figure 3. Research Model

Considering  $p\_value$ , we see that most of the path coefficients have  $p\_value = 0.000$ , which proves that the variables included in the model have an impact on the dependent variable, except that the impact of US on BI is not statistically significant (rejected due to  $p\_value = 0.128 > 5\%$ ).

#### **4.2. Discussion**

From the results of the above study, our team analyzed and made comments on the factors affecting the success of the digital environment in improving work performance and employee satisfaction at the workplace.

Among those factors, SC is considered by the research team to be the factor affecting employee satisfaction at work.

KC was also identified as one of the factors that strongly influenced the satisfaction of employees.

In addition, other factors such as technological characteristics, TTF also affect the success of the digital environment.

CC have a negative effect on job satisfaction, which is in stark contrast to the original hypothesis as well as the expected results that the research team wants.

Given the last point, while Kwiotkowska (2021) focused on how high or low satisfaction of the employees is based on WCM, this research can measure the negative and positive impacts on satisfaction, coupled with evaluating the continue-to-use behaviour.

Besides, the perceived usefulness of digital tools, along with employee satisfaction, will affect the intention to continue using digital tools at work.

The TAM theory applied to the model has not yet produced clear results, the research team concluded that determining the role of employees' perception of ease of use in the types of digitalization in work has not yet affected the intention to continue using digital forms to improve the quality of work output.

#### **5. CONCLUSION**

Our team had researched and given some useful recommendations to help managers and business managers in general based on our study results to increase employee satisfaction and motivation and build a positive digital workplace: Improve safety in the work environment; Focus on employee development; Improve service quality; Create a dynamic and attractive working environment.

From the results of the above study, our team analyzed and made comments on the factors affecting the success of the digital environment in improving work performance and employee satisfaction at the workplace. Among those factors, SC is considered by the research team to be the factor affecting employee satisfaction at work. KC is also identified as one of the factors that strongly influenced the satisfaction of employees.

In addition, other factors such as technological characteristics, TTF also affect the success of the digital environment. CC have a negative effect on job satisfaction, which is in stark contrast to the original hypothesis as well as the expected results that the research team wants. Besides, the perceived usefulness of digital tools, along with employee satisfaction, will affect the intention to continue using digital tools at work. The TAM theory applied to the model has not yet produced clear results, the research team concluded that determining the role of employees' perception of ease of use in the types of digitalization in work has not yet affected the intention to continue using digital forms to improve the quality of work output.

Due to the complexity and wide scope of research, the research team cannot avoid limitations and difficulties in the research process. The model cannot be generalized to the population: This may make the study results not generalizable to the entire population or region. The study may be limited in time

so sufficient data cannot be collected to answer the research question. Survey time-consuming: The questionnaire can cause difficulties and consume more time compared to other survey sets, so the data results may inevitably be wrong when the surveyor takes the survey and must read and think to answer the survey question.

False hypotheses: Research may be affected by incorrect assumptions or unreasonable theories that reduce the reliability of the research results.

## **FACTORS AFFECTING THE COMMITMENT OF WORKERS TO GRASSROOTS TRADE UNION IN VIETNAM IN THE CONTEXT OF IMPLEMENTING NEW – GENERATION FREE TRADE AGREEMENT: A CASE STUDY OF GARMENT ENTERPRISES**

**Author: Bui Phuong Thao<sup>1</sup>, Duong Thu Ngan<sup>2</sup>, Nguyen Ngoc Van<sup>2</sup>**

**Mentor: Nguyen Thi Minh Nhan<sup>2</sup>**

*ABSTRACT: Choosing to study the commitment of workers to grassroots trade union in Vietnam in the context of implementing new-generation Free Trade Agreements: A case study of garment enterprises is necessary to clarify factors affecting the workers' commitment to the grassroots trade union. The study was conducted to evaluate the effect of five factors on the commitment of workers to grassroots trade union at Vietnamese garment enterprises: Protecting the benefits of workers; Communicating about the organization; Representing workers; Participating in management; and Developing welfare. The model is tested with a survey dataset of 221 union officials and workers from Vietnamese garment enterprises. From the research results, recommendations are made to promote the commitment of workers to grassroots trade union in the new context.*

*Keywords: Commitment; Workers; Grassroots Trade Union; Garment enterprise*

### **1. INTRODUCTION**

Trade unions have appeared in Western society since the early 18th century, with the role of a representative organization to protect the legitimate rights and benefits of workers around the world. In Trade Unionism (Sidney and Beatrice Webb's History, 1984), a union is referred to as "an association of wage earners whose purpose is to maintain or improve conditions hire them". At present, at enterprises, trade union organizations struggle and negotiate with employers to protect the rights and benefits of workers, share rights and responsibilities, and settle labor disputes, ... thereby contributing to promoting cooperation and correcting the behavior of stakeholders, thereby promoting healthy industrial relations. Thus, trade union organizations play an increasingly important role in building and developing harmonious and stable labor relations at all levels, especially at the grassroots level (Diep Thanh Nguyen, 2005). In Vietnam, trade unions play an important role in almost all political, economic, cultural, and social fields. Trade union organizations perform many functions and tasks, including the task of representing workers. From there, they help ensure the rights and balance the legitimate benefits between employees and workers, contributing to the harmony of labor relations and stability in production and business activities.

The garment industry is one of the key export industries of Vietnam, playing an important role in the economic growth of the country. Up to now, the textile and garment industry has accounted for 12 - 16% of the total export turnover of the country, specifically according to the announcement of the WTO (2021) export value reached 142 billion USD. In recent years, globalization and international integration have deepened, resulting in firstly, Vietnam's exports have grown rapidly associated with free trade agreements (FTAs), especially the Garment industry; second, Vietnam must ratify international commitments, including the 1998 Declaration of the International Labor Organization (ILO) with Convention 87 - Freedom of association and protection of the right to organise convention. As a result, new non-traditional employee representative organizations will appear and create competition with traditional Vietnamese trade unions in

<sup>1</sup> Thuongmai University, Email: buiphuongthao.tha@gmail.com

<sup>2</sup> Thuongmai University.

attracting, gathering, developing union members, and sharing financial resources. Trade unions and workers' organizations of the new type will have different characteristics and operational purposes. In addition, the historical development factor also makes the grassroots trade union and the new type of worker's representative organization different in terms of organizational system and establishment conditions (Nguyen Thi Hong Nhung, 2019). In that context, it poses new challenges for traditional Vietnamese trade union organizations, that is, they must be ready to drastically change the organizational and operational model, and improve their capacity to bring practical benefits to the workers. Thereby, improving the ability to retain and attract workers to stick with the trade union for a long time. In this study, the research team will conduct a more in-depth study on the topic "Factors affecting the commitment of workers to grassroots trade unions in Vietnam in the new context: A Garment Business Case Study. From there, it is the basis for proposing solutions to promote the commitment of workers to grassroots trade unions at Vietnamese garment enterprises.

This study was conducted to identify and evaluate the impact of factors affecting the workers' commitment to the grassroots trade union in Vietnamese garment enterprises. Thereby proposing solutions and recommendations to help promote the commitment of workers to grassroots trade unions in the context of Vietnam's implementation of free trade agreements. The research consists of 5 main contents as follows: (i) Theoretical framework: The research team focuses on building the theoretical basis for the commitment of employees to the organization and the theoretical basis for the trade union; (ii) Research method: To study the factors affecting the workers' commitment to the grassroots trade union at Vietnamese garment enterprises, the research team used a combination of qualitative method and quantitative method; (iii) Research results and discussion: After descriptive statistics of the research sample, scale reliability analysis, exploratory factor analysis EFA, Pearson correlation, and multiple linear regression, regression equation criteria are given and the impact of the independent variables on the dependent variable is evaluated; (iv) Conclusions: From the research results, the group proposes 5 groups of recommendations to improve the commitment of workers to the grassroots trade union.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Theory of the commitment of employee to the organization**

#### **2.1.1. The concept of employee commitment to the organization**

In 1974, the research by Porter et al. suggested that employee commitment to the organization is a strong belief in and acceptance of the organization's goals, a willingness to do one's best for the organization, and a desire to remain a member of the organization.

According to Meyer & Allen (1997), employee commitment to the organization is to stay with the organization, participate in regular work, make efforts to work every day, protect the organization's assets and believe in the organization's goals.

Through the research by Robinson et al. (2004), organizational commitment is an employee's positive attitude towards the organization and its values. Engaged employees will be aware of the business situation and coordinate with colleagues to improve work performance for the benefit of the organization. Organizations must work to develop and maintain commitment which requires a two-way relationship between employer and employee.

According to Cohen (2007), organizational commitment is the employee's loyalty to the organization, the willingness to give their best efforts for the organization's goals and values, and the desire to remain a member of the organization.

For Macey & Schneider (2008), the employee’s commitment with the organization is the willingness to work actively for the organization, feel proud to be a member of the organization and have a strong attachment to the organization.

Macey et al. (2009) pointed out that employee commitment to the organization is very important because employee commitment is related to individual success and organizational effectiveness office. Employee commitment in the organization helps to predict employee performance, organizational success, and financial performance.

Through the research with different views on “Employee engagement with the organization”, in this study, the research team determined: *Employee commitment to the organization is a reflection of the level of long-term commitment, active participation and pride in the organization, as well as willingness to introduce others to join the organization.*

### 2.1.2. Forms of employee commitment to the organization

According to O’Reilly & Chatman (1986), employee commitment to the organization is measured by Compliance: attraction because of special rewards; Identification: commitment because of the desire to integrate with the organization; Internalization: attraction due to the appropriateness, the similarity between the individual’s values and the value of the organization.

Figure 2.1: Forms of employee commitment to the organization according to O’reilly & Chatman (1986)

Source: O’reilly & Chatman (1986)

In a study by Meyer & Allen (1991), three components of organizational commitment were proposed: Affective commitment: refers to emotional attachment, close engagement, and concentration of mind in the employee’s organization; Continuance commitment: engagement because the employee perceives the high cost (opportunity cost) of leaving the organization; Normative commitment: reflects commitment based on the employee’s obligations to the organization. The model of Meyer and Allen (1991) has been accepted and used a lot in current studies.

Figure 2.2: Forms of employee commitment to the organization according to Meyer and Allen (1991)

Source: Meyer and Allen (1991)

Jaros et al (2005) have the following scales: Affective is the degree to which an individual is psychologically attached to the organization through feelings such as loyalty, feeling fond of the organization, heat love for the organization, satisfaction and feeling of belonging to the organization; Continuance is the degree to which individuals feel committed to the organization because they have to lose so much if they leave the organization; Moral is the degree to which an individual is psychologically attached to an organization through assimilation of the organization's goals, values, and mission.

**Figure 2.2: Forms of employee commitment with the organization according Jaros et al (2005)**

Source Jaros et al (2005)

## 2.2. Theory of Trade Union Organization

In Article 1 of the Trade Union Law 2012 and the 2013 Constitution, the concept of trade unions is as follows: “Vietnam’s trade unions are socio-political organizations of the working class and workers established on a voluntary basis, representing workers, taking care of and protecting the legitimate and legitimate rights and benefits of workers; participating in state management, socio-economic management; participating in inspecting, supervising the activities of state agencies, organizations, units and enterprises on issues related to the rights and obligations of workers; propagating and mobilizing workers to learn, improve their qualifications and professional skills, comply with the law, build and protect the country”.

The Human Resources Law 2003 of Indonesia stipulates: “The trade union is an organization formed by the employees, by the employees and for the employees within the enterprise itself or outside an enterprise and is an a free, open, independent, democratic organization responsible for fighting, protecting and protecting the rights and benefits of workers, and at the same time promoting the improvement of the welfare of workers and their families”.

According to Ho Chi Minh’s point of view: “The trade union organization is first of all for workers to get along with each other for sympathy, secondly to study together, thirdly to correct the way workers live, fourthly to preserve the rights of workers and the last is to help the nation and the world”.

David Macdonald & Caroline Vandenabeele (1996) defined unions as follows: “An association of workers united to protect and promote their common benefits”.

Thus, trade unions are socio-political organizations, the largest mass organization of the working class and the working people. *Trade unions appear when workers are aware of their collective strength and know how to take care of their own interests. The development of trade unions is associated with the growth of the working class, with the development of industry, industry and the association of employers.*

**3. RESEARCH METHOD**

**3.1. Research method**

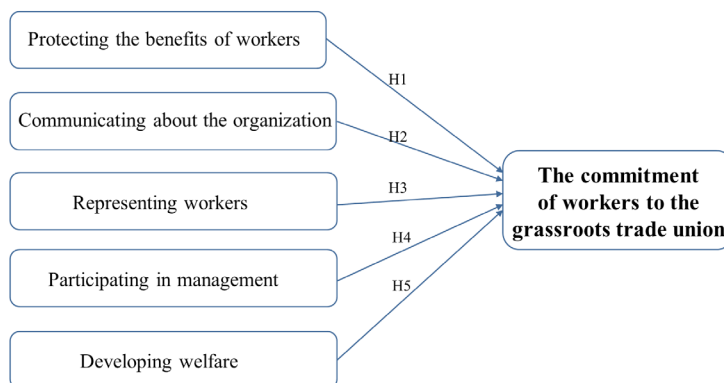

To study the factors affecting the worker’s commitment to the grassroots trade union organization in Vietnam’s Textile and Garment enterprises, the research team used a combination of qualitative research method and quantitative research method.

*For qualitative research method:* The research team used an in-depth interview method and conducted interviews with 9 individuals who are trade union officials and workers in Vietnam Textile and Garment enterprises. In order to collect opinions of interviewees about the proposed questionnaire with scales to adjust/add to suit the research context, thereby forming the official survey questionnaire. Interviewees were carefully selected to ensure representativeness according to specific criteria, including gender, number of years of experience, working position, education level,...

*For quantitative research method:* About data collection method, the study uses document research method through articles summarizing Garment Trade Union activities and Garment industry reports; monographs and specialized national and international journals to collect secondary data on the theoretical and practical basis of the research model of factors affecting commitment of workers to trade unions at Vietnamese garment enterprises. In addition, the research team used the sociological survey method using questionnaires to collect primary data on the factors affecting the worker’s commitment to the grassroots trade union. After the survey, the answer sheets are cleaned and analyzed using SPSS 26 software to create data for analysis, testing, and evaluation by appropriate techniques. There are Descriptive statistical analysis techniques; Techniques to verify the reliability of the scale; EFA analysis techniques; Correlation analysis techniques; Regression analysis techniques.

**3.2. Research model**

After researching and generalizing the theoretical basis and models from domestic and foreign studies on related topics, the research team proposed to develop a research model of factors affecting commitment of employees to grassroots trade unions in garment enterprises in Vietnam based on the inheritance and development from previous studies, especially from the study of Meyer and Allen (1991); Yasmin (2011). Therefore, the factors affecting the workers’ commitment to the grassroots trade union in garment enterprises in Vietnam will also reflect the core functions and tasks of the grassroots trade union. It is the function of protecting the benefits of workers; the function of representing workers; educational, advocacy, and propaganda function; regulatory function; management function (Immanuel Ness, 1998; Johanson and Partanen, 2002; Nguyen Hong Nhung, 2019; Nguyen Thi Diem, 2019; Bui Huu Duc and Le Thi Tu Anh, 2022; Edwing, 2005).

**Figure 3: Proposed research model**

*(Source: Compiled by the research team)*

Hypothesis of the research model:

- Hypothesis 1 (H1): Performing the function of protecting the benefits of workers has a positive effect on the commitment of workers to the grassroots trade union in garment enterprises in Vietnam.
- Hypothesis 2 (H2): Performing the function of communicating about the organization has a positive effect on the commitment of workers to grassroots trade union in garment enterprises in Vietnam.
- Hypothesis 3 (H3): Performing the function of representing workers has a positive effect on the commitment of workers to grassroots trade union in garment enterprises in Vietnam.
- Hypothesis 4 (H4): Performing the function of participating in management has a positive effect on the commitment of workers to the grassroots trade union in garment enterprises in Vietnam.
- Hypothesis 5 (H5): Performing the function of developing welfare has a positive effect on the commitment of workers to the grassroots trade union in garment enterprises in Vietnam.

## 4. RESULTS AND DISCUSSION

### 4.1. Results

#### 4.1.1. Descriptive Statistics

The research team sent survey questionnaires through Internet and social networks such as Zalo, Facebook, Email,... from 25/12/2022 to 05/02/2023. The number of votes collected was 257 votes and after screening the answer sheets, 23 invalid votes were left, and the remaining 221 valid votes (78,9%) were used for data processing.

**Table 1: Descriptive statistics of the survey sample**

	Valid	Frequency	Percentage
Age	18 - 23	86	38,9%
	23 - 35	72	32,5%
	35 - 45	60	27,3%
	Over 45	2	1,3%
Total		221	100%
Sex	Male	59	27,1%
	Female	162	72,9%
Total		221	100%
Job position	Worker	160	72,6%
	Trade union official	61	27,4%
Total		221	100%
Enterprise size	Large	128	57,9%
	Small and medium	92	42,1%
Total		221	100%
Belonging to the province	Ha Noi	103	46,5%
	Vinh Phuc	38	17,3%
	Other provinces	80	36,2%
Total		221	100%

#### 4.1.2. Cronbach's Alpha Test

The scale of independent variables: “Protecting the benefits of workers”, “Communicating about the organization”, “Representing workers”, “Participating in management”, and “Developing welfare”, systematically Cronbach's Alpha numbers are respectively: 0,914; 0,942; 0,826; 0,836; 0,726 > 0,6, this

ensures high reliability. However, the lowest corrected item-total correlation is 2 correlation coefficients of the sum of the variables RW4 (0,059) and DW6 (0,049)  $< 0,3$ , so we remove the observed variables RW4 and DW6 to retest the reliability of the scale for the second time. The reliability of the second scale shows that the variable scales “Representing workers” and “Developing welfare” have Cronbach’s Alpha coefficient of 0,894;  $0,834 > 0,6$  have high reliability, the lowest total variable correlation coefficient is higher than 0,3. Therefore, all variables are used for EFA exploratory factor analysis.

The dependent variable scale “The commitment of workers to the grassroots trade union”, with Cronbach’s Alpha coefficient =  $0,924 > 0,6$  ensures high reliability. The lowest corrected item-total correlation coefficient of 0,792 was higher than 0,3, showing that all observed variables were used for EFA exploratory factor analysis.

**4.1.3. The Exploratory Factor Analysis (EFA)**

When analyzing EFA for independent variable factors, the results show that the coefficient KMO =  $0,85 > 0,5$ ; The sig significance level of Bartlett’s test =  $0,000 < 0,05$  satisfies the condition, so it can be said that the observed variables are correlated with each other. These indexes satisfy the conditions for the exploratory factor analysis model. There are 5 factors extracted based on eigenvalue  $> 1$ , so these 5 factors summarize the information of 26 observed variables based on EFA in the best way. The total variance that these 5 factors extracted is  $71,035\% > 50\%$ . Thus, the 5 factors extracted explain 71,035% of the data variation of 26 observed variables participating in EFA. Analyzing EFA for the COM variable, the results obtained EFA are also consistent with the data because the total variance extracted is  $81,392 (>50\%)$ , KMO =  $0,671 (>0,5)$  and Bartlett’s test is statistically significant ( $\text{sig} = 0,000 < 0,05$ ). So the scale is still used for the next analysis.

Considering the Pattern Matrix component matrix table, it can be seen that the factor loading of the observed variables is greater than 0,5, so it is standard and there are no bad variables.

**Table 2: Rotated Component Matrix**

	Component

#### 4.1.4. Correlation Analysis

Based on the results of Pearson correlation, the research team found that the independent variables have a linear correlation with the dependent variable because the Pearson correlation coefficient of the dependent variables for the independent variable are greater than 0,4. As for the correlation of the independent variables, the variables are correlated with each other but not too strong, so it can be considered as a temporary study without multicollinearity between the dependent variables.

**Table 3: Correlations**

		COM	PB	CO	RW	PM	DW
COM	Pearson Correlation	1	0,591**	0,555**	0,478**	0,491**	0,377**
	Sig. (2-tailed)		0,000	0,000	0,000	0,003	0,000

	Sig. (2-tailed)	0,000	0,000	0,000	0,000	0,000	
	N	221	221	221	221	221	221

Source: Analytical result from SPSS 26

#### 4.1.5. Regression analysis

Analyzing linear regression obtained Linear regression analysis obtained Adjusted R Square = 0,400 shows that the independent variables included in the regression analysis affect 53% of the variation of the dependent variable, the remaining 46,8% due to out-of-model variables and random error; the value of DW = 2,013 ranges from 1,5 to 2,5, so the results do not violate the assumption of first-order series autocorrelation (Yahua Qiao, 2011); sig value is less than 0,05. Therefore, the regression model is suitable.

The variables all have sig value < 0,05. Therefore, these variables are all statistically significant and all affect the dependent variable. Regression coefficients of these independent variables are all positive, so the independent variables have a positive effect on the dependent variable.

**Table 4: Coefficients**

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		B	Std. Error	Beta			Tolerance	VIF
1	(Constant)	1,026	0,241		4,254	0,000		
	RW	0,409	0,070	0,419	5,880	0,000	0,596	1,079
	PB	0,162	0,052	0,190	3,093	0,000	0,799	1,252
	CO	0,161	0,059	0,184	2,706	0,000	0,653	1,531
	PM	0,064	0,053	0,093	1,203	0,001	0,505	1,679
	DW	0,066	0,072	0,079	0,919	0,002	0,407	1,758

Source: Analytical result from SPSS 26

Variables including RW, PB, CO, PM, and DW have test sig < 0,05. Therefore, these variables are all statistically significant and affect the dependent variable COM. The regression coefficients of these independent variables are positive, so the independent variables have a positive effect on the dependent variable.

Standardized regression equation:

$$COM = 0,419RW + 0,190PB + 0,184CO + 0,093PM + 0,079DW$$

Based on the magnitude of the standardized regression coefficient Beta, the order of magnitude of impact from the strongest to the weakest of the independent variables on the dependent variable COM is **RW (0,419) > PB (0,190) > CO (0,184) > PM (0,093) > DW (0,079)**.

**4.2. Discussion**

This research has built and verified a research model that identifies factors that positively affect the “The commitment of workers to the grassroots trade union” according to the decreasing level of impact, including: “Representing workers” has the strongest impact (0,419); “Protecting the benefits of workers” (0,190); “Communicating about the organization” (0,184); “Participating in management” (0,093); “Developing of welfare” (0,079).

**Table 5: Hypothesis testing results**

	Hypothesis	Standardized coefficients	Result
H3	Performing the function of representing workers has a positive effect on the commitment of workers to grassroots trade union in garment enterprises in Vietnam	0,419	Accepted
H1	Performing the function of protecting the benefits of workers has a positive effect on the commitment of workers to the grassroots trade union in garment enterprises in Vietnam	0,190	Accepted
H2	Performing the function of communicating about the organization has a positive effect on the commitment of workers to grassroots trade union in garment enterprises in Vietnam.	0,184	Accepted
H4	Performing the function of participating in management has a positive effect on the commitment of workers to the grassroots trade union in garment enterprises in Vietnam	0,093	Accepted
H5	Performing the function of developing welfare has a positive effect on the commitment of workers to the grassroots trade union in garment enterprises in Vietnam	0,079	Accepted

Source: Synthesis of the research team

For workers in Vietnamese garment enterprises, the factor “Representing workers” has an important meaning for their commitment to the grassroots trade union. This is appropriate because the main characteristics of laborers in the Textile - Garment industry are having a young age, low level of education. Therefore, they need to have a strong grassroots trade union to represent and protect their legitimate rights and benefits. However, according to the statistics of the Vietnam Confederation of Labor (in 2021), the number of strikes and collective work stoppages at garment enterprises in Vietnam always accounts for approximately 40% of the total number of strikes in the country. In which, most of the strikes are illegal, without the participation of the trade union. And most trade union organizations, especially the grassroots trade union, only know about the strike after workers did. Therefore, strikes and collective work stoppages are spontaneous and most do not follow the legal order, without the involvement of leaders of grassroots trade unions. In addition, up to 41% of enterprises assessed did not comply with collective bargaining (Better Word 10th Report). In summary, the grassroots trade union has shown a lackluster role in representing workers to protect the rights and benefits of workers when they are infringed. Therefore, trade unions need to make more efforts to affirm their role of representing workers and being solid support for workers.

The factor “Protecting the benefits of workers” has the second strongest impact on the commitment of workers to the grassroots trade union organization. Workers expect that grassroots trade unions will actively dialogue with employers to protect their legitimate benefits, in order to provide a safe and healthy working environment and conditions for workers. However, according to the survey results of over 1,000 garment workers aged 25-35 at 3 enterprises in Binh Duong, Ho Chi Minh City and Dong Nai, up to 93% of workers are tired after work, 47% body fatigue; 16,7% severe headache; 15,1% burnout; more than 80% of muscle and joint pain in the waist, neck and shoulder area (Phuong Ha, 2012; Ngoc Tu, 2015)... Occupational diseases in the garment industry are mainly cotton dust disease, varicose veins of the legs. Besides these diseases, the rate of garment workers suffering from sinusitis, allergic rhinitis, asthma, occupational chronic bronchitis, dermatitis, hearing loss, occupational deafness... is also very high. Circular No. 07/2016/TT - BLDTBXH of the Ministry of Labor – War Invalids and Social Affairs classifies the textile and garment industry in the group of industries with high risk of occupational accidents and diseases. Therefore, the Vietnam General Confederation of Labor should be more active in directing trade unions at all levels, especially grassroots trade unions, to make greater efforts in participating in the development of policies to ensure safety and hygiene labor protection at enterprises and supervise the strict implementation in order to provide a better and safer working environment for workers at factories.

The workers found that the grassroots trade union had done a good job of communicating and promoting the union’s image and activities to them. In addition, the grassroots trade union also actively propagates the labor law, quickly disseminates new regulations (the Trade Union Law, the Labor Law, the enterprise’s policies, the collective labor agreement,...) to workers, helping them understand better their legal rights and benefits. The forms of communication carried out by the grassroots trade union are very diverse, such as organizing contests: “Textile Kitchen”, “Law and Life”, “Our Roof - Trade Union” Vietnam Textile and Garment”, “To the woman I love”,... have brought about extremely positive effects and created useful playgrounds, thereby creating a source of creativity and inspiration for workers to love life and their jobs more. At that time, workers can understand better the organization, see the benefits of participating, they are more willing to increase their commitment to the grassroots trade union.

The fourth factor is the “Participating in management” factor. This factor contributes a significant part to the commitment of workers to the grassroots trade union in garment enterprises in Vietnam. This reflects the close benefits of grassroots trade union in monitoring the implementation of legal policies

and collective bargaining agreements at enterprises, which has a strong influence on the commitment of workers to grassroots trade union. However, there is still a situation where many factories continue to fail to comply with the provisions on consultation with the union and the collective bargaining agreement approval process, not share information about the collective bargaining agreement with workers, and fail to fully implement terms of the agreement in BWV's 10th reporting period. Therefore, the participation in management of the grassroots trade union will make an important contribution to ensure the legitimate rights and benefits of workers.

Finally, the factor "Developing welfare" has the weakest impact on the commitment of workers to the grassroots trade union in garment enterprises in Vietnam. With a coefficient of 0,079, workers pay little attention to the welfare development that the grassroots trade union deploys. In recent years, the grassroots trade union has been promoting the care for the material and spiritual life of workers and their family with practical, meaningful activities in many flexible forms such as: Tet reunion; Union shelters; Trade union Tet market; Train tickets back home to celebrate Tet,... Grassroots trade unions at Vietnamese garment enterprises have visited, given gifts and encouraged 4385 workers in difficult circumstances; constructed and repaired more than 10 trade union shelters, equipped facilities, ... with a total amount of up to 3,43 billion dong and many cultural, artistic and sports activities attract a large number of workers to participate;... (Vietnam General Confederation of Labor, 2022). However, due to limited financial resources, the welfare development of trade unions, especially grassroots trade union at garment enterprises, has not yet been able to reach the majority of workers.

#### **4.3. Recommendations**

Currently, when Vietnam implements the commitment to Convention No. 87 on freedom of association and on the protection of the right to organize convention in 1998 of ILO, Vietnam General Confederation of Labor and the grassroots trade union in the garment enterprises will have to face a lot of new difficulties and challenges to compete with the new workers' representative organizations that will be born. The grassroots trade union should be ready to objectively view and evaluate the current and future practical situation. From there, overcome challenges and seize opportunities to innovate and strongly improve from models to activities, improving the operational capacity of the organization. Combining research results with practicality, the research team found that grassroots trade unions need to continuously improve operational efficiency in association with the function of representing, protecting of rights and benefits for workers. Grassroots trade unions become workers' organizations, by workers and for workers. In addition, it is necessary to improve the communication quality of the grassroots trade union and effectively develop the welfare regime for workers. In order to promote the commitment of workers with grassroots trade union, the research team has proposed 5 groups of specific solutions, including: First, solutions to improve the protection capacity of grassroots trade union for the workers; Second, solutions to improve the communication quality of grassroots trade union; Third, solutions to improve the representative capacity of grassroots trade union; Fourth, solutions to improve the quality of participation in the management of grassroots trade union; Fifth, solutions to improve the effective development of welfare for workers of grassroots trade union.

#### **5. CONCLUSION**

This study focuses on assessing the influence of factors on the commitment of workers to the grassroots trade union in Vietnam in the context of the implementation of new-generation FTAs, leading to the birth of new worker's organization. This new organization of workers will compete with the grassroots trade union.

Thus, the study on the topic of workers' commitment to grassroots trade unions in Vietnam will bring a lot of meaning, especially when the grassroots trade union is no longer the only organization representing Vietnamese workers. Moreover, in Vietnam, there is no empirical research on this topic and it is expected to make valuable contributions to promote the commitment of workers to the grassroots trade union. The topic has reviewed and inherited previous studies on factors affecting employee commitment (Mowday, Steers & Porter, 1979; Meyer and Allen, 1991; Tran Kim Dung and Morris, 2005... ) and core functions of grassroots trade union (Immanuel Ness, 1998; Johanson and Partanen, 2002;...). Thereby proposing a research model of influencing factors to the commitment of workers to the grassroots trade union in the typical context of the grassroots trade union and Vietnam. We discussed and tested the factors affecting the commitment of workers to the grassroots trade union, from the perspective of the worker's representative organization at the enterprise through the implementation of core functions of the grassroots trade union. Prior studies only focus on the commitment of employers to the organization, from the perspective of the enterprise and through the implementation of the core function of the enterprise. Or only consider the important role and core functions of trade unions in labor relations.

Through the results of empirical research, the study has some new contributions. The research results, it shows that there is an interactive relationship between the functions of the grassroots trade union organization and the commitment of workers to the grassroots trade union through the values that the grassroots trade union brings to workers. The implementation of core functions of the grassroots trade union contributes to improving the union's competitive advantage compared to the new worker's organization. On the other hand, creates the faith of workers in grassroots trade union, which can positively influence the workers' decision to commit to the grassroots trade union. Thereby, proposing 5 groups of solutions associated with core tasks, further promoting the role of representation and protection for workers of grassroots trade union, and contributing to promoting the commitment of workers to grassroots trade union in the context of implementing new-generation free trade agreements. However, the study also has limitations. The study was conducted with a small sample size and limited to the garment industry. Therefore, further studies can exploit these limitations, broadening the scope of the study.

## THE EFFECT OF PERSONAL FACTORS ON THE INTENTION TO BUY FASHION PRODUCTS ON THE SOCIAL NETWORK TIKTOK SHOP OF GEN Z IN HANOI

**Authors: Pham Thi Thu Hang<sup>1</sup>, Nguyen Dieu Linh<sup>1</sup>, Nguyen Thi Quynh Trang<sup>1</sup>,  
Nguyen Thi Le<sup>1</sup>, Do Van Huy<sup>1</sup>  
Mentor: Assc Prof Phan Thi Thu Hoai<sup>2</sup>**

**ABSTRACT:** *Research the impact of the factors of TikTok Shop on buying behavior of fashion products on the basis of information acceptance theory. Research has found that there are 03 groups of TikTok Shop factors that affect buying behavior, including Perceived usefulness (PUS), Reputation level (RL), Perceived risk (PRK), Reference group (RGR). From there, the proposed solutions to improve the activities of TikTok Shop towards Gen Z customers lead to the intention to buy fashion products.*

**Keywords:** *Influential factors, intention to buy, fashion products, TikTok, GenZ*

### 1. INTRODUCTION

TikTok ranks 6th in the favorite social networking platforms in Vietnam. TikTok has a fast growth rate in Vietnam compared to other country markets in Southeast Asia. In the first 3 months of 2019, TikTok reached 12 million monthly regular users. As of the end of 2018, each Vietnamese user spent an average of 28 minutes a day on TikTok. According to GlobalWebIndex, 90% of TikTok users visit the app more than once per day. According to Digiday, users access the TikTok app an average of eight times per day. According to MarketingCharts, about 50% of TikTok's global users are under the age of 34, with 26% between 18 and 24 (Luong Hanh, 2020).

TikTok appeals to Gen Z due to the platform's messaging characteristics. TikTok mainly focuses on short-form video content, which is easier to use and go viral on the app than other social media platforms. It perfectly responds to Gen Z's desire to be creative themselves. TikTok has developed new features for TikTok Shops to sell merchandise to people who visit this app.

The development of information technology and the trend of digital transformation have spurred the strong development of online shopping. TikTok is one of the platforms. It developed from an entertainment medium into the TikTok Shop. TikTok Shop is growing day by day and it is of high interest among young generation of Z. One of the items that Gen Z is interested in is fashion product. The transmission of electronic domains on the internet has a great influence on the purchasing decisions of young people belonging to gen Z. Therefore, it is necessary to study the impact of personal factors on the buying behavior fashion products of gen Z. From there, providing solutions in the direction of promoting the decision to buy fashion products on TikTok Shop of Gen Z customers.

Gen Z (Generation Z) aka Gen Tech, Gen Wii, Digital Natives, Neo-Digital Natives, Net Gen, Plurals, Zoomers, Internet Generation, Generation Z, iGen, iGeneration, Founders, Post millennials, Homeland Generation

<sup>1</sup> 57C2.

<sup>2</sup> TMU.

or post-Millennials, etc. are phrases that refer to a group of people born between 1995 and 2012. Most of Generation Z members have been exposed to and used technology since childhood, so they feel very comfortable with technology, mobile, Internet and social media, from Facebook, Google, Youtube, Instagram, etc. Gen Z can use and find information quickly and without spending. a lot of work but not necessarily highly digital.

**2. LITERATURE REVIEW**

In this study, the theory of planned behavior is the theoretical basis combined with the information acceptance theory used to build the model.

**2.1. Theoretical models**

The Theory of Planned Behavior (TPB) started as the Theory of Reasoned Action in 1980 to predict an individual’s intention to engage in a behavior at a specific time and place. The theory was intended to explain all behaviors over which people have the ability to exert self-control.

The TPB has been used successfully to predict and explain a wide range of behaviors and intentions. The TPB states that behavioral achievement depends on both motivation (intention) and ability (behavioral control). It distinguishes between three types of beliefs - behavioral, normative, and control. The TPB is comprised of six constructs that collectively represent a person’s actual control over the behavior. That are attitudes, behavioral intention, subjective norms, social norms, perceived power, perceived behavioral control (Ajzen Icek, 1991).

**Figure 1. Theory Planned Behavior**

Information Acceptance Theory (IAM) is a model proposed by Sussman and Siegal (2003). This model combines technology acceptance theory and information processing trends model (ELM). The theory of this model suggests that before a message, shoppers are influenced by two factors: central and peripheral. The focus is on the inner content of the message represented by the element of “information quality”. Peripheral refers to issues indirectly related to the content of the message, represented by the element “Reliability”.

**Figure 2. Information Acceptance Theory**

*(Nguồn: Sussman và Siegal, 2000)*

Studies on buying behavior show that, there are 04 groups of factors that affect buying behavior and specifically the purchase intention of consumers, including cultural, social, personal and psychological factors. In which, factors related to individual demographic characteristics, psychological characteristics of consumers have a great influence on purchase intention. Especially factors related to individual cognitive problems, the reference group characteristics of Generation Z have a great impact on their purchase intention. Due to the group of young people their cognitive and psychological factors, and the factors belonging to the reference group have a great influence on their decisions. Therefore, based on the theoretical bases, the personal factors: Perceived usefulness, Reputation level, Perceived risk; Reference group are selected into the research model.

## **2.2. Perceived usefulness**

Perceived usefulness is defined as “The degree to which a person believes that using a system will improve his or her job performance” (Davis, 1989). Perceived usefulness of purchasing on TikTok Shop includes the convenience of finding reviews, product selection, and accurate information. Much of the previous research has pointed to convenience and time saving as the main reasons why customers shop online at TikTok Shop. The consumer’s motivation to use online services g (Jarvenpaa & Todd, 1997) is its usefulness, new technology. Burke (1998) can conveniently purchase at any time and place.

## **2.3. Reputation level**

The reputation of online sellers, of TikTok Shop is similar to perceived usefulness. It is the perception of consumers or potential customers about the prestige and reputation of a fashion product brand and the brand of TikTok Shop. The perception and assessment of the reputation of the TikTok Shop and the seller in the TikTok Shop is not only related to the seller’s images, but also depends on the customer’s reviews and feelings. The results of previous studies show that consumers trust online selling points such as online retail websites and social networks. If consumers perceive that the business has a good reputation and is reputable to the public (Lin et al., 2010), they will trust more and choose to buy at stores.

## **2.4. Perceived risk**

Perceived risk is also known as risk perception. It is the buyer’s perception of the risks associated with products/services sold at the TikTok Shop. Consumers are also very concerned about product/service risks, risks related to online transactions: seller fraud, payment problems, exchange and return, information security.

Product risk in online shopping at TikTok Shop is high because potential customers cannot check with five senses and test product quality and have no choice to substitute (Hsu et al. , 2013, Garbarino & Strahilevitz, 2004).

Product risks in online shopping, especially for new entrants or newbies because buyers cannot check and test product quality before making a decision Besides, Lin et al. (2010) also stated that the risk of losing money, not being able to deliver, or having wrong delivery has a negative impact on online shopping behavior intention.

## **2.5. Reference group**

Reference groups are “groups of people who have an influence on the formation of customer attitudes, perceptions and behaviors towards a product, brand or business” (Vu Huy Thong, 2010). The reference group includes: friends, family, colleagues, the mass media... Especially for the young generation of the Z group, it is often greatly influenced by the member group, and the idol reference group. The opinion of the reference group can affect consumer confidence in online vendors and in TikTok Shops, and in fashion goods sold in TikTok Shops.

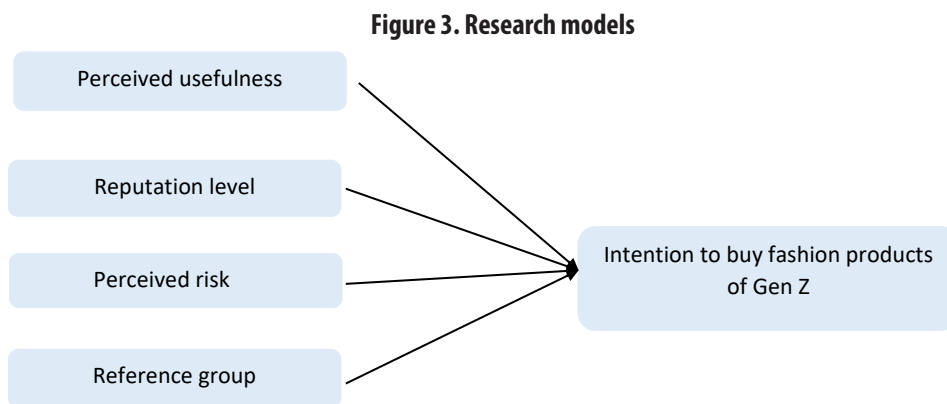

Consumers' intention to use online purchases is dominated by others involved. According to research by Senecal and Nantel (2002) for reference sources of information when buying products online can be divided into three main categories: consumers who have had experience in using the product, the opinions of experts. Research experts on that product field and the system to support consumers' purchasing decisions such as the company's support and consulting staff.

### 2.6. Intention to buy

Purchase intention of a customer or buyer, is the tendency to buy the product or service of that customer or buyer. Purchase intention is considered as a composite of motivational factors influencing a behavior; they are an indication of how much effort people are willing to put in, the level of effort they intend to make to perform the behavior." (Ajzen, 1991, p.181).

## 3. RESEARCH MODELS AND HYPOTHESES

Research conducted to find the level and direction of impact of individual factors that affect the intention to buy fashion products on TikTok network. The research model includes three independent variables, which are personal factors and one dependent variable on the intention to purchase fashion products on GenZ's TikTok Shop in Hanoi.

Source: Research team

From the above research model, there are the following research hypotheses:

H1: Perceived usefulness has a positive influence on Gen Z's intention to buy fashion products on TikTok Shop in Hanoi.

H2: Reputation level has a positive influence on Gen Z's intention to buy fashion products on TikTok Shop in Hanoi.

H3: Perceived risk has a negative effect on Gen Z's intention to buy fashion products on TikTok Shop in Hanoi.

H4: The reference group has a positive influence on Gen Z's intention to buy fashion products on TikTok Shop in Hanoi.

## 4. RESEARCH METHODOLOGY

To test the model hypothesis, the research team has launched surveys to collect data to have information to perform the steps of hypothesis testing of the research model.

Qualitative research. In order to complete the study of the observed variables measuring the variables of the model, the in-depth interview method was carried out. The research team conducted interviews with 3 young people of Gen Z, who are interested in buying fashion products through Tiktok Shop. The interview results are the basis for adjusting the observed variables to better match the reality of gene Z.

Quantitative research. Research on the evaluations of Gen Z youth's assessment of the influence of the observed variables of the variables in the model was included in the survey questionnaire. The survey was conducted in the city area of Hanoi. The respondents are the generation Z (born between 1995 and 2012), who is considering to buy on TikTok . The research team distributed 700 questionnaires on "Google form" sent to list of email, FB of student belong to the generation Z in January 2022. After the survey, 698 questionnaires was collected. There are 657 questionnaires were returned valid (accounting for 93.85%).

The research team sent online survey questionnaires by convenient sampling method. The questionnaires were built Choose to send to current and potential customers who are Gen Z who are studying and living in Hanoi city. Surveys are sent via Messenger and Gmail to each of the Gen Z youths, students, and their friends who belong to the Gen Z group. In addition, the group also posted surveys on some Facebook groups of interested gen Z such as GenZ Universe, Genz Strange, etc.

## 5. RESEARCH RESULTS

To test the hypothesis of the research model, the reliability of Cronbach's Alpha scale is evaluated. The next step is to perform an exploratory factor analysis (EFA). The next step is to analyze the correlation between the independent variables and the dependent variables. Finally, regression analysis on the relationship between individual factors of buyers affecting the intention to buy fashion products of Gen Z youth on TikTok Shops.

Among the respondents are those who have been intending to buy fashion products on TikTok Shop. Regarding the frequency of online shopping, 34.09% of respondents buy 1-2 times/month, 49.32% of respondents buy 3-4 times/month, 16.59% of respondents buy more than 5 times/month. Regarding the average spending for one-time online shopping, the level below or equal to 500,000 VND/time has 38.35%; 500,000 - 1,000,000 VND, accounting for 28.76%; 1,000,000 - 2,000,000 VND, accounting for 15.22%; 2,000,000 - 3,000,000 VND, accounting for 11.11% of the total number of respondents.

To test the hypothesis of the research model. First, the research team analyzed the reliability of the collected data. The results of reliability analysis (see Table 1) of the elements constituting the scales, including all independent variables and one dependent variable, have Cronbach's Alpha > 0.7. The total correlation of the observed variables is greater than 0.3. Therefore, all observed variables will be used for exploratory factor analysis (EFA).

**Table 1. Analysis reliability of variables**

Variables	Items	Corrected Item-Total Correlation	Cronbach's Alpha if Eliminated
Perceived usefulness	Cronbach's Alpha = 0.891		
	PUS1	0.719	0.874
	PUS2	0.762	0.859
	PUS3	0.796	0.845
	PUS4	0.765	0.858
Reputation level	Cronbach's Alpha = 0.819		
	RL1	0.687	0.738
	RL2	0.641	0.785
	RL3	0.692	0.731

Perceived risk	Cronbach's Alpha = 0.867		
	PRK1	0.714	0.833
	PRK2	0.708	0.835
	PRK3	0.660	0.846
	PRK4	0.697	0.838
	PRK5	0.607	0.844
Reference group	Cronbach's Alpha = 0.831		
	RGR1	0.663	0.785
	RGR2	0.615	0.806
	RGR3	0.677	0.779
	RGR4	0.686	0.775
Intention to buy fashion products of Gen Z	Cronbach's Alpha = 0.835		
	PI1	0.738	0.732
	PI 2	0.703	0.708
	PI 3	0.698	0.690
	PI 4	0.715	0.706
	PI 5	0.595	0.669

Source: Analysis of survey data on SPSS

Second, exploratory factor analysis (EFA) was conducted. To determine the appropriateness of factor analysis, KMO and Bartlett’s test should be performed. KMO value = 0.900 > 0.5 and significance level sig. is 0.000, so factor analysis is suitable to meet the requirements in EFA exploratory analysis.

**Table 2 KMO and Bartlett Test**

KMO Measure of Sampling Adequacy		0.900
Barlett Test	Approx. Chi - Square	1300.897
	df	153
	Sig.	.000

Source: Analysis of survey data on SPSS

From the results of EFE analysis, we see that all values meet the conditions, we get the rotation matrix as in Table 3.

Factor rotation matrix

**Table 3 Matrix rotation results**

Rotated Component Matrix				
	Component			
	1	2	4	4
PUS3	.813			
PUS1	.728			
PUS2	.592			
PUS4	.544			
RL1		.523		
RL3		.540		
RL2		.517		
PRK1			.767	
PRK3			.762	
PRK4			.746	
PRK2			.737	

PRK5			.699	
RGR1				.557
RGR2				.526
RGR3				.516
RGR4				.506
Extraction Method: Principal Component Analysis.				
Rotation Method: Varimax with Kaiser Normalization.				
a. Rotation converged in 3 iterations.				

Source: Analysis of survey data on SPSS

The analysis results of the rotation matrix show that the load coefficients of all factors are greater than 0.5 to meet the requirements. Thereby, we can conclude that the customer's purchasing decision scale is influenced by 5 factors with a total of 19 observed variables.

The first factor is perceived usefulness (PUS) consisting of 4 observed variables with codes from PUS1 to PUS4. This is also the strength of the "booths" on TikTok Shop to attract customers to buy products. Especially today's GenZ group often tends to learn more about product information before making a purchase.

The second factor is the Reputation Level (RL) of the product and of the TikTok Shop, consisting of 3 observed variables with codes from RL1 to RL3. GenZ is an object with its own "color". They are willing to test new products. However, they still want the reputation of the product over time and according to the information provided by the TikTok Shop about the reputation of products and of the Shop.

The third factor is perceived risk (PRK) including 5 observed variables with codes from PRK1 to PRK5. The convenience of purchasing on TikTok has not yet made GenZ friends forget about potential risks. These risks are product-related, transaction-related, and personal information when purchased on TikTok Shop.

The fourth factor is the Reference Group (RGR) consisting of 4 observed variables with the codes of Designers1 to Designers4. GenZ tends to rely on the comments or information of a member reference group or aspirational reference group. Information on TikTok social network from opinion leaders / or influencers (KOLs / Influencers), and the influence of opinion leading consumers is also increasing.

The third step, correlation coefficient analysis was performed between 05 independent variables and 01 dependent variable (Table 4), we can see that all independent variables are correlated with the dependent variable intention to purchase products. fashion products on TikTok. Thus, the regression function of the research group at this time still has enough 05 factors that are correlated with the p-value =  $0.00 < 0.05$ , which can be concluded to be statistically significant.

**Table 4. Pearson's Correlation**

	PI	PUS	RGR	PR	RL
PI	1.000				
PUS	0.638	1.000			
RGR	0.619	0.509	1.000		
PRK	0.561	0.610	0.483	1.000	
RL	0.554	0.427	0.602	0.530	1.000

Source: Analysis of survey data on SPSS

The fourth step, on analysis, is to determine the level of impact of 5 independent variables on the dependent variable. The first is to analyze the fit of the model, Table 5 has analyzed the model summary

showing that the adjusted R-squared coefficient is 0.691. That is, 69.1% variation of the dependent variable of intention to buy fashion products on TikTok is explained by 05 independent variables.

**Table 5: Model Summary**

Model Summary <sup>b</sup>					
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	.831 <sup>a</sup>	.691	.685	.502	1.962
a. Predictors: (Constant), PUS, RL, PR, RGR					
b. Dependent Variable: PI					

Source: Analysis of survey data on SPSS

Table 6 shows the results of the analysis on the overall fit of the model. The results in the table show the value  $F = 44,565$  with  $sig = 0.000 < 0.05$ . Show that the R-squared of the population is not 0, this means that the linear regression model built is suitable for the population.

**Table 6 Results of model fit analysis**

ANOVA <sup>a</sup>						
Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	43.856	4	10.964	44.565	.000 <sup>b</sup>
	Residual	35.919	146	.246		
	Total	79.775	150			
a. Dependent: PI						
b. Independent: PUS, RL, PR, RGR						

Source: Analysis of survey data on SPSS

Fifth, the results of the regression analysis on the impact of the independent variables on the purchase decision of the intention to purchase fashion products in Table 7 show that all the regression coefficients are significant due to sig. are all less than 0.05, and there is no multicollinearity between the variables because the VIF values of the variables are all less than 2.

**Table7. Regression analysis**

Coefficients							
Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
	B	Std. Error	Beta			Tolerance	B
(Constant)	.415	.258		1.449	.149		
PUS	.321	.076	.322	3.798	.000	0.681	1.469
RL	.106	.066	.113	1.611	.000	0.737	1.356
PR	-.302	.066	-.310	-4.589	.014	0.845	1.183
RGR	.160	.069	.168	2.316	.000	0.727	1.357
a. Dependent: PI							

Source: Analysis of survey data on SPSS

All variables have a positive influence on GenZ’s intention to buy fashion products on TikTok in Hanoi, RR (- 0.302) is negative, which shows that the perceived risk factor negatively affects GenZ’s intention to buy fashion products on TikTok in Hanoi.

From the regression table as follows:

$$PI = 0.415 + 0.322 PUS - 0.310 PR + 0.168 RGR + 0.113 RL$$

Thus, through determining the reliability of Cronbach Alpha, analyzing EFA for independent variables and regressors. The model is separated into 4 independent factors affecting 1 dependent variable. So from here, the research team comes up with the following new hypothesis:

H1: Perceived usefulness has a positive influence on Gen Z's intention to buy fashion products on Tik Tok in Hanoi.

H2: Reputation level has a positive influence on Gen Z's intention to buy fashion products on Tik Tok in Hanoi.

H3: Perceived risk has a negative effect on Gen Z's intention to buy fashion products on Tik Tok in Hanoi.

H4: Reference groups have a positive influence on Gen Z's intention to buy fashion products on Tik Tok in Hanoi.

## **6. RECOMENDATION**

The analysis results show that there are 03 factors that have a positive impact (Perceived usefulness, Reference group, Reputation level) and 01 factor have a negative impact (factor Perceived risk) on the intention to buy. Shop for fashion products on GenZ's TikTok in Hanoi. The level of impact of these factors in descending order is: Perceived usefulness (0.322), Perceived risk (-0.310), Reference group (0.168), Reputation level (0.113).

The results from the study show that perceived usefulness and quality of information are quite important when considering buying fashion products on the Tiktok platform. The more useful information is, the more it strengthens consumer confidence. Maybe they have never known the product or brand before, but if the usefulness of the information is high, it can create trust. Fashion businesses, the first thing to focus on is to improve the quality of information sources on Tiktok Shop. Information should be easy to understand, clear and objective. Businesses need to pay attention to the form and decoration of TikTok pages. The interface of the page should be eye-catching and elegant. Categories should be clearly displayed, easy to find so that visitors do not feel inconvenient or difficult to use. Each topic on the page should have easy-to-find keywords so that readers find it convenient to find information and feel that the information is trustworthy.

There is a need to reduce perceived risk for potential customers when they make purchases on TikTok Shops. Specifically, sellers on Tiktok Shop need to provide accurate information about the product both in terms of shape and characteristics of the product, style characteristics, and color of the product. Especially the material and form of the product must be exactly as the information. Moreover, it is necessary to ensure the safety and confidentiality of information for users.

To increase the credibility of Tiktok Shop, businesses need to create conditions for consumers to share information, or advice from other online consumers. Especially, today, consumers are more interested in other people's opinions than seller's advertising information. To be able to improve trust, businesses should strengthen the expansion of multiple communication channels from consumers to consumers or influencers.

The influence of influencers needs to be exploited. Consumers often consult friends and family before buying certain products. Especially when it is a new product, the above information is extremely important and useful to them. If using KOLs or KOCs, it is necessary to pay attention to the selection of KOLs to suit the Gen Z group.

## **7. CONCLUSION**

Thus, in order to catch up with the development trend of the Internet in general and the Tiktok social network in particular, along with the demand for online purchases, marketers need to consider doing business

through TikTok Shops. It is necessary to implement effective communication to increase the influence of information acceptance, increase the level of information reliability and combine with the influence of the reference group. For the Tiktok platform, businesses can also develop more features, design an increasingly eye-catching interface that is easy to use. Thereby, the business also brings valuable information, perception of risks to Gen Z young people to motivate them to intend to buy fashion products sold at TikTok Shop.

## FACTORS AFFECTING THE DECISION OF CHOOSING A GREEN LOGISTICS CENTER

**Author: Hoang Nguyen Minh Ngoc<sup>1</sup>, Dinh Thu An<sup>1</sup>,  
Do Thi Phuong Hong<sup>1</sup>, Nguyen Kim Quy<sup>1</sup>  
Mentor: Nguyen Minh Duc<sup>1</sup>**

**ABSTRACT:** *As the awareness of environmental sustainability grows, the field of green logistics has gained significant attention in recent years. Green logistics centers, which focus on minimizing environmental impacts while optimizing logistics operations, have emerged as viable solutions for sustainable supply chain management. In this research paper, we investigate the factors that affect the decision-making process in choosing a green logistics center in Haiphong, Vietnam, using the Fuzzy Analytic Hierarchy Process (AHP) method. This paper aims to identify and prioritize the key factors that influence the decision to choose a green logistics center in Haiphong. The research results show that out of the four main criteria, infrastructure is the most important, the second most important criteria is policy, followed by technology and services, respectively. In addition, the study has ranked the sub-criteria of the main criteria from 1 to 14, which is presented clearly in the table 9. This research paper contributes to the literature on green logistics by providing insights into the decision-making process of choosing a green logistics center in Haiphong. The findings of this study can be valuable to businesses and policymakers in finding the right direction in building a green logistics center and related policies as well as attracting clients' attention.*

**Keywords:** *green logistics center, green logistics, effect criteria, Fuzzy Analytic Hierarchy Process*

### 1. INTRODUCTION

The logistics industry is a vital component of global trade, but it is also one of the most polluting sectors, responsible for 8% of total CO<sub>2</sub> emissions globally. In the Mekong region, including Vietnam, logistics is a fragmented sector that relies on outdated infrastructure and vehicles, leading to high fuel demand and increased CO<sub>2</sub> emissions. According to the Worldbank, the ranking is 39/160 with 3.72 points. The logistics cost in Vietnam is LPI of Vietnam in 2021 accounts for 16.8% value of goods, meanwhile, this cost in the world is just 10.6%. World Bank statistics in 2019 show that road has a very large amount of gas emissions, accounting for 85%, followed by inland waterway transport 10% and air transport 5%. Therefore, the development of green logistics together with a green logistics center has become a common trend worldwide, and Vietnam is no exception. However, the existing literature on green logistics often tends to focus on broader concepts and strategies, such as environmental regulations, green technologies, and overall sustainability practices. There is still a lack of research on the establishment and development of Green Logistics Centers in Vietnam. Moreover, Vietnam has not yet developed and systemized common measures for green logistics such as the set of criteria to measure the level of green logistics development or the green logistics performance index. The research and construction of a Green Logistics Center has not been concerned and studied. According to the master plan to develop the logistics center system in the whole country to 2020, with a vision to 2030, approved on July 9, 2015, the government only focuses on building and developing traditional logistics centers and no green orientation for these centers. The government has just issued the Green Port Development Project in Vietnam approved by the Ministry of Transport on October 29, 2020, without a development orientation and strategy for green logistics centers. In Vietnam, up to 73.2% of surveyed enterprises said that green logistics was in their business strategy, and nearly 65% of surveyed enterprises also said that they have carried out

---

<sup>1</sup> Vietnam Maritime University

environmental control in the enterprise. In which, 66.2% of logistics enterprises said that they do not have an environmental management system that meets ISO.14001 standards.

Hai Phong, the northern port city, in Vietnam, is a great place to build and develop a Green Logistics Center. It has a well-developed infrastructure, a strong transport network, a growing economy, and many supportive policies to encourage sustainable development. All these criteria make Hai Phong City an ideal location for the construction and development of a Green Logistics Center. Besides, Hai Phong is an industrial city with a population of 2,053,493 and an average population growth rate of 0.94%/year. The volume of cargo through Haiphong is expected to double from 2020 to 2030.

This study evaluates the criteria affecting the decision of choosing the Green Logistics Center in Hai Phong City. The object of the study is the factors affecting the choice of a green logistics center in Hai Phong, accordingly, the issues that four key criteria were identified: infrastructure, policy, technology, and services. These criteria are broken down into 14 sub-criteria that will be ranked according to their relative importance in the choosing of the Green Logistics Center.

The results of the study will provide valuable insights into the challenges and opportunities associated with the choice of a Green Logistics Center in Hai Phong City. By examining 14 sub-criteria in each of the four main criteria, the study aimed to identify the most important criteria affecting the success of the Green Logistics Center. Through analysis and evaluation of criteria affecting the selection of a green logistics center to propose solutions to develop a green logistics center in Hai Phong.

The study uses the approach of the “Fuzzy hierarchical analysis process” to evaluate the criteria affecting the decision of choosing the Green Logistics Center in Hai Phong City. The analysis results will be presented in the form of a rating, highlighting the most important criteria and sub-criteria to consider in the process of building and developing the Green Logistics Center.

## **2. THEORETICAL FRAMEWORK**

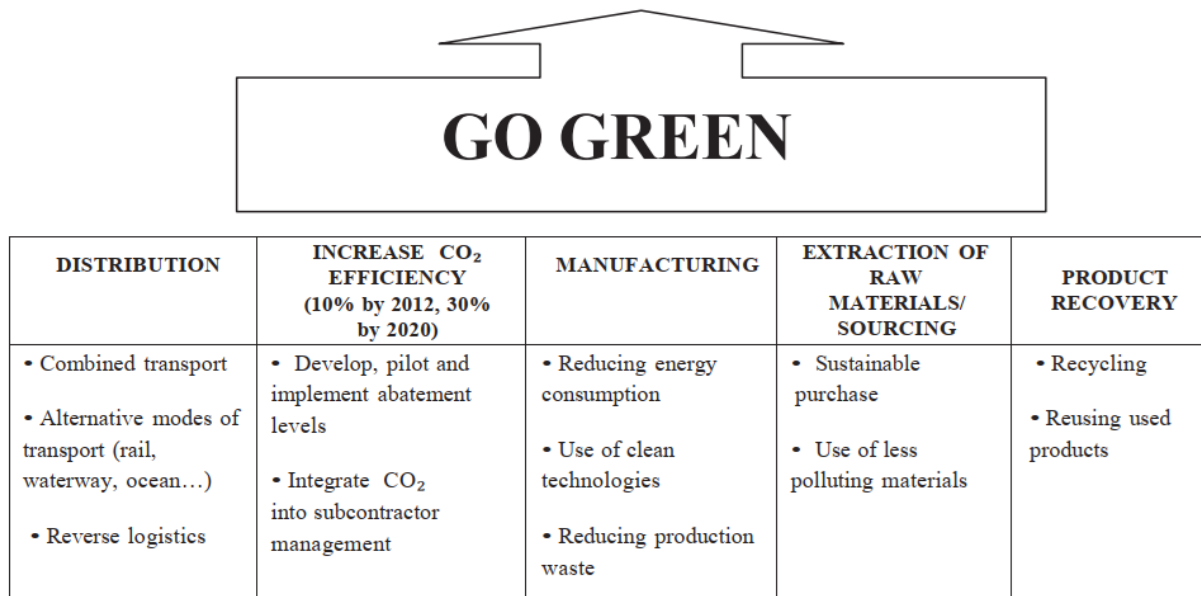

### **2.1. Theory of green logistics**

Logistics centers are divided into two approaches: the transport infrastructure and a generator of business. The transport infrastructure is an intermodal terminal, while the generator of business is a way of measuring and providing advantageous and competitive conditions for enterprises.

The concept of green logistics originated in the mid-1980s and is a concept to describe logistics systems and methods that use advanced technology and equipment to minimize environmental damage during operation without affecting the environment and still increase the use of resources in the system to meet customer requirements. According to Sibihi & Eglese (2009), green logistics activities include measuring the environmental impact of different distribution strategies, reducing energy use in logistics operations, reducing waste, and managing its operations. According to Mesjasz-Lech (2011), green logistics includes all activities related to the ecologically efficient management of forward and reverse flow planning of products, information between the point of origin and the point of consumption in order to meet or exceed customer needs. The study of A.K.M. Mohsin, et al (2022) shows the component of Green Logistics, which is the operation of green supply chains, including green procurement, green transportation, green distribution, and green delivery of environmentally friendly logistics. The research illustrates the relationship between Green Logistics and the environment, allowing industrial activities to avoid the risks associated with non-green operations, leading to ecological sustainability. The study also demonstrates the interaction between Green Logistics and economic growth, increasing market share and buyer faithfulness and advancing corporate financial growth.

**2.2. Theory of Green Logistics Center**

Darko Babiü, et al (2012, p.337) in the “Development of Green logistics centers”, the authors represent the idea of how to develop and apply “green” to the transportation industry and how to develop a “green” logistics center.

**Figure 1. Principles of logistics going green**

*Source: (D. Babiü, 2012), Development of green logistics center.*

The authors also assert that a sustainable logistics center should be judged by how it fits into a finely tuned-supply chain. Although this offers a checklist of various building improvements and operational standards to implement in a logistics center for achieving a “green” facility, following the result of the study in the article, when applying LEED certification in a warehouse sector from Gazeley of a subsidiary of Wal-Mart Stores, a mere 8 percent of building’s impact on the environment occurs during construction. In the study of the “Green Logistics Center Location and Allocation Problem”, the environmental sustainability of the logistics network is enhanced by using multi-objective optimization and carbon tax regulation to optimize the carbon dioxide emissions of the logistics network. The paper also asserts that the logistics industry should take responsibility for controlling carbon dioxide emissions. Irina Harris and co-worker critically examined current techniques for infrastructure modeling as applied to ‘real-world’ supply chains.

**2.2.1. Green logistics center in Vietnam**

Global logistics corporations are implementing green logistics, which is both economically and environmentally sustainable. Saigon Newport Company, Vinafco Corporation, and Gemadept Joint Stock Company have all implemented green logistics initiatives, such as the application of container management software systems at Cat Lai port, the installation of the first green logistics center solar power system in Vietnam, and the use of IT in port management and operation on a large scale. These initiatives have contributed to increasing the cargo handling capacity 3 times before, making Tan Cang - Cat Lai the first port of Vietnam to apply, and reducing CO2 emissions by nearly 1000 tons/year. Vinafco has also invested in a solar power system of 500.96 kWp to save 4.5% of electricity costs per month during the contract term, and 30% after the end of the 12-year contract. Gemadept Joint Stock Company has been providing customers with a logistics center system to ensure an operating supply chain.

### **2.2.2. Green logistics center in other countries**

L. A. F. Rose et al (2017) in the research: Green Logistics Implementation in Malaysian Logistics Industry proposes a way to apply green logistics by using green transportation, green storage, green packaging, green technology, and reverse logistics via a case study. In terms of green transportation, companies should design the layout of the infrastructure in order to save energy and cost such as using natural lighting, installing roof-mounted solar panels, adequate floors, heat-absorbent solar walls, etc. In terms of green storage, companies should design the layout of infrastructure in saving energy and cost, such as using natural lighting, installing roof-mounted solar panels, adequate floors, heat-absorbent solar walls, etc. In terms of green technology, companies should use cutting-edge technology to enhance the management and administration efficiently. In terms of reverse logistics, companies should reuse the heavy-duty wooden pallets and consolidate transportation from various partners to cut down the transportation cost and offer better reverse logistics services for clients.

The German government has invested heavily in logistics centers to optimize routes and facilitate the combination of transport modes, minimizing energy consumption and emissions. Greenhouse gas emissions are expected to be 80-95% by 2040. In 2014, the German government approved an action plan of 100 solutions to achieve the set goals, creating opportunities for domestic enterprises to invest in renewable energy and pursue green logistics. DHL with GO Green service compensates for CO<sub>2</sub> emissions from the transportation process, providing paper Go Green certification for partners.

### **2.3. Relevant factors for choosing a green logistics center**

According to Yan Sun et al (2019) in the area of a Green Logistics Center, it is important to identify the location, allocation, and research method to build a center. The location of a green logistics center is essential for its success, as it can affect transportation costs, efficiency, and environmental impact. It should also provide easy access to transportation infrastructure, green technology, and a skilled workforce. According to EUROPLATFORMS EEIG (2004) the Logistics Center has to connect with road, rail, and port to support its activities. The most crucial infrastructures inside a Logistics center are the warehouse and intermodal terminal. According to the study "Development of green logistics centers" by D. Babiuc et al (2012) Logistics Centers are essential infrastructure components of the macro-logistic system, facilitating an appropriate distribution of labor and improving productivity. Multimodal transport is often more cost-effective than relying solely on road transport. In the research paper: "A Review of infrastructure modeling for green logistics", Irina Harris et al (2007, p.3), building infrastructure modeling is a vital part of Green Logistics. This activity includes the optimum number, location, and allocation of the facilities; whereas implying "an environmentally friendly and efficient transport distribution system" (Rodrigue et al, 2001). Green equipment and green design can reduce the environmental impact of logistics operations and can help logistics centers comply with regulations and avoid penalties.

Digitalization is the process of using digital technologies to improve business processes, such as cloud computing, telematics systems, and ICT. "Advanced technological solutions, such as telematics systems, can be used to monitor and control the supply chain, as well as to reduce emissions and improve efficiency." (Edvardsson et al., 2018). "Design of a warehouse management system for a logistics center" by Y. Wang, X. Chen, and Y. Liu (2019). This paper describes the design and implementation of a warehouse management system for a logistics center. The authors propose a system architecture that includes a database management system, an inventory management module, and a warehouse layout optimization module. L. A. F. Rose et al (2017, p.2) in the research: Green Logistics Implementation in Malaysian Logistics Industry identifies that the

user of cutting-edge technology offers companies to enhance the management and administration efficiently via freight forwarding software, warehouse management system, transport management system, and E-shipping document software. Moreover, Monitoring and Control System (MCS) are important tools in managing the operations of a green logistics center. It is a system that plays an auxiliary role in warehouse management as well as transportation operations, making the supply chain work more efficiently, saving time and costs.

According to expert opinion, government incentives and support are important criteria for green logistics, while government restrictions can limit the cost and effectiveness of green logistics operations. Legal consistency across countries is also important to ensure that green logistics is implemented consistently and efficiently globally. For example, in 2014, the German government approved an action plan of 100 solutions to achieve the set goals, these policies have created opportunities for domestic enterprises to invest in and improve the use of renewable energy, and pursue green logistics, thereby gaining a competitive advantage for the company and reducing dependence on imported energy.

According to expert opinion, green packaging services, customer service, and reverse logistics are all important factors in green logistics, helping to reduce emissions and reduce negative impacts on the environment. L. A. F. Rose et al (2017, p.3) in the research: Green Logistics Implementation in Malaysian Logistics Industry identifies that packaging is also an aspect that the company innovates to drive green packaging. As for reverse logistics, reusing heavy-duty wooden pallets, and consolidating transportation from various partners to cut down the transportation cost and offer better reverse logistics services for clients.

#### 2.4. Research gap

Up to now, many scientific studies referring to implementing green logistics in general and in Northern Vietnam in particular, focusing on the main issues such as concepts, the role, development, challenges, and potentials of green logistics. However, in the perspective of finding the factors that decide the choice of customers in choosing green logistics centers, very little research has been conducted. Even though these factors were mentioned before, it remains challenging to determine their significance to customers. By addressing the gaps in the topic, we aim to evaluate and prioritize such factors which can help investors understand market trends and develop effective strategies to fully utilize green logistics centers in Haiphong. The information obtained from this study will serve as a basis for making informed decisions and maximizing opportunities in the market.

In terms of deciding the set of factors that affect the choices of GLC, a careful reference from previous research was taken. In addition, as the author carried out intensive interviews with experts in the field, a review of such factors was implemented to determine the most suitable ones for the customers in Haiphong. The set of criteria includes 4 main criteria and their 14 subfactors as described below.

**Table 1. The criteria affecting the choosing of a Green Logistics Center**

Code	Criteria	Description
Policy criteria		
PC1	Government's encouragements on GL	The policies, regulations, financial incentives, public awareness campaigns, and research and development support provided by governments to encourage the adoption of sustainable and eco-friendly practices in GL
PC2	Government's inadequacy on GL	The lack of effective policies and regulations put in place by governments to encourage the adoption of sustainable and eco-friendly practices in GL
PC3	The compatibility in policies for green logistics development with other countries.	The adoption of similar policies and practices by different countries to promote sustainable and eco-friendly GL

Technology criteria		
TC1	Warehouse management information system	Software application that helps manage and optimize warehouse operations
TC2	Transport and delivery technology	The technology used for transporting goods from one place to another, which includes vehicles, machinery, tools, software, and communication technologies.
TC3	Monitoring and control system	A system that continuously monitors and regulates the performance of a process, equipment, or system using sensors, instruments, and software to provide real-time feedback to operators.
Infrastructure criteria		
IC1	Modes of transport	The different methods used for moving people or goods from one place to another. The main modes of transport include air, water, rail, road, and pipeline.
IC2	Location	Location refers to the physical location of supply chain nodes, such as warehouses, manufacturing plants, and distribution centers, in relation to each other and to the transportation network.
IC3	Safety conditions and environmental protection	Involve measures to ensure safety and protect the environment and complying with regulations to prevent accidents
IC4	Eco-friendly design and equipment	Involve designing logistics systems and transportation networks that are environmentally sustainable
IC5	Efficiency	The ability to maximize the use of resources, minimize waste, and reduce environmental impact in logistics process
Service criteria		
SC1	Packing service	Packaging goods for transport while minimizing the environmental impact of packaging materials
SC2	Customer service	Providing support to customers while promoting environmentally sustainable practices.
SC3	Reverse logistics	Managing the flow of products and materials back to the point of origin for reuse, recycling, or disposal in an environmentally responsible way.

The above-listed factors are being taken into consideration while performing FAHP in this research.

### 3. RESEARCH METHODS

#### 3.1. Fuzzy AHP Methodology

The objective of this research is to assess the practicability of choosing a green logistics center. The main inquiry is to determine the critical factors that must be taken into account when considering a green logistics center. To address this question, multi-criteria decision-making (MCDM) is an appropriate method for ranking. MCDM includes various tools such as the Analytic Network Process (ANP), the Technique for Order of Preference by Similarity to Ideal Solution (TOPSIS), and Simple Additive Weighting (SAW). In this particular study, Fuzzy Analytic Hierarchy Process (FAHP) is used due to its appropriateness. FAHP is capable of managing uncertain and imprecise data through the utilization of fuzzy logic. Fuzzy logic assigns membership values to elements of a group to represent uncertain or unclear data, making it ideal for decision-making scenarios where data is incomplete or uncertain. FAHP facilitates the integration of various expert opinions and stakeholders in the decision-making process. FAHP's hierarchical structure offers decision-makers the ability to simplify complicated decisions by dividing them into smaller, more feasible components, enabling them to evaluate decision criteria and options at various levels of detail. Additionally, FAHP incorporates uniformity checks to ensure that decision criteria and alternatives are assessed uniformly across all experts, reducing prejudice and enhancing the decision-making process's dependability.

Data from the survey sheet can be denoted by  $\tilde{A}(x) = (l, m, u)$ , with the membership function

$$\mu_{\tilde{A}(x)} = \begin{cases} 0, & x < l \\ \frac{x-l}{m-l}, & l \leq x \leq m \\ \frac{u-x}{u-m}, & m \leq x \leq u \\ 0, & x > u \end{cases} \quad (1)$$

All of the functions  $\mu_{\tilde{A}}(x)$  can be graphically illustrated in Figure

The steps to apply FAHP are as follows:

**Step 1:** Expert input was needed in order to build a fuzzy pairwise comparison matrix. Following the collection of their responses, the matrix was made using the next procedure:

$$\tilde{D} = \begin{bmatrix} \tilde{a}_{11} & \tilde{a}_{12} & \dots & \tilde{a}_{1n} \\ \tilde{a}_{21} & \tilde{a}_{22} & \dots & \tilde{a}_{2n} \\ \vdots & \vdots & \ddots & \vdots \\ \tilde{a}_{n1} & \tilde{a}_{n2} & \dots & \tilde{a}_{nn} \end{bmatrix} \quad (2)$$

The value was used to determine the decision maker’s preference for the criteria. If is represented by a triangle fuzzy number, such as  $(a^l, a^m, a^u)$ , one can calculate the corresponding triangular fuzzy number for  $(\frac{1}{a^u}, \frac{1}{a^m}, \frac{1}{a^l})$ .

**Step 2:** Equation (3) was used to calculate the fuzzy geometric mean as part of the procedure for evaluating the criteria. For each criterion, the fuzzy pairwise preference matrix was examined, and the geometric mean was computed as a result.

$$\tilde{r}_i = \left( \prod_{j=1}^n \tilde{a}_{ij} \right)^{\frac{1}{n}}, \quad \forall i = 1, 2, 3, \dots, n \quad (3)$$

**Step 3:** Compute criteria’ fuzzy weight:

Fuzzy weights  $\tilde{w}_i$  of each criterion  $i$  were calculated by:

$$\tilde{w}_i = \tilde{r}_i \times \left( \sum_{i=1}^n \tilde{r}_i \right)^{-1} \quad (4)$$

**Step 4:** Defuzzy fuzzy weights:

Center of area approach was used to convert  $\tilde{w}_i = (w_i^l, w_i^m, w_i^u)$  into defuzzy weight  $(w_i)$

$$w_i = \frac{[(w_i^u - w_i^l) + (w_i^m - w_i^l)]}{3} + w_i^l \quad (5)$$

**Step 5:** Normalize crisp weights:

The normalized weight  $(N_i)$  for each criterion is obtained by:

$$N_i = \frac{w_i}{\sum_i w_i} \quad (6)$$

### 3.2. Data gathering

Participants in the study had extensive knowledge and experience in the areas of logistics, supply chain management, and transportation. They consist of 3 specialists working for shipping lines, 4 professionals in

freight forwarding, and 3 experts researching logistics and supply chain. In *Table 2*, descriptions of experts are provided. These experts were chosen based on their capacity to offer knowledgeable perspectives on the study subject. A pilot survey was done with a small group of specialists to evaluate the clarity and applicability of the questions in order to guarantee the quality and reliability of the data. A survey approach was utilized to collect the data for the study, which included a series of pairwise comparisons of the criteria and sub-criteria. The survey's objective was to determine whether using a green logistics center was feasible. The experts were asked to give each pairwise comparison a numerical value between 1 and 9, where 1 was given equal weight and 9 was given the highest weight. *Table 3* provides a thorough description of the scale. The importance of each criterion and sub-criterion in the decision-making process was asked of the experts, and they were requested to offer their opinions and observations. In order to show the reality, benefits, and difficulties that green logistics centers are confronting, experts were also interviewed. To make sure that the experts' assessments were consistent, inter-rater reliability checks were also carried out.

**Table 2. Detail of experts**

Number of respondents	Respondent category	Experience and role
3	Freight forwarding	<ul style="list-style-type: none"> <li>• More than 10 years of experience in sales of international freight forwarding services</li> <li>• More than 6 years of experience in a managerial position</li> <li>• Bachelor's Degree in Supply Chain Management</li> </ul>
4	Shipping lines	<ul style="list-style-type: none"> <li>• Shipping Manager Qualifications</li> <li>• More than 6 years of experience in shipping management</li> </ul>
3	Researching	<ul style="list-style-type: none"> <li>• Ph.D. in Logistic major</li> <li>• More than 8 years of experience in teaching in an academic setting</li> </ul>

**Table 3. The scale of importance for the Fuzzy-AHP analysis**

AHP scale	Meaning	Convert into triangular fuzzy scale
1	Equally important	(1, 1, 1)
3	Weakly important	(2, 3, 4)
5	Fairly important	(4, 5, 6)
7	Strongly important	(6, 7, 8)
9	Absolutely important	(9, 9, 9)
2	Intermittent values	(1, 2, 3)
4		(3, 4, 5)
6		(5, 6, 7)
8		(7, 8, 9)

## 4. RESULTS AND DISCUSSION

### 4.1. Results and Analysis

Infrastructure considerations are rated first shown in *Table 4* and *Figure 2*, then policy criteria (PCs), technology criteria, and service factor. This outcome highlights the importance of infrastructure as a key factor influencing the decisions of customers. The second biggest issue is government policy. Below, the importance of the subfactors and their fuzzy ranking are examined. The infrastructure category, with a normalized weight of 0.479, gets the highest rank. This indicates that out of the four criteria, it is regarded as the most crucial. With a normalized weight of 0.316, the policy criterion is ranked second. Lower rankings are achieved by the technology and service criteria, which have normalized weights of 0.144 and 0.061, respectively.

Figure 3. Normalize weight of main criteria

Table 4. Fuzzy and equivalent crisp weights of main criteria

Criteria	Fuzzy weight for criteria	Crisp weight for criteria	Normalized weight	Rank
Policy criteria	(0.215, 0.288, 0.483)	0.329	0.316	2
Technology criteria	(0.121, 0.118, 0.210)	0.150	0.144	3
Infrastructure criteria	(0.304, 0.616, 0.575)	0.498	0.479	1
Service criteria	(0.044, 0.055, 0.090)	0.063	0.061	4

We consider the secondary criteria after assessing the primary variables.

Among the policy concerns of PCs, the focus of experts is more on initiatives taken to encourage the development of GLC rather than restrictions imposed on GLC. This is highlighted in *Table 5*, where uniform legal regulations (PC3) are the next most important concern.

Table 5. Weights and rank of the sub-criteria of economic criteria

Sub-criteria	Local fuzzy weight for sub-criteria	Local crisp weight for sub-criteria	Normalized weight	Rank
PC1	(0.427, 0.627, 0.893)	0.649	0.620	1
PC2	(0.194, 0.280, 0.420)	0.298	0.285	2
PC3	(0.069, 0.094, 0.135)	0.099	0.095	3

The warehouse management information system TC1 remains a major concern among TFs. Transport and forwarding technology PC2, monitoring and control system PC3 follow, as shown in *Table 6*

Table 6. Weights and rank of the sub-criteria of infrastructure criteria

Sub-criteria	Local fuzzy weight for sub-criteria	Local crisp weight for sub-criteria	Normalized weight	Rank
TC1	(0.495, 0.659, 0.863)	0.672	0.656	1
TC2	(0.213, 0.275, 0.366)	0.285	0.278	2
TC3	(0.052, 0.066, 0.085)	0.068	0.066	3

Assessment of the importance of the ICs factors are ranked in *Table 7*. Design of the center, its efficiency and location are considered to be top three influential sub-criteria, respectively.

Table 7. Weights and rank of the sub-criteria of policy criteria

Sub-criteria	Local fuzzy weight for sub-criteria	Local crisp weight for sub-criteria	Normalized weight	Rank
IC1	(0.077, 0.081, 0.132)	0.096	0.094	4
IC2	(0.087, 0.141, 0.150)	0.126	0.122	3
IC3	(0.028, 0.037, 0.051)	0.039	0.038	5
IC4	(0.311, 0.407, 0.546)	0.421	0.409	1
IC5	(0.239, 0.334, 0.470)	0.348	0.338	2

Of the three service criteria (SCs) which are shown in *Table 8*, the main sub-criteria selected is reverse logistics (SC3), whereas packaging service (SC1) has received the least attention.

**Table 8. Weights and rank of the sub-criteria of geographical criteria**

Sub-criteria	Local fuzzy weight for sub-criteria	Local crisp weight for sub-criteria	Normalized weight	Rank
SC1	(0.124, 0.095, 0.222)	0.147	0.141	3
SC2	(0.156, 0.250, 0.352)	0.253	0.242	2
SC3	(0.423, 0.655, 0.849)	0.642	0.616	1

*Table 9* contains a summary of the data, and the formula for determining the overall weight of sub-criteria is calculated as the product of criteria weight and local weight. This creates a way to rank and compare the significance of different sub-criteria. The most prominent factor is the government's encouragement of GL (PC1), followed by design of warehouse (IC4) and warehouse efficiency (IC5). The ranking also includes warehouse management information system (TC1) and the effectiveness of loading and government's restrictions on GL (PC2) in fourth and fifth positions respectively.

**Table 9. Summarizing local weight, global weight and rank of criteria and sub-criteria**

Criteria	Criteria weight	Criteria rank	Sub-criteria	Local weight	Local rank	Global weight	Rank
Policy criteria (PCs)	0.316	2	PC1	0.620	1	0.196	1
			PC2	0.285	2	0.090	5
			PC3	0.095	3	0.030	10
Technology criteria (TCs)	0.144	3	TC1	0.656	1	0.094	4
			TC2	0.278	2	0.040	8
			TC3	0.066	3	0.009	13
Infrastructure criteria (ICs)	0.479	1	IC1	0.094	4	0.045	7
			IC2	0.122	3	0.059	6
			IC3	0.038	5	0.018	11
			IC4	0.409	1	0.196	2
			IC5	0.338	2	0.162	3
Service criteria (SCs)	0.061	4	SC1	0.141	3	0.009	14
			SC2	0.242	2	0.015	12
			SC3	0.616	1	0.037	9

## 4.2. Discussion

Using the AHP methodology, our investigation revealed the level of interest among logistics professionals in green logistics and other related aspects. The ranking of criteria shows that experts representing those who want to use customers who want to use green logistics centers in Hai Phong are more interested in policy and infrastructure criteria than technology and service criteria.

Based on the insights provided by the interviewed specialists, infrastructure is considered as the most critical factor in distinguishing a green logistics center from a conventional one. It is imperative for customers to have access to environmentally-friendly equipment at the center, as it helps in reducing emissions. Since green logistics is a relatively new concept, customers often have queries about government policies. Companies are paying close attention to the incentives and limitations in the policy to establish a well-functioning green logistics center. In Vietnam, it is crucial to incorporate advanced technology systems, but due to insufficient funds, there is a lack of consistency in technology. As a result, users are not particularly interested in technological aspects. Additionally, when establishing a logistics center, it is essential to consider service standards. Despite being overlooked, experts recognize this as a critical

criterion that only becomes evident after the customers have chosen and utilized the center's services, making it challenging for customers to evaluate immediately.

Concerning the prioritization of secondary criteria, government incentives are the most significant factor to customers, as the investment in a new center with technological advancements requires substantial capital investment, leading to high operational expenses. Therefore, the government's policies, such as tax exemptions and creating credit funds to facilitate access to green logistics for investors and customers, are crucial. The "green" design of the center is ranked second in the evaluation criteria. The differentiation brought by the "green" aspects in our research must be clearly manifested in this secondary criterion. Investors need to invest in and equip the infrastructure and technology in the center to minimize the environmental impact of logistics operations and impress potential customers, convincing them to utilize the center's services. Additionally, efficiency in the utilization of the aforementioned infrastructure and superstructure must be ensured, avoiding any negative impact on operational efficiency and ensuring environmental protection. Despite the difficulty, the implementation of automation technology is necessary. Replacing human operators with an information management system for warehouse operation helps reduce costs and time, saving resources and energy while meeting the green criteria for the center.

#### **4.3. Current status of green logistics**

Currently, there is little research on the general challenges of developing green logistics in the country. Studies have identified barriers to the adoption of green logistics practices in Vietnam, including the lack of government policies, technology, infrastructure, and services. Detail:

- ***Policy***

State policies can play an important role in facilitating the development of green logistics, ensuring sustainability and efficiency in the management and operation of the logistics system. Financial support can be provided to enterprises and organizations engaged in green logistics development. Processes and regulations can be adapted, such as implementing standards and regulations on emissions, energy consumption, waste management and reducing risks related to safety and the environment. This helps to improve proactiveness in managing and tracking progress towards these goals. Supporting research and development can also accelerate the adoption of new technologies and solve problems related to green logistics.

In the process of developing state policy on green logistics, there are a number of challenges that may arise. One is lack of capital to invest in new technology, human resource training and system update. Another challenge is the lack of clear strategic direction, leading to ambiguity in investment and development. In addition, legal issues can also hinder the development of green logistics without clear and effective regulations and policies. Finally, promoting the active participation of countries, organizations, businesses and communities can also be a challenge, especially when there is a lack of awareness and interest among stakeholders.

- ***Technology***

Presently, technology is not the main focus of green logistics development because of reasons. Some new technologies require significant initial investment, which can be difficult for SMEs to manage. New technologies require training and implementation, which can be expensive and necessitate changes in organizational structure and work processes. Different technologies may not be compatible with each other, which can be expensive and time consuming to merge. Finally, the collection and use of customer and employee data can raise security and privacy concerns.

- ***Infrastructure***

The development of green logistics centers faces a number of challenges related to infrastructure. One of the main challenges is limited land availability in urban areas, where logistics centers need to be located close to consumers to reduce transportation emissions. This leads to high land prices and limited area for logistics centers, making it difficult to build and expand facilities. In addition, green logistics centers require specialized infrastructure such as renewable energy sources, waste treatment facilities and green roofs. These infrastructure requirements can be expensive to implement and maintain. Another challenge is the need for efficient transport linkages between logistics centers and other modes of transport, such as ports and airports, to enable seamless supply chain integration.

- ***Service***

Services such as reverse logistics, customer service and packaging services are all very important in green logistics. Reverse logistics will help organizations recycle and reuse products, reduce waste and emissions during production and transportation, and bring competitive advantages to businesses. Meanwhile, good customer service not only helps to create satisfaction, but also saves shipping costs and ensures the shipping process. Environmentally friendly packaging also helps to reduce production and packaging waste.

However there still exist challenges in this factor. First, businesses often do not invest enough in improving service quality. Another one is difficulties in finding human resources specialized in logistics service consulting and service management. Moreover, measuring the effectiveness of service elements is also a difficult problem, making the investment for these factors difficult.

#### **4.4. Recommendations**

From the above backlog and research, here are our recommendations to governments, investors and other stakeholders:

- ***Policy***

To develop green logistics through state policies, it is necessary to provide solutions to remove the above difficulties. The first one is increasing investment capital such as tax exemption and reduction for new technologies and equipment in this field. At the same time, create favorable conditions to attract investors and sponsors from international organizations to support the development of green logistics. Also, we should prepare clear strategic direction. The state can develop a clear plan and strategy for the development of green logistics, along with objectives, targets and performance metrics to monitor the development process. This will help increase the synchronization and efficiency of green logistics development activities. Another one is enforcing effective regulations. The state needs to develop effective regulations to support the development of green logistics such as regulations on environmental management. Then it is necessary to enhance stakeholder engagement. To achieve maximum effectiveness in the development of green logistics, it is necessary to increase the participation of stakeholders such as organizations, businesses, communities and experts in the field of logistics.

- ***Technology***

To solve the difficulties in using technology in green logistics, there are a number of solutions that need to be applied. Firstly, we need to increase investment in technology research and development. This section includes creating new technology and improving existing technology. This reduces initial investment costs and increases computational efficiency during the development and exploitation of new technologies. The second one is training people and promoting knowledge sharing, which can help improve technology

usability and increase efficiency. This helps businesses save training costs, improve competitiveness in the market. Thirdly, using interoperability and integration standards enable different technologies to work the same, thereby reducing integration costs and increasing computational and system efficiency. Last but not least, ensuring information security and privacy is important because businesses need to ensure that customer and employee data is secured and used properly.

- ***Infrastructure***

To solve the challenges in building green logistics infrastructure, the following solutions can be implemented. Firstly, regarding government support, the government can provide financial support and encourage businesses to invest in green logistics infrastructure. Secondly, Collaboration can help share technology investment costs and share expertise during adoption. This can help ease the burden on SMEs. In terms of standards and regulations, it helps to reduce regulatory uncertainty and ensure a level playing field for businesses. Training and education including skills development programmes, seminars and workshops. Finally, innovation and research can help reduce infrastructure costs and solve technical difficulties. This may include collaboration between industry and academia.

- ***Service***

Firstly, one way to improve reverse logistics and customer service is implementing a green supply chain. This involves using environmentally friendly inputs and turning process by-products into materials that can be reused or recycled. Secondly, companies should integrate reverse logistics into the green supply chain by including it in all stages, from planning to sourcing, manufacturing and shipping. This multifactorial structure is needed to deal with the new complexities that arise in the process. Another way to improve reverse logistics is to identify the factors that influence its implementation, such as proper planning, control and execution. By understanding these factors, companies can optimize their reverse logistics processes and improve their economic outcomes. In addition, companies can improve their packaging services by partnering with green logistics centers that specialize in environmentally friendly packaging materials and techniques. This will not only improve the company's sustainability profile but also improve customer satisfaction by providing more eco-friendly packaging options.

## **5. CONCLUSION**

In summary, the decision of choosing a Green Logistics Center is an essential step to achieve sustainability in the logistics and supply chain industry. This study evaluates the factors affecting the decision of choosing a Green Logistics Center in Hai Phong City, Vietnam.

The study identified four key factors: infrastructure, policy, technology and services, which are critical to the success of the Green Logistics Center. These factors were further analyzed and it was found that infrastructure was the most important factor, followed by policy, technology and services.

Analysis of 14 sub-factors in each of the main factors shows government incentives, green design and eco-friendly equipment, effectiveness, and compatibility between Vietnam's green logistics development policy and other countries, are the most important factors to build and successfully develop the Green Logistics Center in Hai Phong city.

In theory, the study has systematized the theoretical basis as well as the existing studies on Green Logistics in general and Green Logistics Center in particular. While previous studies focused on the implication of "green" to Logistics in Vietnam, this study has identified and evaluated the factors influencing the decision of choosing a Green Logistics Center in Hai Phong.

In practice, the study has shown that the infrastructure factor is the most important and decisive factor in choosing a Green Logistics Center in Hai Phong. From there, it helps businesses, as well as investors, have a realistic view of investing and building a Green Logistics Center.

In terms of application, the study proposes solutions for each of the above impact factors for businesses, customers, and the government to promote the development of a Green Logistics Center in Hai Phong.

In short, the study demonstrates the importance of considering many primary and secondary factors when selecting the construction and development of Green Logistics Centers. The Fuzzy Hierarchical Process Methodology used in this research can be applied to other decision-making processes, especially those involving subjective and uncertain criteria. The study highlights the need to continue to research and develop sustainable and eco-friendly logistics practices to promote a greener and more sustainable future.

In spite of the fact that giving noteworthy supplementation to the past writing, the think about has a few confinements which ought to be taken into consideration whereas deciphering the comes about due to the time limitations. The test estimate is generally little which may not be agent of the whole clients. Also, comfort inspecting strategies were utilized to enroll members which may have caused testing predisposition. The information collected through self-report measures may have socially alluring inclinations and may be influenced by response inclinations. In spite of the fact that namelessness and secrecy were guaranteed to play down these predispositions, they still may have influenced the comes about. The cross-sectional plan of the consider does not permit for causal inductions, which is another confinement. Finally, the ponder was conducted in two master bunches without including important government partners, so the discoveries may not generalize to the impediments of building a green coordinations center in Northern Vietnam. In spite of these confinements, this consider gives critical bits of knowledge into the variables impacting the decision of choosing a green coordinations center and lays the establishment for future investigate within the future.

## THE ANTECEDENTS OF PURCHASE INTENTION ON SOCIAL NETWORKING APPS OF GENERATION Z IN VIETNAM

**Students: Vu Thi Kim Ngan<sup>1</sup>, Tong Nga Linh<sup>1</sup>, Nguyen Thi Nhat Minh<sup>1</sup>,  
Than Bao Ngoc<sup>1</sup>, Truong Thi Nhu Ngoc<sup>1</sup>  
Mentor: Nguyen Thi Thu Ha, PhD<sup>1</sup>**

*ABSTRACT: Social networking apps are strongly influencing consumption trends in Vietnam, in which Facebook, Instagram, and TikTok are the most popular platforms with the most consumers, mainly Gen Z. Accordingly, this study was conducted to assess the antecedents of purchase intention of Gen Z on social networks based on the theory of information acceptance model (IAM) and adding Trust and perceived prices. A survey method using an online questionnaire was used to collect data from 663 Gen Z in Vietnam. The collected data was then analyzed with structural equation modeling (SEM). Research results show that constructs positively affect Gen Z's purchase intention on social networks, namely Perceived price, Trust, and Information adoption. The findings also reveal that Information adoption is influenced by Information quality, quantity, and credibility. From the research results, the authors have proposed several solutions for enterprises/ sellers on social networking apps to promote purchase intentions of Gen Z on social networking apps in Vietnam.*

*Keywords: Social networking apps; Gen Z; purchase intention; Vietnam.*

### 1. INTRODUCTION

In recent years, using communication media has become a habit and lifestyle of global residents. A report revealed by eMarketer (2023) exposed that the average daily hours spent on mobile phones is more than 3 hours per user. According to Hootsuite's Digital 2022: Global overview report (2022), the number of regular social media users in Vietnam is 76.95 million, accounting for 78.1% of the total population. Social media users are also quite active, with the average time used in a day being 2 hours 28 minutes, higher than the average time of users worldwide (2 hours 27 minutes). The best reason is that the ongoing Covid-19 pandemic has significant impacts on most parts of the world, leading to enormous challenges at the root of lifestyle and the global economy. The heavy impact of the Covid-19 pandemic has motivated the development of e-commerce as a modern and fast-growing business model, as more companies worldwide sell their products on social media and other websites or platforms (Ngo et al., 2022).

The existence of the terms "Digital era" or "Industry 4.0 technologies", which appeared in 2011, is one of the most successful revolutions. Accordingly, the 4.0 revolution has sparked a new method of marketing called Marketing 4.0. In addition, the Internet, along with the advancement of social networks such as Facebook, Instagram or TikTok, has changed how consumers can buy and have the space to approach with the opinions and reviews of products. For example, TikTok, an application, is easy to use and simple to make a video, has attracted rapid growth in users. TikTok users not only watch live streaming and short videos but also go shopping on TikTok shops. The study by Schellewald (2021) shows that TikTok has become one of the most popular short video communities. TikTok has formed a unique business model which has notable differences between TikTok and other e-commerce exchanges on traffic source, page design, and content display (Ouyang et al., 2021). However, research on purchase intentions on such social networking

<sup>1</sup> Thuongmai University, Hanoi, Vietnam.

apps in Vietnam is not abundant. Therefore, based on the Information Adoption Model (IAM), the study investigates the impact of factors, such as perceived price (PRC), trust (TR), and information adoption (IA) on Gen Z consumers' purchase intention (PI) in Vietnam. Additionally, the results give valuable marketing suggestions for enterprises and sellers on social networking apps.

## 2. THEORETICAL BACKGROUND AND HYPOTHESES

### 2.1. Theoretical Background

The Theory of Reasoned Action (TRA) postulated by Fishbein and Ajzen (1975) originated from the areas of social psychology. This model determines the relationship between Trust, Attitude, Norm, Intentions and Behavior of individuals.

According to TRA, the intention to perform the behaviour is the most crucial factor determining human behaviour. Behavioural Intention is influenced by a person's attitude about the behaviour and the Subjective Norm related to the behaviour.

IAM (Information Adoption Model) is formed from the combination of The Technology Acceptance Model (TAM) and The Theory of Reasoned Action (TRA), considered to be more capable of explaining information-receiving behaviours than just using theories like TAM and TRA. In IAM, Information quality, Information quantity, and Information credibility are drivers of information adoption.

### 2.2. Hypotheses

Information quality is defined as the strength of the content embedded in information (Yeap et al., 2014). Moreover, information quality plays a material role in consumers' evaluation of products and services (Filiari & McLeay, 2014). The concept of information quality is a factor that is accurate, complete and timely in providing information that meets the expectations of information users. As social media users can easily access information, the quality and credibility of information become more important to consumers (Reichelt et al., 2014; Erkan & Evans, 2016). Information quality is supposed to be the power of a persuasive message in influencing consumer purchase intention (Park et al., 2007; Yeap et al., 2014). Park et al. (2007) discovered a strongly positive relationship between information quality and purchase intention.

**Hypothesis 1.** *Information quality has a significantly positive effect on information adoption.*

The quantity of information refers to the total number of eWOM reviews (Duan et al., 2008), comments, likes (Cheung & Thadani, 2010), and ratings (Pihlaja et al., 2018). eWOM (Electronic word of mouth) refers to any positive or negative statement made by potential, former or actual customers about product or company which is made available to the multitude of people via the internet (Hennig-Thurau et al. 2004). According to Matute (2016), perceived usefulness mediates the effect of eWOM quantity on online repurchase intention. The more reviews are posted online on social travel websites, the more information is gainful to potential customers' purchase decisions (Chowdhury & Deshpande, 2020). Higher star ratings for hotels have increased online visibility (Neirotti et al., 2016). Young people are more affected by the higher average rating of customers in the online purchase decision process than older people (Helvesen et al., 2018). Neirotti et al. (2016) emphasize that quantitative information should complement the quality information related to the content of eWOM.

According to Park et al. (2007), the number of reviews has been potential to cause consumers to rationalize their purchase decisions by saying to themselves: "Many other people have also bought this product". In addition, referring to word of mouth (reviews of others) is a risk reduction strategy that can help reduce or eliminate discomfort from exposure to risk (Buttle, 1998). Therefore, purchase intention

will increase with the number of online reviews of customers. We have therefore proposed the following hypothesis.

**Hypothesis 2.** *Information quantity has a significantly positive effect on information adoption.*

According to Wathen and Burkell (2002), information credibility is the initial factor in personal persuasion. This judgement determines how much the recipient learns from it and takes in the information. Thus, if people believe the information received is reliable, they will have more confidence to apply eWOM information and use it to make purchasing decisions (Sussman & Siegal, 2003). Previous studies have also shown a relationship between information credibility and consumer purchase intention (Park et al., 2007). Based on the IAM model, the research team predicts that information credibility is also positively related to information adoption other than purchase intention. Hence, the author formulated the following hypothesis.

**Hypothesis 3.** *Information credibility has a significantly positive impact on information adoption.*

The information adoption of the knowledge transfer process concludes that when a user profiles his or her goals to adopt a behavioural element or technology, he or she models specific desires to apply distinctly favoured concepts, behaviours, and beliefs (Sussman et al., 2003). In that sense, information acquisition is a process in which people engage in purposeful use of information.

The behaviour of information adoption is one of the main activities of users to seek to proceed in virtual communities (Cheung et al., 2008). The information-receiving factor is significant because it explains how satisfied a person is with the information received. They, furthermore, agree that information is necessary and momentous, as well as ensuring the validity of the information and affects purchase intention (Erkan & Evans, 2016). Information adoption is one of the factors that have a nonstop and positive impact on the online purchase intention of consumers (Abedi et al., 2019; Erkan & Evans, 2016; Leong et al., 2022; Song et al., 2021). In addition, results from some recent studies confirm that information adoption positively impacts purchase intention on TikTok (Yones et al., 2022; Yang & Lee., 2022). Based on the above discussion, the following hypothesis is proposed.

**Hypothesis 4.** *Information adoption has a significantly positive effect on purchase intention.*

According to Tolulope Folarin (2016), in the online shopping model trust of consumers regarding security and privacy is mandatory. In the increasing popularity of online shopping, previous studies have emphasized the importance of trust as a significant predictor of consumers' attitudes and purchase intentions (Lin, 2011; Hsu et al, 2013). Therefore, the following hypothesis is proposed:

**Hypothesis 5.** *Trust has a significantly positive effect on purchase intention.*

Price is the amount a consumer pays to obtain a product or service (Philip Kotler et al., 2015). Previous studies have all shown that price is one factor that strongly affects consumers' purchase intention (Meghna, 2019). Consumers often believe high prices indicate high-quality products. Therefore, the authors hypothesize the following hypothesis:

**Hypothesis 6.** *Perceived price has a significantly positive effect on purchase intention.*

### 3. RESEARCH METHODOLOGY

#### 3.1. Questionnaire and measures

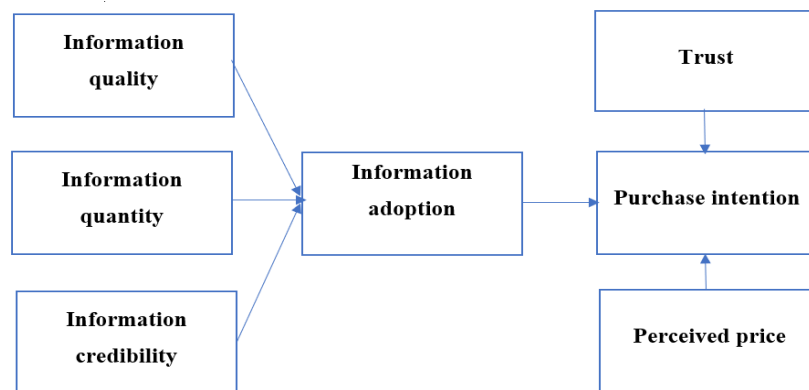

The questionnaire was translated from the original English into Vietnamese using forward and reverse translation (Nguyen et al., 2023). To ensure the validity and reliability of the measurements, most of the measurement units of the constructs were changed from the validated scales of previous studies as part of the research of this work. To ensure the validity of the measures, 02 marketing experts were invited

to review the questionnaire. In addition, 25 students shopping on social networking apps were asked to voluntarily participate in a pilot test to check the wording and meaning of the work.

The final questionnaire consists of three parts, which are as follows: The introduction, demographic questions, and measurement items of the seven constructs. All measures were designed on a 5-point Likert scale, ranging from 1 (strongly disagree) to 5 (strongly agree).

The construct of Information quality was developed from the studies of Khwaja & Zaman. (2020), Abedi et al. (2019), Yones et al. (2022), Leong et al. (2022), Yang & Lee (2022), and Park et al. (2007), including 06 observed variables coded from IQ1 to IQ6. Based on the scales in the studies of Yones et al. (2022) and Song et al. (2021), the construct of Information quantity, including 06 observed variables, was established and coded from IQn1 to IQn6. For the construct of Information credibility, the authors developed four observed variables from the studies of Abedi et al. (2019), Leong et al. (2022), Yones et al. (2022), and Erkan & Evans (2016), coded from IC1 to IC4. The construct of Information adoption was based on the scale in the studies of Abedi et al. (2019), Yones et al. (2022), Song et al. (2021), Leong et al. (2022), Erkan & Evans (2016) and Khwaja & Zaman (2020), including 05 observed variables coding from IA1 to IA5. The construct of Trust was developed from the works of Jarvenpaa (2000) and Nguyen et al. (2019), including six observed variables, denoted from TR1 to TR6. The construct of Perceived price was based on the scale in the studies of Lien et al. (2015), including three observed variables, coded from PRC2 to PRC4 while the authors developed PRC1. Finally, the scale to measure Gen Z consumers’ purchase intention was developed from the studies of Khwaja & Zaman (2020), Yones et al. (2022), Leong et al. (2022), Song et al. (2021) and Erkan & Evans (2016), including five observed variables, coded from PI1 to PI5.

Based on the literature review, a research model on the antecedents of purchase intention on social networking apps of generation Z in Vietnam is established.

**Figure 1. Proposed Research Model**

**3.2. Data Collection and Sample**

Due to the widespread use of the Internet, researchers have adopted online surveys. An online survey was conducted for Gen Z consumers in Vietnam who had purchased via social networking apps. The authors use convenience sampling on social media sites. The questionnaire was created using Google Forms software and was sent via Zalo and Facebook to approximately 1,000 respondents. In our message, we specifically stated the academic purpose of the survey. We emphasized that the data collected is used only for research purposes, will be completely confidential, and will not be disclosed commercially.

The data was collected in two months, from November to December 2022. After removing inconsistent responses, the remaining 663 respondents (91.1%) were used to analyze and confirm the research hypotheses.

SPSS and AMOS 22 (IBM, New York, NY, USA) were used to perform the data analysis. The sample profile is shown in Table 1.

**Table 1: Sample Profile**

Demographic Variables		Quantity	Percentage (%)
Gender	Male	187	69
	Female	454	28
	Non-binary	22	3
Education	College	27	4
	Undergraduate	576	8
	Graduate	13	2
	Others	47	7
Occupation	Student	453	68
	Employee/Employer	35	5
	Student with part-time job	134	20
	Housewife	3	1
	Others	38	6
Monthly income	Less than 10 million VND	571	86
	10 million VND – 19 million VND	53	8
	20 million VND – 29 million VND	18	3
	More than 30 million VND	21	3

## 4. RESULTS

### 4.1. Reliability of Cronbach's Alpha

Cronbach's Alpha coefficients of all seven constructs are greater than 0.7 (Table 2). The correlation coefficient in each variable is greater than 0.4. Therefore, 36 observed variables in seven constructs were kept to continue conducting exploratory factor analysis.

**Table 2. Reliability and standardized factor loadings**

Thang đo	Cronbach's Alpha	Standardized factor loadings
Information Quality (IQ)	0.894	0.75-0.79
Information Quantity (IQn)	0.902	0.72-0.88
Information Credibility (IC)	0.899	0.84-0.86
Information Adoption (IA)	0.897	0.69-0.84
Trust (TR)	0.908	0.77-0.83
Perceived Price (PRC)	0.885	0.76-0.87
Purchase Intention (PI)	0.906	0.81-0.84

### Exploratory factor analysis (EFA)

All the factor loading indices are good after removing the observed variables IQ5; IQ6; IQn1; IQn2; IQn6. The observed variables of the scale are all properly loaded on that construct, and the loading coefficients of the variables are all greater than 0.5. The factor analysis showed that the coefficient KMO = 0.976 met the requirements; the Significance level of Bartlett test = 0.000 (> 0.05); The total variance extracted is 66,403; the factor loading is greater than 0.5, so all indices are satisfactory. Thus, the remaining 31 observed variables were kept for the subsequent analysis steps.

**4.2. Confirmatory factor analysis (CFA) and structural model analysis**

The CFA results show that the research model fits the data ( $\chi^2/df = 2.095$ ; GFI = 0.922; AGFI = 0.905; CFI = 0.971; RMSEA = 0.041). Next, the study conducted tests of convergence validity, discriminant and reliability. The result of the first testing of convergent validity and discriminant validity was not satisfactory when MSV values of Trust construct, Information Quality construct, and Information Adoption construct were greater than their AVE values. Therefore, observed variables with the lowest standardized factor loadings were removed to make sure that the values of AVE were higher than those of MSV, and the square root of the AVE for each construct was larger than its estimated correlation coefficients with other constructs. After removing observations TR1, TR3, IA1, IQ6, IA1, IA2, IC1 from the original CFA model, the CFA model still ensures a good fit with:  $\chi^2/df = 1.746$ , GFI = 0.948, AGFI = 0.934, TLI = 0.981, CFI = 0.984 and RMSEA = 0.034, the AVE and MSV values satisfy the requirements and the correlation coefficients between observations are all less than or equal to 0.8 (both satisfy the requirements). The standardized factor loadings of all constructs ranged from 0.69-0.88 (Table 2). The results of testing convergence and reliability are presented in Table 3, showing that CRs are from 0.855 to 0.919, and AVEs are from 0.605 to 0.717. The value of AVEs was greater than MSVs. Therefore, it can be confirmed that the scales in the research model have both convergent and discriminant values to continue testing the hypotheses.

**Table 3: Convergent Validity and Discriminant Validity**

	CR	AVE	MSV	ASV	IQn	TR	PI	IQ	IA	PRC	IC
IQn	0.863	0.679	0.637	0.515	0.824						
TR	0.877	0.641	0.632	0.533	0.689	0.801					
PI	0.919	0.695	0.610	0.528	0.674	0.754	0.834				
IQ	0.860	0.605	0.584	0.519	0.744	0.708	0.647	0.778			
IA	0.855	0.663	0.637	0.576	0.798	0.722	0.743	0.747	0.814		
PRC	0.878	0.643	0.610	0.529	0.671	0.709	0.781	0.706	0.776	0.802	
IC	0.884	0.717	0.632	0.566	0.720	0.795	0.752	0.764	0.767	0.713	0.847

**4.3. Hypotheses testing**

The results of running SEM for the formal research model to evaluate the influence of factors on the purchase intention on social networking apps of Gen Z emphasize that indicators:  $\chi^2/df = 1.908$ ; GFI = 0.942; AGFI = 0.927; TLI = 0.977; CFI = 0.980; and RMSEA = 0.037 satisfy the requirement. Thus, the model is considered suitable for conducting hypothesis evaluation. Specifically, the results of the paths analysis presented in Figure 2 and Table 4 show that all paths have a statistically significant relationship.

Among the constructs, Information quantity has the strongest impact on consumers' Information adoption ( $\beta = 0.436$ , p-value < 0.001), followed by Information credibility ( $\beta = 0.338$ , p-value) < 0.001) and information quality ( $\beta = 0.173$ , p value < 0.001). Therefore, hypothesis H1, H2, H3 are accepted. The research results also confirm that perceived price is the most important factor in purchasing intention ( $\beta = 0.388$ , p-value < 0.001). Next, the factor of trust and receiving the information has a positive effect on purchase intention with standardized  $\beta$  values of 0.327 (p < 0.001) and 0.227 (p < 0.05), respectively. Thus, hypothesis H4, H5, H6 is also accepted.

Figure 2: Standardized paths analysis

Table 4: Hypotheses testing

Hypotheses	Relationship			B	S.E	t-Value	p-Value	Hypotheses testing
H1	Information quality	→	Information adoption	0.173	0.060	2.878	**	Accepted
H2	Information quantity	→	Information adoption	0.436	0.054	7.806	***	Accepted
H3	Information credibility	→	Information adoption	0.338	0.052	6.707	***	Accepted
H4	Information adoption	→	Purchase intention	0.227	0.053	4.879	***	Accepted
H5	Trust	→	Purchase intention	0.327	0.057	6.513	***	Accepted
H6	Perceived price	→	Purchase intention	0.388	0.053	7.943	***	Accepted

Note: \*\*\*  $p < 0.001$ ; \*\*  $p < 0.05$

5. DISCUSSION

Research results contribute to clarifying the influence of factors such as information adoption (information quality, information quantity and information reliability), perceived price and trust on the purchase intention of Gen Z on social networking apps in Vietnam.

Research results have demonstrated that price is the factor that has the strongest influence on Gen Z’s purchase intention on social media ( $\beta = 0.388$ ). When all other constructs’ values are equal, one unit increase in price will boost Gen Z’s purchase intention to 0.388 units. This study’s results are consistent with Changan et al. (2021) and Tran Thach et al. (2021).

The research results also confirm that the trust factor positively impacts Gen Z’s purchase intention on social media with  $\beta$  value of 0.327. When all other constructs’ values are equal, one unit increase in trust

will boost Gen Z's purchase intention to 0.327 units. The findings adhere to previous studies by Changan et al. (2021) and Hsu et al. (2013). Surprisingly, in the context of Vietnam, the results support the previous findings of Ngo et al. (2022) and Tran Thach et al. (2021) to confirm that trust plays an important role in promoting Gen Z consumers' purchase intention via social networking apps, e.g., TikTok.

According to the research results, Information adoption also positively impacts the purchase intention on social media of Gen Z ( $\beta = 0.227$ ). When other factors are held constant if information adoption increases by one unit, Gen Z's purchase intention will increase to 0.227 units. This result is consistent with previous research results of Erkan & Evans (2016), Abedi et al. (2019), and Tran Thach et al. (2021).

Information quantity has the strongest influence on Information adoption ( $\beta = 0.436$ ). Information credibility and quality also positively affect information reception with  $\beta$  of 0.338 and 0.173, respectively. When information quality, quantity, and credibility are enhanced, consumers will quickly absorb the Information, leading to purchase intention. When other factors are constant, the quantity of Information, the trust of the Information and the quality of information increase by 1 unit, which will promote the consumer's information reception to increase by 0.436, 0.338, and 0.173, respectively. This result is consistent with the results of previous studies (Yeap et al., 2014; Park et al., 2007; Leong et al., 2022)

## 6. IMPLICATIONS AND SUGGESTIONS

According to the research results, perceived price is the most important factor affecting the purchase intention on social networking apps of Gen Z. Hence, enterprises/ sellers on social networking apps need to adjust price policies to match the value of the product/service. The price is not necessarily cheap but competitive with other competitors in e-commerce platforms. Creating discount codes to satisfy young consumers' psychology will help businesses/sellers increase the number of orders and sales of inventory products. Flash sale programs also stimulate consumer buying behaviour in a certain period.

Trust is found to have positive influences the purchase intention of Gen Z on social networking apps. When consumers have confidence in products and services as well as satisfy with information secure and after-sales service, their purchase intention will be likely improved. Thereby, enterprises should pay attention to the recruitment and training of staff with expertise and attitudes that cause consumer sympathy. Strengthening the support team and speeding up the process of resolving queries and complaints to increase consumer confidence are crucial. Enterprises should also set up consulting services to impart knowledge to consumers so that they better understand the potential and uses of the products. In addition, businesses/sellers need to prioritize the security of customer information. Enterprises should build an effective customer information security system by continuously upgrading software, using multiple layers of security, building a secure internal network, and regularly checking for security errors.

Information adoption has significantly positive influences on the purchase intention of Gen Z. There are more and more products and services displayed in social networking apps, which leads to consumers' increasingly consciousness to seek information before making purchase decision. Hence, improving information quality, information quantity, and information credibility is vital.

Firstly, enterprises/ sellers should create trending, unique and funny content on videos regularly; images in videos are clear, and posted products need clear images and descriptions to get more feedback quality. In addition, sellers can attach cards to thank consumers in the packages sent to the customer. Moreover, businesses should display the number of reviews and how good they are and sort them by the quality and star rating from high to low. The total number of reviews and star ratings will make it easier for consumers to receive product information and increase their purchase intention.

Secondly, enterprises/ sellers should describe their products with outstanding features; businesses need to list them along with specific evidence and evidence to prove it. This contributes to creating trust for customers with shared product/store information. In addition, businesses need to select and bring in necessary, relevant and highly persuasive information to convey to consumers most effectively. At the same time, businesses/sellers can upload close-up photos/videos of their products on social networking applications to prove the information they share. Once the information shared is reliable, it will increase the level of information receptivity of consumers.

Finally, enterprises/ sellers need to improve the quality of information by describing product information clearly and objectively to make it easy for consumers to understand. The basic information about the product needs to be described, such as product name, category, brand, function, etc. In particular, it is necessary to focus on highlighting the product's benefits because customers are usually most interested in the use of the product. The entire product information description will help customers understand what the product is, how it is used, and how to use it, making it easier to make a purchase decision.

## 7. SOME LIMITATIONS AND FUTURE RESEARCH DIRECTIONS

Firstly, the study has just been conducted for Gen Z respondents in Vietnam. Therefore, further studies should expand the scope of research on customer groups of different ages or cultures.

Secondly, in terms of research methods, the research team only used qualitative and quantitative research methods (SEM model). Further studies can use other methods such as observation and experiment, to compare and have a more specific and general view of Gen Z's purchase intention on social media apps.

Finally, although the factors in the research model are the main factors in the IAM model that affect Gen Z's purchase intention on social media apps, future studies should add other factors such as product variety, interests, subjective standards, and reference groups.

## ANALYSIS OF FACTORS AFFECTING THE INFORMATION TECHNOLOGY SKILLS OF STUDENTS SPECIALIZING IN ACCOUNTING-AUDITING MAJORS RESPONSE TO THE INDUSTRIAL REVOLUTION 4.0

Author: Do Huyen Trang<sup>1</sup>, Ho Trong Tien<sup>1</sup>, Vu Thi Thanh Thuy<sup>1</sup>

Mentor: Nguyen Thi Hong Lam<sup>1</sup>, Lai Thi Thu Thuy<sup>1</sup>

**ABSTRACT:** *The objective of this study is to find out the current situation and causes of the application of IT skills by students majoring in accounting-auditing at the Economics Universities in Hanoi responding to the industrial revolution 4.0 from which to propose solutions to improve students' IT skills. Through a survey of 200 students majoring in accounting - auditing at the Economics Universities in Hanoi, the research team has shown the influence of the factors about awareness, knowledge and practice, education program, and advances in science and technology. This is also the basis for the research team to propose some recommendations for helping students majoring in accounting - auditing to improve and enhance IT skills to create convenient and open learning environment for future job opportunities.*

**Keywords:** *Information technology, information technology skills, industrial revolution 4.0.*

### 1. INTRODUCTION

As we all know, the 4th industrial revolution (Industry 4.0) has brought many great applications to all areas of society. It also brings positive influences and valuable values in areas such as the economy, society, and culture of countries in general and Vietnam in particular. Therefore, it can be seen that mastering IT skills will help improve work efficiency, reduce costs, and increase global cooperation, thereby gaining competitive advantages (Mamahani, 2006). It can be said that IT skills are not only important for working people, but for students, this is one of the necessary skills. Because when students graduate, IT skills are a useful tool to support work and one of the factors that employers consider when choosing.

Experiencing the complicated breakout of the covid epidemic, affecting the whole world in all aspects: life, economy, and society...large enterprises and organizations have faced challenges and they cannot work directly, instead working online is a reasonable and effective choice. It can be said that the IT skills are becoming more and more necessary. Training and educational institutions at that time also had to deploy online learning to maintain and disseminate knowledge. Piccoli et al, (2001) conclude that *"This further confirms that IT skills have had a significant influence on teaching and learning effectiveness"*.

Currently, students' IT skills are still facing many limitations. Specifically, employers only rate the proficiency of accounting and auditing staff's computer literacy at an average of 5.35/7 (Binh, 2019). In addition, students majoring in accounting-auditing at economics universities in Hanoi rated this skill proficiency as 3.78/5 (Binh, 2017). There can be different reasons such as students not having the right awareness and not having proficient IT skills training, training programs, or the constant change of time in the industrial revolution 4.0. More specifically today, there are more and more appearances of modern technologies, machines, and equipment, as well as software with practical applications in other professions and specialized in accounting - auditing majors.

<sup>1</sup> Thuong Mai University.

From the issues mentioned above, studying the factors affecting normal skills, it is also necessary to cultivate more skills in using software, programming, etc.... not only suitable for students in accounting - auditing majors but also helpful in other majors, meaningful in both theory and practice for students. This study will focus on understanding the factors affecting the IT skills of students. The main object of the research is accounting-audit students at economics universities in Hanoi. The research results are the basis for proposing some recommendations to help students understand the impact of factors on their IT skills and improve their proficiency.

## 2. LITERATURE REVIEW

Information technology (IT) is a branch of engineering that uses computers and computer software to convert, store, protect, process, transmit, and collect information, there are great achievements of the current scientific and technological revolution (Nguyen Thi Yen, 2016). From another point of view, according to the decision of the Government in our country in the 1990s: *“IT is a collection of scientific methods, modern technical, means, and tools - mainly techniques, computer technology, and telecommunication order to organize, exploit and effectively use information resources which are rich and potential in all fields of human and social activities”*. In short, IT is a technical discipline that includes modern scientific and technological methods set on computers and computer software to distribute and process data and exchange information. Moreover, exchanging and storing data in many different forms adapt to the demands of people today so this is the bridge between people and modern technology.

Information Technology Skills are the ability to use computers and computer software to convert, store, protect, process, transmit and collect information (Phan Ngoc, 2021). This skill can be described as follows: Proper use of ICT (information technology) equipment to perform specific tasks; identifying the components of the basic ICT system; being able to use learning support software in different organizing, and at the device and on the network. In general, IT skills are the skills to use or perform proficiently one or a series of office computer applications; learning tools; remote meeting software (zoom, google meet, trans,...); software for storing and processing data (cloud, debased on basis of knowledge (knowledge or experience).

Information technology skills have been studied for many years in both the world and Vietnam by such as Picoli et al., (2001); Medlin, Dave, & Vannoy (2001); Caruso and Salaway (2007); K. Lee and Mirchandani (2010); Salini Rosaline & J. Reeves Wesley (2017); Acemoglu and Restrepo (2017); MS c, NCS. Vu Thi Thanh Binh (2018); L.T.T.Thuy (2019); L.T. Han (2019); Dr. Vu Thi Thanh Binh (2019); Dr. Vu Thi Thanh Binh, Dr. Tran Thi Nga (2021);... These studies all refer to the factors affecting students' information technology skills with 5 main factors: Awareness, knowledge and practice, program training, and advancement in science and technology.

### \* *Awareness:*

The ever-changing business and technology environment requires professional IT skills (Medlin, Dave, & Vannoy, 2001). Advances in science and technology are dramatically changing and shaping the world where university students are the subject of research (Caruso and Salaway, 2007). In addition, the development of Internet technology significantly impacts student learning in IT skills training in universities (Picoli et al., 2001).

Regarding the importance of IT skills, K. Lee and Mirchandani (2010) used a questionnaire to survey 70 IS managers representing 21 companies in the Midwest United States. The study shows the growing importance of IT skills and aims to suggest essential IT skills preparation for current and future information systems professionals and educators.

*H1: Elements of awareness of IT skills*

**\*Knowledge and practicing:**

A study by Galanek et al. (2018) examined data on 64,536 students from 130 institutions in 9 countries and 36 US states. Research results show that all students have access to technology that promotes student success. The use of the e-learning system is popular in educational institutions and student satisfaction, most students express their love for the e-learning environment, and students spend 1- 4 hours of online learning per day.

From there, the study makes several recommendations such as providing students with basic technology, ending the ban on Internet use in the classroom, and improving the quality and coverage of wifi on campus. At the same time, it helps to increase students' interest in using IT, and continuing education enhance insight into tools and improves IT problem-solving skills. It can be seen that learning and practicing the IT environment helps to improve students' IT skills and raise the level of satisfaction with the learning environment.

*H2: Elements of knowledge and practice of IT skills*

**\*Education programs:**

In the learning environment, Piccoli et al. (2001) Preliminary study and evaluation of the effectiveness of basic IT skills training in demonstrating the effectiveness of virtual learning environments (VLEs). Research results show that there is no significant difference in the learning outcomes of students in the traditional environment and the VLE learning environment. The results of these studies also have important contributions to the current implementation of IT in online learning.

Caruso and Salaway (2007) collected data online to improve academic performance and enhance students' IT skills; based on qualitative data analysis, in-depth interviews with 50 groups of students; Based on data collected through a survey of 4,752 students obtained from 65 organizations based on longitudinal analysis. Research by Caruso and Salaway (2007) shows the use of IT skills and experiences of university students in courses. At the same time, the study also pointed out the importance of teaching staff in IT education; awareness of the use of IT in courses; and the impact of IT on student learning outcomes in courses.

*H3: Elements of the training program for IT skills*

**\*Advances in science and technology:**

According to previous studies by ACCA (2019), Audit and Technology, it is highly estimated that globally there will be about 400 million jobs displaced (MGI 2017). However, history should not ignore the lesson that the introduction of new technology will eventually create new jobs (Acemoglu and Restrepo, 2018).

As technology is conceptualized as replacing human labor in tasks that used to do even jobs reserved for more educated people (Acemoglu and Restrepo, 2018). Strong, proactive worker training and retraining efforts, and immediate action, are essential for problem-solving, as well as consideration of policy issues related to current work arrangements and non-standard future (ILO, 2019; Karacay, 2018). The impact of technology on jobs and workers is varied and complex, requiring workers to be up-to-date with new IT skills or else they will gradually become obsolete and then automatically become obsolete. expulsion. Technology was born to increase worker productivity (Acemoglu and Restrepo 2017). Thereby, with the advent and rapid change of new software or applications today, employees must have professional IT skills as well as adaptability to be able to meet the needs of customers.

*H4: Elements of scientific and technological progress of IT skills*

### 3. RESEARCH METHODS

The survey subjects of this study are full-time students majoring in accounting - auditing from economics universities in Hanoi: Thuring Mai University, Academy of Finance, Banking Academy, National Economics University,...is conducted through survey questionnaires. The questionnaire includes Likert-type items (from 1 = “strongly disagree” to 5 = “strongly agree”) to measure 4 independent variables and the dependent variable – IT skills.

According to Hair et al 2006 (Tran Van Quy & Cao Hao Thi, 2009), the general rule for the minimum sample size in EFA exploratory factor analysis is 5 times the number of observed variables and the number of samples suitable for the analysis. Multivariate regression is also 5 times the number of observed variables. The group has given 15 observed variables for 4 independent variables, so the minimum sample size will be 75. However, it is also suggested that the minimum number of samples is 10 times (x) the number of variables. The sample size in this study is  $n = 200$ , which meets the standard for the research model. The study used a random sampling method to select the sample.

To test the scale model and assess its relevance of the model, as well as analyze the influence of factors on the IT skills of accounting-auditing students at economics universities, the study used exploratory factor analysis (EFA) and regression analysis.

### 4. RESEARCH RESULTS

#### 4.1. Demographic characteristics

The research team conducted a survey of 200 accounting and auditing students at universities in the economy in Hanoi. The survey results show that 60% of survey respondents are female and 40% are male. Besides, the results that the authors have collected after the investigation show that the students mainly come from Thuring Mai University (36%), followed by schools such as the Banking Academy, the National Economics University National, the Academy of Finance, and the Economics University - VNU. At the same time, the author group also got 13% of the votes, which came from other universities in the field of economic training such as Industry Hanoi University, and Foreign Trade University,...This shows that the distribution of survey questionnaires at universities of economics in Hanoi city is quite wide and even. Thereby, the statistics table also aims to show the certain interest and importance of IT skills for students of other majors in general, and majoring in accounting and auditing in particular.

#### 4.2. Regression analysis

*Firstly*, the study analyzes the reliability of the scales in the model by Cronbach’s alpha coefficient. The values of other variables in the scale have high reliability with the total variable correlation coefficient  $> 0.3$  and Cronbach’s Alpha coefficient  $> 0.6$ .

*Then*, the research team carried out exploratory factor analysis EFA to evaluate the value of the scale by the KMO coefficient Bartlett’s test. The scale is accepted when  $0.5 \leq KMO \leq 1$ ; Sig coefficient. = 0.000 of Bartlett’s test indicates that the observed variables are statistically significant; The total variance extracted is  $\geq 50\%$  and the factor loading factor  $\geq 0.5$  proves that the scale value is suitable for factor analysis.

#### *For the independent variable*

Performing the first analysis shows that the KMO coefficient is  $0.5 \leq 0.798 \leq 1.0$ , demonstrating the appropriateness of the EFA model; The Bartlett test is significant for Sig. = 0.000. Then, analyzing the extracted variance of the factors showed that the total extracted variance of the factors was  $64.653\% > 50\%$  met the standard. However, when performing rotation, there is 1 variable: TP1 uploads in both factors, so

this variable is removed and the second analysis is performed.

**Table 1. KMO and Bartlett’s test results (2nd time)**

Kaiser -Meyer -Olkin Measure of Sampling Adequacy		.819
Bartlett’s Test of Sphericity	Approx Chi-Square	Chi-Square
	df	91
	Sig.	.000

Source: Summary of survey results

The test results after removing the variable with the KMO coefficient of  $0.5 \leq 0.819 \leq 1.0$ , demonstrate the suitability of the EFA model; The Bartlett test is significant for Sig. = 0.000 indicates that the observed variables are correlated with the total number of observations.

Then, perform data has been extracted by factors. Table 2 shows that the total variance extracted for the factors is  $63.555\% > 50\%$  meets the standard, that is, 63.555% of the variation of the data is explained by 4 factors.

**Table 2. Rotation matrix results (2nd time)**

	Component			
	1	2	3	4
PK2	.854			
PK4	.806			
PK3	.697			
PK1	.645			
C4		.808		
C1		.737		
C2		.725		
C3		.660		
TP4			.824	
TP3			.740	
TP2			.701	
ST1				.795
ST3				.760
ST2				.728

Source: Summary of survey results

For the dependent variable:

KMO and Bartlett’s scale (Kaiser-Meyer-Olkin) with the value = 0.785 satisfy the condition in the range from 0.5 to 1; Bartlett’s test result has the value Sig = 0.000. Factor analysis fits real data.

The total variance extracted from factors is 60.196%, which means a 60.196% possibility that the factors are explained by the observed variables. The results of the rotation matrix show that there is a factor extracted from the observed variables included in the EFA analysis.

After testing reliability and analyzing EFA, the research team used Pearson’s correlation coefficient to test the correlation between the dependent variable and the independent variable. The results show the Sig value. between each independent variable and the dependent variable is less than 0.05, so it does not

remove any kind of factors. In other words, all the independent variables have a linear relationship with the dependent variable.

To examine the impact of independent variables on the dependent variable, multivariate regression was performed. The results in Table 3 show that R Square = 0.552, F-test (ANOVA) = 0.000; therefore, the regression model is suitable, as about 55.2% of the variation of the dependent variable is explained by the independent variables in the model.

**Table 3. Results of ANOVA analysis**

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	.743 <sup>a</sup>	.552	.543	1.44105	2.287

ANOVA<sup>a</sup>

Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	499.140	4	124.785	60.091	.000
	Residual	404.940	195	2.077		
	Total	904.080	199			

Source: Summary of survey results

Table 4 presents the results of multivariate regression as follows: The independent variables all have an impact on the dependent variable because the Sig value is less than 0.05 in which the science and technology variable has the strongest impact and the (C) variable has the worst move. The VIF coefficients of the independent variables are all less than 2, so there is no multivariable nearly.

**Table 4. Multivariable regression model results**

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		B	Std. Error	Beta			Tolerance	VIF
1	(Constant)	2.038	.793		4.066	.011		
	C	.086	.043	.113	6.718	.046	.732	1.366
	PK	.270	.043	.356	5.337	.000	.710	1.409
	TP	.192	.051	.200	2.718	.007	.801	1.248
	ST	.374	.053	.361	2.115	.036	.875	1.143

Source: Summary of survey results

The authors give conclusions in order of the impact of the independent variables on the dependent variable of IT skills as follows:

- (i) All four hypotheses are accepted
- (ii) Regression model (standardized coefficients) is determined as follows:

$$SAT = 0,361*ST + 0,356*PK + 0,200*T + 0,113*C$$

This is completely consistent with the reality of today's students, when the progress in science and technology is increasing, students need to change quickly to catch up with the general trend and adapt to the changes. At the same time, knowing and practicing skills also helps students gain a deeper understanding of IT, find out how to handle it quickly, and create efficiency. In addition, good facilities also facilitate the development of IT skills for students and students need to have the right awareness to gain new perspectives on how important and necessary IT skills are, help me bring many benefits in study and work.

Besides, students majoring in accounting - auditing are trained by many reputable universities, providing a lot of important knowledge to IT skills to help students gain a large amount of understanding. The

different teaching of the lecturer also brings about diversity in the student's understanding and perception of IT. However, students also need to hone their IT skills outside such as in supplementary IT skills classes or the working environment, and improve their sense of self-study and teamwork so that students' IT skills can be improved significantly and quickly.

## 5. CONCLUSION AND RECOMMENDATIONS

From the results of the research model regression, it is shown that it is necessary to have solutions to stimulate students' understanding and adaptation to the continuous change in technology to help students become proficient in IT skills. Therefore, the group has proposed some solutions to improve the proficient use of IT skills of students majoring in accounting - auditing to create open opportunities and improve understanding of Industrial Revolution 4.0 for students as follows:

*Firstly*, students need to try harder to learn new knowledge and always update new applications and software because the specificity of IT is always changing very quickly. The knowledge about changes in hardware systems and software applications should also be disseminated regularly to students right from the time they are in school. At the same time, students also need to adapt and absorb new advances quickly to be able to keep up with the daily and hourly changes in science and technology.

*Secondly*, students need to actively enroll in and play a key role in IT courses on and off campus. In addition, students need to maintain spending time practicing their existing skills and increase the frequency of practicing new IT skills through available applications, software, or Web sites. Besides, students can also create study groups with friends or lecturers to share the IT skills needed during their studies or can serve for work in the classroom in the future.

*Thirdly*, leaders of training institutions need to innovate and organize seminars on Industry 4.0 for lecturers and students of the university to raise awareness about the importance of IT application. At the same time, universities specializing in accounting and auditing need to equip students with IT skills when building training plans such as Excel, PowerPoint, Google Docs, or accounting software as well as other software. Training institutions specializing in accounting and auditing should also add training programs related to IT skills used in majors such as Blockchain, and cloud so that students can have faster and clearer access to them, creating opportunities for students to understand and apply flexibly in the future working environment.

*Fourth*, students need to be proficient in computer applications; support online, and distance learning; tools to exchange and store data (cloud, drive, ...) so that we can understand and realize the important value of IT skills. Students also need to learn and gradually approach new applications and technologies related to their major.

However, the research results still have some limitations as follows: limited scope, subjects, and time to conduct the study, the new study was conducted on students majoring in accounting - auditing at economics universities in Hanoi but has not done it with students with a broader scope and scale. Therefore, in the future, the authors wish to expand the survey object and scope to have more accurate analytical results and give more practical recommendations to improve the survey results.

## THE ROLE OF ATTITUDE IN EXPLAINING VIETNAMESE CONSUMERS' INTENTION TO ADOPT MOBILE MONEY

**Authors: Tran Thi Thom<sup>1</sup>, Nguyen Thi Phuong Thao<sup>1</sup>, Nguyen Thi Anh Thu<sup>1</sup>, Chu Quang Hieu<sup>1</sup>  
Supervisor: PhD. Vu Thi Thuy Hang<sup>1</sup>, Master. Le Viet Hung<sup>1</sup>**

**ABSTRACT:** *The study was conducted to determine the role of attitudes in explaining vietnamese consumers' intention to adopt mobile money, thereby recommending some solutions to improve the effectiveness of this activity. This paper extends the original Technology Acceptance Model (TAM)(Davis et al., 1989), by integrating self-efficacy (SE), technology anxiety (TA). The research model is assessed with survey data of 307 consumers living and working in Vietnam with a partial least squares structural model (PLS-SEM) using SMART PLS 3.0 software. The result indicated that Vietnamese consumers' intention to use mobile money is influenced by Perceived ease of use and Perceived usefulness through Attitudes towards mobile money. Some solutions were recommended: (1) Limiting the scope of operations, (2) Upgrading and investing in infrastructure, and telecommunications network systems, (3) promoting communication about the features and benefits of mobile money. The article also suggested some future research directions, including the need to expand the scope of the research, to expand the sample size, to expand the business customers, and to add other factors such as the influence of the social environment, association, and confidentiality... to supplement and complete the model.*

### 1. INTRODUCTION

Along with the development of mobile commerce, mobile payment is becoming an inevitable trend in the world and in Vietnam. Those are payment services operated under financial regulation and made from or through a mobile device. Instead of paying with cash, checks or credit cards, consumers can use mobile phones to pay for services and goods (Felix Hoffler et al., 2019). Aware of the role and importance of non-cash payments, the Prime Minister issued Decision No. 1813/QD-TT in 2021, approving the project of developing non-cash payments in the period of 2021 - 2025 in Vietnam.

However, the speed of mobile payment development in Vietnam is not commensurate with the potential. According to the Statista Digital Market Prospects Report 2021, although about 73% of the Vietnamese population has a mobile network connection, only about 29% of the population uses mobile phones and the average spending of each Vietnamese customer is limited, the mobile market is still very modest, about 74 USD in 2021. The reason is that people's habit of using and paying in cash is still quite popular. In addition, low-income users often live far away from central areas, and the cost of accessing financial services is quite high, reducing access opportunities. In order to bring financial services to remote areas, mobile money services have been piloted since March 9, 2021, with Decision No. 316/QD-TTg of the Prime Minister on approval. pilot implementation of using telecommunications accounts to pay for goods and services of small value (Decision No. 316/QD-TTg). According to statistics from the Ministry of Information and Communications, Vietnam has more than 3.9 million mobile money users by 30 April. The number of people using mobile money in Vietnam increased triply compared to the figure in April 2022. The number of users in rural, mountainous, and remote areas reached more than 2.7 million, accounting for 69% of the total service users. Lately, there are 9,953 mobile money service points nationwide, an increase of 12% compared to March 2023. The number of units accepting payment via Mobile Money was 15,326, up 0.2%.

<sup>1</sup> Thuongmai University.

The total number of transactions using mobile money was more than 26.1 million, with a total transaction value of over 1,683 billion VND. On 19 May 2023, the Ministry of Information and Communications issued the official dispatch No. 1865/BTTTT-CVT which proposes to continue piloting mobile money service from 18 November 2023 until 31 December 2025.

However, with the great potential of the Vietnamese market, the number of users is still low, which has not yet ensured the Government's goal of bringing financial services to remote areas. This is an urgent fact that is being concerned by businesses providing mobile money services as well as the Government. At the same time, it is a scientifically meaningful and topical dilemma when there is very little research on the relationship between customers' attitudes and behavior of Vietnamese consumers accepting the use of mobile money.

With the above statements, it can be seen that mobile money services are still very new to consumers in Vietnam. The purpose of this research was to investigate the role of attitudes in explaining vietnamese consumers' intention to adopt mobile money. The rest structures include as follows. The second section presented a theoretical basis, while the third discussed the model, hypothesis and research scales on the role of attitudes towards the intention to use mobile money. The fourth section presented methodology employed. The fifth section has findings and discussion, and the last is the conclusion.

## **2. THEORETICAL BASIS**

### **2.1. Theoretical basis about mobile money**

#### **2.1.1. Definition of mobile money**

According to Aker and Mbiti (2010), Jack and Suri (2011), Donovan (2012): Mobile money is a provision of financial services through a mobile device, it encompasses a range of services, it offers banking services, peer-to-peer (P2P) transfers, insurance products. It can be used in "different ways which include sending text messages to transfer value or retrieving bank account details via the mobile phone are available that allow phones to transfer money to other contactless cash registers" (Donovan, 2012). That is, the provision of financial services without a physical presence of a financial institution but an enabled means of carrying out financial transaction business through mobile phones and other handheld mobile devices (Aker and Mbiti, 2010).

In 2017, World Bank defined: At the most basic level, mobile money as the provision of financial services through a mobile device. This broad definition encompasses a range of services, including payments (such as peer-to-peer transfers), finance (such as insurance products), and banking (such as account balance inquiries).

According to Morawczynski (2009), mobile money transfer services accelerate money transfers when money is converted into electronic form instead of physical form. To transfer money, mobile phone users register with a mobile money transfer agent and then deposit cash (Bisht and Mishra, 2016). This cash is displayed as cryptocurrency in the e-wallet on the sender's SIM card (Morawczynski, 2009). Cryptocurrency can be sent to the recipient's phone. Recipients can convert crypto balances into cash upon arrival at the dealer (Morawczynski, 2009).

In this study, the research team chooses: Mobile money is a payment method that does not require users to own/link to a bank account and this payment account is attached to the owner's SIM card.

#### **2.1.2. Characteristics of mobile money**

According to Sunduzwayo Madise (2019) mobile money has characteristics such as:

Firstly, Utility and Value: No bank account is required: With mobile money, users can recharge their bank accounts directly through transaction points. The parties involved in the transaction, even though using

telecommunications services of different carriers, can still perform money transfer/receipt transactions with each other;

No need to use a smartphone/3G/4G: With mobile money, old phones with basic functions can still be used to pay and transfer money via mobile. In fact, mobile money has a special feature because money is in the account, mobile money is attached to the SIM and differentiated from the telecommunication account;

Money transfer, receive money, pay anytime, anywhere via mobile wave: Due to the advantages attached to the SIM, mobile money users can still easily transact via SMS.

Second, about the unit of Account: Mobile money has a one-to-one ratio with cash deposited in an account domiciled at a commercial bank. This ensures that it serves as a unit of account.

According to Sunduzwayo Madise (2019) mobile money has six characteristics which are:

*Utility and value:* The greater the number of those accepting payments using mobile money, the more mobile money is similar to cash. Mobile money digitally represents itself as a store of value. A person can transfer the value to another one, peer to peer, and the person who receives such transferred value is free to deal with it in any manner. The storage of value indicates that mobile money is a representation of cash.

*Unit of account:* Mobile money has a one-to-one ratio with cash deposited in an account at a commercial bank. The mobile money provider opens a pool account with a bank where cash from mobile money users is deposited. The provider then issues out mobile money based on these deposits. Mobile money users exchange cash for mobile money and vice versa. In other words, mobile money users are not required to have a bank account. Mobile money, therefore, retains the same properties of a unit of account as cash does.

*Portability:* The ubiquitous nature of the mobile phone has meant that mobile money can also be carried virtually anywhere, and in a cost-effective manner too. Compared to cash, mobile money is safer to carry around. Additionally, an internet connection and a smartphone are not necessary to make transactions using mobile money. In this case, mobile money is not only portable but also convenient.

*Consistency:* As it has a one-to-one ratio with cash, mobile money is consistent. It maintains the same value across time and space. When used within its ecosystem, mobile money does not lose its value when it moves around. Any loss of value occurs mostly at the point of transition between cash and mobile money, usually at the point of cashing out. A transaction fee is levied on the service.

*Recognition:* Within its ecosystem, mobile money is easily recognized and accepted. It is credited after a transaction has been completed and someone has been paid. In the same way, with cash, once it is presented, it is recognizable, even before the vendor puts it into the cash box.

*Legal tender:* Madise (2019) indicated that mobile money was social tender and definitely not fiat money. However, we found the opposite evidence. According to GSMA (2010) and Decree: Regulations on non-cash payments (2019), electronic money is stored value held in the accounts of users, agents, and the provider of the mobile money service. Therefore, mobile money can be defined as a form of electronic money that is legal tender according to the Governor of the State Bank of Viet Nam. As a consequence, mobile money basically is fiat money.

### **2.1.3. Benefits and drawbacks of mobile money**

#### **\* Benefits of mobile money**

According to the World Bank, accessing to financial services as a ‘critical step’ towards reducing poverty and inequality. Furthermore, a lot of scholars such as Muto and Yamano (2009); Aker and Mbiti (2010); Wesolowski et al. (2012) also content that access to financial services is crucial for development.

However, majority of the population in developing countries have been excluded from access to financial services because of the high cost associated with delivering the services, especially in the rural areas.

For the macroeconomy, mobile money promotes financial inclusion (Donovan, 2012), promotes economic growth (Beck et al., 2018) and has a significant impact on other macro outcomes such as interest rate and inflation (Mawejje, 2019; Aron et al., 2015).

For the micro-economy, mobile money facilitates the safe storage and transfer of money, makes it easy for people to pay for goods and services, and facilitates trade (Jack and Suri, 2007). Many researchers also point out that mobile money brings convenience and flexibility to money users because they can transact anytime, anywhere [Bank of Uganda Annual Report 2015/2016, Bisht and associates (2016), Chauhan (2015)]. With that safe storage mechanism, mobile money can change saving habits, increase net savings and savings distribution of households (Aker et al., 2016); Consumption Smoothing, and activate risk-sharing networks to control negative shocks (Jack and Suri, 2014). Besides, the studies of Kikulwe et al. (2014), Jack and Suri (2014), Mbiti and Weil (2011), Aker et al. (2011), Johnson and Nino-Zarazua (2011) also revealed that mobile money usage can promote access to and use of financial services, especially among the rural population. Not only that, mobile money has improved people's welfare by positively impacting household income (Kikulwe et al., 2014). Remittances received contribute directly to income, thereby minimizing risk exposure and liquidity constraints (Kikulwe et al., 2014). This has promoted the commercialization of agriculture, rural development and poverty alleviation (Kikulwe et al., 2014).

Furthermore, Donovan (2012); Lochan et al. (2010) also contend that mobile money service helps in improving the productivity and efficiency of the unbanked microenterprise owners by avoiding the lengthy queue time, reducing transaction cost and leakage, and improving security (see also Aker and Wilson, 2013).

#### **\* Drawbacks of mobile money**

In addition to the above benefits, according to Tobin, 2011; Winn and Koker, 2013; Gutierrez and Tony, 2014; GSMA, 2018, mobile money still has many limitations. The first is a security issue: customer data can be compromised; the possibility of users losing personal information due to the use of mobile transactions; customer's money may be lost without a proper management plan; Transactions may fail or fail when a problem occurs in the transaction chain of the payment system. In terms of the amount of time it takes to execute a trade, there can be a lot of risk. At the same time, there are also many legal risks that mobile money fraud will increase if there is a lack of supervision in the mobile money space, especially when the supervision of state management agencies is not as tight as in other traditional financial sectors. Therefore, when an adverse event occurs, the consequences will be very serious.

Besides, according to Kasekende (2014), The largest potential risk facing mobile money is probably an operational risk and central banks are concerned about its potential disruptive impact on the payments system.

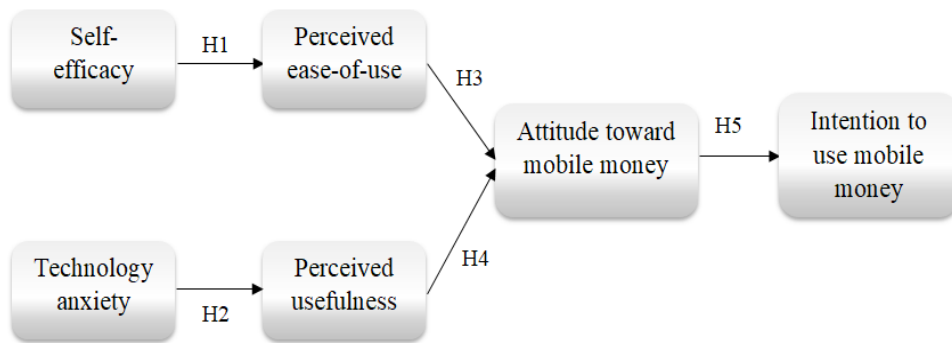

## **2.2. Theoretical basis about intention to use in technology**

Intentions are assumed to capture the motivational factors that influence a behavior; they are indications of how hard people are willing to try, of how much of an effort they are planning to exert, in order to perform the behavior (Ajzen, 1991). Davis (1985) states that intention to use is the degree to which someone has developed a plan to perform or not to perform some particular behavior in the future. Davis et al. (1989) later in a study suggested that intention to use is a person's willingness to accept the use of technology. Cheng et al. (2006) argue that the intention to use is used to refer to the consumer's intention to use.

Based on the definition of mobile money and many of the intention-to-use concepts listed above, the intention to use mobile money used in this study has one meaning: consumer willingness to use mobile money .

### 3. MODEL, HYPOTHESIS AND RESEARCH SCALES ON THE ROLE OF ATTITUDES TOWARDS THE INTENTION TO USE MOBILE MONEY OF VIETNAMESE CONSUMERS

The research team builds the model based on the studies of Davis et al. (1989), Fishbein & Ajzen (1975), Ajzen (1991), Precious Chikezie Ezeh & Nwu Kamaka Nwankwo (2018), Emmanuel Kofi Penney et al. (2021). In our model, we considered six constructs: self-efficacy, perceived ease-of-use, technology anxiety, perceived usefulness, attitude toward mobile money and intention to use mobile money. Figure 1 summarizes our proposed model and hypotheses.

**Figure 1: Research model**

*Source: Author's recommendation based on literature review*

The research hypotheses are formulated as follows:

#### \* Self-efficacy (SE)

Self-efficacy is considered to be a major factor in the intrinsic motivation of individual consumers (Davis et al., 1989) and was found to have an indirect influence on behavioral intention (Davis et al., 1989; Bandura, 1994).

In particular, self-efficacy has long been associated with ease of use seen in the literature on technology adoption (Pavlou and Fygenon, 2006; Polites and Karahanna, 2012). Several empirical studies support the effect of effectiveness on technology adoption behavior (Ellen et al., 1991). Consumers with high levels of self-efficacy are more motivated to perform a certain task than consumers with low levels of self-efficacy because they are more confident in achieving task-positive outcomes. (Noe and Wilk, 1993; Davis et al., 1989). In particular, consumers with high levels of technological self-efficacy were more engaged in the use of technology-based services (Dabholkar and Bagozzi, 2002).

Therefore, consumer self-efficacy can predict consumer adoption of mobile money. We thus hypothesize that:

*Hypothesis 1 (H1): Self-efficacy has a significant positive impact on the perceived ease-of-use.*

The scale for this hypothesis consists of four observed variables: SE 1 - I learn how to use mobile money on my smartphone easily; SE 2 - I could use mobile money if someone showed me how to do it; SE 3 - I could use mobile money if someone supports me when I am in trouble; SE 4 - I can complete a money transfer or pay a bill with mobile money if I have plenty of time.

#### \* Technology anxiety

Technology can evoke feelings of anxiety in consumers (Meuter et al., 2003), which can influence consumers' attitudes and behavior towards technology use. Similarly, Parasuraman (2000) suggests that these consumers' positive or negative feelings toward technology are closely related to their behavior.

Technological anxiety can cause consumer discomfort with technology itself (Liljander et al., 2006). Research by Meuter et al (2003) has shown that technology anxiety is an important indicator of consumers' intention to use technology-based services.

Gelbrich and Sattler (2014) find that anxiety about technology reduces mental acceptance of technology; Consumers feel nervous about using new technology for the first time, leading to a negative impact on intention to use. Similarly, anxiety about technology has a negative effect on the adoption and adoption of new forms of technology (Chen and Chang, 2013). Hence, we proposed the following hypotheses:

*Hypothesis 2 (H2): Technology anxiety has a negative impact on perceived usefulness.*

The scale for this hypothesis consists of four observed variables: TA 1 - Mobile money service makes me feel uncomfortable; TA 2 - I feel apprehensive about using new technology; TA 3 - I fear that I will do the wrong thing when I use new technology; TA 4 - I am worried about my data being compromised when using mobile money.

#### **\* Perceived ease-of-use**

Perceived ease of use is the extent to which an individual believes that a system would be easy to use and that the system should not be complex in order to encourage its adoption (Carter & Belanger, 2004; Rogers, 1995). This means to use a particular form of technology, users should need little effort (Liu & Li, 2010). This effort can be physical and mental (Davis, 1993; Taylor & Todd, 1995). Extensive researches have documented evidence of the significant effect of PEOU on user BIs (see Adam, Nelson, & Todd, 1992; Davis, 1989; Carter & Belanger, 2004; Guriting & Ndubisi, 2006; Ramayah, Jantan, & Aafaqi, 2003; Ramayah, Siron, Dahlan, & Mohamad, 2002). In the mobile money services, PEOU includes how easy the registration procedure is, ease of use of the payment method, easy access to customer services, minimal steps required to make a payment, availability of mobile money transfer agents and how accessible the service is on mobile phones with the basic features and software. With these easiness, the study hypothesized that:

*Hypothesis 3 (H3): Perceived ease-of-use has a positive impact on attitude toward mobile money.*

The scale for this hypothesis consists of four observed variables: PEOU 1 - Mobile money allows me to easily control over my financial transactions; PEOU 2 - Mobile money brings convenience to use; PEOU 3 - Steps to use mobile money are easy with me; PEOU 4 - Mobile money gives me more freedom of mobility.

#### **\* Perceived usefulness**

PU is defined as “the degree of users' assessment of whether employing a specific product or service can improve their job performance and efficiency” (Davis, 1989). In this research, PU refers to the degree of users' personal assessments of whether using mobile payment contactless technologies can improve their job performance and efficiency. It can be suggested that the higher the usefulness of mobile payment contactless technologies, the higher the users' satisfaction will be. The existing literature provided evidence that PU has a considerable impact on satisfaction (Daragmeh et al., 2021; Puriwat and Tripopsakul, 2021; Rahi et al., 2021). Furthermore, it can be suggested that the higher the usefulness of mobile payment technologies, the higher the users' sustained use will be. Prior studies also supported the fact that PU has a major impact on sustaining the use of mobile payment technologies (Daragmeh et al., 2021; Puriwat and Tripopsakul, 2021; Rahi et al., 2021). Hence the next hypothesis has been constructed:

*Hypothesis 4 (H4): Perceived usefulness has a positive impact on attitude toward mobile money.*

The scale for this hypothesis consists of five observed variables: PU 1 - In general, mobile money could be useful for me; PU 2 - I can use mobile money to make financial transactions by phone easily; PU

3 - The mobile money service system is a useful mode of payment; PU 4 - Mobile money saves me time doing transaction services; PU 5 - Mobile money saves me shopping time.

**\* Attitude toward mobile money**

According to the TRA developed by Fishbein and Ajzen (1975), the behavioral intention can be explained by the attitude toward behavior that is defined as individual positive and negative feelings about behaving in a particular way. Furthermore, in TAM proposed by Davis et al. (1989) behavioral intention can be explained by attitude toward a system. Lin (2011) found a significant and positive linkage from attitude to behavioral intention to explain the adoption or continued usage of mobile banking. Deb and David (2014) empirically established the positive influence of attitude on behavioral intention. Thus, the following hypotheses are formulated:

*Hypothesis (H5): Attitude toward mobile money has a positive impact on intention to use mobile money.*

The scale for this hypothesis consists of four observed variables: In sum, how would you classify your overall attitude towards using smartphones for m-money? AT 1 - Negative-Positive; AT 2 - Unfavourable-Favourable; AT 3 - Poor-Excellent; AT 4 - Unattractive-Attractive.

**\* Intention to use mobile money**

Intention to use is a familiar research topic in marketing. Intention to use can be found in research on the Theory of Intended Behavior (TPB) (Ajzen, 1991). Intention to use is considered the best predictor of the actual behavior of adoption and use of any new technology (Liébana-Cabanillas et al., 2015), (Venkatesh et al., 2003). Therefore, the intention to use mobile commerce is selected as a dependent variable when assessing the level of acceptance of using mobile commerce by consumers.

**\* Intermediate relationships**

In the recent study by Gbongli et al (2019), the authors tested the hypothesis of an indirect relationship through intermediate variables and most of them were accepted. The research plan from their study, the research team put forward the following hypotheses:

*Hypothesis (H6): Attitude towards mobile money is a mediating factor in the relationship between perceived ease of use and intention to use mobile money.*

*Hypothesis (H7): Attitude towards mobile money is a mediating factor in the relationship between perceived usefulness and intention to use mobile money.*

**Table 1. Conceptual framework of variables.**

Encode	Scale	Source
	Self-efficacy	
SE1	I learn how to use mobile money on my smartphone easily.	Venkatesh et al. (2003); Venkatesh et al. (2008)
SE2	I could use mobile money if someone showed me how to do it.	
SE3	I could use mobile money if someone supports me when I am in trouble.	
SE4	I can complete a money transfer or pay a bill with mobile money if I have plenty of time.	
	Technology anxiety	
TA1	Mobile money service makes me feel uncomfortable.	Park et al. (2019); Meuter et al. (2003)
TA2	I feel apprehensive about using new technology.	
TA3	I fear that I will do the wrong thing when I use new technology.	
TA4	I am worried about my data being compromised when using mobile money.	
	Perceived ease-of-use	

PEOU1	Mobile money allows me to easily control over my financial transactions.	Upadhyay et al. (2016); Venkatesh & Davis (2000); Davis et al.(1989)
PEOU2	Mobile money brings convenience to use.	
PEOU3	Steps to use mobile money are easy with me.	
PEOU4	Mobile money gives me more freedom of mobility.	
Perceived usefulness		
PU1	In general, the mobile money could be useful for me.	Davis et al. (1989); Daragmeh et al. (2021)
PU2	I can use mobile money to make financial transactions by phone easily.	
PU3	The mobile money service system is a useful mode of payment.	
PU4	Mobile money saves me time doing transaction services.	
PU5	Mobile money saves me shopping time.	
Attitude toward mobile money		
AT1	Negative-Positive	Fishbein and Ajzen (1975); Lin (2011); Deb & David (2014)
AT2	Unfavourable-Favourable	
AT3	Poor-Excellent	
AT4	Unattractive-Attractive	
Intention to use mobile money		
IU1	I intend to use/reuse mobile money in the short term/long term.	
IU2	When I have appropriate conditions (mobile device or financial ability or access to mobile money service providers...), I will use mobile money service.	
IU3	I will learn how to use mobile money better.	
IU4	I will make use of mobile money for my trading activities to the extent possible.	

(Source: Compiled and developed by the autor team)

## 4. RESEARCH METHODOLOGY

### 4.1. Data collection and Procedure

A purposive sampling technique was applied to select the various study areas, and simple random sampling was employed to sample the users of the service. Survey participants are consumers in 8 regions of Vietnam including Northeast, Northwest, Red River Delta, North Central, Central Highlands, South Central Coast, Southeast and Mekong River Delta or Southwest. Samples are guaranteed in all areas with uniform proportions.

According to Hinkin, an ideal sample size should have an item-to-response proportion ranging from as low as 1:4 to as high as 1:10 for each set of scales to be factor examined. In this study, there were 25 items to be assessed; hence, an ideal sample size should be between 100 and 250 respondents for adequate factor analysis. From this perspective, a total of 307 responses from the collected data were found to be usable after excluding partial returns and missing responses (whether in the scale section or the demographic section).

Based on the results of the literature review, the research team built a scale and questionnaire to conduct research directly and online through Google Forms for consumers in Vietnam, the data collected is for quantitative research.

### 4.2. Data Analysis

For data processing, the study uses SPSS 20 software to evaluate the reliability of the scale with Cronbach's Alpha numerical system and exploratory factor analysis (EFA), valid variables will be included in the analysis. by describing the partial least squares structural configuration (PLS-SEM) using SMARTPLS 3.0 software. Structural Equation Modeling (SEM) is a second-generation statistical analysis technique developed to analyze multidimensional relationships between multiple variables in a model (Haenlein & Kaplan, 2004). Linear structural modeling (SEM) is evaluated as a modern and popular data analysis method, used by many researchers to test research models in many different fields. The study

uses partial least squares structural equation model (PLS-SEM) to test the hypothesis because PLS-SEM has outstanding advantages: (1) Ignoring problems related to small sample size, the data is not normally distributed; (2) Can estimate complex research model with many intermediate, hidden and observed variables, especially structural model; (3) Suitable for exploratory studies, research based on undeveloped theory (Joseph F. Hair et al., 2019).

The partial least square structural equation modeling (PLS-SEM) was used to estimate and test the hypothesized model. The minimum sample size for a PLS model should be at least ten times the largest number of inner model paths directed at a particular construct in the inner model (Barclay et al., 1995). In the present case, the sample size was 307, which was more than the minimum required (Hair et al., 2017). Furthermore, the reason for choosing PLS is that it requires no distributional assumptions, whereas SEM assumes a normal distribution for the data. In addition, research supporting the claim for PLS having greater efficacy at small sample size is inadvertently misleading as it has focused on accuracy rather than statistical significance (Goodhue et al., 2006). The PLS-SEM is a multivariate technique and is being used in various functional areas of management such as accounting (Lee et al., 2011), marketing (Hair et al., 2012), operations management (Peng and Lai, 2012), etc. PLS-SEM is useful for predictive purposes and exploratory research. The technique is very widely used by researchers when the data are non-normal and the sample size is small (Reinartz et al., 2009).

## **5. RESULTS AND DISCUSSION**

### **5.1. Descriptive statistic**

#### **5.1.1. Sample Profile**

Gender of the respondents: the percentage of women participating in using mobile commerce was higher at 56.03% compared to that of men at 43.97%.

Age of respondents: regarding generational distribution, Gene X (1965-1980) accounts for 30.29%, followed by Gene Y (1981-1996) with 38.11%, and Gene Z (1997-2012) representing 31.6% of the generations. Some other individuals had limited access to mobile phones, faced challenges in adapting to new technology, or did not require mobile money usage.

Respondent's residence: evenly distributed in areas with the rate of 14.66% respectively in the North West; 13.68% in the Mekong Delta; 13.03% in the Northeast; 12.7% in the Central Highlands; 12.38% in North Central; 12.05% in the Southeast; 11.4% in the Red River Delta and finally 10.1% in the South Central Coast.

Education level: respondents mainly graduated from University/College with 40.07% and High School/Vocational Intermediate with 33.88%. The remaining interviewees accounted for 14.1% with postgraduate qualifications, 9.77% had graduated from lower secondary school, and 2.28% had achieved only an elementary level of education.

*Occupation:* the research team conducted a comprehensive survey across various occupational groups, ensuring equal representation. The surveyed members consisted of: 11.07% students/students, 10.75% office assistants, 9.77% employees with advanced technical expertise, 9.45% simple laborers, 9.45% leaders, 9.45% skilled workers in agriculture, forestry, and fishery, 8.79% individuals working in personal services, security, and sales, 8.47% skilled craftsmen and other related technicians, 8.14% assemblers and operators of machinery and equipment, 6.84% workers with intermediate technical skills, and 7.82% from various other occupations.

*Income:* The majority of interviewees have an average monthly income of 4-9 million (accounting for 37.13%); next, people with incomes in the range of 9-14 million accounted for 28.66%; the rest of other income levels account for 10.75% of people with incomes in the range of 14-19 million; 10.75% of people with income between 19 million and more; 8.47% of people with income below 4 million and 4.23% of survey respondents have no income.

### **5.1.2. The current situation of using mobile money of consumers in Vietnam based on the survey results of the research team**

*Using mobile money services of carriers:* The data obtained shows that Viettel's mobile money users are the highest: 144 people (42.1%); The second is VNPT with 112 people (32.7%) and the last is MobiFone with 86 people, accounting for 25.1%.

*Accessing:* According to survey data, the majority of people using mobile money were recommended by their friends (55.0%); Advertising on television, social networks (45.8%); Referred by relatives (43.6%); Referral colleagues (33.9%); Mobile money dealers (21.1%); Public transport advertising (bus, taxi...) (20.9%) and other reasons/options (5.7%).

*Frequency of seeing mobile money ads:* According to a survey on mobile money users in Vietnam, in 1 week, the frequency of users encountering mobile money ads is mostly less than 3 times /week (55.6%); 3 to 6 times/week (38.9%) and more than 6 times/week (5.6%).

*Frequency of using mobile money services:* According to survey results, the majority of people use mobile money services more than 6 times/month, accounting for 56.4%; from 4 to 6 times/month, accounting for 22.8%; from 2 to 4 times/month accounted for 13.2% and less than 2 times/month accounted for 7.6%. This frequency explains that users have not favored using mobile money services regularly in transactions and daily life. This is influenced by the majority of consumers who use other financial methods and services such as e-wallets, online banking, and mobile banking.

*Percentage of respondents using other financial services:* According to the results of the research team, up to 95.3% of respondents use other financial services such as e-wallets, online banking, and mobile banking... and the remaining 4.7% are not. This can be explained by the fact that most consumers now have access to mobile commerce, and the popularity and utility of mobile commerce applications also motivate users to use them. This also partly leads to the low number of people using mobile money services compared to other financial services and applications.

*Percentage of having agents, and mobile money transaction counters (Viettel, VNPT, MobiFone) at the respondents' places of residence:* According to the survey data obtained, 93% of the places where the respondents reside have agents, agents and mobile money counters (Viettel, VNPT, MobiFone) and the remaining 7% are not available. The frequency of explaining the popularity and investment to agents of carriers in Vietnam also contributes to promoting and creating good conditions for consumers to access mobile money and services.

*Using mobile money for the following purposes:* The majority of users use services when there is a need for telecommunications services (Top up phone cards, scratch cards, buy packages, ...) accounting for 64, 6%; Money transfers and receipts accounted for 61.4%; Bill payment (Electricity, water, Internet, ...) accounted for 55.3%; Shopping, entertainment (Lotto...) accounted for 28.9%; Finance, insurance (borrowing money, savings ...) accounted for 23.1%; Travel, tourism (Hotel booking, ...) accounted for 13.5% and other purposes accounted for 16.1%.

*Reason for knowing/choosing mobile money service:* According to survey data, the majority of people use mobile commerce because friends refer (55.0%); Advertising on television, social networks (45.8%);

Referred by relatives (43.6%); Referral colleagues (33.9%); Mobile money dealers (21.1%); Means of transport (bus, taxi...) (20.9%) and other reasons/options (5.7%).

**5.2. Scale’s reliability**

**\* Cronbach’s Alpha (CA)**

As a rule of thumb, a reliability coefficient of 0.70 or higher is considered “acceptable” in social science research (Nunnally, 1978). Table 2 shows the results of reliability coefficients. Most variables achieved an acceptable level of internal consistency since all scores were greater than the rule of thumb (>0.70). Technology anxiety obtained the highest Cronbach’s alpha (.914), whereas Attitude toward mobile money obtained the lowest alpha (.752). Thus, the remaining 25 observed variables continue to be included in the EFA exploratory factor analysis.

**Table 2: Cronbach’s Alpha (CA)**

Scale		Item-Total Statistics			Scale		Item-Total Statistics		
		Corrected Item-Total Correlation	Cronbach’s Alpha if Item Deleted	Cronbach’s Alpha			Corrected Item-Total Correlation	Cronbach’s Alpha if Item Deleted	Cronbach’s Alpha
Self-efficacy (SE)	SE1	.601	.737	.790	Perceived ease-of-use (PEOU)	PEOU1	.668	.837	.860
	SE2	.635	.719			PEOU2	.717	.817	
	SE3	.601	.737			PEOU3	.707	.821	
	SE4	.556	.758			PEOU4	.733	.810	
Technology anxiety (TA)	TA1	.791	.893	.914	Attitude toward mobile money (AT)	AT1	.583	.675	.752
	TA2	.802	.888			AT2	.564	.688	
	TA3	.829	.879			AT3	.548	.694	
	TA4	.797	.892			AT4	.505	.721	
Perceived usefulness (PU)	PU1	.640	.798	.833	Intention to use mobile money (IU)	IU1	.552	.762	.787
	PU2	.623	.803			IU2	.630	.719	
	PU3	.649	.795			IU3	.573	.745	
	PU4	.657	.793			IU4	.636	.712	
	PU5	.597	.811						

(Source: Data processing results using SPSS 20.0)

**\* Exploratory Factor Analysis**

The results of EFA analysis stopped at the first rotation. The Kaiser-Meyer-Olkin measure of sampling adequacy was found to be 0.907 > 0.5; Bartlett’s test has the coefficient Sig.= 0.000 < 0.05. Thus, the application of factor analysis was deemed appropriate.

The value of Eigenvalues of all factors is high (>1), the 6th factor has the smallest Eigenvalues coefficient of 1,085 > 1. The standard for accepting extracted variance is when the total variance is extracted (Total Variance Explained) > 50%. The factors selected explain 56,010% of the variances of the variables. Conclusion: 56,010% change of factors is explained by observed variables. Thus, after analyzing EFA exploratory factors, 6 scales with 25 observed variables were extracted.

**Table 3: Rotated Component Matrix**

### 5.3. Estimation of measurement and structural model

#### 5.3.1. Measurement model

When evaluating the resulting measurement model on SMARTPLS 3.0, the research will focus on the main issues: quality of observed variables (indicators), reliability, convergence and discriminability of the scales.

#### \* Outer loadings

Two rounds of outer loadings were conducted. A study with an external loading factor (outer loading)  $> 0.6$  was accepted, and an exploratory study accepted an external factor loading factor  $> 0.4$  (Moores & Chang, 2006),  $\geq 0.7$  (Joseph F. Hair et al., 2019). At the first round of outer loadings, TA did not meet the outer loadings test. Thus, TA was removed from the model and was not used in further analysis. At the second round of outer loading, the results show that all observed variables with outer loading coefficients are high  $[0.735 - 0.859] > 0.6$ . The quality of observed variables is guaranteed (Table 4).

**Table 4. Outer loadings**

Scale		Outerloading	Scale		Outer loadings
1. Self-efficacy	SE1	0.813	3. Perceived usefulness	PU1	0.775
	SE2	0.798		PU2	0.735
	SE3	0.768		PU3	0.786
	SE4	0.750		PU4	0.803
2. Perceived ease-of-use	PEOU1	0.813		PU5	0.770
	PEOU2	0.847	5. Intention to use mobile money	IU1	0.748
	PEOU3	0.840		IU2	0.790
	PEOU4	0.859		IU3	0.790
4. Attitude toward mobile money	AT1	0.849		IU4	0.804
	AT2	0.774			
	AT3	0.778

**\* Validity and Reliability of Constructs**

According to Hair et al. (2016), internal consistency reliability and convergent validity should be established while testing for moderation effect. In testing the reliability of the construct used two measurements, namely the composite reliability and Cronbach alpha. Construct reliability, both composite reliability and Cronbach’s alpha, was measured to vary from 0 to 1, with 1 being a perfect estimate of reliability, but the construct was declared reliable if the composite reliability and Cronbach’s alpha values were greater than 0.7 (Henseler & Chin, 2010). Thus, the results of the construct reliability and validity tests revealed that the variables of AT, IU, PEOU, PU and SE had reliability coefficients of 0.843, 0.864, 0.906, 0.882 and 0.863, respectively. Besides, based on the Average Variance Extracted (AVE) index to evaluate the convergence of the scale, a scale reaches a convergence value if the AVE is 0.5 or higher (Höck et al., 2010). The construct validity figures for the variables were 0.642, 0.614, 0.706, 0.599 and 0.612 for AT, IU, PEOU, PU and SE, respectively. The results of the construct reliability and validity for the variables are shown in Table 5.

**Table 5. Construct Reliability and Validity**

	Cronbach’s alpha	Composite reliability (rho_c)	Average variance extracted (AVE)
AT	0.723	0.843	0.642
IU	0.791	0.864	0.614
PEOU	0.861	0.906	0.706
PU	0.834	0.882	0.599
SE	0.790	0.863	0.612

(Source: Data processing results using SMART-PLS)

**\* Discriminant validity**

To evaluate the discriminant of the scale, the study used the Heterotrait-monotrait Ratio (HTMT). The discriminant value between the two latent variables is guaranteed when the HTMT index is less than 0.9 (Henseler et al., 2015). Research results in Table 5 show that the discriminant of the scale is very good, which means that all HTMT values are much smaller than the threshold of 0.85. Thus, the factors all meet the requirements of discriminant value. These results are indicated in Table 6.

**Table 6. Discriminant Validity for the constructs (HTMT)**

	AT	IU	PEOU	PU	SE
AT					
IU	0.635				
PEOU	0.578	0.713			
PU	0.625	0.657	0.740		
SE	0.570	0.596	0.684	0.643	

(Source: Data processing results using SMART-PLS)

### 5.3.2. Evaluate SEM model configuration on SMART PLS

Before evaluating the structural model, in order to be able to generalize the research results to the whole, the model needs to be tested for reliability. The authors used the bootstrapping technique with a repeated sample size of 1000 observations (n=1000). Estimation results from 1000 observations show that the original weights are significant with the mean weights of bootstrapping. The estimates in the model can be concluded to be reliable because all the weights are within the 95% confidence interval.

To evaluate the structural model, it is necessary to consider: the multicollinearity evaluation VIF coefficient, the impact coefficient and the significance of the impact levels, and the coefficient R Square, f Square.

#### \* Collinearity statistics (VIF)

Another vital checking involved checking collinearity issues. If the VIF more than 5, the model is likely to appear multicollinear (Joseph F. Hair et al., 2019). The structures in the SEM model in Table 7 have VIF coefficients [1,000 - 1.664] all less than 2, so there is no collinearity issue.

**Table 7. Collinearity statistics (VIF)**

	AT	IU	PEOU	PU	SE
AT		1.000			
IU					
PEOU	1.664				
PU	1.664				
SE			1.000		

(Source: Data processing results using SMART-PLS)

#### \* Coefficient of determination (R-square)

The adjusted R-squared reflects the explanatory level of the independent and dependent variables in the research model. In the study, the adjusted R-squared of IU was 0.240, so the independent variables explained 24% of the variation (variance), the remaining 76% was from systematic error and from other factors. outside the model.

**Table 8. R - Square**

	R-square	R-square adjusted
AT	0.282	0.277
IU	0.243	0.240
PEOU	0.324	0.321

(Source: Data processing results using SMART-PLS)

**\* F-Square**

The coefficient f Square evaluates the strong and weak impact of the independent variable on the dependent variable. The f Square index to evaluate the importance of the independent variables is as follows: f Square < 0.02 level of impact is extremely small or no impact;  $0.02 \leq f \text{ Square} < 0.15$  is small impact;  $0.15 \leq f \text{ Square} < 0.35$  average impact; f Square  $\geq 0.35$  is a large impact (Cohen, 1988). According to the obtained data, the impact level of variable AT on IU is average with f Square value of 0.321.

**Table 9. F-Square**

	AT	IU	PEOU	PU	SE
AT		0.321			
IU					
PEOU	0.048				
PU	0.100				
SE			0.478		

*(Source: Data processing results using SMART-PLS)*

**\* Testing Hypothesis**

In the end, a bootstrapping method was implemented in smart PLS to determine the path coefficient and its associated t-value for both the direct and mediating relationships. Path Coefficients is the regression coefficient of the path model representing the relationship between latent variables in the SEM model. At this step, no impact path has been concluded with statistical significance or no statistical significance.

The results of Path Coefficients after Bootstrap analysis are shown in Table 10. The smart PLS results showed that all the direct impacts are positive and significant, consequently, hypotheses H1, H3, H4 and H5 were supported respectively. The Original Sample (O) column shows the specific relationship between the variables in the SEM model, in which: The variable AT is dependent, under the influence of two variables, PU, and PEOU with the corresponding standardized regression coefficients. is 0.346; 0.240. Variable IU is dependent, under the influence of variable AT with a standardized regression coefficient of 0.493. Additionally, all the specific indirect effects were found to be positive and significant supporting the mediation effects of attitude in the relationships between: perceived ease of use and intention to use mobile money (t-value = 2.771, p = 0.006<0.05); perceived usefulness and intention to use mobile money (t-value = 4.257, p = 0.000<0.05), hence supporting hypotheses H6 and H7 was supported.

**Table 10. Study Tested Hypotheses**

Paths	Original sample (O)	Sample mean (M)	Standard deviation (STDEV)	T statistic (O/STDEV)	P values	Results
SE -> PEOU	0.569	0.571	0.058	9.732	0.000	Accepted
PEOU -> AT	0.240	0.241	0.074	3.225	0.001	Accepted
PU -> AT	0.346	0.348	0.071	4.861	0.000	Accepted
AT -> IU	0.493	0.498	0.050	9.805	0.000	Accepted
PEOU -> AT -> IU	0.118	0.121	0.043	2.771	0.006	Accepted
PU -> AT -> IU	0.170	0.173	0.040	4.257	0.000	Accepted

*(Source: Data processing results using SMART-PLS)*

Figure 2 shows the structural path model:

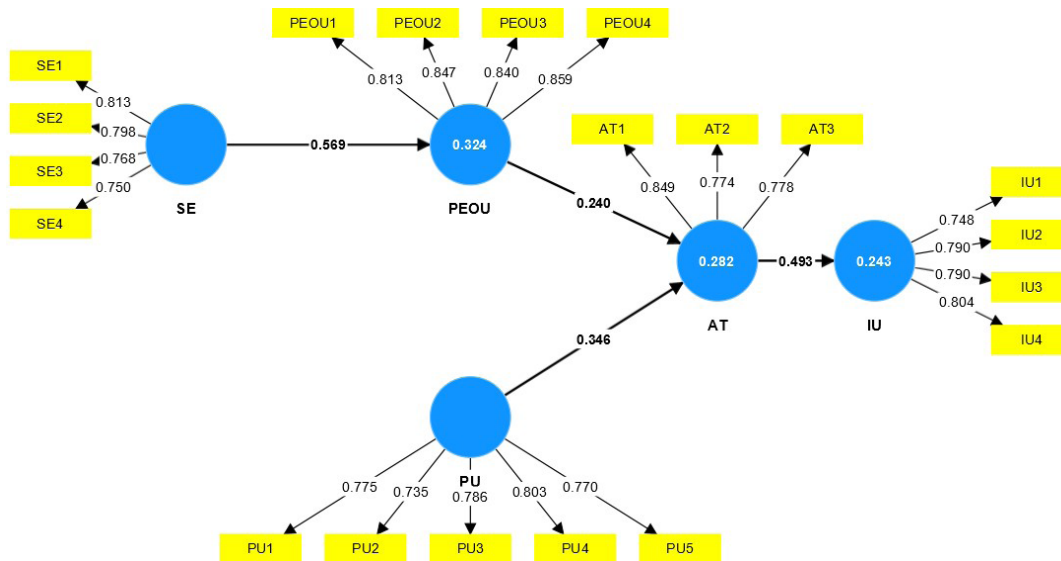

Figure 2. Structural Model Assessment

(Source: Data processing results using SMART-PLS)

This study was established to examine direct factors influencing intention to use mobile money of Vietnamese consumers and the indirect effect through attitudes toward mobile money. As hypothesised, the results of structural equation modelling using Smart PLS (version 3) analysis supported 4 out of the 5 the direct paths and all paths were positive and significant. More specifically the findings supported the first set of research hypotheses. First, there was a direct positive significant impact of Self-efficacy on the perceived ease-of-use, which supported H1. Second, there was a direct positive significant impact of Perceived ease-of-use on attitude toward mobile money supporting H3. Third, the results supported H4 on a direct positive significant impact of Perceived usefulness on attitude toward mobile money. Fourth, the results supported H5 on a direct positive significant impact of Attitude toward mobile money on intention to use mobile money, which supported H5. These results extend the use of TAM by integrating self-efficacy (SE) and confirming that perceived ease-of-use and perceived usefulness, are determinants of attitude and have an impact on attitude toward mobile money, which also coincidence with the results of previous research studies, e.g., (Lin, (2011); Deb and David (2014); Yousafzai et al. (2007)). The abovementioned analytical results reveal that the research model examined in this study is acceptable.

Self-efficacy in mobile money service (SE) has the highest normalized importance. This finding supports prior researches on mobile payment acceptance (Bailey et al. (2017); He et al. (2018)). Notably, self-efficacy will lead a consumer to believe in his or her ability or to see the procedure of performing mobile money ease-of-use, therefore carrying out successfully mobile money adoption.

PU is the more significant factor in determining AT as well as the one having the higher normalized value than PEOU. This can be explained by mobile money services remain a relatively new phenomenon in the field of e-business, and most mobile financial companies are still in an early stage of diffusion. Moreover, users will be unwilling to welcome the novel technology if they do not know how it works. Supporting for this result is earlier empirical studies in mobile banking of Muñoz-Leiva et al. (2017).

Besides, this study detected that two factors impact attitudes significantly towards the application of mobile money, including perceived perceived ease-of-use and perceived usefulness. The results presented

that mobile money users in Vietnam are not only attracted by the usefulness of mobile money services, but are also concerned with the ease of use in its operations.

Additionally, this study showed a significant influence of AT in predicting the IU, which is consistent with the prior study (Bailey et al. (2017)). According to the findings of this study, a person has a good attitude about using mobile money, behavioral intention to use it will follow.

## **6. CONCLUSION**

### **6.1. Policy implications**

Vietnam is full of approving conditions to develop mobile money payment products and services, contributing to promoting non-cash payments and meeting the increasing needs of the people. However, consumers' attitudes towards mobile money are still not very positive with this new type of service because of risks in customer authentication (KYC), technology, and telecommunications infrastructure... Therefore, with the aim of deploying mobile money services effectively, it is necessary to minimize risks by limiting the scope of activities, geography, goods, services and transaction norms; Enterprises can upgrade and invest in infrastructure and telecommunications networks; promote communication about the beneficial features of mobile money to enhance positive attitudes towards service intention.

This finding is particularly important for organizations in formulating effective strategies for service delivery channels to retain and expand their existing customer base. Managers need to focus more on using marketing communications in order to widely publicize the advantages associated with the use of mobile money. Bankers and mobile network operators can use advertising to influence consumers' attitudes toward financial services, which, in turn, affects the intention to use this new payment method. Word-of-mouth (WOM) is another way to influence consumers' attitudes that can take place in a telephone conversation or within the context of a chat group on the internet (Kasper Helsdingen and Vries, 1999). Thus, both advertising and WOM processes offer special solutions to the problem of intangibility of services and they might help to overcome a service's problem of credibility (Bayus, 1985). Furthermore, personal selling is another way to increase customer awareness and influence their attitudes (Burnett and Moriarty, 1998; Kasper et al., 1999). Besides, mobile money service providers need to improve security features in their systems to assure customers that e-banking services are secure. Emphasize positive safety features that can contribute to changing negative customer perceptions, collecting data on customer preferences and feedback to enhance the service's value. This can be done through online surveys and/or a discussion forum. Such actions can improve the intention to use mobile money services in particular and cashless payment methods in general.

### **6.2. Limitations**

Several limitations were found in this research. Firstly, research was conducted in Viet Nam, hence, results may not generalize customer attitudes towards mobile money to other geographies. Future researchers can overcome such limitations by carrying out a cross-country comparative study. Secondly, it used a cross-sectional survey approach and the effect of time was consequently not examined. It is suggested that a longitudinal survey may be conducted in the future. In addition, another limitation is that it uses multiple-choice responses, which does not certainly give as much freedom in responses as free-form responses do and may lead to unreliable data. On the other hand, the survey directed at the use of mobile money would allow a more in-depth and specific analysis of the relationship between attitude and intention to use mobile money. Finally, there should be an analysis of the impact of customer loyalty or customers' character traits on customer intention.

### 6.3. Further research direction

Digital financial services in the form of mobile money have a positive quantitative and qualitative impact on the development of financial inclusion in the developing economy. Therefore, the common question that is currently being raised is how consumers can effectively use mobile money to promote financial transactions in remote and disadvantaged areas. Basically, future research orientation will beneficially apply the influence of mobile money to the development of non-cash payment activities, enhancing the accessibility and use of specialized financial services in rural areas, remote, frontier and islands of Vietnam. Therefore, following research directions will focus on the right awareness of customers about the beneficial features of mobile money. When fully understanding and grasping mobile money usage information, users will then change their beliefs as well as service usage trends to match the customer's behavior and social motivation. Additional research should be conducted as this study does not cover all the variables that affect the intention to use mobile money services. With appropriate expansion variables, the following research should cover a wider range, with a larger sample size and higher objectivity; focus on other variables, such as the influence of the social environment, confidentiality, riskiness, and legal corridors. On the other hand, conducting comparative research in other countries with similar conditions would also greatly enrich and enhance current knowledge.

## FACTORS AFFECTING LEARNING MOTIVATION OF STUDENTS IN INTERNATIONAL TRAINING PROGRAMS AT THUONGMAI UNIVERSITY

Nguyen Minh Anh, Tran Thuy Anh, Nguyen Trong Dai

Mentor: Do Thi Mai Quyen

**Abstract:** *The research explores learning motivation among students in the international training program at ThuongMai University, aiming to identify influential factors and propose strategies to enhance learning quality. A comprehensive data collection approach, including interviews, surveys, and secondary sources, is utilized. The analysis reveals that student skills have the most significant impact on learning motivation, followed by the curriculum and job demands. However, factors such as bachelor's program characteristics, learning environment, faculty, passion, and family have a comparatively lesser influence. These findings contribute to a deeper understanding of how to improve students' learning motivation in an international educational context and provide valuable insights for educational practitioners.*

**Key words:** *international training programs, learning motivation, students, factors.*

### 1. INTRODUCTION

In recent years, determining learning motivation and the relationship between learning motivation and learning outcomes of learners has been attracting the special attention of many researchers in Vietnam. If learners have the right motivation, they will be more active in their studies, take exams more honestly, and pay more attention to study and self-study skills, hone the skills needed for their future. In other words, learning motivation plays an important role in orienting and stimulating learners' learning activities. As the factors affecting learning motivation receive great attention from schools, students, and parents around the world, studies on learning motivation have also resulted in great results there are many authors about this topic in Vietnam as well as in the world such as Nguyen T.M.L. (2021); S.E, Z.K (2016); Hamidah A.R., A.R., Shah R.A.W., Faizah M.N., Wan Z.W.Z., and M.A.B. (2017); E.H., N.Y.K. (2021) They have shown that family and teacher factors have a significant impact on student's motivation. Some other studies suggest that the new learning environment is the same as that of Pinar C. (2011); MSc. Le N.D.T., MSc. Nguyen M.L., (2021).

Based on the aforementioned research review, it is evident that although there have been numerous studies conducted on learning motivation both domestically in Vietnam and internationally, there is a significant gap in the literature concerning the learning motivation of undergraduate students, particularly within the context of the Thuongmai University's international associate program. Moreover, the research team's focus on providing solutions to enhance students' learning motivation for the purpose of improving the overall quality of education adds a novel aspect to their study compared to previous research endeavors.

Consequently, our research project was undertaken with the primary objective of investigating and analyzing the factors that influence the learning motivation of international undergraduate students enrolled in the Thuongmai University. Furthermore, our aim was to identify the most influential factors among these variables and subsequently propose recommendations to both students and the university administration, in order to devise effective strategies for enhancing students' motivation to learn and thereby facilitating improved learning outcomes. Additionally, it is important to acknowledge that the ultimate goal of this

research endeavor is to create favorable conditions for students, enabling them to access numerous opportunities within the job market upon their graduation.

Research objectives and research questions in the study: When conducting research on the factors influencing the learning motivation of undergraduate students in the international associate program at Thuongmai University, the authors have set the following objectives:

- Identify the factors that influence the learning motivation of undergraduate students in the international associate program at Thuongmai University.
- Evaluate the level of influence of each factor on the learning motivation of students.
- Propose solutions to support and enhance the learning motivation of students, aiming to improve their academic performance and teaching quality.

Thus, the research topic aims to answer three main questions:

- What factors influence the learning motivation of undergraduate students in the international associate program at Thuongmai University?
- Which factor has the greatest impact, and which factor has the least impact?
- How can we improve the factors that have the strongest impact on the learning motivation of students to enhance their learning quality?

## **2. LITERATURE REVIEW**

### **Motivation concept**

Hilgard, E. R. (1977) states that motivation is any state that affects the willingness to initiate or continue a certain behavior. Nguyen Quang Uan et al. (2003) also said that motivation is what motivates people to work to satisfy needs, which gives rise to positivity and determines the tendency of that positive direction. Motivation is a direct stimulus, a direct cause of behavior. (Nguyen Quang Uan, 2003). Each author has different views, but between them, there is still a common point: motivation is a psychological factor that determines the choice and direction of human behavior. Motivation is what is reflected in the human head, motivating people to act to satisfy certain needs.

### **Learning motivation concept**

The term “motivation to learn” stands for a series of cognitive and emotional processes that enable self-control toward goal-directed behavior. Thus, learning motivation can be understood as a general term for all the emotional and cognitive processes that help learners learn something new. The degree of learner’s motivation to learn depends on the changing relationship between the personality characteristics of the learner (ability, level of motivation) and the incentives of the personal situation that can be affected. influenced by the teacher. (Stangl, 2022).

### **Factors affecting learning motivation**

There have been studies conducted both domestically and internationally investigating the factors influencing learning motivation, with the main factors identified as follows:

#### **Instructor-related factors**

According to research by Elliot (2009), teachers’ classroom management skills are the main determinants of forming an effective classroom atmosphere. The communication skills that teachers have in this field have a very important place in student motivation. The teacher-student relationship is established in a qualified communication environment and self-confidence affects both student motivation and academic success

positively (Erwin, 2003). In addition to formal classroom communication skills, informal communication outside the classroom strengthens the relationship between educators and students (Pogue and Ahyun, 2006; Jones, 2008). In this way, students have the opportunity to share their topics and problems with the teacher and stay active in a way that is more motivated, and feeling more valued (Jaasma and Copper, 1999; Lau, 2003).

### **Requirements of the job**

In the research of Nguyen Ba Chau (2018), there is a mention of a factor affecting the CTU which is: “The factor that requires the society in terms of qualifications, capacity, skills, ... to meet the requirements of the public sector. The job is the objective factor that has the strongest influence on students’ academic achievement, ranked No. 1. This shows that the influence of the market economy in today’s society has been posing opportunities and challenges. for SVs. This result shows that students are aware of the new requirements and requirements of society about human resources. To get a job in the right major, a high salary is the desire of students and it is also a motivation for students to strive. Therefore, this factor is assessed by students as having the most influence on their academic achievement”. (Nguyen Ba Chau, 2018)

### **Family factors**

Studies around the world have shown that the lack of support from parents in career orientation has a negative impact on children’s career decision-making and causes many challenges in the career development process. such as uncertainty in career choice, inability to make career decisions or lack of confidence in a career (Constantine et al., 2005). On the contrary, there are individuals who, despite not having favorable environmental factors, still have good career goals and are confident that they will achieve the career goals they pursue. These people tend to have professional achievements and are largely due to the support and companionship from their parents regarding their career choices (Constantine et al., 2005). This has shown the importance of the family, especially parents, to their career orientation as the learning motivation of their children.

### **Study environment**

According to the research of lecturer Phan Thi Cam Giang (Vietnam Women’s Academy, Vietnam), the factor of facilities conditions accounts for 92.8%. These factors can be grouped together as learning environment factors, and through this result, the learning environment factor is also a factor that has a significant influence on student’s academic achievement. (Phan Thi Cam Giang, 2021). Research by Tran Thuy Nghiem (2018) also makes the following statement: “The learning environment is favorable, which means that there is close attention of the academic advisor to students, the transfer of knowledge in a way. science and enthusiasm of lecturers, friends in class unite and support each other in learning; no when the class is fun and exciting

Many class activities are organized so that students have the opportunity to have fun and practice themselves. That will help students feel secure and excited in learning.” (Tran Thuy Nghiem, 2018)

### **Curriculum and content of instruction**

Textbooks and lesson content also account for a high percentage of the factors affecting students’ learning motivation, with rates of 96.8% and 94.4%, respectively (Phan Thi Cam Giang, 2021). According to the research of Nhan & Thuy (2014), it is necessary to develop a training program with modules associated with knowledge and practical skills of the profession; through which, students can apply their learning knowledge and skills to work practice, meeting the needs of today’s tourism labor market. Lecturers should invest in building curriculums or lectures that are aesthetically pleasing, vivid, and highly intuitive; In addition, the documents provided to students must ensure clarity. Using active teaching methods and diversifying methods will help learners gain interest. (Human & Thuy, 2014).

**Thuongmai University.**

**Features of the training system**

The number and scale of international joint training programs being implemented at the Institute of International Training is constantly expanding at undergraduate and graduate levels, especially international joint training programs. economics in English. The affiliated partners of the Thuongmai University are all prestigious universities of the Republic of France, Austria, Great Britain, Canada, China, Taiwan, etc. These are also advanced training programs. Modernization allows the addition of high-quality human resources with appropriate qualifications and good communication skills in foreign languages for Vietnamese enterprises, contributing to improving the competitiveness of enterprises. Vietnam in the context of international integration. (International Training Institute -2022)

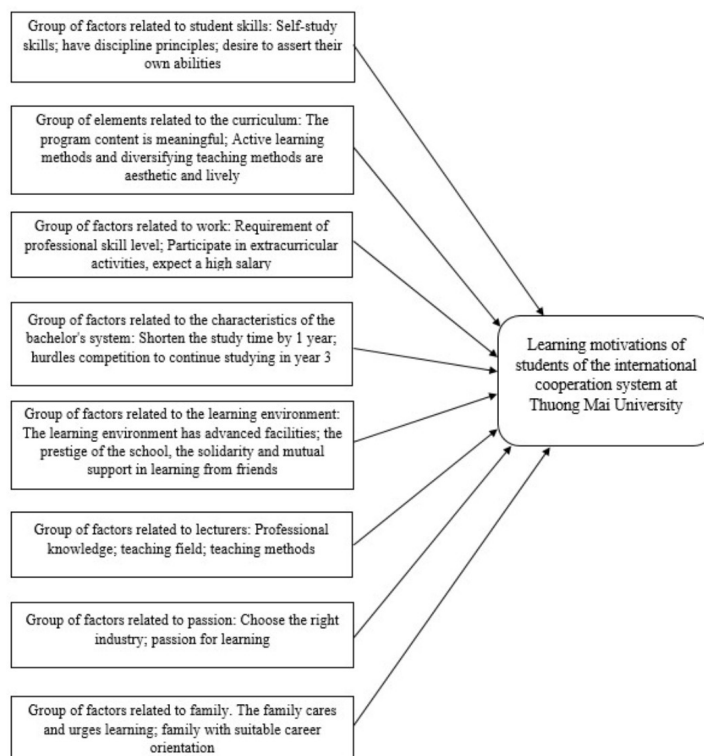

**Passion and interest in the field of study**

According to a research article by Nguyen Ba Chau (2018), interest in learning is also believed by many students to have a great influence on their learning motivation. Interest in learning will help students overcome difficulties and obstacles to accomplish their own goals. If there is apathy and boredom toward learning, nothing can be achieved. Therefore, this factor is also chosen by the majority of students. The remaining two factors are own personality and own learning ability, which are also assessed by students as having a great influence on learning motivation. (Nguyen Ba Chau, 2018)

**Student learning ability**

According to Van Pham, Hoa Le, and Nguyen Thi, current students are also aware of the role and importance of self-study time. This shows that if students focus on learning a lot, they have higher academic achievement. Pourtaaharian (2016) has also shown the relationship between study habits and cognitive discipline that affect learning motivation for students to improve.

**Research models**

**Research Hypothesis**

Hypothesis 1: Factors related to lecturers have a positive impact on the learning motivation of students of the international cooperation system at the Thuongmai University

Hypothesis 2: The demanding factor of work has a positive impact on the learning motivation of international students at the Thuongmai University.

Hypothesis 3: The influence of family has a positive impact on the learning motivation of international students at the Thuongmai University.

Hypothesis 4: The learning environment has a positive impact on the learning motivation of students of the international cooperation system at the Thuongmai University.

Hypothesis 5: The program and teaching content have a positive impact on the learning motivation of students of the international cooperation system at the Thuongmai University

Hypothesis 6: The characteristics of the training system have a positive impact on the learning motivation of students of the international linkage system at the Thuongmai University.

Hypothesis 7: Passion and interest in the field of study have a positive impact on the learning motivation of students of the international association system at the Thuongmai University.

Hypothesis 8: Student learning ability has a positive impact on the learning motivation of international students at the Thuongmai University.

### **3. METHODOLOGY**

#### **3.1. The scale**

The eight primary variables of the scale were obtained from diverse sources. Consequently, Instructor-related factors, Requirements of the job, Family factors, Study environment, Curriculum and content of instruction, Features of the training system, Passion and interest in the field of study, and Student learning ability are expected to influence an individual's inclination towards learning motivation.

#### **3.2. Sample and data collection**

To address the research questions, we employed both qualitative and quantitative research methods. Regarding the qualitative research method, we utilized it to gather and analyze qualitative data related to the objectives, training programs, and factors influencing the model, as well as the desired improvements in learning motivation. The quantitative research was used to validate scales and determine the level of influence of the factors.

##### **Data Collection Method**

##### **In-depth Interviews:**

In this study, we employed the in-depth interview method to refine the research model regarding the factors influencing the learning motivation of students in the international affiliate program at the ThuongMai University. To conduct in-depth interviews, we interviewed three faculty members and five students from the international undergraduate program. These faculty members had extensive experience in teaching the international training program at Thuongmai University. The students represented various majors within the international programs. We also utilized in-depth interviews to explore the desires and solutions put forth by both faculty members and students to enhance learning motivation.

##### **Survey by questionnaire:**

The objective of this method is to validate the constructed model regarding the groups of factors influencing the learning motivation of students in the international affiliate program and to determine the extent

of influence of each factor. Conducting a survey through a questionnaire with learners helps validate the model and answer the research hypotheses and questions. We conducted a survey with a sample of 276 participants, who were students enrolled in the international undergraduate program at the ThuongMai University, from the 16th to the 19th cohorts. The sampling method used was convenience sampling. The survey questionnaire was divided into two main sections: Section 1 included questions related to the learners' personal information, such as their cohort, gender, major, and level of goal-setting frequency for studying. Section 2 comprised 50 questions related to the eight factors constructed in the model. We employed a 5-point Likert scale to measure the extent of influence of each factor on students' learning motivation.

### 3.3. Data analysis methods

The qualitative data from in-depth interviews and group discussions, including notes, recordings, synthesis, and summarization, were processed and analyzed. The quantitative data from the survey were analyzed using two methods: descriptive statistics and statistical techniques such as factor analysis, reliability analysis, and regression analysis, performed using SPSS 25 software

## 4. RESEARCH FINDINGS

### **Factor analysis show the items remained for regression analysis are below:**

*Factor analysis results revealed the following factors related to faculty members (GV):* only observed variables met the requirements for factors related to faculty members, including extensive knowledge and high level of specialization, interesting teaching field, and teaching methods employed by the faculty members.

*Factors related to job characteristics (CV)* included variables that met the requirements, such as the requirement for qualifications and specialized skills, participation in extracurricular activities to deepen job-related knowledge, and the desire for a high salary that motivated students' learning.

*Factors related to family background (GD)* included observed variables that met the requirements, such as family support and having a suitable career orientation within the family.

*Factors related to the learning environment (MTHT)* included variables that met the requirements, namely an advanced learning environment with modern facilities that enhanced students' passion for learning, the credibility of the university that provided significant motivation for learning, and the unity and support from peers in studying that increased students' learning motivation.

*Factors related to personal passion (NEM)* included observed variables that met the requirements, such as choosing a field of study aligned with one's passion, which consistently sparked interest in learning, and a genuine enthusiasm for learning that facilitated concentration in class.

*Factors related to student skills (KNSV)* included observed variables that met the requirements, including self-directed learning skills with clear learning goals and a desire to improve one's learning, self-discipline in studying, and the affirmation of learning abilities.

*Factors related to teaching program content (CTGD)* included observed variables that met the requirements, such as meaningful teaching content, active and diversified teaching methods, and aesthetically pleasing, vivid, and intuitive teaching materials or lectures.

*Factors related to the characteristics of the bachelor's program (DTHCN)* included observed variables that met the requirements for factors related to the specific nature of the bachelor's program, such as a shortened study duration of one year compared to the regular program and overcoming hurdles in order to continue studying in the third year.

After factor validation, reliability testing, and correlation analysis, the research team developed a model that illustrates the impact and degree of influence of these factors on the learning motivation of

students in the international associate program at Thuongmai University. The model is as follows: [Please provide the specific model for further translation.]

#### 4.1. Model and hypotheses testing

The survey took place over 5 months from October 2022 to February 2023, on a total of 276 students in the international joint training system of the University of Commerce. According to the collected data shown in Table 1, the number of female students who participated in the survey at schools accounted for a larger share than the number of male students, a common characteristic of the number of schools in the field of economics. Besides, the number of students participating in the survey is also concentrated in the range K17–K19, mainly students majoring in e-commerce and digital marketing (26.5%); K16 students participated in an insignificant number (2 people). Through the survey, the research team concluded that the students of The international joint training system regularly sets learning goals for themselves at 45.7%, and only a very small number of students never set learning goals (19 people, or 6.9%).

Exploratory factor analysis and scale testing were performed on 50 initial questions. Each scale removes 2 to 3 items to make Cronbach's alpha more reliable. Cronbach's alpha of 9 scales is all greater than 0.5 and less than 0.95, which is the level of reliability (Nunnally, 1978). The correlation coefficients of the sum of the components are all 0.3, showing that the scales are valid and reliable. The research model has been reduced from the original 50 items to 23. Indicators The correlation is shown in Table 2.

According to the general model analysis in Table 4, the R value is 0.700. That is, in 100% of the variation of the dependent variable, 70% of the variation is due to the effects of the independent variables included in the model, and the rest is due to random errors or other factors outside the model. impact. The level of impact of these factors is analyzed in detail as follows:

The factors that affect students' learning motivation according to the coefficient analysis in Table 5 with the order from highest to lowest are: 1- "skills of students" ( $\beta = 0.289$ ); 2-"educational program" ( $\beta = 0.250$ ); 3-"work" ( $\beta = 0.167$ ); 4-"specialty of bachelor's system" ( $\beta = 0.150$ ); 5-"Learning environment" ( $\beta = 0.072$ ); 6-"lecturer" ( $\beta = 0.071$ ); 7-"passion" ( $\beta = 0.047$ ); 8-"family" ( $\beta = 0.008$ )

#### 4.2. Discussion

In addition to the common elements described in other earlier research papers both domestically and overseas, such as family, learning environment, lecturers, and educational program, there are other factors in the study paper's content. The research model now includes the qualities of a bachelor, students' interests, and their talents. The aforementioned criteria have been demonstrated through the process of surveying and data processing. have an effect on pupils' motivation for learning

According to the research results mentioned in part 2, the research team came to the conclusion that 8 observed variables including skills of students; educational program ; work; specialty of bachelor's system ; Learning environment; lecturer ;passions and finally family all have an influence on the learning motivation of students of Thuong Mai University's international cooperation system .

### 5. RECOMMENDATIONS

#### 5.1 Recommendations to students

Based on the identified factors that affect students' learning motivation, the research team recommend the following for students of Thuong Mai university in the future:

- Develop your skills: As the survey results showed students who had better skills tended to be more motivated to learn. Therefore, it is important for future students to work on developing their skills to enhance their learning motivation.

- Choose the right educational program: The educational program played a significant role in motivating students to learn. Therefore, future students should carefully select a program that matches their interests and passions.
- Find a balance between work and study: The survey results showed that work can negatively impact students' learning motivation. Therefore, future students should try to find a balance between work and study to avoid burnout and maintain their motivation.
- Consider the specialty of the bachelor's system: The research findings indicated that the specialty of the bachelor's system influenced students' learning motivation. Future students should choose a specialty that aligns with their interests and passions to increase their motivation to learn.
- Consider the specialty of the bachelor's system: The research findings indicated that the specialty of the bachelor's system influenced students' learning motivation. Future students should choose a specialty that aligns with their interests and passions to increase their motivation to learn.
- Pay attention to the learning environment: The learning environment can greatly impact students' motivation to learn. Future students should choose a school that provides a supportive and conducive learning environment such as Thuong Mai University.
- Take courses with engaging lecturers: Lecturers were found to significantly impact students' motivation. Future students should seek out courses that are taught by engaging and enthusiastic lecturers.
- Pursue your passions: The survey results showed that students who were passionate about their studies were more motivated to learn. Therefore, future students should pursue their passions and interests to enhance their learning motivation.
- Utilize family support: Family support was found to positively influence students' learning motivation. Future students should seek out the support of their families to motivate them towards academic success.

## **5.2. Recommendations to Thuong Mai university**

From the results of the study, the research team determined that the University of Commerce can play a very important role in improving the quality of learning motivation of current and future students. Here are some future nominations for the university

- Enhance the Skills of Students: The university can offer more professional development opportunities such as workshops seminars or conferences. These events can provide students with the latest skills knowledge and trends in their field of study.
- Improve Educational Program: Evaluate the academic program regularly to ensure it is aligned with the practical needs of the industry and that it meets the expectations of the students. The curriculum can be updated regularly to maintain the relevance of the skills being taught.
- Focus on Future Work: The University of Commerce can provide students with an understanding of the job market with opportunities to learn and gain experience in the workplace. Also careers fairs and job search can be organized to help students gain more exposure to the current job market.
- Offer Specialization Programs: Offering a Bachelor's program specific to the student's interest or academic strength can help students improve their learning motivation.
- Improve Learning Environment: The university should create an environment that is conducive to learning. For example, the university can provide quiet study areas access to research resources and innovative teaching methods can be used to keep students engaged.
- Improve Lecturer Quality: The university can ensure that its lecturers are knowledgeable enthusiastic and engaging. Lecturers should be committed and passionate about teaching and ensuring their students succeed.

- **Encourage Passion-driven Learning:** The University of Commerce must motivate students to pursue their passions hobbies or interests. Encourage students to take part in extracurricular activities join clubs participate in academic events and take leadership roles.

- **Leverage Family Support:** The University of Commerce needs to involve parents guardians and families in its students' academic journey. The school can schedule open house events conferences or parent-teacher meetings to encourage parent involvement in their students' education.

In conclusion by improving the factors that affect students' learning motivation the University of Commerce can increase students' outcomes while achieving their academic goals.

## **6. CONCLUSIONS, LIMITATIONS, AND FUTURE RESEARCH**

The research focuses on examining the factors influencing the learning motivation of international affiliated students, specifically those at Thuong Mai University. Based on theory and prior study, the authors have developed a research model the primary study methodology used is collecting data using questionnaires and using the statistical software SPSS for data analysis. The findings show that student abilities have the greatest impact on learning motivation.

This research holds significant importance for both the university and the students. For the university, it provides valuable information on the factors influencing the learning motivation of international affiliated students, enabling them to adjust and improve the learning environment, teaching programs, and interactions between faculty and students to create the best conditions for student development. For students, this research enhances their awareness of the factors influencing their learning motivation. They can utilize the research findings to self-evaluate, enhance their skills and abilities, and explore effective approaches to strengthen their learning motivation. Additionally, the research can offer suggestions and solutions to help students maximize the resources and learning opportunities available in the international affiliated environment.

ThuongMai University's foreign associated students are the sole group on whom the research focuses. The conclusions and solutions offered might not be entirely relevant to different situations. Therefore, more study and a wider scope are required to adapt the findings to various situations. To further understand students' viewpoints and experiences, deeper investigations can be carried out using a wider population sample, in-person interviews, and surveys.

Further investigation into the topic of learning motivation among foreign associated students at ThuongMai University and in other educational settings has fascinating new avenues opened up by this study. Investigating the influence of the classroom and instructional strategies in promoting learning motivation among foreign associated students may be one potential topic for future research. Investigating the effects of linguistic, social, and cultural aspects on students' motivation to study helps enhance research. A possible study direction is to contrast various teaching philosophies and techniques to promote learning motivation in foreign students. We can improve the efficiency of instruction and the growth of foreign students in multicultural learning contexts by investigating and developing this study further.

Overall, ThuongMai University's study on the learning motivation of affiliated overseas students has produced important findings and useful data for both the school and the students. Additionally, it creates chances for additional study and the improvement of policies and practices that promote students' willingness to learn, not just in the context of international affiliation but also in diverse areas and nations.

**APPENDIX**

**Table 1: results from the collection of student personal data.**

<b>Name of category</b>	<b>items</b>	<b>Frequency (number of student)</b>	<b>percentage (%)</b>
Number of students participating in the survey	K16	2	0,7
	K17	80	29
	K18	111	40,2
	K19	83	30,1

## A STUDY OF FACTORS INFLUENCING THE DECISION OF UNIVERSITY STUDENTS TO CREATE CURRICULUM VITAE ON ONLINE PLATFORMS

**Authors:** Do Thi Tuyet Mai<sup>1</sup>, Hoang Binh Nguyen<sup>1</sup>, Pham Thi Nga<sup>1</sup>

**Mentors:** Trinh Thi Nhuan<sup>1</sup>, Vu Van Thinh<sup>1</sup>

**ABSTRACT:** *Purpose* – The purpose of the study is to determine the factors influencing university students' decisions to create curriculum vitae on online platforms.

*Design/methodology/approach* – The study uses the Theory of Planned Behavior (TPB), the Technology Acceptance Model (TAM), the combined Technology Acceptance model and Theory of Planned Behavior (TAM-TPB), the Unified Theory of Acceptance and Use of Technology (UTAUT) as the core research framework. It identifies Perceived Usefulness (PU), Perceived Risk (PR), Social Influences (SI), and Perceived Behavioral Control (PBC) as key external variables that form the research model for the study. Research data was collected from 536 students from universities in Vietnam. This study uses qualitative and quantitative research methods and tests the research model and hypothesis through Partial least squares structural equation modeling PLS-SEM.

*Findings* – Perceived Usefulness (PU), Social Influences (SI), and Perceived Behavioral Control (PBC) positively affect the decision of university students to create curriculum vitae on online platforms. Meanwhile, Perceived Risk (PR) does not affect it.

*Practical implications* – The study implies that university students need to take advantage of the features of online platforms to increase their chances of getting admission. In addition, businesses need to improve the online platform system and services to attract these talented groups of candidates for employment.

*Originality/value* – The study is a new, independent, creative topic. It does not duplicate any previous research work. Besides, the study provides insight for students on the benefits of using online platforms to create curriculum vitae and promotes the growth of these online platforms in Vietnam.

**Keywords:** Curriculum vitae, CV online, Curriculum vitae on online platforms.

### 1. INTRODUCTION

According to the survey data of the Center for Training Support and Human Resource Supply, Ministry of Education and Training, the report in 2020 summarizes the employment situation of graduates of 220/236 higher education institutions (good students in 2019) shows that the percentage of students without a job accounted for 32%.

Many different factors affect a student's ability to find a job but it is clear that the job market is looking for high-quality graduates who not only possess academic qualifications but also can be competitive and creative. According to Shukran and Saodah (2005), besides self-motivation, CV writing skills are also very important for graduates to approach potential employers. The curriculum vitae provides complete and detailed personal information, education level, qualifications, and experience of students, from which employers consider selecting suitable candidates. Having a scientifically designed, beautiful curriculum vitae, ensuring the form and content will impress the employer to increase the likelihood of being hired. However, a traditional CV does not effectively highlight a candidate's strengths, skills, and achievements. Traditional CVs provide a list of achievements and personal details that are inconsistent with modern employment patterns and career changes (Holmes, 2003).

In today's digitalized era, the development of science and technology has led to a series of new technologies, and new utility products born. They bring breakthroughs, and different benefits compared to

<sup>1</sup> Thuongmai University.

the traditional conventional form before. That's why many people choose to use technology solutions instead of doing it themselves, including creating CVs - curriculum vitae but created on online platforms. Before the limitations of traditional CVs, the utility side of creating CVs - curriculum vitae on online platforms is even more emphasized. Creating job applications on online platforms will be easy to do and bring many opportunities for students to get admission. The question is what factors can influence a student's decision to create a curriculum vitae on online platforms? Is there a way to improve the use of students with this method of job search? What aspects do site creators need to pay attention to develop this online platform in the long run that will attract users, especially students - who are inherently sensitive and quickly adapt to technology? Currently, to meet the needs of both employers and job seekers, online job search platforms have been born and are growing strongly. According to the education site FPT.education, online job search platforms are like bridges between job seekers and employers. Therefore, it has also become the address that many people come to because of its convenience, speed as well as extremely large reach. There are quite a few job search sites on a large scale, gaining millions of weekly visits and gaining the trust of users. Thus, not waiting for the future, but now online platforms are also expanding the popularity of the website to users, especially students.

However, when searching and referring to previous research papers on creating curriculum vitae on online platforms, the authors found that: for foreign research, there are not many research papers on the issue; for domestic research, research on this issue has not been conducted. That is the reason why the research team chose the topic "Study of factors influencing the decision of university students to create curriculum vitae on online platforms". It can be seen that the research team's topic is new, independent, creative and does not overlap with any previous research. It contributes to providing a theoretical basis and practical basis. The study raises students' awareness of using online platforms to create job applications, thereby promoting the development of these online platforms in Vietnam.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Overview of CVs – curriculum vitae and online curriculum vitae**

#### **2.1.1. Concept of job application**

Curriculum Vitae or CV, is a Latin phrase born in the early 20th century with the meaning "process of life". The Oxford Dictionary (2011) defines a CV as a brief statement of a person's education, qualifications, and previous professional experience, usually sent with a job application. Jaime A. Teixeira da Silva et al (2020) stated that a CV is a curriculum vitae that highlights the professionalism of the writer's career. Accordingly, the curriculum vitae will contain the writer's information to provide relevant information on academic qualifications and achievements to the employer. According to the Wikipedia website, a CV - application form (abbreviated from Curriculum vitae) is a set of documents containing summary documents about yourself, your education, training, and work experience used to apply for a job.

Therefore, a CV will have the function of providing information about the writer's education, qualities, work experience, and achievements, helping readers understand and better understand the writer.

#### **2.1.2. The concept of online job application**

The online curriculum vitae concept and m-CV concept (mobile career) were first presented by a group of UiTM Penang students during the Career Talk seminar on March 19, 2011. It's an online CV presentation using a weblog as a development platform that comes with web and mobile versions.

According to the website [vieclamvui.com](http://vieclamvui.com), an online curriculum vitae is understood as a candidate's application file submitted to the employer via email, the online application system on job websites that

the company provides. that company cooperates in recruitment or submits it through the websites of the company or business that the candidate applies for. The online curriculum vitae also provides basic information about the candidate including personal information, qualifications, skills, and work experience.

**2.2. Some theories of the research problem**

**2.2.1. Theory of expected behavior**

Ajzen (1991) who is the author of TPB theory found that “perceived behavioral control” affects people’s intentions, whereby people’s “behavioral intentions” are affected by the factors “attitude”, “subjective norm” and “perceived behavioral control”.

**Figure 2.2.1: The Theory Model of Expected Behavior TPB**

*Source: Ajzen, 1991*

Based on Ajzen’s TPB theory, before a person has a positive attitude and receives support from those around him, that individual will be affected by the act of perceiving the ease or difficulty of doing it. activities on online curriculum vitae creation platforms. If a person can perceive and control behavior easily, it will bring a feeling of comfort and satisfaction. Therefore, individuals will tend to receive and lead to an intention to use online platforms to create curriculum vitae in the future.

**2.2.2. TAM technology acceptance model**

Based on the theory of rational action (TRA), Davis (1989) developed the Technology Acceptance Model (TAM) which is more specifically related to the prediction of the acceptability of an information system.

**Figure 2.2.2: TAM Technology Acceptance Model**

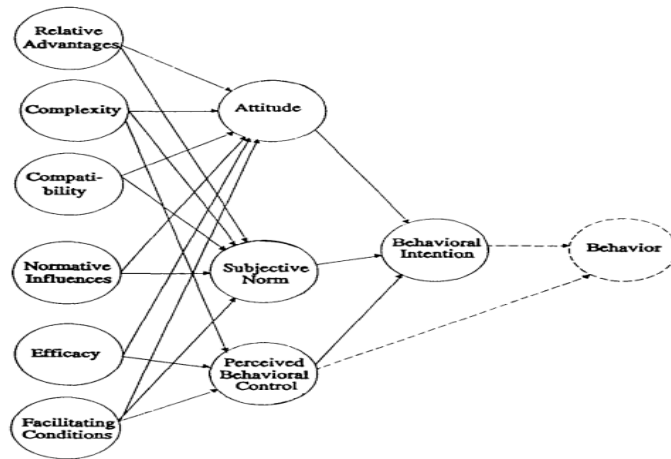

*Source: Davis, 1989*

The purpose of this model is to predict the acceptability of a tool and determine the modifications that must be introduced into the system to make it acceptable to the users. This model shows that the acceptability of an information system is determined by two main factors: perceived usefulness and

perceived ease of use. Thus, the TAM model assumes that the use of technology products is determined by behavioral intentions, but on the other hand, behavioral intentions are determined by each individual’s attitude when using technology products and also by the individual’s perception of the usefulness of the technological product.

**2.2.3. Combined model of TAM and TPB**

Taylor and Todd (1995) have added two main factors to the TAM model, namely subjective norm and perceived behavioral control. According to Taylor and Todd (1995), adding two factors to the TAM technology acceptance model combined with the behavioral intention theory TPB will provide a more appropriate model for the use of information technology products.

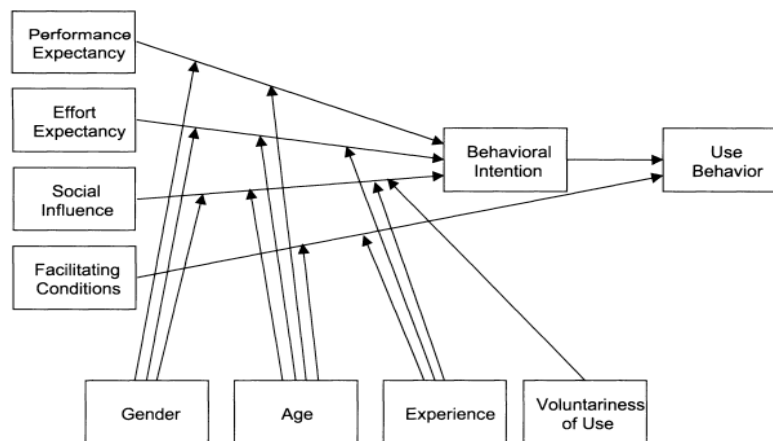

**Figure 2.2.3: Model combining TAM and TPB**

*Source: Taylor and Todd, 1995*

**2.2.4. Unified Model of Technology Acceptance and Use (UTAUT)**

The UTAUT model, also known as the Unified Theory of Acceptance and Use of Technology (UTAUT) model, was developed by Venkatesh et al. (2003) for testing technology acceptance and using a more unified approach. The UTAUT model is relatively new, but it explains 70% of use intent cases, better than any previous model, which can only explain 30% to 45 percent of the time. The UTAUT model has significantly overcome some of the disadvantages of TAM mentioned above.

**Figure 2.2.4: Model combining TAM and TPB**

*Source: Taylor and Todd, 1995*

### 2.3. Research model and hypotheses

After conducting a brief study of foreign documents, combining the practice of creating job applications on online platforms in Vietnam, the authors propose a research model with 4 factors: influence students' decisions to create curriculum vitae on online platforms:

**Figure 2.3: Model to measure the influence of factors**

Source: Group of authors

Perceived usefulness is also understood as “*the extent to which a technology is expected to improve the performance of a potential performer*” (Davis et al., 1996). Nyoro et al (2015) consider that perceived usefulness is “*belief that using a particular system will motivate the individual to perform the task*”. Perceived helpfulness can directly influence the decision to use an online platform to create a resume (BY Mah et al., 2011). Perceived usefulness in the study: a person’s feeling that online platforms will bring what they want in creating a profile such as fast, safe, cost-effective while still ensuring detailed and complete information.

**H1: The factor “Perceived usefulness” has a positive impact on the decision to create a curriculum vitae on online platforms.**

Perceived risk has appeared in previous research on customer behavior. It has been proposed as a major factor influencing buyer behavior decisions (Bauer, R.A., 1960). Perceived risk is defined as the combination of uncertainty and severity of associated consequences (Bauer et al., 1967). Litter and Melanthiou (2006) define perceived risk as a consumer’s perception of uncertainty and possible consequences when purchasing a product or service. Perceived risk in the study: feelings of uncertainty, distrust, and fear of revealing personal information, create many different risks.

**H2: The factor “Perceived risk” has a negative impact on the decision to create a curriculum vitae on online platforms.**

Social influence is considered by Venkatesh et al. (2003) as one of the four factors that directly and positively affect the intention of customers to use. Venkatesh et al. (2003) also define social influence as “*the extent to which an individual perceives that others, who are important to him/her believe he or she should use the new system*”. Social influences in the study: include influence from family, friends, relatives, or influencers and think that the individual should use an online platform to create a curriculum vitae.

**H3: The factor “Social influences” has a positive impact on the decision to create a curriculum vitae on online platforms.**

According to Ajzen, I. (1991) and Ajzen, I. (2002), perceived behavioral control is defined as “*Perceived behavioral control is the perception of the easy or difficulty of performing a given behavior and involves*

*control beliefs about the presence of factors that may facilitate or impede the performance*". Perceived behavioral control in the study: the user's perception that he or she has sufficient knowledge, skill, or ability to use an online platform to create a profile.

**H4: The factor "Perceived behavioral control" has a positive impact on the decision to create a curriculum vitae on online platforms.**

### **3. RESEARCH METHODS**

#### **3.1. Research sample**

Sample size: the group of authors chose the number of research samples to be 600 samples, intending to achieve 80% of the original goal, actually achieved 89.33%, and obtained 536 valid samples. Objects of investigation: the subjects of the survey are students of universities; aimed at students who have worked part-time and used an online platform to create a curriculum vitae or have experience. Collect data: primary data of the research team is collected through posting on websites, scientific research groups of universities, student unions, and student groups... Secondary data of the research team: the research was collected through searching, researching, and selecting reputable information sites.

89.3% of students have used an online platform to create a curriculum vitae, and 10.7% of students have never used an online platform to create a curriculum vitae. The sample has 40.7% male students, 59.3% female students. 61% of the sample is third-year students (the highest rate) and 22.8% of fourth-year students. 57.3% students majoring in Business - Management, 9% of students belong to Engineering, 5% students in Architecture - Construction, 7.3% students in Computer - Information Technology, 4.9% in Journalism - Information - Communication, 2.1% students in the Education Division and 14.6% students in other majors. The number of students who used to work part-time accounted for 97.9%. Besides, there are 11 students who have not yet worked part-time but have used the online platform to create curriculum vitae, accounting for 2.1%. 61.8% students work in jobs related to their majors and 36.2% of students do part-time jobs that are not related to their majors. Besides, the number of students who have not worked part-time accounts for 2.1%. 59.3% of the sample is students who have less than 1 year of part-time work, 24.1% of students have part-time jobs from 1-2 years, 11.9% students have part-time jobs from 2-3 years and 4.7 % of students who have worked part-time for more than 3 years. Most of the students use the website "TopCV.vn" to create job applications, accounting for 30.4%; The website "Vieclam24h.vn" has 294 students using it, accounting for 20.6%, and other online platforms. The study was carried out through two phases: qualitative research and quantitative research.

#### **3.2. Qualitative Research**

The research team conducts qualitative research to check the suitability of the theoretical model, and at the same time helps to discover, adjust and supplement the observed variables used to measure the research concepts to ensure the correct scale built following the research theory. Target: Check and screen the independent variables in the research model that the authors have proposed, discover new causes, and at the same time determine the relationship between the independent variable and the dependent variable.

Method: Conduct preliminary interview with 10 students by face-to-face interview with 5 students, interview via the Internet (Video chat) with 5 students (due to geographical distance). The authors compare the views and opinions of the interviewees, then find the similarities and differences and conclude to propose the model. Result: Basically, the group theory model proposed by the authors is suitable.

### 3.3. Quantitative Research

**Table 3.3: Research scale**

Hypothesis		Symbol	The scale	Source
Perceived Usefulness (PU)	1	PU1	Creating profiles on online platforms saves me time	Group of authors
	2	PU2	Creating curriculum vitae on online job search platforms saves me money.	
	3	PU3	Creating a curriculum vitae on online job search platforms keeps me updated with complete and detailed information.	
	4	PU4	The process of creating a curriculum vitae on online job search platforms is clear and easy to understand.	
	5	PU5	I work easily on online job search platforms to create a curriculum vitae.	(Mah et al., 2011), (A Parikh et al., 2021)
	6	PU6	I easily taught myself how to use online job search platforms to create a curriculum vitae.	
Perceived Risk (PR)	1	PR1	Creating a curriculum vitae on online job search platforms caused me to leak personal information.	Group of authors
	2	PR2	Curriculum vitae templates on online job search platforms are not renewed, causing me to overlap with many other candidates.	
	3	PR3	The system of online job search platforms often has technical problems and data loss.	
Social influence (SI)	1	SI1	My family advised me to use online job search platforms to create a curriculum vitae	(A Parikh et al., 2021)
	2	SI2	Friends advised me to use online job search platforms to create a curriculum vitae.	
	3	SI3	People who are reputable to me recommend that I use online job search platforms to create a curriculum vitae.	
	4	SI4	I was intrigued by the advertisements for online job search platforms.	Group of authors
Behavioral Control (PBC)	1	PBC1	I have the necessary knowledge to use online job search platforms to create curriculum vitae.	(A Parikh et al., 2021)
	2	PBC2	I can use online job search platforms to create curriculum vitae.	
	3	PBC3	I have complete control over my use of curriculum vitae creation online job search platforms.	
Decide to use (DU)	1	DU1	Using online job search platforms to create a curriculum vitae is the right decision.	Group of authors
	2	DU2	I will continue to use online job search platforms to create curriculum vitae in the future.	(Mah et al., 2011), (A Parikh et al., 2021)
	3	DU3	I would gladly recommend my acquaintances to use online job search platforms to create curriculum vitae.	Group of authors

Data analysis: After collecting, coding, and cleaning, the data was analyzed by SPSS software version 26 and processed by SmartPLS 4.0 software.

- Descriptive statistics to calculate the mean and standard deviation of the perception of the factors affecting the decision to create a curriculum vitae on online platforms.

- Test the reliability of the scale by Cronbach's Alpha coefficient to assess the reliability and value of the scale.

- Test the difference between the survey groups to assess the difference in the evaluation criteria of the sample groups with different characteristics.

- Data analysis process based on using SmartPLS software in three steps: Data encryption and descriptive statistics; Evaluation of the measurement model; Evaluate structural models.

**4. RESULTS AND DISCUSSION**

**4.1. Results**

**4.1.1 Descriptive statistics of observed variables**

Through the survey, the independent observed variables all have relatively high mean values ranging from 4.37 (SI2) to 5.31 (PU2), proving the large influence of the observed variables on the decision to create student curriculum vitae on online platforms. Besides, the dependent variables show that the majority of students decide to continue using online platforms to create curriculum vitae in the future (Mean value is 5.17 – DU2) and they give that using online platforms to create curriculum vitae is the right decision (DU1) and are happy to recommend acquaintances to use online job search platforms to create curriculum vitae (DU2). This is evidenced by the mean values of 5.13 and 5.07, respectively.

The standard deviation of the observed variables ranges from 1,236 (PU6) to 1.648 (SI1) because the scale used by the authors is a 7-level Likert scale, so with this standard deviation, the value shows the object. The number of answers does not differ much.

**Table 4.1.1: Descriptive statistics of observed variables**

Variable	Mean	Standard Deviation	Variable	Mean	Standard Deviation
PU1	5.2	1.427	SI1	4.37	1.648
PU2	5.31	1.447	SI2	4.99	1.447
PU3	5.23	1.339	SI3	5.07	1.326
PU4	4.97	1.318	SI4	5.12	1.423
PU5	5.16	1.353	PBC1	5.17	1.431
PU6	5.28	1.236	PBC2	5.13	1.499
PR1	4.96	1.474	PBC3	5.21	1.316
PR2	5.11	1.455	DU1	5.13	1.203
PR3	4.82	1.371	DU2	5.17	1.297
			DU3	5.07	1.477

**4.1.2. Scale verification results through measurement model evaluation**

*a, Reliability and convergence value of the scale*

Since the latent variables in the research model are reflective, the quality of the observed variables is assessed through the external loading coefficient of the observed variables. This is an index showing the degree of association between the observed variable and the latent variable. The outer loading results show that the scales all meet the requirements greater than 0.7. Therefore, the observed variables are all significant in the model.

**Table 4.1.2: Outer loadings results**

	Behavioral Control	Perceived Usefulness	Decide to use	Perceived Risk	Social influence
PU1		0.88			
PU2		0.925			
PU3		0.83			
PU4		0.899			
PU5		0.906			
PU6		0.874			
PBC1	0.927				
PBC2	0.922				
PBC3	0.894				

	Behavioral Control	Perceived Usefulness	Decide to use	Perceived Risk	Social influence
DU1			0.915		
DU2			0.92		
DU3			0.93		
PR1				0.84	
PR2				0.919	
PR3				0.887	
SI1					0.71
SI2					0.897
SI3					0.905
SI4					0.882

Source: Data processing results from SmartPLS software

The reliability of the scale is assessed based on two main indicators, namely Cronbach's Alpha coefficient and the composite reliability coefficient CR (Composite Reliability). Researchers often prefer to choose the composite reliability CR over Cronbach's Alpha because Cronbach's Alpha coefficient evaluates the lower reliability. According to Henseler et al. (2013), these two coefficients need to reach values greater than 0.6 with exploratory studies and will achieve a good confidence level when these two values reach the threshold of 0.7.

To evaluate convergence, the author relies on the extracted variance index (AVE). According to Hock and Ringle (2010), a scale achieves a convergence value if the AVE is 0.5 or higher. This level of significance means that the average parent latent variable will explain at least 50% of the variation of each child observation.

**Table 4.1.2: Results of evaluating the reliability and convergence value of the scale**

	Cronbach's Alpha	rho_A	Composite Reliability (rho_c)	Average Variance Extracted (AVE)
Perceived Usefulness	0,945	0,947	0,956	0,785
Perceived Risk	0,857	0,866	0,913	0,779
Social influence	0,872	0,889	0,913	0,727
Perceived behavioral control	0.902	0.903	0.939	0.836
Decide to use	0,912	0,916	0,944	0,849

Source: Data processing results from SmartPLS software

The results show that the coefficients of Cronbach's Alpha of all variables in the model are greater than 0.7 and range from (0.857 to 0.945). Composite Reliability is greater than 0.7 and AVE is greater than 0.5, showing that latent variables in the model explain more than 50% of the variance of the scales. Thus, the scales are reliable and convergent.

#### *b. Discriminant value test*

Discriminant value indicates how distinct a structure is when compared to other structures in the model. To test the discriminant value of the variables in the research model, two indexes can be used, namely the square root of AVE proposed by Fornell & Larcker (1981) or the HTMT index proposed by Henseler et al (2015). propose. Fornell & Larcker (1981) suggested that discriminability is guaranteed when the square root of the AVE of each latent variable is higher than all correlations between the latent variables. With the HTMT index, according to Henseler et al. (2015), the discriminant value is established between the structures when the HTMT index is below 0.9, but Kline (2015) applies a more stringent standard threshold of 0. 85.

The Fornell-Larcker index results in the table show that the top value of each column is larger than the other coefficients in the column, that is, the square root of AVE is larger than the correlation between latent variables.

**Table 4.1.3: Fornell-Larcker index results**

	Behavioral Control	Perceived Usefulness	Decide to use	Perceived Risk	Social influence
Behavioral Control	0,914				
Perceived Usefulness	0,798	0,886			
Decide to use	0,795	0,828	0,922		
Perceived Risk	0,664	0,759	0,7	0,882	
Social influence	0,721	0,72	0,759	0,682	0,852

Source: Data processing results from SmartPLS software

The HTMT index of each structure, shown in Table 4.24 is less than 0.9, thus meeting the criteria of Henseler et al. (2015). Thus, it can be concluded that the constructs have discriminant validity.

**Table 4.1.4: HTMT index results in**

	Behavioral Control	Perceived Usefulness	Decide to use	Perceived Risk	Social influence
Behavioral Control					
Perceived Usefulness	0,865				
Decide to use	0,873	0,888			
Perceived Risk	0,751	0,841	0,786		
Social influence	0,808	0,783	0,843	0,789	

Source: Data processing results from SmartPLS software

Thus, after evaluating the measurement model, the observed variables measuring the research factors remain the same as at the beginning.

**4.1.3. Results of model testing and research hypotheses through structural model evaluation**

To evaluate and test the structural model, the authors performed Bootstrap estimation with a magnification factor of 5000 samples with the significance level of the test at 5%. The bootstrap technique in PLS-SEM is a repeated random sampling method to help test research hypotheses.

**4.1.3.1. Multicollinear Detection**

Multicollinearity in the model will be checked through the VIF index. Because the latent variable in the model is reflective, the result of the VIF coefficient will be displayed in the Inner VIF Values result in SmartPLS software. According to Hair et al. (2016), a VIF value < 5.0 means no multicollinearity will occur.

**Table 4.1.3.1: Multicollinearity test results in**

	Behavioral Control	Perceived Usefulness	Decide to use	Perceived Risk	Social influence
Behavioral Control			3,146		
Perceived Usefulness			3,849		
Decide to use					
Perceived Risk			2,594		
Social influence			2,547		

Source: Data processing results from SmartPLS software

The results of the VIF value in Table 6.6 show that the VIF coefficients are all < 5.0, so the model does not have the phenomenon of multicollinearity between the latent variables and the test of the correlation between the guaranteed variables. guarantee the reliability of the study. Thus, all latent variables are eligible to perform the next analysis.

**4.1.3.2. Test model and research hypothesis**

To test the research hypotheses, the indexes used include Path Coefficients, P-Value, T-Value, and f squared-test criteria to confirm or accept the research hypothesis at 95% confidence level, T-Value > 1.65, P-Value < 0.05. The coefficient f2 will show the degree of influence of the independent variable on the

dependent variable. Cohen (1988) proposed an index table  $f^2$  to evaluate the importance of independent variables as follows:  $f^2 < 0.02$  (the level of impact is extremely small);  $0.02 \leq f^2 < 0.15$  (small impact level);  $0.15 \leq f^2 < 0.35$  (medium impact);  $f^2 \geq 0.35$  (high impact).

**Table 4.1.3.2: Results of testing the research hypotheses**

	Cronbach's Alpha	rho_A	Composite Reliability (rho_c)	Average Variance Extracted (AVE)
Perceived Usefulness	0,945	0,947	0,956	0,785
Perceived Risk	0,857	0,866	0,913	0,779
Social influence	0,872	0,889	0,913	0,727
Behavioral Control	0.902	0.903	0.939	0.836
Decide to use	0,912	0,916	0,944	0,849

Source: Data processing results from Smart PLS software

The values of the hypotheses H1, H3, and H4 have T-Value  $> 1.65$ , P-Value  $< 0.05$ , so in this model the hypothesis H1; Hypothesis H3, hypothesis H4 is accepted. Besides, because hypothesis H2 has T-Value  $< 1.65$ , P-Value  $> 0.05$ , this hypothesis is not statistically significant, so hypothesis H2: “perceived risk has an impact. negatively on the decision to create curriculum vitae on online platforms” was rejected.

Considering the coefficient  $f^2$  of the hypotheses H1, H3, and H4, we find that: The factor “Perceived Usefulness” has a great positive impact on the decision to create a curriculum vitae on online platforms with the coefficient  $f^2$  being 0.177. The remaining factors influence at a small level according to Cohen’s (1988) evaluation rule and in the order of “Social influence” ( $f^2$  is 0.099), “Perceived behavioral control” ( $f^2$  ). is 0.093).

The coefficient of determination  $R^2$ :  $R^2$  shows how much the independent variables in the model explained the variation of the dependent variable. The measurement results of the R-square adjusted coefficient and adjusted  $R^2$  coefficient are shown in Table.

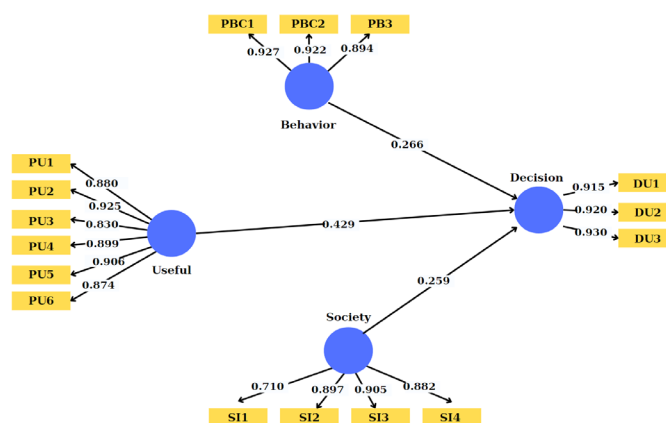

**Table 4.1.3.3: Coefficient of determination R-square adjusted**

	R-square	R-square adjusted
DU	0,765	0,763

Source: Data processing results from SmartPLS software

From Table 4.1.3.2.2 it can be seen that the adjusted  $R^2$  value of the dependent variable DU is 0.763. This shows the strong explanatory power of the model. Thus, the constitutive factors explained 76.3% of the variation in the decision to create an online curriculum vitae.

**Figure 4.1.3: Overall structural model**

Source: Data processing results from SmartPLS software

## 4.2. Discussion

The factor “Perceived Usefulness” has the strongest influence on students’ decision to create curriculum vitae on online job search platforms. Students feel that creating curriculum vitae on online platforms saves time and money compared to creating a traditional curriculum vitae. They believe that creating curriculum vitae on online job search platforms helps them update complete and detailed information. The process of creating a resume on online job search platforms is clear and easy to understand. They can easily manipulate and teach themselves how to use online job search platforms to create curriculum vitae. This conclusion is also mentioned in the study of BY Mah et al (2011). “*The study notably found that students’ perceived usefulness may have directly effects on their intention to adopt m-CV. It showed that students’ perceived ease of use might be mediated by their perceived usefulness, which had considerable indirect effects on their intention to use m-CV.*” (BY Mah et al, 2011).

Perceived Behavioral Control is the second influential factor on students’ decision to create curriculum vitae on online job search platforms. Students have complete control over using the online resume platform when equipped with enough knowledge. Therefore, they will decide to use it to create curriculum vitae.

The factor “Social Influence” positively influences students’ decision to create curriculum vitae on online job search platforms. The fact that relatives, friends and advertisements about online platforms will encourage them to use online platforms to create curriculum vitae.

The factor “Perceived Risk” does not influence the decision to create a resume on online platforms. Online platforms causes negligible damage and the frequency is so small that student can be resolved and accepted by themselves. This reason is also mentioned in the study of Yoon Kin Tong et al (2009). Research suggests that job seekers are generally aware of these risks but still use online recruitment sites because this method’s ease of use, usefulness, and speed of posting offers many advantages over other methods.

## 4.3. Recommendations

### 4.3.1. Recommendations for individual students to use online platforms to create curriculum vitae

#### 4.3.1.1. Make the most of online platforms to create curriculum vitae

Online platforms for creating curriculum vitae bring many benefits and conveniences, helping students save money because they don’t have to buy paper curriculum vitae, and do not have to buy additional curriculum vitae. else if spelled incorrectly. Curriculum vitae on online platforms allow students to freely modify and design their curriculum vitae without limits, without fear of making mistakes.

The operation of creating a curriculum vitae on online platforms is also simple and easy to understand, making it easier for students to work on online platforms to create a curriculum vitae and create a curriculum vitae by themselves. apply for a job without difficulty.

Online platforms provide ready-made curriculum vitae templates for students to choose and design to their liking, so they don’t need to spend a lot of time and effort to think of ideas. In addition, students can reuse curriculum vitae on these online platforms to submit in multiple places. Therefore, applying for jobs on online platforms helps students have more opportunities to apply at many different companies and businesses, helping to increase their chances of being recruited.

Students should know how to make the most of the online platform’s features to create a curriculum vitae that best suits them, and seize the opportunity to apply for the job of their dreams.

#### 4.3.1.2. Improve knowledge and necessary conditions for creating curriculum vitae on online platforms

To facilitate the creation of job applications on online platforms, students should constantly improve their knowledge and necessary conditions. Knowledge here is knowledge about how to use that online

platform, how to create a satisfactory curriculum vitae, how to use that platform... As students hone their skills The above knowledge and conditions will be convenient in creating your profile easily to avoid confusion or technical problems in creating your profile.

#### *4.3.1.3. Update features and curriculum vitae templates regularly*

Regular updates of features and curriculum vitae templates help students enjoy incentives and benefits from the fastest online platform. Update useful features that automatically correct spelling errors or automatically suggest necessary information items for your profile, compatible with different devices, without errors in fonts, images, etc. This feature will help students complete their online curriculum vitae professionally and perfectly. In addition, students need to update the curriculum vitae templates regularly to avoid duplicates with other candidates as well as have more diverse choices. Depending on the nature of the job, needs, and interests, students can choose the appropriate curriculum vitae template. As a result, students can make an impression on employers through these professional curriculum vitae templates.

#### **4.3.2. Recommendations for businesses providing online platforms**

##### *4.3.2.1. Enhance the sense of usefulness*

According to the research results, “Perceived Usefulness” is the main factor that has the strongest impact on students’ decision to create a curriculum vitae on online platforms today (Beta = 0.4). This is easy to see because today’s online platforms always focus on increasing the utility for customers to attract users, proving that the greater the benefits that students perceive, the more they tend to use. use it. Therefore, businesses providing online platforms must focus on solutions that increase the usefulness and ease of use for their online platforms.

First, in order for students to save time and money when creating a curriculum vitae, the online platform provider should integrate the website with the function of automatically searching and recommending curriculum vitae templates for students. suitable for an affordable cost. The online platform has an eye-catching website interface design, the headings are arranged in a scientific way, and the operations are simple. At the same time, the online platform also needs to regularly update the search questions and send the most feedback to gather at the help center to help users choose the content they need without spending a lot of time searching.

Secondly, to bring the highest efficiency and convenience to students, the online platform needs to catch up with the trend of the times and update the modern, youthful, diverse and appropriate curriculum vitae templates. professions to avoid duplication, creating comfortable conditions for students to choose profile designs.

Businesses should optimize the interface of the online platform, and design a clear and easy-to-operate website, customers do not need to take too many steps to search or design a profile, and the page load speed is fast. It is an important factor in increasing the perception of ease of use.

Long-term investment in modern technology systems, such as building high-security technology systems, careful risk contingency plans, ensuring online information is safe, and minimizing risks. security risks, helping customers have confidence and peace of mind when using to create job applications on their online platform.

Regularly review and evaluate the safety of the system, proactively detect security holes, and fix them. All of these issues need to be widely communicated to target customers, thereby creating more peace of mind when participating in creating job applications on the online platform.

#### 4.3.2.2. Promoting social influence

Research results show that social influence has an impact on students' decision to create curriculum vitae on online platforms. Thus, friends, family, and reputable people support an individual who creates a curriculum vitae on an online platform or is attracted to advertisements about the online platform that route or not will affect the psychology and behavior of the individual who decides whether to create a curriculum vitae on that online platform or not. Therefore, to take advantage of and promote this feature, businesses providing online platforms need:

*Firstly*, Promote marketing through social media channels. This is an effective marketing channel for businesses. Media products that have impressed customers make them remember. Therefore, businesses also need to continue to maintain their image on media such as Youtube, Tiktok, Facebook, and Instagram... These tools help businesses reach more target customers, thereby helping businesses reach more target customers. help increase traffic to your website.

*Secondly*, Enterprises need to promote brand recognition to students using communication: using led poster screens at schools to promote to users.

*Thirdly*, businesses should promote marketing through influencers (Influencer marketing). Influencer marketing is growing strongly, making it easier to promote products and services and reach users in a natural and friendly way. Using this form of communication is one of the effective ways for businesses to connect with a large number of users: students. However, to be suitable for students, businesses also need to consider choosing the right influencers because each influencer focuses on exploiting different content, targeting people who are interested in the field. while following them.

*Finally*, businesses need to pay attention to improving user experience, especially students: listening and absorbing user opinions through usage surveys... to promptly fix and improve their online platforms. The reason is that students' decisions to create curriculum vitae on online platforms are also influenced by friends who have used them before. So if they have a good experience, they will also refer more users to the business, and if they have a bad experience using it, they will not recommend that online platform to others. This is also known as "word of mouth" advertising.

#### 4.3.3 Limitations of the study and directions for further research

Although the research has made certain contributions in theory as well as practice, this is also a new topic for students, leading to certain limitations:

Firstly, the number of samples collected is only 536 samples according to the convenient sampling method in some provinces/cities directly under the Central Government. Therefore, it is not possible to represent all Vietnamese students. Therefore, the generality is not high.

Secondly, the proposed research model includes only 4 factors that affect students' decision to create job applications on online platforms today. There may be other factors that have not been mentioned.

Thirdly, the survey respondents are only on the demand side (students) but not on the supply side (providers) of online platforms.

Finally, the study period was conducted in a short period (within 3 months from September 20, 2022, to February 10, 2023).

The above limitations are suggestions for future research directions.

## 5. CONCLUSION

The study has achieved success in building a model "Factors influencing the decision to create curriculum vitae on online platforms" and has achieved outstanding points. Research has shown important

groups of variables that directly affect students' decisions to create curriculum vitae on online platforms. According to the research results, the factors that have a positive effect in decreasing order of magnitude are perceived usefulness (standardized beta is 0.4), and perceived behavioral control (standardized beta is 0.263). ), social influences (normalized beta is 0.244)

The research model that the authors built with the hypothesis: The factor “perceived risk” negatively influence the decision to create a curriculum vitae on online platforms is rejected. To explain the above problem, the research team conducted a small interview including 5 people, through the answers, most of the students said that the risk that creating a curriculum vitae on the Internet Online platforms cause negligible damage and the frequency is so small that they can be resolved and accepted by themselves.

## THE IMPACT OF PERCEIVED VALUE, SOCIAL INFLUENCE AND SITUATIONAL INFLUENCE ON PERFORMANCE EXPECTANCY AND E-BOOK USER SATISFACTION: THE CASE IN HANOI

**Authors: Pham Thi Thuy Huong<sup>1</sup>, Bui Thi Thu Ha<sup>1</sup>, Nguyen Thi Thanh Huyen<sup>1</sup>,  
Le Thanh Huyen<sup>1</sup>, Nguyen Tuan Hung<sup>1</sup>  
Mentor: Luu Thi Thuy Duong<sup>1</sup>**

**ABSTRACT:** *In the context of strong digital transformation today, increasing the satisfaction of e-book readers is essential to enhance reading behavior and improve the effectiveness of e-book usage. Based on the Expectation Confirmation Model (ECM) and the Theory of Planned Behavior (TPB), this study clarifies the central role of efficiency expectations in user satisfaction with e-books. Data collected through a survey of 555 university students in Hanoi was processed using Smart-PLS 4.0 software. The results have confirmed the central role of efficiency expectation when this factor has a direct and significant impact on user satisfaction with e-books. In addition, all factors such as “perceived value”, “social influence”, and “situational influences” have a direct impact on the reader’s expectations of e-book effectiveness. Some implications of this study are discussed for increasing user satisfaction with e-books.*

*Keywords: e-books, perceived value, reading performance expectancy, satisfaction.*

### 1. INTRODUCTION

Currently, Vietnamese reading culture is receiving more attention and interest than ever before. The development of technology and the strong trend of digital transformation have led to the emergence of digital products, especially e-book readers. Besides, the evolution of the Covid-19 pandemic in the past 3 years has led to a change in consumption behavior. As a result, reading e-books is being mentioned as a trend in society. In particular, Vietnam has a young population structure that loves technology, is eager to learn and has need to update new trends; therefore, e-book is a modern and convenient reading method, suitable for the digital age. The Vietnamese e-book market has experienced more than 10 years of development with some initial successes. As of 2021, Vietnam has had 2,300 electronic publications in circulation. According to the report of the Waka e-book application, the average daily reading time of e-books by Waka readers has continuously increased and is currently at around 30 minutes per person per day. Vietnamese readers are also increasingly willing to pay more for e-books. Specifically, on the Waka platform, in 2017, three out of ten readers were willing to pay more than 100,000 VND per year for e-books. These are positive numbers, opening up hopes that the number of e-book users in Vietnam will continue to increase and the e-book market will develop continuously to better meet the growing trend of reading culture.

According to the General Statistics Office (2021), Vietnamese education system has 242 universities with a total of approximately 1,906,000 undergraduate students. With such a large scale, the demand for using electronic books such as textbooks and learning materials for research is very high.

As a digital product, e-books offer many undeniable advantages over conventional printed books in terms of mobility, convenience, visual appeal, interactivity, accessibility and low cost (Verkijika, 2019; Tosun, 2014). Therefore, e-books tend to be increasingly used by many countries, especially in education

---

<sup>1</sup> Thuongmai University

(Wang & Bai, 2016; Alhammad & Ku, 2019). Furthermore, the explosion of information technology and the context of the Covid-19 pandemic have led to a change in learning and researching at universities from traditional to online methods, from using paper books to using e-books. In this context, universities have built diverse e-learning resources to serve the purposes of teaching, learning and research for lecturers as well as students with the motto of being accessible anytime, anywhere. E-learning materials bring vividness, attractiveness, convenience and innovation in teaching and learning methods. These affirm the importance of researching the factors influencing the behavior of students in using e-books as well as contributing to enhance the reading and learning effectiveness of students, while opening up a direction for Vietnamese universities to replace traditional books in the future.

This study investigates the factors affecting the use of e-books among university students, with a focus on Hanoi. The research model is developed based on the ECM and TPB with hypotheses about the positive impact of three factors (social influence, perceived value, situational influences) on reading performance expectancy and the relationships between reading performance expectancy and satisfaction of e-readers.

## **2. THEORETICAL FRAMEWORK**

### **2.1. E-books**

Electronic book (abbreviated as e-book or eBook), is a digital version of a traditional book. According to Tosun (2014), an e-book includes both hardware (e-book reader) and software called rich text features that allow readers to perform tasks such as marking up text and taking notes, just like with traditional books. E-books can be accessed from a variety of devices, including dedicated e-book readers (e.g., Kindle, Kobo, Nook, etc.), desktop computers, laptops, smartphones, or any other screen-navigable device.

E-books simulate the basic features of traditional books in an electronic format. The attributes of traditional books can be better provided in the digital environment with features such as searching, hyperlinking, and annotations (Vassiliou & Rowley, 2008). E-books can be read on dedicated e-readers or on any screen-enabled computing device, including desktop computers, laptops, tablets, smartphones, and pocket PCs.

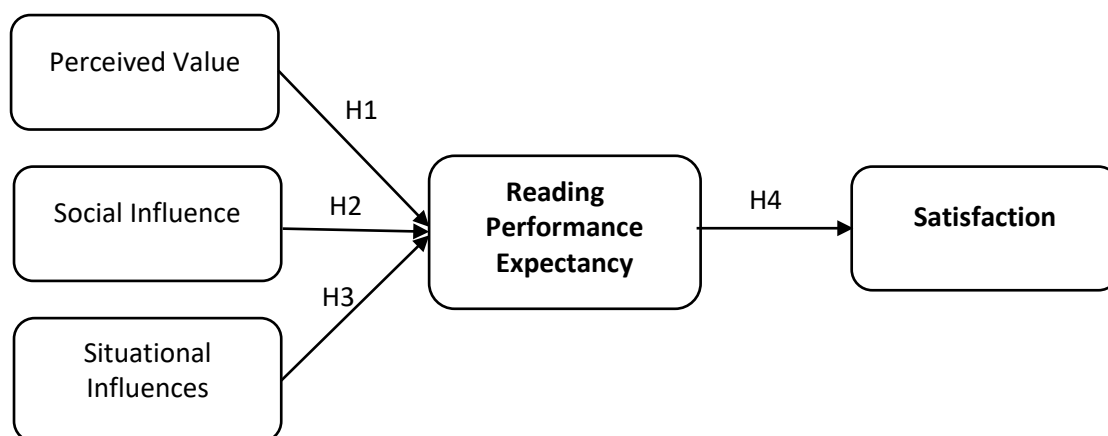

### **2.2. Expectation Confirmation Model (ECM) and Theory of Planned Behavior (TPB)**

Bhattacharjee (2001) proposed the Expectation-Confirmation Model (ECM) based on the Expectation-Confirmation Theory (ECT) in marketing and the perceived usefulness of the Technology Acceptance Model (TAM) in information system/ information technology (IS/IT). ECT emphasizes that customer experience plays an important role in performing purchasing behaviors by explaining the relationship between expectations, satisfaction, disconfirmation, attitude, and intention (Bhattacharjee, 2001). The “Perceived usefulness” factor in the TAM model is an important predictor of the intention to use IS/IT (Davis, 1989). In ECM, “Expectation” refers to the degree to which users’ expectations are satisfied, based on their experience of using IS/IT; “Perceived usefulness” is the extent to which users believe that using IS/IT is beneficial; “Satisfaction” is a positive emotional state resulting from the evaluation of technology usage, and “Continuance Intention” refers to the intention to repurchase technology or use the service continuously (Bhattacharjee, 2001). If expectation is met through the use of IS/IT, users tend to be satisfied and perceive the IS/IT as useful. In turn, they tend to keep using the technology (Bhattacharjee, 2001).

The Theory of Planned Behavior (TPB, proposed by Ajzen, 1991) was developed by the earlier Theory of Reasoned Action (TRA, proposed by Ajzen & Fishbein, 1980) that is applicable and predictive across a wide range of contexts. TPB and TRA can be applied to voluntary behaviors and are supported by rational intentions and thoughts. Additionally, these theories have been widely used by researchers in various fields such as marketing, psychology, management, medicine, and finance. Based on the results of TRA, Ajzen (1991)

introduced the Theory of Planned Behavior (TPB), which has many advantages over the previous model. Essentially, TPB extends TRA by adding “Perceived Behavioral Control” (PBC) in addition to “Attitude” and “Subjective norm”, which is the reference opinions of those around. TPB, with the addition of PBC, has demonstrated its value and effectiveness in a range of psychological studies related to human behavior.

### 3. RESEARCH MODEL AND HYPOTHESIS DEVELOPMENT

**Figure 1. Proposed model**

Figure 1 illustrates the proposed model of this study, which was developed based on the ECM and the TPB. In this research model, the independent variables include: Perceived value, Social influence, and Situational influences. Among them, “Situational influences” is considered as an independent variable because there are many comments that the impact and context of the Covid pandemic in the period of 2019-2022 have promoted the use of e-books by readers stronger than in previous years. The intermediate variable in the research model is “Reading performance expectancy” of e-readers, also known as the variable “Performance Expectancy” (Maduku, 2015) or “Perceived usefulness” in the ECM model of Bhattacharjee (2001). In the following section, we review relevant literature and propose four hypotheses.

#### 3.1. Relationship between Perceived value and Reading performance expectancy

Perceived value can be determined by comparing the effective benefit of a purchase with the sacrifices required to make the purchase (Kim et al., 2007). Performance expectancy is the expectation of performance results, defined as the degree to which an individual believes that using the IS/IT will enable them to achieve returns in job performance (Venkatesh et al., 2003). Perceived value represents an overall estimate of the utility of a product or service (Zeithaml, 1988). From the perspective of consumer’s choice, consumers estimate the value of a product or service by considering all factors of benefits and costs involved (Constantiou & Mahnke, 2010). Researchers have found that, in shopping contexts such as online music services (Chu & Lu, 2007), social networking sites (Lu & Hsiao, 2010) and online auction sites (Lu & Hsiao, 2010), perceived value has a significant and positive impact on payment intention. From the above studies, it can be assumed that when e-readers perceive the net benefit from reading e-books is high, they are likely to maintain a positive attitude towards this product. Based on the above argument, the first hypothesis was proposed:

*H1: Perceived value has a positive impact on the reading performance expectancy.*

#### 3.2. Relationship between social influence and reading performance expectancy

Social influence is a fact of daily life. Social influence is enormous, encompassing everything from mere existence and imitation effects to more (Dahl, 2013). Forsyth (2013) defined social impact as “an

interpersonal process that changes human emotions, thoughts, or behavior”. Pratkanis (2007) assumed that social influence is essentially non-coercive. Social impact includes how individuals adjust their behavior to meet the needs of the social environment. Deutsch & Gerard (1955) described two psychological needs that lead people to obey the expectations of others. These include the need for correctness (information society influence) and the need to be liked (normative society influence). According to Venkatesh et al (2012), the factor “subjective norm” in the TPB model can be understood as the variable “Social influence” in the UTAUT model. Many previous studies have has proven that there is a stronger association between social influence and intention to use e-book (Maduku, 2015; Hsu et al., 2017; Okocha, 2019). Jin (2014) has shown that subjective norm impact significantly on e-book users’ perceived usefulness. In this study, we argue that: due to the influence of people’s information and expectations about e-books, readers’ expectations of e-books may increase. Therefore, this study proposed the following hypothesis:

*H2: Social influence has a positive impact on the reading performance expectancy.*

### **3.3. Relationship between situational influence and reading performance expectancy**

Situational factors, according to Ross & Robertson (2003), contain “all factors that do not relate to the decision-maker as an individual (e.g., personality and physical characteristics) or to the decision alternatives”, but play an essential role in shaping and strengthening online purchasing motivations (Hand et al., 2009). Situational factors include physical factors such as the purchase location, layout, music, lighting, etc. In addition, some other factors, such as social situation, time context, the reason for purchase, and consumer mood, also influence consumers’ buying behavior. Such information is crucial in formulating marketing strategies (Kotler, 2000) and retail planning (Levy & Weitz, 1992).

The COVID-19 pandemic can be regarded as an important situational factor affecting user behavior in the context of online consumption (Nguyen et al., 2020). We argue that: in the context of the COVID-19 pandemic, when people have to limit travel and face-to-face contact, reading e-books has almost become a newly created habit; increasing users’ expectations of e-reading performance for their life as well as their learning in the new context. Thus, we proposed the following:

*H3: The effect of the situation has a positive impact on the reading performance expectancy.*

### **3.4. Relationship between reading performance expectancy and e-book readers’ satisfaction**

The common feature of many theoretical models related to technology user behavior (such as TAM, UTAUT, DIT, etc.) is that IS/IT user behavior is strongly influenced by factors related to the benefits brought by new technologies. Cooper (2019) also argued that one of the drivers for the success of a new product is its unique superiority, which means it must provide unique benefits and propose a convincing value to customers and/or users. In this study, the benefits that e-books bring to readers are understood in terms of improving the efficiency of professional work (the effectiveness of reading and learning for learners) and other benefits of e-books to readers (more useful information in life) (Lee, 2013; Jin, 2014). According to Bhattacharjee (2001), perceived usefulness has a significant and consistent impact on attitude in both the pre-adoption and post-adoption of IS/IT. Perceived usefulness has been shown to have a direct and positive impact on reader satisfaction (Jin, 2014; Joo et al., 2017; Verkijika, 2019). Therefore, we hypothesize the following:

*H4: Reading performance expectancy has a positive effect on e-book readers’ satisfaction.*

## **4. RESEARCH METHODOLOGY**

### **4.1. Developing measurement items and questionnaire**

The scales (items) in this paper are adopted and adapted from previous studies (Appendix 1). In which, the items of the variable “Situational influence” are inherited from Nguyen et al. (2020); the items of the

variable “Social influence” are inherited from Jin (2014); the antecedents of “Perceived value” are adapted from Hsiao & Chen (2017); the items of “Reading performance expectancy (RP)” are adapted from Lee (2013) and Jin (2014); the items of “Satisfaction” were adopted from Jin (2014).

To evaluate the model and test the research hypotheses, a survey method was implemented to collect primary data from the survey subjects who are students studying at universities in Hanoi.

As of the end of June 2022, there were 2,835 schools with more than 2.2 million students in Hanoi, including 120 universities and colleges belonging to ministries with nearly 1 million students (Xuan, 2022). Hence, in this study, we used non-probability sampling method, whereby, we conduct a student survey focused on 7 large-scale higher education institutions, including: Thuongmai University, Academy of Finance, National Economics University, Foreign Trade University, Hanoi University of Industry, ThuyLoi University, Posts and Telecommunications Institute of Technology. We exclusively questioned students who have been using e-books for the goal of examining reasons resulting in satisfaction of e-book (post-adoption stage) as this target group has had specific experience evaluating the usage of e-books.

Based on the initial scales, a questionnaire was set up, then a pre-test was carried out to obtain feedback on the questionnaire’s content and translation validity. As a result, a complete questionnaire was established. The questionnaire is organized as three parts. Firstly, we used the question “Are you using any sorts of e-book?” to weed out respondents who have not used e-books yet. Part 1 provided broad information about the behavior of using e-books. Part 2 covered the rationale for using e-books. Personal information about the respondents such as gender, school, and year of study, was included in part 3.

#### 4.2. Survey and data analysis

Both direct and online methods were used in this study. A direct questionnaire was delivered to target respondents with the support of faculty assistants, academic advisors, and instructors. An online survey was conducted by emailing and submitting Google form links. After 2 months, we received 112 responses via the link and 582 votes directly. After removing the invalid votes, 555 valid votes were obtained. This sample size exceeded Hoyle’s (1995) recommendation on the minimum size to ensure the reliability of the analytical results.

Table 2 presents some basic descriptive statistics regarding the respondents. Among them, 46.5 percent were male, 53.5 percent of the 555 respondents were female, and they came from 7 Vietnam’s higher education institutions. Third-year students made up the majority with 50.3% of the group; the remaining participants were 1<sup>st</sup> year (15.1%), 2<sup>nd</sup> year (20.5%), and 4<sup>th</sup> year (14.1 %), respectively.

**Table 2. Profile of sample respondents**

	<b>Profile category</b>	<b>Frequency</b>	<b>Percentage (%)</b>
Gender	Male	258	46.5
	Female	297	53.5
University	Thuongmai University	134	24.1
	National Economics University	79	14.2
	Hanoi University of Industry	68	12.3
	Foreign Trade University	76	13.7
	Academy of Finance	87	15.7
	Posts and Telecommunications Institute of Technology	48	8.6
	ThuyLoi University	63	11.4
University year	First-year student	84	15.1
	Second-year student	114	20.5
	Third-year student	279	50.3
	Fourth-year student	78	14.1

This study uses the partial least squares (PLS)-based structural equation modeling technique (SEM), which is more suitable for predicting and discovering structural relationships (Hair et al., 2016). Accordingly, the data will be analyzed in two stages: First, measurement model analysis is evaluated to consider the relationship between the latent variables and determine the reliability of the scale, calculate the validity of the scale, convergent value as well as the discrimination of the variables (Hair et al., 2016). Second, analyze the structural model to test the hypotheses in the research model.

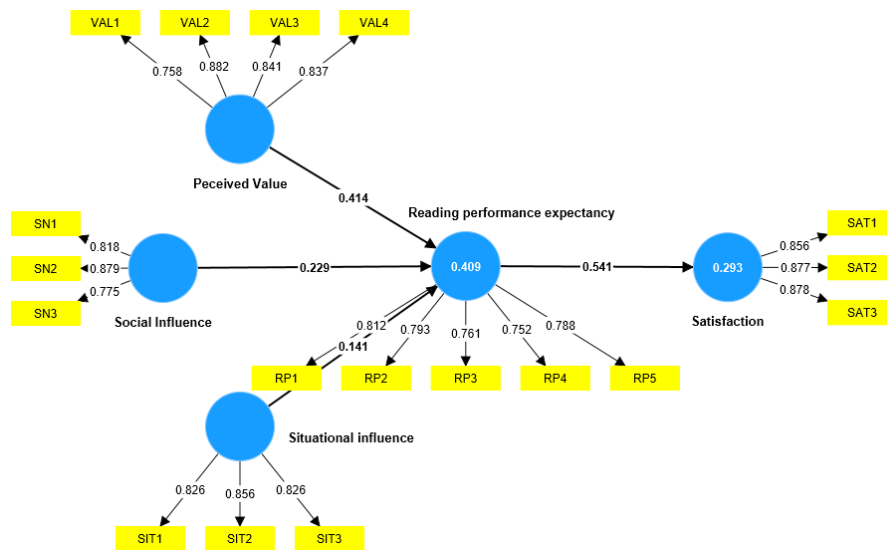

**5. RESULTS AND DISCUSSION**

**5.1. Results**

**5.1.1. Measurement model**

*Reliability and convergent validity:*

The process of evaluating the measurement model was carried out using statistical criteria, including composite reliability (CR) and Cronbach’s alpha to assess the internal consistency of each variable’s scales (Henseler et al., 2015; Hair et al., 2016). Outer loadings and average variance extracted (AVE) to assess the convergent validity (Hair & colleagues, 2016); the HTMT ratio to assess the discriminant validity (Henseler et al., 2015).

**Figure 3. Measurement model**

The results from table 3 show that the outer loading values of all measurement scales in the research model are over 0.7; the Cronbach’s alpha coefficients of all variables in the research model are between the ranges (0.765-0.850); the CR coefficients of all variables are > 0.7; and the AVE indices are > 0.5. This means that each latent variable in the model explains more than 50% of the variance of the measurement scales (Hair & colleagues, 2016). Therefore, the measurement model has qualified reliability and convergent validity (Hair et al., 2016).

**Table 3. Outer loadings, Cronbach alpha, CR and AVE**

Variable	Outer loadings	Cronbach Alpha	CR	AVE
Reading performance expectancy (RP)		0.840	0.887	0.611
RP1	0.812			
RP2	0.793			
RP3	0.761			
RP4	0.752

VAL3	0.841			
VAL4	0.837			

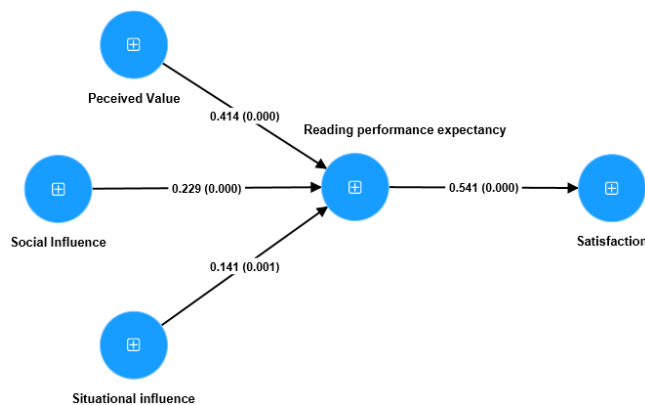

*Discriminant validity:*

The hetrotrait–monotrait (HTMT) ratio is used to assess the discriminant validity of the constructs in this investigation (Henseler et al., 2015). Accordingly, the HTMT value should be less than 0.85 (Henseler et al., 2015). The results present in Table 4 show that all the HTMT values were below the threshold value of 0.85, thus, the discriminant validity of this research model is established (Kline, 2015).

**Table 4. Discriminant validity though HTMT**

	Perceived value	Reading performance expectancy	Satisfaction	Situational influence
Reading performance expectancy	0.679			
Satisfaction	0.641	0.638		
Situational influence	0.498	0.497	0.521	
Social influence	0.584	0.602	0.552	0.527

**5.1.2. Structural model**

**Figure 4. Structure model**

The structural model was evaluated through tests of multi-collinearity (VIF), path coefficients, effect size ( $f^2$ ), coefficient of determination ( $R^2$ ), and hypothesis testing (Hair et al., 2016). As shown in Table 5, all constructs had a VIF value of less than 5 (Hair et al., 2016), indicating no multicollinearity among the variables as shown in the results of Table 6.

**Table 5. Results of multicollinearity detection (VIF)**

	Reading performance expectancy	Satisfaction
Perceived value	1.546	
Reading performance expectancy		1.285
Situational influence	1.442	
Social influence	1.475	

To evaluate the model as well as test the research hypotheses, the path coefficient values for latent variables, T-Value, P-Value, and confidence interval (CI), and  $R^2$  are used. The findings of the structural model assessment and hypothesis testing are presented in Table 6. All four hypotheses H1, H2, H3, and H4 are accepted with a P-value  $<0.05$  and T-Value  $>1.65$ . This means that all the factors, “Perceived value” “Social influence” and “Situational influence” have direct impact on “Reading performance expectancy” (hypotheses H1 to H3). Among them, perceived value has the strongest impact on readers’ expectations about e-books ( $\beta=0.414$ ), followed by social influence ( $\beta=0.229$ ), and situational influence ( $\beta=0.141$ ). In turn, reading performance expectancy has a direct and significant impact on e-readers’ satisfaction with  $\beta=0.541$  (H4).

**Table 6. Hypotheses testing**

	Original sample	Standard deviation	T statistics	P values	VIF	Confidence interval		Results
						5%	95%	
H1: VAL -> RP	0.414	0.049	8.522	0.000	1.395	0.314	0.503	Accepted
H2: SN -> RP	0.229	0.046	4.998	0.000	1.395	0.137	0.318	Accepted
H3: SIT -> RP	0.141	0.040	3.48	0.001	1.300	0.063	0.221	Accepted
H4: RP -> SAT	0.541	0.032	16.846	0.000	1.000	0.473	0.599	Accepted

$R^2$  value is evaluated for all endogenous variables in the model. The coefficient of determination ( $R^2$ ) reveals the extent to which the variation of the endogenous variable is explained by the exogenous variables (Hair et al, 2016). Table 7 reports the coefficient of determination ( $R^2$ ) reaching 0.409 and 0.293. It means that three (03) independent variables (perceived value, social influence, situational influence) explained 40.9% of “Reading performance expectancy” and the variable “Reading performance expectancy” explained 29.3% of e-readers’ satisfaction.

**Table 7. Coefficient of determination ( $R^2$ )**

	$R^2$	Adj. $R^2$
Reading performance expectancy	0.409	0.409
Satisfaction	0.293	0.293

**5.2. Discussion**

This study has shown that Reading performance expectancy has a direct and significant impact on e-readers’ satisfaction. This result is consistent with previous research by Jin (2014), Joo et al (2017), and Verkijika (2019). Besides, all the factors including “perceived value”, “social influence” and “situational influence” have a direct impact on readers’ expectations about the effectiveness of e-books.

Among the factors affecting “expectations about the effectiveness of e-books”, perceived value is the factor with the most positive impact. When readers perceive that reading e-books is more beneficial than the

necessary costs, effort and time, they have a higher expectation of reading efficiency, leading to the higher satisfaction of e-readers.

“Social influence” is the following factor that has a positive effect on “reading performance expectancy” of e-book users. Specifically, when e-readers see that people around them have used e-books or have positive feelings about e-books, or people who influence them using e-books, they will have high expectations about the effectiveness of e-books, which will lead to more eagerness to use them. The results are similar to the previous study by Jin (2014) which demonstrated that subjective norms is one of the main factors affecting e-readers’ perceived usefulness.

The research results show that the situational influence has a moderate positive effect on reading performance expectations of users. It can be reasoned that situational influence (including the location of the store, the sound, the light or the situation of the time, the social situation and the mood of the users) also influence their buying behavior. Typically in the context of the Covid-19 pandemic, purchasing and reading e-books have helped people limit travel and face-to-face contact, thereby increasing their expectation about the effectiveness of e-book to their life and work. This is also considered a new point in this study as no previous study has demonstrated the impact of the situation (related to the Covid-19 pandemic) on the expectations of the effectiveness of e-books.

## 6. CONCLUSION

The results of this study demonstrated that efficiency expectations have a positive effect on satisfaction for e-book users. Therefore, when applying to a teaching and learning environment, the effectiveness of an e-book must include assessments and other adaptive contents designed to support active learning. Next, universities need to develop convenient infrastructure and internet access for students to exploit e-books from open-access e-book sources. Libraries should pay attention to exploiting and building open-access e-book sources, old versions of e-books (usually at low cost), collecting and developing e-book libraries for students to access, especially electronic textbooks in Vietnamese. In addition, suppliers need to adopt unlimited e-book subscriptions that include access to high-quality digital learning resources, geared toward higher education institutions in the event of a global pandemic or other catastrophic events that cause an abrupt diversion to online learning. In addition, such a system both has a positive impact on student achievement and is appreciated by students. To satisfy student needs better, remove barriers to their success, and improve student outcomes, universities must play a key role in supplying reasonable course content. The global pandemic has forced organizations to consider the benefits of integrated digital learning solutions, which are increasingly considered as more valuable than traditional textbooks because they are sold at much lower prices, and they are highly accepted by learners and is beneficial for active learning.

## 7. APPENDIX: MEASUREMENT ITEMS AND VARIABLES

Variables	Construct	Items	Sources
1. Situational Influences (SIT)	SIT1	Many traditional bookstores are closed during the Covid-19 pandemic.	Nguyen et al. (2020)
	SIT2	Buying books at traditional stores is very risky during the Covid-19 pandemic.	
	SIT3	Reading e-books becomes a trend during the Covid-19 pandemic.	
	SIT4	E-book reading websites/apps expand book catalogs during the Covid-19 pandemic.	
	SIT5	Websites/apps that read e-books have many promotions during the Covid-19 pandemic.	
2. Subjective norms (SN)	SN1	There are others who are using e-books around me	Jin (2014)
	SN2	People who know me have positive feelings about using e-books	
	SN3	People who influence me want to use e-books	

Variables	Construct	Items	Sources
3. Perceived value (VAL)	VAL1	Compared to the fee I need to pay, the use of the e-books offers value for money.	Hsiao & Chen (2017)
	VAL2	Compared to the effort I need to put in, the use of the e-books is beneficial to me	
	VAL3	Compared to the time I need to spend, the use of the e-books is worth while to me	
	VAL4	Compared to the time I need to spend, the use of the e-books is worthwhile to me	
4. Reading performance expectancy (RP)	RP1	Reading e-books is very helpful for my daily life.	Lee (2013), Jin (2014)
	RP2	Using e-books gives me useful information in life .	
	RP3	Using e-books can make my academic and reading behavior more efficient.	
	RP4	Using e-books is a convenient reading behavior	
	RP5	Using e-books is, overall, an efficient way to read.	
5.Satisfaction (SAT)	SAT1	Using e-books will meet my expectations.	Jin (2014)
	SAT2	I am satisfied with the quality of available e-book content	
	SAT3	I am satisfied overall with e-books.

## EXPLORING FACTORS AFFECTING THE KNOWLEDGE- SHARING ACTIVITIES OF ACCOUNTING STUDENTS IN HANOI

**Authors: Pham Tra Mi<sup>1</sup>, Pham Tra Giang<sup>1</sup>, Ta Lan Anh<sup>1</sup>**

**Mentor: PhD. Phan Huong Thao<sup>1</sup>**

*ABSTRACT: Under the strong impact of the current digital transformation and digital economy, knowledge-sharing activities play an increasingly important role in the development and achievement of competitive advantages for each individual and society as a whole. Knowledge is the core thing, the driving force for human development in the new era. Knowledge - sharing is a way to learn and accumulate new knowledge. When we have understanding and extensive knowledge of all areas of social life, each individual can easily achieve his or her own goals and dreams. Therefore, knowledge-sharing contributes to demonstrate abilities (educational level, communication ability,...) in today's ever-evolving society, especially in the context of booming digital transformation. The purpose of this paper is to explore the influence of factors on the knowledge-sharing activities of accounting students in Hanoi, then the author proposes some recommendations to improve the efficiency of knowledge-sharing activities of accounting students and at the same time improve the quality of knowledge for students. The article uses a combination of qualitative and quantitative research methods to assess the influence of factors on the knowledge-sharing activities of accounting students in Hanoi in the context of digital transformation. We found 3 factors that affect knowledge-sharing activities of accounting students. They are information technology; the support of university and the confidence of students. Based on the results, universities and accounting students will know which elements they need to improve in their training programs to improve the efficiency of students' knowledge sharing.*

**Keywords:** Knowledge – sharing, accounting students, factors affecting

### 1. INTRODUCTION

We live in an era where the world economy is transforming from an economy based primarily on the limited resources of nature to an economy of information and intelligence. Natural resources are left out of the competitive agenda, with knowledge and skills alone as resources that create a sustainable competitive advantage. As such, knowledge is increasingly becoming a resource, rather than a resource for wealth creation, it is widely recognized that knowledge is an important asset for individuals and organizations to succeed in the economy increasingly fierce competition (Syed khan and Rowland 2004, Van den Hoff and De Ridder 2004, Yang 2007). For accounting students at universities in Vietnam, knowledge-sharing activities need to be focused on and promoted furthermore. To become a good accountant in future, students need to prepare themselves with a lot of knowledge and skills. Accounting with industry characteristics is to receive and process a large amount of professional and professional knowledge. On the other hand, legal documents on accounting regulations and guidelines are often changed and supplemented, requiring accountants to learn; update and innovate to improve their capacity. Accounting work is closely related to economic activities taking place in the market, requiring students to be equipped with practical professional knowledge. At present, knowledge-sharing activities of accounting students in studying and working are limited and have not received adequate attention. Accounting students are often quite timid and lack of confidence when exchanging their knowledge in the field due to psychological uncertainty about their understanding. To improve the efficiency of knowledge-sharing activities of accounting students, one of the prerequisites is to identify the factors affecting knowledge-sharing.

<sup>1</sup> Thuongmai University..

The store of knowledge of each person is endless and diverse. Every moment we are constantly receiving new knowledge and experiences. Much of our knowledge comes from the sharing of others. Most of the scientific knowledge and understanding is not discovered by us but inherited from the accumulation and transmission of many previous generations. *And the definition of “knowledge - sharing” is synthesized as “providing information related to the task being performed and how to solve the problem, generating new ideas, and finalizing policies or plans”* (Lin, Ye, Bi, 2014). According to Grant (1999), “*knowledge-sharing activity is a process that enhances organizational effectiveness by maximizing the use of knowledge shared by organizational members*”.

## 2. THEORETICAL FRAMEWORK

### 2.1. Literature review

Nguyen Manh Cuong, and Nguyen Tien Loi (2016) identified and measured the factors affecting the knowledge-sharing process of students through a quantitative research method with a sample of 504 observations collected from students at Hanoi University of Industry. Research shows that there are 4 groups of factors affecting the knowledge-sharing process of students at Hanoi University of Industry, which are: (1) Pressure from lecturers; (2) Encouragement support system; (3) Personal attitude; (4) Ability to access information.

Among the factors mentioned above, 3 factors including: Encouragement support system, personal attitude, and ability to access information have a positive influence on the results of the knowledge-sharing process. Research results show that the sharing and reception of knowledge in learning are most affected by their attitude and then the incentive support system, the ability to access information.

Akosile, A., & Olatokun, W. (2020) identified and measured the factors affecting knowledge-sharing among scholars at Bowen University - Nigeria. The method used is quantitative research through survey questionnaires with 151 answers obtained with 3 research variables: *Organizational factors* (Organizational culture; Reward system; Management support; University policy); *Personal factors* (Individual ability; Trust and willingness to share; Personal interaction; Personal expectations), *Technological factors*: (Availability of IT infrastructure; Use social media).

Research results from collected data show that in organizational factors, university policies significantly affect knowledge-sharing; while individual factors have faith significantly affect knowledge-sharing. Technological factors do not affect knowledge-sharing behavior. The findings extend knowledge and build theory in knowledge-sharing through conceptual frameworks. The study recommends that there should be a university policy on knowledge-sharing, accompanied by rewards to motivate scholars to share their knowledge.

Nguyen Le Nhan et al (2021) determined the factors affecting the knowledge-sharing behavior of students in general and students of Duy Tan University in particular. Through a mixed research method based on a survey of 300 students, the research results show that there are 4 factors affecting the knowledge-sharing behavior of students of Duy Tan University today: (1) *Rewards*; (2) *Information technology*; (3) *Belief in knowledge*; (4) *Teamwork*.

Quantitative statistics show that two factors have the greatest influence on students' knowledge-sharing activities: Rewards and information technology. Besides, the remaining factors also have a significant influence on the perception of knowledge-sharing activities. The article assessed the influence of factors on students' knowledge-sharing behavior; offered solutions to improve the efficiency of training and learning activities at universities.

Walaa J. Ali (2021) explored factors affecting knowledge-sharing among university students in Iraq. This study aimed to examine the impact of beliefs, attitudes, and information communication technology on knowledge-sharing among university students. The results show that all three variables: trust, attitude, and information and communication technology, have a positive and significant impact on knowledge-sharing among university students. However, the results show that trust is the most important factor that enhances knowledge-sharing among students. The university should improve the culture of knowledge-sharing among students to increase their productivity and knowledge. This study has some limitations as it was conducted in only one faculty within the university, which cannot generalize the results to all universities in Iraq. Furthermore, research conducted at a private university may have a different environment when compared to public universities.

## **2.2. Background theories**

### **2.2.1. Role theory**

According to Lattimore et al. (2004), a role is a set of daily activities of a person. Some researchers suggest that roles are related to an individual's expectations of how to behave in a given situation. Role theory is a sociological perspective that attempts to explain interactions between individuals in organizations by focusing on the roles that individuals hold. Role behavior is influenced by role expectations for appropriate behavior in that role. For example, accounting students have the role of guiding and advising their classmates in studying to successfully complete the final exam, most of their behaviors are influenced by expectations for their students in that role.

From our point of view, in the field of knowledge-sharing, role theory is applied to study the knowledge-sharing behavior of the organization in general, and students in particular (including accounting students) also considered necessary need because understanding the knowledge-sharing of students will help universities improve their operational efficiency and contribute to perfecting their knowledge management system in today's digital information environment. From different points of view, there are roles that students have to take on in the learning process, that is, the role of learners and researchers. In addition, role theory contributes to perfecting students' knowledge-sharing activities. Behavior is closely related to the role, or in other words, the role that guides the behavior of each individual. In the process of interacting with information, the role also contributes to the orientation of students' knowledge-sharing activities.

### **2.2.2. Social behavior theory**

The theory of social behavior was in the early twentieth century. Typical representatives of this theory were J. Watson – the first founder of behavioral theory, E. Thorndike, B.Ph. Skinner, E. Tolman, C. Hull and A. Bandura. Classical behavioral psychologists believed that the origin of behavioral factors was due to external environmental factors impact. According to behavioral theory, behavior is considered to be the result of a direct relationship between a stimulus and a response to that stimulus. Stimuli belongs to the world of action, and behavior is produced by the body. These studies are regulated on the study of creating an environment of stimuli and arranging them in a certain logical order to form desired responses, i.e. the process of “behavioral conditioning” (Partica H.M., 1989). On that basis, the Social behavior theory introduced by Blau (1964) is used to investigate the knowledge-sharing behavior of an individual. The theory proposed a model that could measure guided human actions, while also predicting the occurrence and performance of a particular act.

## **2.3. Research model proposal**

- *Information technology is a factor affecting the knowledge-sharing activities of accounting students.*

Information technology has been identified as a facilitator of knowledge-sharing (Mitchell, 2003). The role of information technology in knowledge-sharing and transfer becomes more and more important over time due to the advancement of technology. In the following years, many researchers have contributed to

explore the role of information technology in knowledge-sharing and transfer. Han and Anantatmula (2007) found that the availability and usability of technology are associated with the level of knowledge-sharing. Kim and Lee (2005) explored that information technology applications are one of the main variables affecting knowledge-sharing.

*- Confidence in personal abilities is a factor affecting the knowledge-sharing activities of accounting students.*

According to social exchange theory, not only benefits and costs, but also trust plays an important role in the exchange process between people. Wang and Noe (2010) argued that the importance of trust had so far received little attention in the knowledge-sharing literature. Therefore, the research has focused on two aspects of self-confidence that are closely related to self-efficacy when sharing knowledge and apprehension when evaluating, namely competence-based confidence and self-belief based on benevolence. Confidence is an important element of any information society as it enables social exchange, and knowledge-sharing (Alat et al., 2016; Jameel et al., 2020). If individuals in the network participate actively in knowledge-sharing activities, they can display their talents, kindness, and honesty to allow other participants to gauge their confidence (Evans et al., 2015; Massoudi et al., 2020).

*- Benefit of knowledge-sharing is a factor affecting the knowledge-sharing activities of accounting students.*

The social exchange framework also tells us about possible interactions between the perceived benefits of sharing and evaluative understanding. If the perceived benefit of an exchange is large enough, it may outweigh the expected negative effects of assessing the costs of knowledge-sharing. That is, the benefits of sharing may outweigh the costs involved. In other words, the negative relationship between assessment apprehension and knowledge-sharing may be stronger when perceived benefits are lower than when perceived benefits are high. Therefore, we predict that the benefit factor will have a certain influence on knowledge-sharing activities. Some other studies also support the view that organizations should create conditions for individuals to expand their social relationships because thereby knowledge-sharing is enhanced and more effective (Szulanski, 1996; Argote, 1999)

*- Process of knowledge-sharing is a factor affecting the knowledge-sharing activities of accounting students.*

Effective knowledge-sharing among students at all levels enhances collaborative learning by implementing a shared attitude that contributes to greater efficiency in the testing process. In education and development, it is important to share information, skills, ideas, and personal experiences. Knowledge-sharing is a series of activities related to sharing knowledge or assisting others. Mousa et al. (2019) clarified that knowledge-sharing is a twofold activity: Knowledge source and knowledge seeker, while information exchange applies only to the flow of knowledge through an entity, not between individuals. Knowledge-sharing refers to the activity through which people in an organization exchange information, skills, or expertise (Ayodele et al., 2016). According to Bartol and Srivastava (2002), knowledge-sharing refers to the action in which individuals disseminate essential information to others throughout an institution

*- The support of the university is a factor affecting the knowledge-sharing activities of accounting students.*

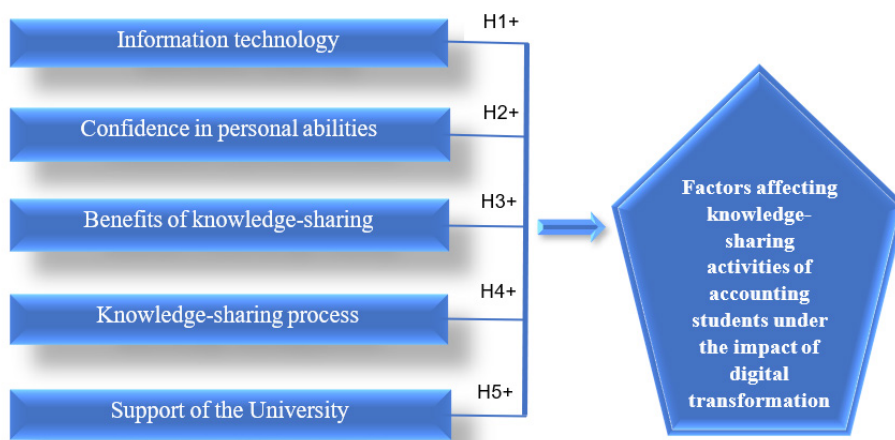

Top management support has been recognized as an important factor in supporting knowledge-sharing. This variable related to knowledge-sharing has been studied extensively by researchers in the context of knowledge-sharing. According to Cabrera (2006), increased support will positively affect knowledge-sharing. Due to pressure from managers and colleagues, employees will be more active in collecting or

contributing knowledge to other employees. If publications related to knowledge-sharing and transfer are scrutinized, it can be inferred that top management support has been researched and identified as motivating or facilitating knowledge-sharing (Cavaliere & Lombardi, 2015; McNichols, 2010; Titi Amayah, 2013). Top management support is believed to have a strong impact on knowledge collection and donation behavior (Cavaliere & Lombardi, 2015).

Based on related empirical studies, we synthesized the factors affecting knowledge-sharing process of accounting students in Hanoi in table 1 and figure 1 below:

**Table 1: Synthesis of factors affecting knowledge-sharing activities of accounting students in Hanoi**

H1	Information technology is a factor affecting the knowledge-sharing activities of accounting students at universities in Hanoi.
H2	Confidence in personal abilities is a factor affecting the knowledge-sharing activities of accounting students at universities in Hanoi.
H3	Benefit of knowledge-sharing is a factor affecting the knowledge-sharing activities of accounting students at universities in Hanoi.
H4	Knowledge-sharing process is a factor affecting the knowledge-sharing activities of accounting students at universities in Hanoi.
H5	Support of the university is a factor affecting the knowledge-sharing activities of accounting students at universities in Hanoi.

**Figure 1: Proposed research model**

**3. RESEARCH METHODS**

Research methods used include: documentary research method, descriptive statistical method, method of comparison, etc. All of these methods are derived from the subject’s point of view dialectical and historical materialism aim to solve related problems in a dialectical and logical way. And the two main research methods used in combination in this article are the qualitative and the quantitative research method.

The qualitative research method is conducted through theoretical research and previous studies related to the factors affecting knowledge-sharing activities of accounting students at universities in Hanoi. The objective of qualitative research is to test, screen, and determine the relationship between variables in the theoretical model, on that basis, propose a research model. In addition, the study also calibrated and developed the scales inherited from previous studies to suit the research objectives.

In the research model, the proposed model has 5 independent variables with 22 observed variables, the sample size is expected to be about 250. After the experimental investigation and the correction of the questionnaire, the official survey was conducted on a large scale for accounting students in Hanoi via google forms and email within 3 months (from November 2022 to January 2023, we received 296 answer sheets, respectively 100%). After screening and analyzing, the group used 271 valid answer sheets. All responses with missing data were excluded from the analysis.

Data processing methods were implemented, including: descriptive statistics, exploratory factor analysis, scale testing (Cronbach's Alpha), correlation analysis, and regression analysis - testing hypotheses. Data collected from questionnaires are processed by 2 softwares:

- Microsoft Excel software for summarizing, descriptive statistics of objects and survey contents.
- SPSS 20.0 software to check the reliability of the scale and research hypotheses. We used descriptive methods to interpret the obtained statistical results.

## **4. RESULTS AND DISCUSSION**

### **4.1. Results**

#### **4.1.1. Qualitative research results**

The method used is the theoretical background method. As follows:

we collected data by interviewing, then arranged the data into groups, then linked the groups together, and finally found the nuclear information. After the process of data collection and analysis, we formed 5 hypotheses which were 5 factors of digital transformation affecting the knowledge-sharing activities of accounting students at universities in Hanoi.

With the method of direct distribution of votes to 15 random students majoring in Accounting in Hanoi The group has summarized the following results:

- All 15 students have applied digital transformation in knowledge-sharing activities: 100%
- The factors of digital transformation affecting knowledge-sharing activities of accounting students after analyzing, obtained the following results:

- The information technology factor: 100%
- The factor of confidence in personal abilities: 60%
- The benefit of knowledge-sharing factor: 53.3%
- The knowledge-sharing process factor: 20%
- The support of the university factor: 80%

*Thus, it can be seen that:*

- Hypotheses about information technology, confidence in personal abilities, benefits of knowledge-sharing, and support of the university are accepted.

- The factor of information technology and the support of the university are the two factors that have the most impact on the knowledge-sharing activities of accounting students at universities in Hanoi.

#### **4.1.2. Check the reliability of the scale**

The results of Cronbach's Alpha coefficient show that all independent and dependent variables in the research model: "The information technology factor", "The factor of confidence in personal abilities", "The benefit of knowledge-sharing", "The knowledge-sharing process", "The support of the university" and "Knowledge-sharing" have Cronbach's Alpha from 0.781 to 0.870. At the same time, all observed variables had total correlation coefficients greater than 0.3. All these indexes are larger than the minimum to ensure the reliability and discriminability of the factors (Hair et al., 2010) and should be included in the analysis in the next steps.

#### **4.1.3. Exploratory factor analysis EFA**

After meeting the requirements of the reliability test, we included an exploratory factor analysis with 22 observed variables of independent variables in the research model. Because the sample size of the group was 271,

when analyzing the EFA exploratory factor, the group chose a Loading factor of 0.35. Through table 4.4, it can be seen that all observed variables have Factor Loading load factor > 0.35; however, there is still the phenomenon of observed variables uploading in both factors and the difference in loading factor is not guaranteed from 0.3 so the group removed five variables: QT3, QT2, QT4, QT1, LI3; in case the observed variable is uploaded in both factors, but the difference between the two variables is greater than 0.3, the observed variables NT1, NT3 are kept to conduct the second EFA discovery coefficient analysis shown in Table 1:

**Table 1: EFA factor analysis**

Rotated Component Matrix<sup>a</sup>

	Component		
	1	2	3
CN1	0.693		
LI4	0.670	0.403	
CN5	0.670		
CN3	0.656		
LI1	0.653		
LI2	0.631		
CN2	0.626		
LI5	0.562	0.407	
CN4	0.545		
NT2		0.767	
NT1		0.743	
NT4		0.743	
NT3		0.730	
TT3			0.820
TT1			0.810
TT4			0.785
TT2			0.751

(Source: Authors' survey)

Table 1 shows that there are still observed variables that have the phenomenon of uploading in both factors and do not guarantee the difference in loading factor from 0.3, so the group continues to exclude variables: LI4, LI5 to conduct coefficient analysis explore EFA for the 3rd time with 15 observed variables (table 2):

**Table 2: EFA factor analysis**

Rotated Component Matrix<sup>a</sup>

	Component		
	1	2	3
CN1	0.711		
CN3	0.687		
CN5	0.661		
CN2	0.650		
LI1	0.623		
CN4	0.590		

LI2	0.564		0.361
TT3		0.826	
TT4		0.803	
TT1		0.796	
TT2	0.352	0.746	
NT2			0.776
NT1			0.763
NT3			0.740
NT4			0.738

(Source: Authors' survey)

After the 3rd EFA exploratory factor analysis, there is still a case that the observed variable uploads in both factors and does not guarantee the difference in loading factor from 0.3 is the variable: LI2, however, the case where the observed variable is uploaded in both factors but the difference between two variables is greater than 0.3, so in this case, the observed variable TT2 is accepted, next we conduct the elimination of LI2 variable and performs the 4th exploratory factor analysis (Table 3):

**Table 3: EFA factor analysis**

**Rotated Component Matrix<sup>a</sup>**

	Component		
	1	2	3
CN1	0.708		
CN3	0.700		
CN2	0.661		
CN5	0.638		
CN4	0.633		
LI1	0.576		
TT3		0.830	
TT4		0.809	
TT1		0.794	
TT2		0.752	
NT2			0.779
NT1			0.770
NT3			0.746
NT4			0.736

(Source: Authors' survey)

Table 3 shows the accepted variables. Thus, after analyzing EFA, the group eliminated 8 observed variables (table 4) and obtained those variables: CN1, CN2, CN3, CN4, CN5, LI1, TT1, TT2, TT3, TT4, NT1, NT2, NT3, NT4.

**Table 4: KMO and Bartlett's Test**

KMO and Bartlett's Test		
<b>Kaiser-Meyer-Olkin Measure of Sampling Adequacy.</b>		<b>.902</b>
Bartlett's Test of Sphericity	Approx. Chi-Square	1727.519
	df	91
	Sig.	.000

(Source: Authors' survey)

The KMO coefficient of 0.902 (> 0.5) is very high and sig = 0.000 < 0.5, so it can be concluded that observed variables are correlated with each other in the population and EFA factor analysis is appropriate. The total variance used to explain the factors is 62.638% > 50%, so the conditions are satisfied for the factor analysis (table 5).

**Table 5: Total Variance Explained**

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	6.132	43.802	43.802	6.132	43.802	43.802	3.038	21.697	21.697
2	1.518	10.846	54.647	1.518	10.846	54.647	2.941	21.007	42.704
3	1.119	7.991	62.638	1.119	7.991	62.638	2.791	19.935	62.638
4	.770	5.497	68.136						
5	.640	4.568	72.704						
6	.629	4.490	77.194						
7	.570	4.071	81.265						
8	.522	3.371	84.997						
9	.470	3.355	88.352						
10	.419	2.990	91.341						
11	.391	2.789	94.131						
12	.310	2.211	96.342						
13	.297	2.122	98.464						
14	.215	1.536	100.000						

(Source: Authors' survey)

The 4th EFA exploratory factor analysis results extracted 3 factors with a very high KMO index of 0.902 (> 0.5), Eigenvalue index of 1,119 (> 1), total variance extracted was 62,638% (> 50%), Bartlett's test has a significance level of 0.000 (<0.05). So these factors are independent variables and included in the next steps to test the research model (table 6).

**Table 6: Component Score Coefficient Matrix**

	Component		
	1	2	3
TT2	.739	-.417	
CN5	.701		
TT4	.701	-.492	
NT3	.691		
NT2	.689	-.353	
CN3	.684		
TT3	.668	-.542	
NT1	.661	.392	
NT4	.658		-.432
LI1	.650		
CN2	.634		
TT1	.632	-.528	
CN1	.622		
CN4	.506		.427

(Source: Authors' survey)

Through analyzing the influence of each observed variable on each factor, the group found that the observed variables all affect factor 1 in a positive direction, so these variables positively affect factor 1 and at the same time, these variables also create a positive relationship with the factor and increase the value of

factor 1. For factor 2, five variables are showing a negative relationship, namely TT1, TT2, TT3, TT4, and NT2 variables, so these five variables create a negative impact on factor 2 or reduce the value of the factor. Factor 3 also has a variable representing the negative relationship, the variable NT4, so this variable harms factor 3 and at the same time reduces the value of this factor.

**4.1.4. Results of exploratory factor analysis EFA for the dependent variable**

The research model of impacts of digital transformation on knowledge-sharing activities of accounting students at universities in Hanoi is expected through the following equation:

$$KS = \beta_0 + \beta_1CN + \beta_2TT + \beta_3NT + \epsilon$$

EFA results for the dependent variable KS (Knowledge-Sharing) is drawn. EFA also fits the data because the total variance extracted is 76,306 (> 50%), KMO = 0.729 (> 0.5), and the Bartlett’s test is statistically significant (sig = 0.000 < 0.05). So the scale is still used for the next analysis (shown in table 7 and 8).

**Table 7: KMO and Bartlett’s Test**

KMO and Bartlett’s Test		
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		0.729
Bartlett’s Test of Sphericity	Approx. Chi-Square	333.479
	df	3
	Sig.	.000

(Source: Authors’ survey)

**Table 8: Total Variance Explained**

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	2.289	76.306	76.306	2.289	76.306	76.306
2	.374	12.468	88.775			
3	.337	11.225	100.000			

(Source: Authors’ survey)

The results of the regression analysis of the effects of knowledge-sharing activities of accounting students at universities in Hanoi are shown in Table 9 as follows:

**Table 9: Total Variance Explained**

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Colinearity Statistics	
	B	Std. Error	Beta			Tolerance	VIF
1	(Constant)	.556	.258		2.158	.032	
	TECHNOLOGY	.571	.079	.447	7.265	.000	.538
	CONFIDENCE	.099	.048	.116	2.085	.038	.655
	UNIVERSITY	.223	.061	.213	3.642	.000	.596

(Source: Authors’ survey)

Table 9 shows that all factors have sig significance < 0.05, all variables are correlated and have statistical significance in the research model. Variance magnification factor VIF < 2, so it can be concluded that there is no multicollinearity between these three factors.

The linear regression equation showing the effects of digital transformation on knowledge-sharing activities of accounting students at universities in Hanoi is shown as follows:

$$KS = 0.556 + 0.571CN + 0.099TT + 0.223NT$$

Based on the magnitude of the normalized regression coefficient Beta, the order of impact level from the highest to the lowest of the independent variables on the dependent variable CSKT is as follows: (1) CN:0.571; (2) NT: 0.223; (3) TT: 0.099, where: *KS: Knowledge-sharing; CN: The influence of technology factor; NT: The influence of the university factor; TT: The influence of the confidence factor*

#### 4.2. Discussion

Through the above equation, it shows that there are 3 impacts on knowledge-sharing activity of accounting in Hanoi. Specifically:

With a Beta coefficient of 0.571, the factor CN (technology - CN1, CN2, CN3, CN4, CN5, LI1) has the greatest influence on knowledge-sharing activities of accounting students at universities in Hanoi. The positive sign (+) of the Beta coefficient indicates a positive relationship. The regression results show that the Beta coefficient is 0.571 and Sig = 0.000 (<0.05), that is, when other factors are unchanged if the technology hypothesis is increased by 1 unit, the knowledge-sharing activity of students will increase to 0.571 units. Research results show that when students are aware and highly appreciative of the technology factor or have a good technology background, it will increase the efficiency of knowledge-sharing activities. Thus, the technology factor has a positive impact on the knowledge-sharing activities of accounting students at universities.

The second factor that affects the knowledge-sharing activities of accounting students at universities in Hanoi is the university factor (NT1, NT2, NT3, NT4). The positive sign of the coefficient Beta means that the relationship between these two factors is a positive relationship. With the coefficient Beta = 0.223 and Sig = 0.000 (<0.05), that is, when other factors remain unchanged if the benefit is increased by 1 unit, the knowledge-sharing activity of students will increase by 0.223 units. Research results show that when students study in a good university training environment, with enthusiastic support from the university, it will increase the efficiency of knowledge-sharing activities of accounting students.

The last factor that affects the knowledge-sharing activities of accounting students is the confidence factor (TT1, TT2, TT3, TT4). The positive sign of the coefficient Beta means that the relationship between these two factors is a positive relationship. With the coefficient Beta = 0.099 and Sig = 0.038 (<0.05), that is, when other factors are unchanged if the confidence factor increases by 1 unit, the knowledge-sharing activity of students will increase by 0.099 units. Research results show that the confidence factor is compatible with the application of digital transformation in the knowledge-sharing activities of accounting students.

#### 5. CONCLUSION

The study of factors affecting knowledge-sharing activities of accounting students at universities in Hanoi is necessary, contributing to raising awareness and understanding of the importance of knowledge - sharing; thereby promoting the process of knowledge-sharing among students, and improving the learning and working efficiency of accounting students at universities. At the same time, from a certain perspective, it helps organizations, universities and training institutions be better understand the psychology of students, especially teaching organizations, to be able to capture information, apply successfully use the scientific and technical achievements of the digital transformation process to adjust the mode of knowledge-sharing between lecturers and students and between students inside and outside the university.

This result shows the level of impact from low to high on the knowledge-sharing activities of accounting students at universities in Hanoi. Before sharing knowledge in certain activities or fields to develop more skills and improve self-awareness, students always equip themselves with confidence in their own abilities, confidence in communication skills, expression skills, persuasion skills, and other soft skills to be able to confidently share and impart their knowledge to everyone. This is considered an extremely important factor, because it not only helps students become more confident in terms of specialized knowledge and professional handling skills in presenting their personal views and opinions when still in university, but in the long-run, this is also a factor for employers and leaders to evaluate and choose the right factors for the positions of the business, or in other words, this is a factor that creates opportunities for advancement and career development after graduation.

Next is the support of the university factor, the university creates supportive policies, creating favorable conditions for accounting students to better understand the importance of the digital transformation process of knowledge transfers, and have the opportunity to have more access to the sciences, advanced technology, and modern. The university provides equipment or prepares skills, training sessions on how to apply digital transformation to make knowledge exchange easier and more convenient.

Then is the influence of Information technology or the application of scientific achievements of the 4.0 technology revolution to knowledge-sharing activities. Learners will learn the supporting software and applications when applying digital transformation to this activity, consider whether they help in the process of sharing their knowledge and whether the technology level is fully compatible and consistent with the knowledge-sharing process. Therefore, this is also a factor affecting the knowledge-sharing of learners themselves.

The next level of influence is the factors belonging to Benefits of knowledge-sharing such as: help improve learning results, help adapt to change better, adapt well to changes in the trend of technology, serve as a premise to adapt to the process of international integration in future work; in addition, it also helps me to be more confident, have more opportunities to learn and make friends, and give me the opportunity to be recognized and trusted. Although its impact is not as great as The Information technology factor and the support of the university factor, it is also a factor affecting the knowledge-sharing activities of learners.

Besides, the remaining factor, like Knowledge-sharing process, completely does not affect the knowledge-sharing activities of learners. This result is consistent with knowledge-sharing activities of accounting students in the current period. Because this is only a small, insignificant external impact, it may partially affect the knowledge-sharing process of accounting students in the study area, as a factor to consider, but this factor will not completely affect students' knowledge-sharing activities.

## SELLER REPUTATION, TRUST AND ONLINE PURCHASE INTENTION OF CONSUMERS IN VIETNAM

**Authors: Vu Thu Ha<sup>1</sup>, Nguyen Thi Huong Giang<sup>1</sup>, Nguyen Duc Huy<sup>1</sup>**

**Mentor: PhD. Vu Thi Thuy Hang<sup>1</sup>, Master Tran Ngoc Diep<sup>1</sup>**

**ABSTRACT:** Prior research has found that reputation significantly affects trust (Doney & Cannon, 1997; Grazioli & Jarvenpaa, 2000) and reputation building is extremely important for merchants. In recent years, the income of Vietnamese citizens has been on the rise, but still remains average compared to neighboring countries and low compared to the global average. While traditional shopping methods are still commonly used, there is a growing preference among Vietnamese consumers for electronic commerce platforms. However, they are careful and consider many factors in online shopping. In this paper, we explored the role of seller reputation in the relationship between trust and online shopping by building a model with 4 variables, 6 hypotheses and 21 observed variables. A sample of 267 consumers from Vietnam were surveyed, and all analysis is performed using structural equation modeling (SEM) by SmartPLS. Research results show that seller reputation influences the relationship between trust and online shopping intention of Vietnamese consumers through customer service quality. The article provides recommendations to improve trust and online shopping intention for Vietnamese consumers, offering solutions for consumers, e-sellers, and related associations and organizations.

**Key words:** Seller reputation, Trust, Online purchase intention, Consumer in Vietnam

### 1. INTRODUCTION

According to statistics of the Ministry of Information and Communications, up to September 2021, Vietnam has 72.1 million people using the Internet in daily life. Vietnamese users spend an average of 7 hours a day engaged in Internet-related activities. The Internet has become an essential part of Vietnamese people's lives, particularly among the younger generation.

Originating from changes in technology, people's behavior in other countries has changed as well. In Vietnam, this is especially evident. Despite the COVID-19 pandemic hitting Southeast Asia hard, e-commerce in Vietnam has not only remained unaffected, but has also been promoted to develop more strongly than ever before, leading to consumers' behaviors and habits also changing. According to a survey of 6,500 consumers in Vietnam, Australia, Indonesia, Korea, Thailand, the Philippines, and Taiwan (China) about business conversations conducted by Meta and Boston Consulting Group in 2022, Vietnam has the highest conversational turnover among the surveyed markets, up to 73% of Vietnamese consumers use chat messages to approach businesses. According to Meta, this shows that Business Messaging continues to play a role in improving the customer experience and bringing businesses closer to customers, as it enables customers to interact with online stores in a more natural and conversational way.

The White Book on Vietnamese Business 2022 published by the Ministry of Industry and Trade, the number of Vietnamese shopping online reached more than 51 million, up 13.5% over the previous year. This paper also shows that the percentage of Internet users buying online reached 74.8% and their expenditure on this kind of shopping approximated to 12.42 billion USD. According to the Decision No. 645/QĐ-TTg about the master plan for e-commerce development during 2021 - 2025, Vietnam's e-commerce is predicted to grow an average of 25% per year, reaching 35 billion USD by 2025, accounting for 10% of

<sup>1</sup> Thuong mai University.

total retail sales and service revenue. This indicates the trend of e-commerce in Vietnam, particularly the online shopping trend.

A majority of consumers use the internet to browse for information concerning their future purchase item on Internet shopping websites, however, only a small number of them actually buy that item online (Chen & Barnes, 2007; Johnson, 2007). It suggests that consumers may not be fully convinced of the reliability and trustworthiness of these service providers.

In many studies, reputation is a direct factor influencing trust (Anderson et al.; Weitz, 1989; Doney et al.; Cannon, 1997; Grazioli et al.; Jarvenpaa, 2000). For that reason, building reputation is crucial to sellers, and on that basis, this study examines the role of seller reputation in the relationship between belief and online purchase intention. The findings of this research are intent on recommending some solutions to improve the trust of online consumers.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Consumers and Online Consumers**

#### **\* Consumers**

According to Clause 1, Article 3 of the Law on Protection of Consumer Rights 2010: “Consumers are those who purchase and use goods and services for consumption and daily life purposes of individuals, families or organizations”. In the scope of this research paper: Consumers include not only individual consumers but also organizations (such as state management agencies, businesses, social organizations, industry associations, etc.) ) purchase and use goods and services for the purpose of consumption, serving the daily needs of that individual, family or organization.

#### **\* Online consumers**

Magdalena Jaciow et al. (2011) define online consumers by combining the two concepts “consumer” and “online”. The term “online customer” is sometimes used interchangeably with “online consumer,” although the two terms have many differences. Specifically, the concept of “online customer” has a broader meaning, because it is a person who uses a computer or mobile device with an Internet connection to buy a product or service regardless of the purpose of use (Nguyen Thanh Do & Ha Ngoc Thang, 2014; Tran Van Hoe, 2008); while “online consumers” make purchases only to serve the daily needs and consumption of individuals, households or an organization.

Based on these definitions, the research team defines online consumers as individuals, households, or organizations that use electronic devices connected to the Internet to purchase and use products, goods, and services for personal or organizational consumption and daily-life purposes, either in part or in full.

### **2.2. Trust and Online trust**

#### **\* Trust:**

According to Crosby et al. (1990), from the perspective of the relationship between sellers and buyers, trust is the confidence that the seller will act in the interests of the customer. while Zaheer et al. (1998) conceptualize trust as an expectation that sellers will fulfill their obligations, act fairly, and refrain from taking advantage of personal interests. In this study, the authors argue that trust can be considered as “consumer’s expectation on seller’s behavior to meet customers’ needs and interests, through taking risks in the transaction process”.

#### **\* Online trust:**

Subjects in online trust are different from traditional beliefs, including the Internet, Websites and technology (Chanidapa P. et al., 2012). Online trust is mainly associated with trust on the Internet and, in particular, with e-commerce (Taddeo, 2011). Beldad, de Jong, & Steehouder (2010) argue that it is “a

confident attitude in an online risk situation that one's vulnerabilities will not be exploited." Based on the above perspectives, online trust can be defined as "the willingness to be vulnerable in the online environment, where direct contact and physical communication are absent, and interactions are mediated by digital and technological devices, where social norms and ethical values are perceived differently by each individual".

## **2.2. Seller reputation and Service quality**

### *\* Seller reputation*

Seller reputation is defined as customers' positive perception of a seller due to the customer's exposure to the seller's products/services or any prior associated with the seller. (Chatpong Tangmanee et al., 2016).

### *\* Service quality*

Most of the studies on service quality use the definition of Parasuraman et al. (1985) who argue that service quality is "the gap between customers' expectations and their perception of the outcome of the service experience." In this study, the research team defines the seller's service quality as the service that the seller provides to satisfy the needs in the consumer's shopping process, as determined by the consumer's perception used during the experience.

## **2.3. Relationship between customers' trust and online purchase intention of Vietnamese consumers**

Online shopping trust (Customer Trust) can be defined as a set of beliefs held by online consumers regarding certain characteristics of an online seller, also as possible behaviors of future online sellers (Coulter and Coulter, 2002). Trust becomes more important in e-commerce because consumers cannot touch, feel or smell the actual product. In that case, trust plays a crucial role in the relationship between consumers and e-vendors. (Fung & Lee, 1999).

Moreover, trust is the emotional foundation for building close relationships with customers (Halliburton, 2010). According to the research literature, trust is recognized as a factor that brings good results for businesses, especially for those dealing in items with high risk and uncertainty. Additionally, trust helps create customer loyalty. When customers trust a business, they are more willing to establish lasting deals, spend more, and refer the community to that business.

## **3. RESEARCH MODEL AND HYPOTHESES**

### **3.1. Research models**

Theoretical models and theories used to study shopping beliefs online shopping and online shopping intent include TPB, TAM, TRA, and C - TAM - TPB. The above-mentioned theoretical models can help to study this problem with similar variables in terms of perceived behavioral control (perceived ease of use, perceived risk,...) security, privacy, quality of customer service,...).

After synthesizing the theoretical foundations and research overview, the authors found that the studies confirmed the positive impact of the trust factor affecting the intention to shop online (Varma et al. associates, 2019; Dan J.Kim et al., 2008; Neelam Chawla et al., 2021; M. Koufaris, 2002; Chatpong Tangmanee, 2016). The seller Reputation factor plays a causal role: website reputation has the highest degree of positive impact while trust contributes the least to purchase intention, i.e. reputation The higher the quality of the website or the high trustworthiness of the website, the higher the purchase intention will be (Chatpong Tangmanee, Chayanin Rawsena, 2016). The quality of customer service is the mediating factor to promote the online shopping intention of consumers (Brian J. Corbitt, 2003; B. Daroch, 2020).

From the process of research overview, the authors build a research hypothesis model as follows:

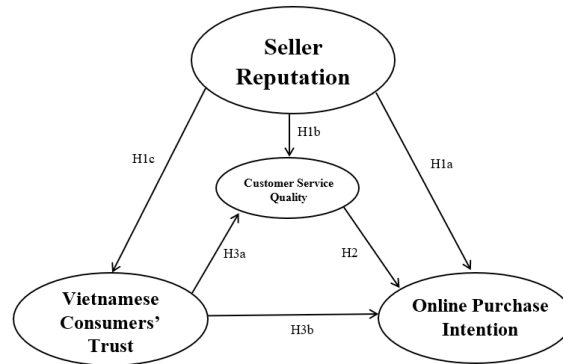

Figure 1: Research model

Source: Author's Team

### 3.2. Research hypotheses

The research model hypotheses are explained as follows:

#### (1) Seller reputation

In the article “Consumer Trust in Brand: Can it be Built Through Brand Reputation, Brand Competence and Brand Predictability” (2010), brand reputation is defined as the attitude of consumers towards a brand as being good and trustworthy. Reputation has a direct influence on trust, as indicated by Anderson and Weitz (1989), Doney and Cannon (1997), and Grazioli and Jarvenpaa (2000). Companies build their reputation by showing care and honesty towards their customers (Doney & Cannon, 1997).

According to Jarvenpaa and Tractinsky (1999), consumers are more likely to trust a company with a good reputation. Gefen (2000) suggests that people use reputation to trust a company if they do not have enough information and experience with it.

Based on these insights, the authors hypothesize the following:

**H1a: Seller reputation has a positive effect on online purchase intention.**

**H1b: Seller reputation has a positive effect on customer service quality.**

**H1c: Seller reputation has a positive effect on Vietnamese consumers' trust.**

#### (2) Quality of customer service

The three main elements of an e-vendor's service - customer communication, delivery, and after-sales service - are significantly related to online buyers' trustworthiness (Nguyen Ngoc An, 2006). In terms of communication, although customers can obtain product-related information from recommendations, photos, and reviews from other buyers on the website, they may still need to contact the supplier directly through phone or instant messaging for further explanations or clarifications. In these situations, the customer experience will be significantly influenced by the communications conducted by supplier representatives who can inspire customer trust and confidence by their professionalism and understanding (Malin Gustavsson, Ann-Marie Johansson, 2006). With regard to delivery, online shoppers are not in the same geographical location as the supplier. If the buyer can receive the goods as promised, confidence in the supplier's ability and commitment to keeping their promises is enhanced. Moreover, there may be cases where customers are disappointed by the product's non-conformity with their expectations. Unless e-vendors show empathy for these concerns and offer opportunities to return products, online shoppers will not be willing to transact in the future. Based on these findings, the authors hypothesize that:

***H2: Customer service quality has a positive impact on online purchase intention.***

### **(3) Vietnamese consumers' trust**

Trust can be defined as the tendency of customers to repurchase a certain electronic supplier's products with a lower degree of doubt when they have experienced satisfaction with that supplier (Nguyen Ngoc An, 2006). Gefen (2002) suggests that specific beliefs about integrity, ability, and benevolence are seen as preconditions for overall trust. A lack of trust has been noted as one of the main reasons that discourage consumers from shopping online (Jarvenpaa, 2000; Lee, 2001). If trust is not established, online transactions are impossible (Winch, 2016). Therefore, customers' trust in online sellers is the foundation of online shopping (Chen, 2012). In the context of online shopping, trust plays a crucial role because customers perceive higher transaction risks in the online environment as they do not have direct contact with the seller or the product they intend to buy (Jarvenpaa, 2000; Pavlou, 2003).

Trust is built when online providers offer good quality products and services (Gefen, 2002). Therefore, when consumers have a foundation of trust based on past experiences, the challenge for providers is to continually improve service quality to meet customers' expectations. Otherwise, the customer's trust in the seller will quickly be broken.

Based on the above arguments, we propose the following hypotheses:

***H3a: Vietnamese consumers' trust has a positive effect on customer service quality.***

***H3b: Trust has a positive effect on online purchase intention.***

### **(4) Online purchase intention**

Intention is a factor used to assess the ability to perform a behavior in the future (Blackwell et al., 2001). According to Ajzen (1991), intention is the motivating factor that encourages an individual to be willing to perform a behavior. Therefore, Delafrooz et al. (2011) argue that "online shopping intention is the certainty of consumers' ability to make purchases over the Internet." Shopping intention is typically viewed as one of the two factors that decisively influence consumer buying behavior (Blackwell, 2001).

According to Hess (2008), a seller's reputation is the buyer's perception of how the seller takes care of their customers, and it affects the relationship between frustration and purchase satisfaction, thereby influencing purchase intention after a customer has a poor service experience. Additionally, Chatpong Tangmanee (2016) highlights that the reputation of a shopping website helps to shape customers' online trust, which also positively impacts their purchase intention.

## **4. RESEARCH METHOD**

\* ***Sample object:*** In this study, the sample object is Vietnamese consumers across all 63 provinces and territories of Vietnam. The survey sample is guaranteed to be from all socio-economic regions of Vietnam.

\* ***Sample size:*** This sample size is proposed based on the opinion of Hair et al. (2006) that the minimum sample size to be achieved must be greater than or equal to  $m*5$  (where  $m$  is the number of variables). In this study, with a total of 21 observed variables, the minimum sample size must be greater than or equal to 105. However, to ensure high reliability, the team conducted a survey of 267 consumers. During the investigation, only 198 valid votes were obtained, of which 191 respondents had previous experience shopping online, while the remaining 7 had not.

\* ***Survey method:*** In this article, the authors use a combination of two research methods: qualitative and quantitative. Qualitative is the object observation and the review of research materials, while quantitative is done by surveying using questionnaires according to a Likert scale with 7 levels from (1) "Completely no influence" to (7) "Completely influence".

\* **Measurement and validity:** This study uses SPSS software to ensure the accuracy of the data and the reliability of the scale based on Cronbach's Alpha coefficient analysis. In addition, the group also analyzed EFA exploratory factors, which made it possible to examine the relationship between variables in all different groups (factors) in order to discover observed variables that load more or observed variables are factored differently from the beginning.

\* **Data analysis techniques:** In addition, the variables after being found to be valid will be analyzed by the partial least squares structure model (PLS-SEM) using SMARTPLS 4.0 software.

## 5. RESEARCH RESULTS

### 5.1. Sample profile

According to the survey results of 198 consumers, the percentage of Vietnamese female consumers (69.2%) is higher than that of men (30.3%), showing that Vietnamese women tend to be more interested in shopping and consuming than men.

In terms of age, a large proportion of participants in this survey are young people under 24 years old (90.9%). The age group from 55 - 64 years old and over 65 years old both account for 0.5%, this age group is considered as the elderly, less exposed to the Internet and shopping online than young people. Students dominate the sample at an accumulated proportion of 89% because this is a dynamic group of consumers, who acquire quickly, use technology proficiently, and have high shopping needs. The survey also found that the majority of consumers in this group are young and have a monthly income of under 5 million VND (40.4%) or no income at all (42.4%). The research sample represents consumers living in many different regions and regions with The majority of respondents coming from the Red River Delta and Northeast coast, specifically the capital Hanoi. This is a developed economic area with high living standards and good technology infrastructure, therefore their online shopping experience here is also more diverse than in other regions.

191 consumers who responded to the survey said they have had an online shopping experience (96.5%) and 160 of them (97.9%) intend to continue to buy in the future. In terms of shopping channels, Vietnamese consumers prefer using e-commerce platforms (Tiki, Shopee, Lazada, ...) with 164 respondents, accounting for 85.9% of those who have purchased online. Regarding shopping channels, social media channels such as Facebook and Instagram accounted for 7.3% of online purchases, while online shopping applications made up 3.6%, and seller websites were responsible for 3.2%. These findings demonstrate the growing trend of e-commerce platforms in the online shopping market, due to the convenience, competitive prices, and variety of products that they offer. Customers are able to research, compare prices, and read product reviews, which has led to changes in their purchasing habits.

The frequency of online shopping among Vietnamese consumers is currently relatively low, the majority choose that they shop less than once a week (60.7%), followed by 1-3 times/week accounted for 33% of respondents, only 4.7% of consumers shop online 3-5 times/week and the lowest is the frequency of shopping more than 5 times/week with 1.6% of respondents. The most commonly purchased product category on online shopping platforms is fashion, which accounted for 90.4% of total respondents; followed by cosmetics (66.7%) and personal care products (58.1%). These results reflect the fact that a majority of respondents (69.2% female) are interested in beauty care products. However, for products with a short shelf life, such as food, only 35.9% of respondents were comfortable buying them online. The pharmaceutical and functional foods industry had the lowest percentage of online shoppers at 22.2%.

Regarding payment methods, 48.2% of the respondents who shopped online preferred the payment method by e-wallet because of its convenience and speed, followed by the forms of using credit cards (25.7

%) and COD (24.6%), debit cards (7.9%). Some respondents choose different payment methods for each transaction.

## 5.2. Results of the model test

### *\* Evaluate the reliability of the scale with Cronbach's Alpha coefficient:*

Cronbach's Alpha coefficient has a variable value in the interval [0,1]. According to Nunnally (1978), a good scale should have a Cronbach's Alpha reliability of 0.7 or higher. Besides, according to Cristobal et al. (2007), a good scale is when the observed variables have a Corrected Item - Total Correlation value from 0.3 or more.

The results of the analysis of each scale are shown in the following table:

**Table 1. Evaluate the reliability of the scale with Cronbach's Alpha coefficient**

Encryption	Corrected Item-Total Correlation	Cronbach's Alpha if item Deleted
Customer Service Quality (CS): Cronbach's Alpha Reliability = 0.950		
CS1	0.720	0.950
CS2	0.827	0.943
CS3	0.857	0.941
CS4	0.803	0.944
CS5	0.830	0.942
CS6	0.826	0.943
CS7	0.861	0.941
CS8	0.812	0.944
Seller Reputation (BR): Cronbach's Alpha Reliability = 0.918		
BR1	0.820	0.890
BR2	0.876	0.871
BR3	0.795	0.899
BR4	0.757	0.912
Consumer's Trust (TR): Cronbach's Alpha Reliability = 0.910		
TR1	0.734	0.897
TR2	0.829	0.877
TR3	0.790	0.886
TR4	0.796	0.884
TR5	0.710	0.902
Online Shopping Intention (IP): Cronbach's Alpha Reliability = 0.889		
IP1	0.753	0.859
IP2	0.805	0.840
IP3	0.757	0.859
IP4	0.717	0.873

Source: The author's team synthesized the results of SPSS survey data processing.

Based on the table above, it is evident that all scales in the research provided by the authors are highly reliable, with Cronbach's Alpha coefficient greater than 0.8.

### *\* EFA exploratory factor analysis:*

- Testing the model's suitability (Kaiser Meyer-Olkin) and correlation between the observed variables (Bartlett's Test):

The table for KMO and Bartlett's Test below shows that the KMO index exceeds the threshold of 0.5, with a value of 0.922, indicating that exploratory factor analysis is suitable for real data.

**Table 2. KMO and Bartlett’s Test**

<b>Kaiser-Meyer-Olkin Measure of Sampling Adequacy.</b>		<b>.922</b>
Bartlett’s Test of Sphericity	Approx. Chi-Square	3797,199
	DF	.210
	Sig.	.000

Source: The author’s team synthesized the results of SPSS survey data processing.

The Bartlett’s Test results have a significance value (Sig) of 0.000, which is less than the significance level (0.05). Therefore, we can conclude that the observed variables are correlated with each other in each factor group.

- Test the extracted variance of the factors (% Cumulative variance):

Based on the results presented below, we observe that the total variance extracted in the Factor 4 row and Cumulative% column is 71.183%, which exceeds the 50% threshold required to meet the criteria. Moreover, all the eigenvalues of the extracted factors are high (>1), with the fourth factor having the smallest eigenvalue coefficient of 1.164>1. Consequently, we can conclude that these 4 extracted factors provide an optimal summary of the information from the 21 observed variables included in the EFA and explain 71.183% of the variation in the data of the 21 variables observed in the EFA. The following table presents the results of the extracted variance test of the factors:

**Table 3. The total of the extracted differences between variables**

Factor	Total Variance Explained						Rotation Sums of Squared Loadings Total
	Initial Eigenvalues			Extraction Sums of Squared Loadings			
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	
1	11,353	54,064	54.063	11.071	52.720	52.720	9,357
2	2,088	9,945	64.008	1,797	8,557	61.277	7,380
3	1.465	6.974	70.982	1.214	5.781	67.058	7,765
4	1.164	5.545	76.527	.866	4.125	71,183	7.819
5	.676	3,220	79.747				
6	.562	2.675	82.423				
7	.459	2.184	84.606				
8	.451	2.148	86.754				
9	.386	1,840	88.593				
10	.310	1.477	90.071				
11	.307	1.460	91.531				
12	.287	1.367	92.897				
13	.257	1.223	94.120

15	.201	.959	96.121				
16	.187	.890	97.011				
17	.160	.763	97.773				
18	.141	.670	98.443				
19	.139	.660	99.104				
20	.108	.516	99.620				
21	.080	.380	100.000				

Extraction Method: Principal Axis Factoring.

a. When factors are correlated, sums of squared loadings cannot be added to obtain a total variance.

Source: The author’s team synthesized the results of SPSS survey data processing.

- *Checking factor loading with Pattern Matrix rotation table:*

The research team used the Principal Axis Factoring method with Promax rotation when running the data. The results showed that even in the first analysis, all factors had coefficients of factor load  $>0.5$ , meaning that no shuffling, splitting, or pooling of data occurred. As a result, the team concluded that the EFA results were consistent with the model.

**Table 4. Pattern Matrix**

After filtering the data due to unsatisfactory responses, only 198 samples were included in testing the model. Four variables were selected for the SEM linear structural model evaluation after checking the reliability and quality of the scales during EFA.

**\* Analysis of SEM (Structural equation modeling):**

When evaluating the SEM, the research model must go through two evaluation steps: the evaluation of the measurement model and the structural model (Henseler and Chin, 2010).

- *Evaluation of the Measurement Model:*

Before evaluating the model, we must assess the quality of the observed variables (indicators):

According to Hair et al. (2014), the outer loading coefficient must be greater than 0.4 to be reliable in exploratory research. Moorees and Chang (2006) accepted a study with an external factor loading factor  $>0.6$ . Additionally, Hair et al. (2016) believe that an observed variable is of quality if the outer loading factor is greater than or equal to 0.708.

The results below demonstrate that all observed variables have high outerloading coefficients ( $>0.708$ ), indicating that the quality of the observed variables in the study is guaranteed.

**Table 5. Coefficients for Loading of Observed Variables in External Factors**

*- Reliability Assessment using the Reliability Scale and Convergence:*

In addition to requiring Cronbach’s Alpha to reach a threshold of 0.7 or higher (according to DeVellis, 2012), researchers also use Composite Reliability (CR), which is preferred because Cronbach’s Alpha underestimates reliability more than CR. According to Chin (1998), in exploratory research, CR should be 0.6 or higher. In confirmatory studies, a threshold of 0.7 is the appropriate level of the CR index (Henseler & Sarstedt, 2013). Many other researchers also agree that 0.7 is the appropriate threshold for the majority of cases, such as Hair et al. (2010) and Bagozzi & Yi (1988).

The results in *Table 5* show that all scales have high reliability with a Cronbach’s Alpha coefficient ( $>0.7$ ) and a CR coefficient ( $>0.8$ ).

*- Convergence Rating:*

To evaluate convergence on SmartPLS, people rely on the average variance extracted (AVE). According to Hock and Ringle (2010), a scale has a converged value if the AVE is 0.5 or higher. This level of 0.5 (50%) means that the average parent latent variable will explain at least 50% of the variation of each observed child variable.

Based on the results in *Table 6*, all scales have an AVE  $> 0.5$ , which proves that the scales are of good quality and convergence is guaranteed.

**Table 6. Assessment of Reliability and Convergence**

	<b>Cronbach's alpha</b>	<b>Composite reliability (rho_a)</b>	<b>Composite reliability (rho_c)</b>	<b>Average variance extracted (AVE)</b>
BR	0.918	0.921	0.942	0.804
CS	0.961	0.951	0.959	0.745
IP	0.890	0.890	0.924	0.752
TR	0.910	0.913	0.933	0.735

Source: Author team synthesized from the results of SmartPLS survey data processing

*- Discriminant Validity Assessment*

To assess the discriminant validity, we used the HTMT index (Heterotrait-Monotrait Ratio). Garson (2016) suggests that the discriminant validity between two latent variables is ensured when the HTMT index is less than 1. Henseler et al. (2015) propose that if the value is below 0.9, discriminant validity is ensured. Meanwhile, Clark & Watson (1995) and Kline (2015) use a more stringent threshold of less than 0.85. According to the results in the table below, all HTMT values are less than 0.85, indicating that the discriminant validity of the scale is very good. Therefore, all factors meet the requirements for discriminant validity.

**Table 7. Assessment of Discriminant Validity**

	<b>BR</b>	<b>CS</b>	<b>IP</b>	<b>TR</b>

*\* Evaluation of PLS - SEM Measurement Structure Model:*

To evaluate the structural model PLS - SEM, our research team conducted bootstrap analysis with 5000 bootstrap iterations. When evaluating the structural model, we considered the following criteria: VIF coefficient evaluation, multicollinearity evaluation, impact factor evaluation, significance of impact levels, R-Square coefficient, and f-Squared coefficient.

*- Evaluation of Linear Multicollinearity:*

According to Hair et al. (2019), if the VIF index is 5 or greater, the model has a very high probability of having multicollinearity. Based on the results in the table below, the structures in the SEM model with VIF coefficients ranging from 1,000 to 1,951 are all less than 5, indicating that the model does not have multicollinearity.

**Table 8. Evaluation of Linear Multicollinearity**

	<b>BR</b>	<b>CS</b>	<b>IP</b>	<b>TR</b>
BR		1.489	1.951	1.000
CS			1.938	
IP				
TR		1.489	1.651	

Source: Author team synthesized from the results of SmartPLS survey data processing

*- Assessing the explanatory power of the independent variable on the dependent variable (adjusted R2):*

In research, the adjusted R-squared metric gauges the explanatory power of the independent and dependent variables in the model. As shown in the table below, the adjusted R-squared value for IP is 0.528, indicating that the independent variables account for 52.8% of the variation (variance). The remaining 47.2% is attributable to system error and external factors not accounted for in the model.

**Table 9. R-squared adjusted (R<sup>2</sup> adjusted)**

	R-square	R-square adjusted
CS	0.484	0.479
IP	0.535	0.528
TR	0.328	0.325

Source: Author team synthesized from the results of SmartPLS survey data processing

- Value of the influence of the independent variable on the dependent variable:

The coefficient f-square helps us understand the strength and weakness of the impact of the independent variable on the dependent variable. Cohen (1988) proposed the f-square index table to evaluate the importance of independent variables as follows:

f Square < 0.02: the effect is extremely small or has no effect.

0.02 ≤ f Square < 0.15: small impact.

0.15 ≤ f Square < 0.35: medium impact.

f Square ≥ 0.35: high impact

Based on the analysis results in the table below, BR has a medium impact on CS (0.310), an extremely small or no impact on IP (0.012), and a large impact on TR (0.489). CS has a small impact on IP (0.119), TR has a small impact on CS (0.109), and a medium impact on IP (0.222).

**Table 10. Impact value of f - square**

	BR	CS	IP	TR
BR		0.310	0.012	0.489
CS			0.119	
IP				
TR		0.109	0.222	

Source: Author team synthesized from the results of SmartPLS survey data processing

- Evaluation of impact relationships

To evaluate the impact relationships, we'll be using the results of the bootstrap analysis. There are two indicators we need to keep an eye on: the normalized effect coefficients (original sample) and P values (sig value compared to the significance level of 0.05).

Based on the table, most of the effects have a P value of 0.05, which means that these effects are statistically significant. However, there is a variable that affects BR on IP with P values of 0.204 > 0.05, which indicates that this relationship is not statistically significant. Nevertheless, this could be due to cases of data noise or errors in the sampling process.

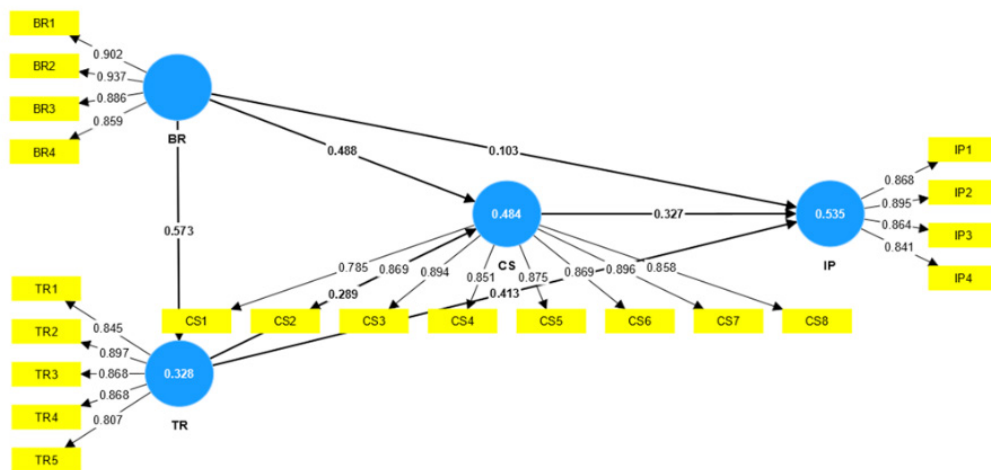

The Original Sample column (O) displays the particular relationship between the variables in the SEM model, where: IP is the dependent variable, influenced by two variables, TR and CS, with normalized impact coefficients of 0.413 and 0.327, respectively; CS is a dependent variable, affected by two variables, BR and TR, with normalization coefficients of 0.488 and 0.289, respectively; and finally, IP is affected by CS with a normalization factor of 0.327.

**Table 11. Coefficient Values for Impact Relationships**

	Original Sample (O)	Original Mean (M)	Standard Deviation (STDEV)	T Statistics ( O/STDEV )	P Values
BR → CS	0.488	0.485	0.079	6.172	0.000
BR → IP	0.103	0.108	0.081	1.270	0.204
BR → TR	0.573	0.572	0.058	9.839	0.000
CS → IP	0.327	0.321	0.084	3,915	0.000
TR → CS	0.289	0.292	0.073	3,975	0.000
TR → IP	0.413	0.415	0.071	5.797	0.000

**6. CONCLUSION AND RECOMMENDATIONS**

**6.1. Conclusion**

SEM estimation results indicate that Seller Reputation does not affect Online Purchase Intention but has a positive impact on Customer Service Quality and Consumers’ trust. Meanwhile, Customer Service Quality has a positive influence on Online Purchase Intention. Vietnamese Consumers’ trust has a positive influence on both Customer Service Quality and Online Purchase Intention.

**6.2. Recommendations**

**\* Recommendations for consumers:**

- Choose reputable online product/service providers: Consumers need to be more careful when choosing online sellers by considering factors such as the seller’s reputation, product quality/services, and information provided, etc. This can help avoid falling into risky situations in the online environment.
- Actively stay updated on trends and new forms of online shopping: Continuously updating information can help consumers stay current and access new and improved shopping models to protect their interests.

**\* Recommendations for E-sellers:**

- Ensure the reputation of after-sales and warranty policies: The survey results of the study showed that

consumers tend to be more satisfied with the quality of services provided by online sellers, who show that their warranty service is always available. Therefore, sellers need to ensure that they are always available to assist customers in situations where support is required.

- Invest in marketing campaigns: Online sellers can deploy appropriate forms of online marketing. Sellers need to constantly research and expand the scope of Marketing to a variety of platforms and online channels.

- Clearly demonstrate community responsibility and actively participate in customer-oriented activities, in particular, and the community in general: From a social responsibility standpoint, corporate social responsibility (CSR) is essential for online sellers. When online sellers adhere to commitments to business ethics and contribute to sustainable economic development, they can improve the quality of life for employees and their families, local communities, and society at large.

- Ensure the quality of information on information and sales pages: Online sellers need to pay more attention to the accuracy and completeness of information about products and services provided. It is important to give short, easy-to-understand messages as an effective way to facilitate decisions (Silverman 2001).

- Strengthen market research activities: Online sellers can collect information from a variety of sources for research purposes. In addition, they need to regularly monitor the development and trends of the sales platform they are using, the business activities of competitors, etc. to determine the most appropriate strategy for their business.

**\* Recommendations for Related Associations and Organizations:**

- Actively protect the interests of online consumers: Associations of businesses in various fields need to encourage individuals and organizations to provide quality products and services while building a reputable brand name in the market. Activities that reward and honor organizations and individuals for protecting consumer interests should be promoted. Social organizations that protect consumer interests should continue their role as a reliable source of advice and support, assisting consumers to resolve complaints with service and goods providers.

- Promote propaganda and exchanges that raise awareness of online consumers: It is necessary to promote regulations, policies, and laws related to consumer rights and responsibilities. Organizations and individuals that trade goods and services should be made aware of their responsibilities, as should state management agencies and social organizations that protect consumers' interests.

- Focus on supporting and resolving consumer concerns about the risks they may face when participating in online shopping: Organizations and associations that protect consumer interests, such as the Association Protecting Vietnamese Consumers, should promote their role in guiding and consulting to resolve consumer complaints.

### **6.3. Limitations and directions for future research**

**\* Limitations:**

- The research is limited in terms of time and funding; therefore, it lacks generality and coverage of the entire territory of Vietnam.

- Some consumers do not have sufficient knowledge and skills, which leads to misunderstandings and emotional responses, leading to deviations from other answers in the questionnaire.

- The theoretical basis and presentation of the content have some shortcomings due to the research team's inexperience.

- This study only examines the role of seller reputation in the relationship between trust and intention. There may be other important factors that affect the relationship between trust and intention, but they are not mentioned in this research.

- The solutions proposed by the research team are specific to the appropriate extent for the actual situation.

**\* Future research directions:**

- Conduct follow-up studies to develop research models with more appropriate and extended variables.
- Expand the scope of the research, with a larger sample from diverse demographics.
- Explore and identify other factors that affect the relationship between Trust and Online Purchase Intention.

## APPLICATION OF THE SEM MODEL TO EVALUATE THE EFFECTIVENESS OF SUPPLY CHAIN MANAGEMENT USING BLOCKCHAIN TECHNOLOGY: A STUDY ON SHOPEE.VN

**Authors: Hoang Thi Quynh Nga<sup>1</sup>, Phung Mai Linh<sup>2</sup>, Nguyen Thi Thuy An<sup>2</sup>, Nguyen Thi Ngoc Khanh<sup>2</sup>**

**Mentor: Dr. Nguyen Thi Hoi<sup>2</sup>**

*ABSTRACT: Supply chain management (SCM) plays a crucial role in the operations of organizations, particularly on e-commerce platforms. In the fast-developing environment of international supply chains, the traditional network of manufacturers and suppliers has evolved into a vast ecosystem of different products moving through multiple parties, requiring cooperation among all involved. Blockchain technology has shown promising results in improving the supply chain network in recent applications, deeply impacting society and lifestyles by reshaping many business and industrial processes. In an effort to understand the integration of Blockchain technology in supply chain management, particularly on e-commerce platforms, this study uses a linear SEM model and UTAUT model to discover the effects of Blockchain technology on enhancing the effectiveness of supply chain management on the Shopee.vn e-commerce platform. The experiment shows that expected effectiveness, effort, facilitating conditions, supply chain traceability application, behavioral intention, and cost value have a proportional impact on the effectiveness of supply chain management.*

**Keywords:** SEM, Blockchain, SCM, UTAUT, E-Commerce.

### 1. INTRODUCTION

Supply Chain Management (SCM) is the process of managing operational activities related to the production, transportation, and distribution of products to end customers. SCM is an important sector in business and plays a crucial role in optimizing processes, enhancing flexibility, and reducing costs. According to the report (MarketSandMarkets, 2022), with the development of information technology, SCM can be optimized and improved by applying advanced technologies such as Blockchain. Markets and Markets forecasts the global SCM market size to grow from USD 28.9 billion in 2022 to USD 45.2 billion by 2027, at a Compound Annual Growth Rate (CAGR) of 9.4% during 2022–2027. The major growth drivers for the market include increasing demand for greater efficiency and transparency in supply chain data and distribution processes.

According to (Kouhizbaeh et al, 2021; Kuhn et al., 2019; Rejeb et al, 2019) Blockchain is a technology that focuses on creating a decentralized and secure ledger system. In SCM, Blockchain can be used to create a supply chain management system that helps all parties involved track and store information related to products, from the manufacturing process to transportation and storage. Blockchain provides high transparency and helps increase trust among supply chain stakeholders. Applications of Blockchain in SCM include product source management, process optimization, and cost reduction. According to (GrandViewResearch, 2023), Blockchain in the SCM market is expected to reach a total value of USD 3.3 billion by 2025, with an average annual growth rate of 49.9% in the forecast period. Additionally, a study by DHL and Accenture shows that 83% of SCM experts believe that Blockchain will have a positive impact on their supply chain within the next three years.

With the support of Blockchain Technology, SCM can create an efficient, secure, and decentralized supply chain management platform for e-commerce (Korpela et al., 2017; Boucher, 2017; Vyas et al., 2019;

<sup>1</sup> Faculty of Economic Information Systems & E-Commerce – Thuongmai University, Email: hoangnga2592003@gmail.com

<sup>2</sup> Faculty of Economic Information Systems & E-Commerce – Thuongmai University.

Swan, 2017). This helps address existing issues such as difficulties in tracking product sources, compliance with complex regulations, and managing stakeholders. Companies that integrate Blockchain Technology into SCM can optimize processes, reduce costs, and increase revenue. According to PwC, using Blockchain in SCM can reduce transportation and storage costs by up to 10% and increase operational efficiency by up to 15%. Therefore, SCM with Blockchain can help enhance the competitiveness of businesses and increase customer trust (Leng et al, 2018; Giri and Manohar, 2021).

Blockchain Technology provides four key features that can enhance integration and coordination among the members of an SC (Sultan and Lakhani, 2018; Vyas et al., 2019; Yaga et al., 2018): (1) transparency, (2) validation, (3) automation, and (4) tokenization. Transparency relates to the shared ledger of information which is aggregated from various sources and participants of the Blockchain. Immutability of records and consensus-based verification enable validation of information. Automation refers to the opportunity to execute smart contracts based on verified information on the Blockchain. Blockchain Technology allows creation of tokens that represent a specific claim on any valuable asset and their exchange between Blockchain members (tokenization). Enabled by these four key features of Blockchain Technology, one can derive corresponding use case clusters in SCM that build on one another: Supply Chain Visibility; Supply Chain Integrity; Supply Chain Orchestration; Supply Chain Virtualization; Finally, Supply Chain Finance.

In addition, the application of Blockchain technology in e-commerce in Vietnam is still limited. However, there are a number of projects and products that are in the process of being built and developed. One of the products using Blockchain technology is Remitano, a cryptocurrency exchange founded in 2016. Remitano has become one of the largest cryptocurrency exchanges in Vietnam and Southeast Asia. In addition, Binance, another cryptocurrency exchange, has introduced a Vietnamese version, allowing users to buy and sell cryptocurrencies in VND.

Although there are still many challenges and limitations that need to be removed such as: a lack of understanding of Vietnamese users about Blockchain technology; problems with legal regulations and information security; The cost of investing and implementing Blockchain technology is still quite high... However, with the potential and benefits that Blockchain technology brings, businesses are gradually realizing the value of using this technology. The development of products and services applying Blockchain technology in e-commerce will continue to be encouraged and promoted in the coming time.

In the context of the increasing attention and development of Blockchain applications in SCM, a research team has conducted a study on the topic “*Evaluating the Effectiveness of Blockchain Technology on Supply Chain Management Systems: A Study on Shopee.vn*”. The aim of the study is to identify factors that impact the acceptance of Blockchain Technology by companies and businesses in supply chain management operations in Hanoi and provide some policy implications for businesses and the government. The paper is divided into three main sections: theoretical background, research results, and proposed policy implications. The final part is the conclusion and reference materials.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Blockchain technology**

Blockchain is a decentralized technology that helps record transactions between parties in a secure and long-lasting manner. According to (Boucher, 2017; Kühn et al., 2019; Karim et al., 2018), Blockchain can be defined as a distributed ledger technology that allows parties to exchange data securely without intermediaries. Blockchain can facilitate the transition from a centralized to a distributed system, freeing up data that was previously held in secure data warehouses.

The application of Blockchain in SCM is one of the main reasons for the development of this technology. According to (Boucher, 2017; Casado et al., 2018; Leng et al., 2018; CTA and GIZ, 2019; Chien, 2020; Miraz et al., 2019), using Blockchain in SCM improves transparency and the reliability of information in the supply chain, reduces risks related to information security and counterfeit goods, reduces transportation and storage costs, and increases operational efficiency. Blockchain in SCM helps enhance transparency and monitoring of the supply chain by allowing stakeholders to verify the origin and history of products, reducing incidents during transportation and storage, and minimizing risks related to information security and counterfeit goods.

Blockchain is also applied in e-commerce to ensure the safety and transparency of transactions (Hameed et al., 2018; Zhu and Kraemer, 2005; Hastig and Sodhi, 2020). The use of Blockchain in e-commerce can reduce order processing time from several days to just a few hours, reduce shipping costs, etc. Additionally, Blockchain helps increase transparency in the transaction process and prevent information leakage. These studies also showed that the use of Blockchain in e-commerce can build trust with customers and increase their willingness to continue shopping on e-commerce platforms. With this feature, Blockchain has been widely applied in many fields, from finance and insurance to supply chain management and e-commerce.

In the case of the Shopee platform, Blockchain technology can improve the linkage in the supply chain by providing secure and transparent transactions. It can help to enhance the coordination and collaboration among different stakeholders, such as suppliers, logistics providers, and customers. By allowing stakeholders to verify the origin and history of products, Blockchain can improve the transparency and traceability of the supply chain, which can lead to better performance and customer satisfaction.

## **2.2. Supply Chain Management**

According to (Christopher, 1998; CSCMP, 2018; Hameed et al., 2018; Moosavi et al., 2021), “Supply chain includes all activities directly or indirectly related to meeting customer demand. The supply chain involves not only manufacturers and suppliers but also transportation, warehouses, retailers, and customers.” Supply Chain Management (SCM) is an important concept in the field of business management. It refers to the management of the entire process of production, storage, and distribution of products from suppliers to customers. SCM includes activities such as supply chain management, manufacturing, storage, transportation, and product distribution. The goal of SCM is to optimize this process to ensure that products are distributed to the right place, at the right time, and with the best quality, while reducing costs and enhancing the competitiveness of the business.

Technology has played a vital role in the development of supply chain management. Technologies such as the Internet of Things (IoT), Artificial Intelligence (AI), Blockchain, and Big Data have been applied to improve the operations of the supply chain. Many studies have shown that using these technologies in supply chain management can increase efficiency and reduce costs. For example, (Rejeb et al., 2019) presented an IoT-based supply chain monitoring platform that improved the ability to track products and reduce waste during transportation. In another study, (Pournader et al., 2020; Miraz et al., 2019) demonstrated that Blockchain Technology can provide transparency and security for transactions in the supply chain, reducing the risk of counterfeiting and fraud. (Hameed et al., 2018) also highlighted that using Big Data in SCM can optimize production and transportation processes, thereby improving the efficiency of the supply chain. Meanwhile, (Kuhn et al., 2019; Hastig and Sodhi, 2020) presented the concept of a “digital twin” in supply chain management, a new technology aimed at addressing the complexity of supply chain management and identifying the causes of the “bullwhip effect” phenomenon.

In e-commerce, supply chain management is an important factor to meet the increasing demand of customers and create a competitive advantage in the industry. According to a report by (Statista.com, 2022), the global market value of e-commerce is expected to reach over 6.3 trillion USD by 2024. Applying appropriate SCM strategies can help reduce transportation costs, maximize profits, and enhance the shopping experience of customers. Some mass e-commerce businesses, such as Amazon and Alibaba (WTO, 2019; AWS, 2022), have heavily invested in optimizing SCM with modern technologies such as AI and Blockchain. For example (AWS, 2022), Amazon has implemented an automated supply chain management system with the support of AI, optimizing warehouse management, predicting product demand, and improving transportation processes. Additionally, Alibaba has developed a global supply chain management system using Blockchain, increasing transparency and accuracy in information management and reducing the risk of counterfeit goods. Using appropriate SCM strategies and applying modern technologies helps e-commerce businesses enhance their competitiveness, optimize production and transportation processes, and create significant benefits for customers with effective and convenient shopping experiences.

One important difference between Blockchain and a traditional centralized network is that Blockchain-stored data is undeletable and un-editable. In a centralized database, there is always the risk of fraud or external hacker attacks, while in a Blockchain, the network will work consistently unless an attacker manages to take control of the majority of the network; therefore, a large number of users almost significantly reduces the possibility of fraud (Arman and Philip, 2018; Dursun et al., 2020).

In a supply chain, ownership of products changes several times among participants until they are delivered to consumers. For low-added-value products such as agricultural commodities and certain types of mining commodities, supply chains function as an aggregation method by which goods are provided by many small-scale producers to larger-scale supply chain partners for further processing towards an end-product. Consumers cannot be sure about the reliability of data in current supply chain systems. The existing model becomes even more burdensome in the global supply chain. A reliable system is difficult, even impossible, to build on a global scale without building trust. With the advent of Blockchain as a disruptive technology for most processes related to our daily lives, the transition to the use of Blockchain Technology (CSCMP, 2018; Moosavi et al., 2021; Bolssey et al., 2019) has begun to overcome all these challenges in supply chains. Participants and their roles in a typical Blockchain-integrated supply chain flow can be depicted.

### **2.3. The e-commerce platform Shopee.vn**

Shopee is an online shopping application (Shopee Live) and e-commerce exchange based in Singapore, owned by Sea Ltd., founded in 2009 by Forrest Li. Shopee is now available in the following countries: Singapore, Malaysia, Thailand, Taiwan, Indonesia, Vietnam, the Philippines, and Brazil (Shopee.vn; Jaipong, 2020)

Shopee.vn (<https://shopee.vn>) is a big e-commerce platform in Vietnam, founded in 2015. Shopee holds the largest market share and is the most successful online sales channel in the country, the top 2 and top 3 are Lazada and Tiki respectively. This online platform provides buying, selling, delivery, and online payment solutions for businesses and individuals. Currently, Shopee.vn is one of the largest and most popular e-commerce platforms in Vietnam, with over 20 million users and 50,000 registered businesses. Recently, Shopee.vn has made significant progress, especially in the context of the rapidly developing e-commerce market in Vietnam. Initially, the business model that Shopee pursues is C2C (consumer-to-consumer), i.e., as an intermediary between individuals. Currently, Shopee has expanded the B2C model

(business-to-consumer), i.e., buying and selling between businesses and individuals, where Shopee still acts as an intermediary link. However, now Shopee Vietnam has become a hybrid model when there is both B2C (business to consumer) and Shopee has charged the seller's fee, commission, and product listing fee. This platform not only provides effective business solutions for companies but also brings convenient and reliable shopping experiences to consumers. However, to maintain and develop Shopee.vn in the future, continuous investment and research on the latest business solutions and technologies are necessary. In particular, the use of Blockchain Technology to enhance the safety and transparency of supply chain management on Shopee.vn is being proposed and researched to address challenges related to customer information management and protection, as well as to improve the integrity and reliability of the supply chain on this e-commerce platform.

Shopee uses a quantitative sourcing model, in which products are stored at distribution centers across the country. Once an order is placed, the product is shipped to the nearest processing center for packaging and shipping to the customer. The typical about Shopee's supply chain is that Shopee has suppliers from many different countries, providing customers with a variety of products in terms of categories and prices. About the Shipping System, Shopee uses an integrated and diversified shipping system, including major shipping partners and domestic shipping services. This helps ensure that products are shipped to customers quickly and on time. Unlike Shopee, Lazada manages from the ordering process to the delivery to the customer. Therefore, shipping fee is higher and the delivery time is longer than Shopee.

The supply chain on the Shopee platform is an important process in Shopee's business. It includes the steps from ordering, packaging, shipping, to the product being delivered to the customer. The goal of the supply chain on Shopee is to ensure that the buying and selling processes happen quickly and on time. In addition, the supply chain also helps Shopee manage inventory, optimize shipping costs and ensure product quality. Inventory management helps Shopee know the number of products in stock and update the status of the goods. Optimizing shipping costs helps Shopee save costs and reduce product prices, while attracting customers. Ensuring product quality helps Shopee create customer trust and maintain its reputation in the market. With the support of the supply chain on Shopee, Shopee is able to provide quality products at competitive prices and respond to customers' needs quickly and efficiently.

Therefore, this study chose Shopee to conduct a survey to analyze and make an assessment of the role of Blockchain in supply chain management.

### **3. RESEARCH METHOD**

#### **3.1. Related works**

Currently, research on Blockchain in supply chain management is limited and sparse. Most of the sessions are merely focused on introducing the theoretical concepts of Blockchain, discussing its potential benefits, and providing a general overview of its application landscape.

According to (Ho and Bui, 2018; Ghode, 2020; Altaf, 2022), Blockchain Technology enables transparent, robust systems that are less dependent on intermediaries through clear and easily traceable origin tracking, facilitating accountability in supply chains. (Blossey et al., 2019; Nguyen, 2020; Cole et al., 2019), Blockchain Technology is still in its early stages, and leading global corporations such as IBM (USA), Samsung (South Korea), and Walmart (USA) are making efforts to experiment with and grasp this future technology. According to (Kühn et al., 2019; Blossey et al., 2019; Treiblmaier, 2018) conducted a study on the current application of Blockchain in logistics service providers and based on the Technology-Organization-Environment (TOE) framework, identifying supporting and limiting factors. The study concluded that small and medium-sized

logistics service providers in Germany are not actively involved in Blockchain Technology. Larger logistics service providers, however, have started identifying their own use cases and are making further efforts to develop them through collaborative projects with partners. According to (Miraz et al., 2019; Ghode, 2020; Giri and Manohar, 2021) conducted a study exploring the factors related to the organizational structure for applying Blockchain in the post-supply chain. The theoretical foundation of this research is the Unified Theory of Acceptance and Use of Technology (UTAUT). The authors addressed innovation in applying the IT capabilities of companies and utilized factors such as e-logistics, IT capability, service quality of employees, and post-supply chain performance adjusted from other international standards to demonstrate the effectiveness of applying Blockchain to these factors. Studies revealed that excellent service quality from employees, an IT capability system, and the implementation of Blockchain significantly impact the operational efficiency of post-supply chain companies.

Currently, the application of Blockchain in the SCM field is still relatively new, and there have been no experimental deployment results that have reached the maturity level required to provide data for research purposes. The latest scientific papers on the application of Blockchain for information retrieval analyze the theoretical aspects. Building upon the advantages and limitations of previous studies, the author approached an extended UTAUT model, supplemented with new observed variables, and conducted quantitative testing in a new environment, which is Hanoi, where no similar study has been conducted before.

**3.2. Research method**

This study combines qualitative and quantitative research. For qualitative research, it first builds and strengthens a theoretical research model through existing research and behavioral research models. For quantitative research, it identifies and measures factors affecting the efficiency of SCM when using Blockchain in businesses and for Shopee users in Vietnam. The study was carried out through the data collection of live survey questionnaires and online questionnaires, and we used a 5-point Likert scale: 1 being completely disagreed, 2 being disagreed, 3 being neutral, 4 being agreed, and 5 being completely agreed.

*Qualitative research:* This method involved data collection, synthesis, and evaluation of literature, referencing measurement scales, and conducting interviews to draw appropriate conclusions for the study.

*Quantitative research:* The research team performed this method by collecting data from survey questionnaires, which were then processed using software such as Stata, SPSS, and AMOS. Data analysis techniques include descriptive statistics, Cronbach’s alpha reliability coefficient test, exploratory factor analysis (EFA), confirmatory factor analysis (CFA), and structural equation modeling (SEM).

**3.3. Proposed research model**

Based on the accepted and widely used theoretical frameworks such as UTAUT, UTAUT2, Theory of Reasoned Action (TRA), Theory of Planned Behavior (TPB), Technology Acceptance Model (TAM), integrated TPB and TAM models, Innovation Diffusion Theory (IDT), Motivation Model (MM), Perceived Computer Utility Model (MPCU), Social Cognitive Theory (SCT), and relevant surveyed stakeholders, the factors included in this research are presented in Table 1 below:

**Table 1: Table of Impact Factors**

	Sign	Factor	Referential interpretation
H1	EE	Expectation of Efficiency	(Miraz et al., 2019), (Venkatesh et al., 2003), (Davis et al., 1989, 1992), (Venkatesh and Davis, 2000), (Davis et al., 1993), (Thompson et al., 1991), (Rogers, 1995), (Compeau and Higgins, 1995).

H2	EA	Expectation of Attempt	(Miraz et al., 2019), Venkatesh et al., (2003), Davis et al., (1989, 1992), Venkatesh and Davis (2000), Thompson et al., (1991), Rogers (1995).
H3	FC	Facilitating Condition	Miraz et al., (2019), Venkatesh et al., (2012), Ajen (1985, 1991), Davis et al., (1989, 1992), Thompson et al., (1991), Rogers (1995), Venkatesh (2000).
H4	SI	Social Influence	Francisco et al., (2015), Lu et al., (2017), Nguyễn Thị Thùy Vân and Nguyễn Duy Thanh (2016), Taylor and Todd (1995), Venkatesh et al., (2003), Wu and Chen (2017), Fishbein and Ajzen (1975, 1980), Davis et al., (1989, 1993), Venkatesh and Davis (2000), Thompson et al., (1991), Rogers (1995).
H5	ST	Supply Chain Traceability Application	Kouhi ZBAeh et al., (2021), Leng et al., (2018), Chien (2020), Hastig and Sodhi (2019), de Cremer (2016), Blossey et al., (2019).
H6	BI	Behavioral Intention	Ajzen (1991), Venkatesh et al., (2003, 2012).
H7	PV	Price Value	Venkatesh et al., (2012), Zeithaml (1988), Dodds et al., (1991).
H8	PR	Perceived Risk	Bauer (1960), de Cremer (2016).
H9	BA	Blockchain Application	Miraz et al., (2019), Venkatesh et al., (2012), Puschel et al., (2010), Zhu et al., (2005), Kausar et al., (2017), Kimengsi and Gwan (2017).
H10	ES	Efficiency of Supply Chain Management	Ul-Hameeda et al., (2019), Korpela et al., (2017).

The research questions based on the proposed model include:

*Does the expectation of efficiency (EE) have a positive impact on the application of Blockchain?*

*Does the Expectation of Attempt (EA) have a positive impact on the application of Blockchain?*

*Do facilitating conditions (FC) have a positive impact on the application of Blockchain?*

*Does social influence (SI) have a positive impact on the application of Blockchain?*

*Does supply chain traceability (ST) have a positive impact on the application of Blockchain?*

*Does behavioral intention (BI) have a positive impact on the application of Blockchain?*

*Does price value (PV) have a positive impact on the application of Blockchain?*

*Does perceived risk (PR) have a negative impact on the application of Blockchain?*

*Does the Blockchain application (BA) have a positive impact on supply chain management's (SCM) effectiveness?*

From there, the research team proposes hypotheses according to the following research model:

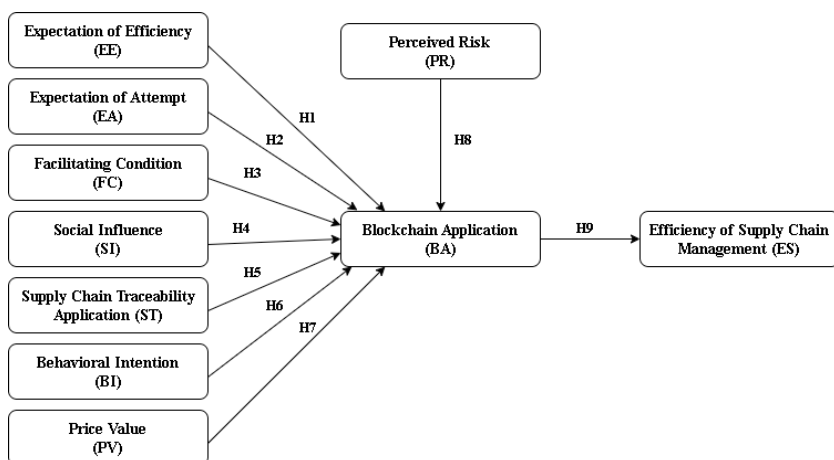

Figure 1: Proposed research model

## 4. RESULTS AND DISCUSSION

### 4.1. Descriptive sample statistics

The study conducted statistical data analysis based on a survey form sent by online in the form of an online questionnaire on Google Form to the survey subjects and also through direct interviews where the responses were recorded on survey forms. The results obtained included 265 survey forms, of which 248 were valid, corresponding to a utilization rate of 83% as research data. At the same time, the survey form was divided into two groups: businesses (148 forms) and individual users (248 forms), with some businesses including individual users in the survey. Through distinguishing characteristics, the description of the research sample shows that:

**Table 2: Description of the research sample for businesses**

Classification Criteria	Instances	Percentage (%)	
What supply chain services does your company or business provide?	Warehousing	42	28.38%
	Domestic transportation	23	15.54%
	Packaging	20	13.51%
	Freight forwarding	17	11.49%
	Shipping costs	14	9.46%
	Documentation	13	8.78%
	Other	19	12.84%
Do you believe that improving the efficiency of supply chain management is crucial for a company or business?	Very important	63	42.57%
	Quite important	32	21.62%
	Important	28	18.92%
	Normal	20	13.51%
	Not important	5	3.38%
How do you evaluate the effectiveness of the supply chain management process in your company or business?	Very effective	20	13.51%
	Quite effective	47	31.76%
	Effective	33	22.3%
	Normal	30	20.27%
	Ineffective	18	12.16%
Do you intend to apply new and modern technologies to improve the efficiency of supply chain management in your company or business?	Very willing to apply	51	34.46%
	Intend to apply	44	29.73%
	Normal	19	12.84%
	Never thought of it	12	8.11%
	Do not want to apply	22	14.86%
Do you know about Blockchain technology?	Know well	30	20.27%

## 4.2. Results

### 4.2.1. Cronbach's alpha test results

Before conducting factor analysis, the research will test the scale's reliability using Cronbach's alpha coefficient with Stata 17 software to assess the reliability of the measurement of effective supply chain management

components and the correlation between observed variables. After performing the Cronbach’s alpha test, the results are summarized in the statistical table of the final testing outcomes for each variable group as follows:

**Table 4: Statistical results of Cronbach’s Alpha test**

No.	Factor	Sign	The first observation variable	The remaining observed variable	Cronbach’s alpha	Discarded variable
1	Expectation of Efficiency	EE	4	4	0.6795	0
2	Expectation of Attempt	EA	4	4	0.7062	0
3	Facilitating Condition	FC	4	3	0.6345	1
4	Social Influence	SI	4	0	0.5955	4
5	Supply Chain Traceability Application	ST	4	4	0.6947	0
6	Behavioral Intention	BI	4	4	0.7395	0
7	Price Value	PV	4	4	0.7003	0
8	Perceived Risk	PR	4	0	0.5567	4
9	Blockchain Application	BA	4	4	0.8348	0
10	Efficiency of SCM	ES	4	4	0.7510	0

(Source: The results of the survey analysis using Stata 17)

The results of Cronbach’s alpha analysis (Table 4) show that the majority of the scales have Cronbach’s alpha coefficients greater than 0.6, and the variable-to-total correlation coefficients are greater than 0.3 (Hair et al., 2010). Therefore, the scales meet the standards and ensure reliability, making them suitable for exploratory factor analysis (EFA).

**4.2.2. Exploratory Factor Analysis (EFA)**

After conducting EFA analysis for the independent variables, some observed variables of the EE, EA, ST, and PV factors did not meet the standard factor locating criteria after performing EFA analysis three times and were thus excluded from the model during the experimental phase.

Finally, based on the third model evaluation table, the study obtained results that satisfied the requirements of the proposed research hypotheses.

**Table 5: Results of the final model evaluation**

Factor	Total Variance Explained						
	Initial Eigenvalues			Extraction Sums of Squared LoBAings			Rotation Sums of Squared LoBAings <sup>a</sup>
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total
1	3.307	18.375	18.375	2.866	15.924	15.924	1.966
2	2.369	13.161	31.536	2.002	11.124	27.048	2.233
3	2.280	12.669	44.204	1.878	10.436	37.484	2.277
4	1.697	9.427	53.632	1.266	7.034	44.518	1.859
5	1.616	8.980	62.612	1.055	5.860	50.377	1.190
6	1.136	6.311	68.922	.582	3.232	<b>53.610</b>	1.604
7	.758	4.213	73.136				
8	.670	3.722	76.858				
9	.627	3.485	80.342				
10	.612	3.400	83.742				
11	.521	2.892	86.634				
12	.427	2.374	89.009				
13	.412	2.290	91.298				
14	.365	2.026	93.325				
15	.332	1.842	95.167				
16	.324	1.800	96.967				

17	.282	1.568	98.535			
18	.264	1.465	100.000			

Extraction Method: Principal Axis Factoring.

(Source: The results of survey analysis using SPSS)

Based on the table results above, it shows that all observed variables explain 53.61% of the variation in the model (the higher the percentage, the better the model, with a maximum of 100%).

**Table 6: Final rotation results (Pattern Matrix<sup>a</sup>)**

Pattern Matrix <sup>a</sup>						
	Factor					
	1	2	3	4	5	6
ST2	.853					
ST4	.779					
ST3	.759					
EA2		.851				
EA4		.767				
EA1		.695				
BI4			.832			
BI2			.681			
BI1			.567			
BI3			.530			
PV2				.826		
PV1				.755		
PV3				.749		
FC3					.645	
FC1					.597	
FC2					.586	
EE4						.693
EE3						.549

Extraction Method: *Principal Axis Factoring.*  
 Rotation Method: Promax with Kaiser Normalization.  
 a. Rotation converged in 5 iterations.

(Source: The results of survey analysis using SPSS)

The above is the rotated matrix table of observed variables. The results show that all variables meet the standard factor loading criteria and are accepted. No variable loads onto two different factors, and no observed variable is solely separate from a factor. To measure the statistical values of the variables, the groups are divided as follows:

- Group 1 includes variables ST2, ST3, and ST4.
- Group 2 includes the variables EA1, EA2, and EA4.
- Group 3 includes the variables: BI1, BI2, BI3, and BI4.
- Group 4 includes the variables PV1, PV2, and PV3.
- Group 5 includes the variables FC1, FC2, and FC3.
- Group 6 includes variables: EE3, EE4,

**Table 7: Final EFA results for the mediator variables**

KMO and Bartlett's Test	
Kaiser-Meyer-Olkin Measure of Sampling BAequacy.	.808

Bartlett's Test of Sphericity	Approx. Chi-Square	373.391
	df	6
	Sig.	.000

(Source: The results of survey analysis using SPSS)

The KMO index is  $0.808 > 0.5$  and  $\text{Sig.} = 0.000$ ; therefore, it is accepted. All indices in the Communalities table are greater than 0.5, meeting the requirements.

**Table 8: Final EFA results for the dependent variable**

KMO and Bartlett's Test		
Kaiser-Meyer-Olkin Measure of Sampling BAequacy.		.734
Bartlett's Test of Sphericity	Approx. Chi-Square	258.598
	df	6
	Sig.	.000

(Source: The results of survey analysis using SPSS)

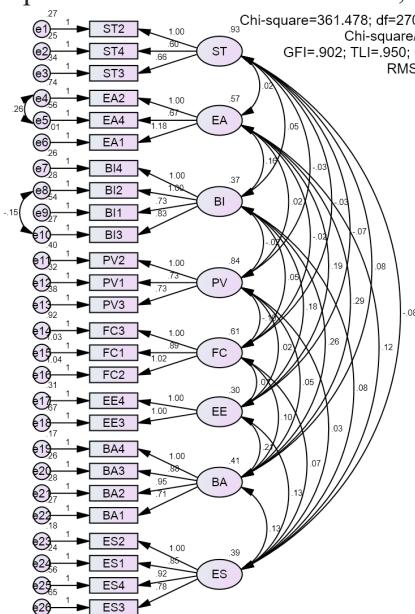

The KMO index is  $0.734 > 0.5$  and  $\text{Sig.} = 0.000$ ; therefore, it is accepted. All indices in the Communalities table are greater than 0.5, meeting the requirements.

Therefore, all criteria in EFA are met to carry out CFA and SEM.

**4.2.3. Confirmatory Factor Analysis (CFA)**

Upon examining the Model Fit indices threshold according to Hair et al. (2010), we found that the CFA model's indices were at the limit before improvement, with  $\text{CMIN}/df = 1.538$  (less than 2);  $\text{TLI} = 0.921$ ;  $\text{CFI} = 0.933$  and  $\text{RMSEA} = 0.047$ . However, the GFI index = 0.888, which according to Hair, a GFI greater than 0.9 is good, but Hair also suggests that the acceptable thresholds for Model Fit indices will vary based on sample size, number of factor groups, and number of observed variables. For a sample size less than 250 as in this study, a GFI value of 0.9 is difficult to achieve. Therefore, the minimum value of 0.8 is still acceptable according to Baumgartner and Homburg (1996), Doll et al. (1994).

Furthermore, the concepts of the error terms are correlated, so the model cannot achieve unidirectional properties (e4 and e5; e8 and e10). By improving the model by connecting variables e4 with e5 and e8 with e10 (Figure 3.1), we obtained a  $\text{CMIN}/df = 1.339$  (less than 2), which is good; a  $\text{TLI} = 0.950$  (greater than 0.9), which is good; and a  $\text{CFI} = 0.958$  (greater than 0.9), which is good. The GFI index is 0.902, which still meets the GFI threshold of 0.9 even though the sample size is less than 250. In addition, the RMSEA index of 0.037 (less than 0.08) is good.

**Figure 2: Results of the CFA limit model**

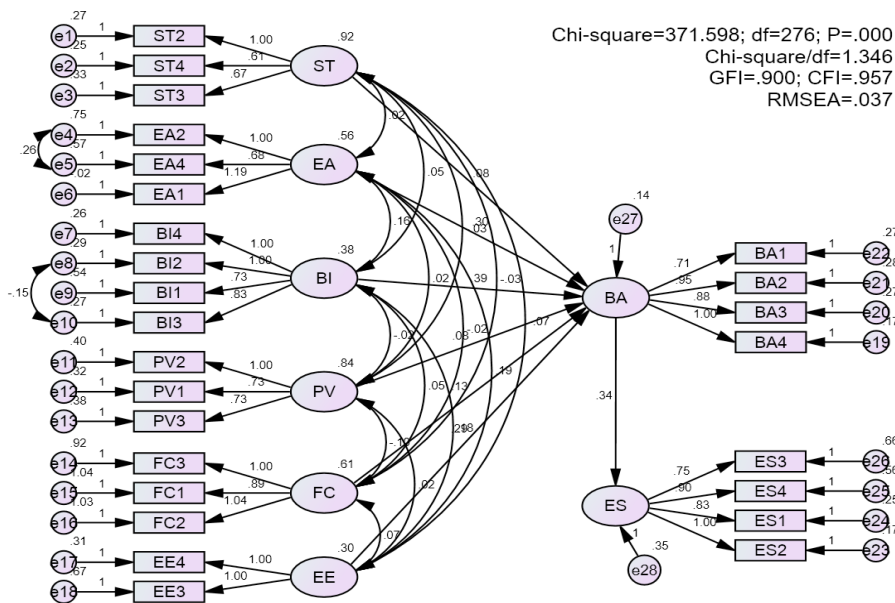

(Source: The results of survey analysis using AMOS)

Note: ST: Supply Chain Traceability Application; EA: Expectation of Attempt; BI: Behavioral Intention; PV: Price Value; FC: Facilitating Condition; EE: Expectation of Efficiency; BA: Blockchain Application; ES: Efficiency of Supply Chain Management

Therefore, CFA for the concepts achieves unidirectional properties, ensures convergence values, ensures reliability, and provides discriminant validity. The research model is suitable for the research data, and the estimation results are statistically significant.

**4.2.4. Linear Structural Equation Modeling SEM Analysis**

The estimated results of the research model (Figure 3) show that the values of CMIN/df = 1.346 (less than 2) are good; CFI = 0.957 (greater than 0.9) is good; and the RMSEA index = 0.037 (less than 0.08) is good. Furthermore, the GFI index of 0.900 still meets the criteria according to Hair et al. (2010), even though the sample size is less than 250. At the same time, the indices of CMIN = 371.598 and df = 276 with a p-value less than 0.05 all meet the requirements. This shows that the linear structural equation model is appropriate and meets the conditions for analysis.

**Figure 3: Results of the SEM model**

(Source: The results of survey analysis using AMOS)

b) Testing research hypotheses using the linear structural equation model

The estimated results of the research model using the SEM show that most of the hypothesized relationships in the formal research model have statistical significance with a p-value less than 0.05, reaching the necessary significance level at 95% confidence. From there, we can construct a regression coefficient table for the research model as follows:

**Table 9: Regression coefficients of the formal research model**

Hypothesis	Relationship	Unstandardized Coefficient	Standardized Coefficient	Standard Error (S.E)	Critical Ratio (C.R)	P-value (P)	Accept/Reject
H1	BA EE	0.290	0.249	0.125	2.322	0.020	Accept
H2	BA EA	0.296	0.347	0.059	5.027	0.000	Accept

H3	BA ← FC	0.129	0.158	0.055	2.341	0.019	Accept
H5	BA ← ST	0.084	0.127	0.038	2.223	0.026	Accept
H6	BA ← BI	0.390	0.375	0.082	4.779	0.000	Accept
H7	BA ← PV	0.078	0.111	0.039	2.007	0.045	Accept
H9	ES ← BA	0.335	0.339	0.074	4.542	0.000	Accept

(Source: The results of survey analysis using AMOS)

### 4.3. Discuss the results of the experiment

Through the results obtained from the data analysis software Stata 17, SPSS, and AMOS, the study shows that:

Firstly, the adoption of Blockchain technology (BA) is influenced by the variables of expected efficiency (EE), expected effort (EA), favorable conditions (FC), supply chain traceability application (ST), behavioral intention (BI), and price value (PV), and this intermediate variable has an impact on the dependent variable, supply chain management efficiency (ES). Specifically, the preliminary evaluation of the scale of variables in the proposed research model shows that the variables EE, EA, FC, ST, BI, PV, BA, and ES have Cronbach’s alpha coefficients greater than 0.6, satisfying the reliability requirement. However, two variables, social influence (SI) and perceived risk (PR), are eliminated due to Cronbach’s alpha coefficients being less than 0.6. With the exploratory factor analysis (EFA), the results show that there are six factor groups, and the basis of this division or reduction is based on the linear relationship of factors with observed variables. At the same time, the total extracted variance value is determined to be 53.61%. After determining the six representative factor groups, the study conducted a confirmatory factor analysis (CFA) to test the suitability of the factor groups with the theory. The CFA results show that the concepts are unidirectional, ensuring convergence, reliability, and discriminant validity. Finally, the study tested the model and hypotheses using structural equation modeling (SEM). Based on the standardized estimation weights, the study retained the independent variables EE, EA, FC, ST, BI, and PV. These six variables have a combined and explanatory effect of 66.8% on the decision to adopt Blockchain, in which the normalized regression coefficient of BI is the largest at 0.375, indicating that BI has the greatest impact on the variable BA. Similarly, the intermediate variable BA explains 11.5% of the variation in supply chain management efficiency (ES). It can be concluded that the expected efficiency, expected effort, favorable

Secondly, regarding the positive impacts of the factors on businesses, the Expectation of Efficiency (EE) factor indicates that companies managing supply chains in Hanoi expect that the application of Blockchain will bring high supply chain management efficiency. They believe that if contracts can be signed early without knowing each other, the market will be very efficient through smart contracts. They are excited that in the future, negotiations and contract signing can be automated through the transport management system and supply chain management system linked together. This can help companies increase productivity and optimize their supply chain management time. This result corresponds to the study by Blossey et al., (2019), who found that the Blockchain-based supply chain coordination system is an innovation. Regarding the Expectation of Attempt (EA) factor, it has been shown that companies managing supply chains in Hanoi have a positive attitude towards Blockchain technology, even if they only have theoretical knowledge of it. These companies have acknowledged the importance and advantages of Blockchain in the future. They have shown interest in learning about processing and operating procedures when using Blockchain technology to enhance efficiency and minimize risks in supply chain management processes. In addition, the Facilitating Condition (FC) factor also brings positive values to companies when they have advantages

in resources, knowledge, and serious investment in infrastructure and technical support, especially the information technology system in the company, to meet the needs of Blockchain operations and solve difficulties in supply chain management processes. However, these are just conclusions drawn from the research scale, and there is no solid evidence to show that these conclusions will hold true on a larger scale. Therefore, further research is needed to provide more accurate and precise findings.

Conditions, supply chain traceability application, behavioral intention, and price value have a direct impact on the decision to adopt Blockchain technology by companies in supply chain management activities in Hanoi at different levels.

Thirdly, regarding the existing practical issues, the results of the impact assessment of the application of Blockchain show that companies managing supply chains in Hanoi are only observing Blockchain technology and the market. These companies are mainly in a waiting position, and most of them do not fully understand the use of Blockchain technology. Most of the supply chain management companies in Hanoi are still uncertain about which processes should be implemented with the help of Blockchain technology. The research suggests that these companies should focus more on Blockchain technology and identify their own use cases since there is no available model or field applicable to each supply chain service provider. All supply chain service companies in Hanoi evaluate Blockchain technology positively rather than negatively. However, according to Kühn et al., (2019), the level of readiness for change may vary among companies of different sizes. The study by Kühn et al., (2019) found that larger companies are more involved in applying Blockchain technology. These companies eliminate individual use cases and develop Blockchain more in cooperative projects with partners. Therefore, this research does not consider the scale factor of companies and its impact on the application of Blockchain.

In summary, Blockchain technology has shown promising results in improving the supply chain network in recent applications, deeply impacting society and lifestyles by reshaping many business and industrial processes. In an effort to explore the integration of Blockchain technology in supply chain management, especially on e-commerce platforms, this study uses a linear SEM model and a UTAUT model to identify the impacts of Blockchain technology on enhancing supply chain management efficiency on the Shopee.vn e-commerce platform. The results show that the expectation of efficiency, expectation of attempt, facilitating condition, supply chain traceability application, behavioral intention, and price value have a proportional impact on supply chain management efficiency.

## **5. CONCLUSION AND POLICY IMPLICATIONS**

In the Industry 4.0 era, Blockchain technology is an effective solution for tracking the information of goods and services and enhancing operational efficiency in management activities at companies applying supply chain management. With outstanding advantages of immutability, data transparency, and security, applying Blockchain is considered a modern and smart trend in this era.

Based on the research results and testing of the normalized regression coefficients, which were obtained in order and influence level, including behavioral intention 0.375, expectation of attempt 0.347, expectation of efficiency 0.249, facilitating condition 0.158, supply chain traceability application 0.127, price value 0.111, and Blockchain application 0.339, the authors propose some implications for users, businesses using the supply chain in Hanoi, as well as for state agencies in the application of Blockchain technology to enhance the efficiency of supply chain management.

*In terms of the implications for users:* Firstly, users should be trained and educated on supply chain management processes, information security, and confidentiality requirements to ensure the accuracy

and transparency of data when using Blockchain. Secondly, standards for information authentication, information security, and data integrity can be established to ensure that users comply with the procedures and standards in supply chain management. Thirdly, the activities of users can be checked and monitored to detect unusual or invalid activities using Blockchain technology. Fourthly, users need to learn how to deal with problems when managing the supply chain using Blockchain technology. Finally, in order to ensure the effectiveness and reliability of the supply chain management system, users should build a community that promotes cooperation and consensus in managing the supply chain through Blockchain technology and hold events that encourage stakeholder engagement.

*In terms of the implications for businesses using supply chains:* Firstly, businesses need to thoroughly understand the working mechanism of Blockchain, the relationship between business interests, and the technical feasibility of Blockchain in order to find a reasonable business model and apply it appropriately to the actual conditions of the business. Secondly, in order to avoid the conflict and difficulty of unifying blocks in this technology, businesses should cooperate closely and build a single Blockchain solution. Thirdly, with the quality of information technology infrastructure being increasingly improved, automation and data digitization are the first steps for businesses to take advantage of Blockchain technology. Finally, due to the influence of COVID-19, digital transformation is the focus and goal of the government, so this is an opportunity for businesses to transform and improve their competitiveness in the world market.

*In terms of the implications for state agencies:* Firstly, the state agencies need to consider promulgating a legal corridor for new technologies to attract and promote domestic and foreign technology projects. Secondly, they need to pay attention to reducing complicated procedures to encourage businesses to make breakthroughs and progress by applying technology to their operations and management processes. Thirdly, they should prioritize promoting the research movement of some core technologies in which Vietnam has advantages and strong breakthroughs, such as AI, Blockchain, big Data... Finally, the state should support the promotion of Blockchain technology as well as corresponding reference models to improve the efficiency of supply chain operations in Vietnam.

In summary, with the topic “*Application of the SEM model to evaluate the effectiveness of supply chain management using Blockchain technology: a study on the Shopee.vn marketplace*”, the authors have completed the initial objectives, including: Firstly, the authors presented the theoretical framework of Blockchain technology, supply chain management, and the e-commerce platform Shopee.vn. Secondly, the survey on the application of Blockchain technology in the supply chain management of businesses, which is on the e-commerce platform Shopee.vn, showed that most businesses still face many limitations in terms of scale, capital, experience, and management qualifications. Thirdly, the authors proposed a research model and related hypotheses about the factors affecting the application of Blockchain technology in enhancing the efficiency of supply chain management. Fourthly, the authors conducted a survey and analyzed the results of the research model for users and businesses on Shopee.vn in an effort to apply Blockchain technology to their supply chains. Finally, through the research results, the authors presented the benefits and opportunities that Blockchain brings to business, pointed out the current limitations, and boldly stated some proposals to enhance the application of Blockchain technology in SCM in general.

Despite trying to perfect the research, the study still has some limitations, such as a small sample size (248 observed samples), the scope of the research being only in Hanoi, and the field being only on Shopee.vn. Therefore, future research could focus on solving the limitations of sample size, expanding the scope of research in many provinces, researching in other fields such as stock exchanges, other popular e-commerce platforms in Vietnam like Tiki, Lazada, etc., or expanding research on the impact of company size on Blockchain adoption, on the impact of Blockchain on different types of companies, etc.

## APPENDIX

### SURVEY FORM

#### APPLICATION OF SEM MODEL TO EVALUATE THE EFFECTIVENESS OF SUPPLY CHAIN MANAGEMENT USING BLOCKCHAIN TECHNOLOGY: A study on the Shopee.vn marketplace

Dear Sir/Madam,

We are second-year students from the Faculty of Information Technology and E-Commerce at the University of Commerce. We are currently conducting a scientific research project on “*Application of the SEM model to evaluate the effectiveness of supply chain management using Blockchain technology: A study on the Shopee.vn marketplace*”.

The authors of this survey aim to investigate the factors that influence the effectiveness of supply chain management using Blockchain technology. Our goal is to create a premise for businesses to develop and manage their supply chain structure with higher efficiency. Therefore, we would greatly appreciate it if you could take 3-5 minutes to complete this survey honestly and seriously. Your opinions are valuable and meaningful to us and will help us obtain the most objective and accurate evaluation. We assure you that all information you provide will be kept confidential and used solely for research purposes. If needed, we are willing to provide a summary report of this survey for your reference. We deeply appreciate your enthusiastic support and assistance!

*Thank you very much for your time and cooperation!*

#### A. INDIVIDUAL INFORMATION

Please provide the following information to serve the research process:

1. What is your gender?

- Male
- Female

2. What is your age?

- Under 19 years old
- 19 - 29
- 30 – 39
- 40 – 49
- Over 49 years old

3. What is your educational level?

- University
- Post-graduate
- Bachelor’s degree
- Skilled worker
- Import - export certificate
- Other

4. What is your position in the company?

- Director
- Manager
- Employee
- Other

5. What supply chain services does your company/business provide?

- Warehousing
- Domestic transportation
- Packaging
- Freight forwarding
- Shipping costs
- Documentation
- Other

### **B. SUPPLY CHAIN MANAGEMENT ACTIVITIES INFORMATION**

Please answer some questions for the dependent variable “*behavioral intention*”:

1. Do you believe that improving the efficiency of supply chain management is crucial for a company/business?

- Very important
- Quite important
- Important
- Normal
- Not important

2. How do you evaluate the effectiveness of the supply chain management process in your company/business?

- Very effective
- Quite effective
- Effective
- Normal
- Ineffective

3. Do you intend to apply new and modern technologies to improve the efficiency of supply chain management in your company/business?

- Very willing to apply
- Intend to apply
- Normal
- Never thought of it
- Do not want to apply

4. Do you know about Blockchain technology?

- Know well

- Have some understanding
- Heard of it
- Do not know
- Not interested

5. In your opinion, does the application of Blockchain technology in supply chain management bring more benefits and effectiveness?

- Very effective
- Quite effective
- Effective
- Normal
- Ineffective

**C. FACTORS AFFECTING THE EFFECTIVENESS OF SUPPLY CHAIN MANAGEMENT USING BLOCKCHAIN TECHNOLOGY**

Using a 5-point Likert scale with the following conventions for each level:

Strongly disagree	Disagree	Neutral	Agree	Strongly agree
①	②	③	④	⑤

Question	1	2	3	4	5
<b>H1: The "Expectation of Efficiency" factor</b>					
1.1. Using Blockchain technology will increase opportunities for businesses.					
1.2. Applying Blockchain technology significantly improves the quality of supply chain management processes.					
1.3. Applying Blockchain technology significantly increases the efficiency of my work.					
1.4. Applying Blockchain technology increases the effectiveness of SCM.					
<b>H2: The "Expectation of Attempt" factor</b>					
2.1. Learning to use Blockchain technology does not take much time.					
2.2. Business processes using Blockchain technology are easy to use.					
2.3. The application of Blockchain technology in SCM is flexible and interactive.					
2.4. The SCM process using Blockchain technology is simple and easy to understand.					
<b>H3: The "Facilitating Condition" factor</b>					
3.1. I have the necessary resources to use Blockchain technology.					
3.2. I have the necessary knowledge to use Blockchain technology.					
3.3. Blockchain technology is compatible with other systems I am using.					
3.4. A department (or a group of employees) in the SCM operation is always ready to support with difficulties related to the application of Blockchain technology.					
<b>H4: The "Social Influence" factor</b>					
My decision to use Blockchain technology may be influenced by the following groups:					
4.1. People who are important to me.					
4.2. People on social media (Facebook, TikTok, etc.) sharing about Blockchain technology.					
4.3. Top-level managers in SCM operations.					
4.4. Investors for my business.					
<b>H5: The "Supply Chain Traceability Application" factor</b>					
5.1. The information retrieved from Blockchain is accurate.					
5.2. Retrieving information from Blockchain takes less time.					

5.3. Retrieving information from Blockchain helps build trust with customers.					
5.4. Retrieving information from Blockchain helps to better manage the production process in real-time.					
H6: The "Behavioral Intention" factor					
6.1. I will use Blockchain technology for the benefits it brings to SCM.					
6.2. I believe that applying Blockchain technology in my business is a right decision.					
6.3. I believe that my business will continue to use Blockchain technology.					
6.4. I see Blockchain as suitable for the SCM process of businesses.					
H7: The "Price Value" factor					
7.1. The cost of implementing Blockchain technology is appropriate for the revenue of the business.					
7.2. Blockchain technology has a lower implementation cost compared to other technologies.					
7.3. At the current price, Blockchain provides more value than not using Blockchain.					
7.4. My business cannot afford the operational costs of implementing Blockchain technology in the SCM process.					
H8: The "Perceived Risk" factor					
8.1. Applying Blockchain is vulnerable to hacker attacks.					
8.2. It is difficult to change incorrect information when applying Blockchain technology.					
8.3. Blockchain has many security keys that I cannot remember.					
8.4. It is difficult to operate SCM processes using Blockchain technology.					
H9: The "Blockchain Application" factor					
9.1. I will frequently use Blockchain technology if my business implements this new technology.					
9.2. I will use Blockchain technology to process current business operations.					
9.3. Applying Blockchain technology in SCM operations will solve most traditional business operations.					
9.4. Using Blockchain technology can reduce transaction costs for businesses.					
H10: The "Efficiency of Supply Chain Management" factor					
10.1. The supply chain will operate effectively if there is a balance between product, customer, and transportation factors.					
10.2. Proper business strategies will bring good efficiency to the supply chain.					
10.3. The supply chain needs to be continuously upgraded in many aspects to maximize benefits for all parties involved.					
10.4. Choosing appropriate criteria for the business while keeping the risks low will help increase the effectiveness of supply chain management.					

*Thank you very much for completing the survey! Wishing you a day full of joy and positive energy!*

## RESEARCH FACTORS AFFECTING EMOTIONAL INTELLIGENCE ON THE RESULTS OF STUDIES ON STUDENTS IN SOME UNIVERSITIES IN HANOI CITY

**Author: Le Thi Van Anh<sup>1</sup>, Vu Thuy An<sup>2</sup>**

**Mentor: Dr. Nguyen Thi Hoi<sup>2</sup>**

*ABSTRACT: Emotional intelligence is often talked about in terms of human emotions and states, but in the developing technology era, the influence of technology devices and digital platforms has made the role of personal emotions more important. change multiplier. In this study, the research team used a quantitative method based on four factors: emotional intelligence, self-control, sociability, and happiness, to determine the influence of emotional intelligence or happiness. The emotional intelligence of students towards learning and research results at some universities in Hanoi is based on the collection of actual data from students with different majors in Hanoi combined with analysis using SPSS. The results of the analysis show that all four factors affect the academic and research results of students in both economic and technical disciplines. Among them, self-control and emotional well-being had the greatest influence. Based on the results of the study, the group offers a number of implications to support the development of each individual's emotional intelligence, improve learning efficiency, and increase feelings of happiness in students. In today's world, life is full of pressures and impacts from technological devices and technical applications.*

**Keywords:** *emotional intelligence; sympathy; self-control; sociability; well-being.*

### 1. INTRODUCTION

Many people think that emotions only play a role in love relationships or provoke people to increase arousal and explosiveness. In reality, however, emotions are everywhere: they shape our decisions, help us make sense of the world, and play an important role in any of our interactions with people (Daniel, 2008).

The success in both one's professional and personal lives has been largely attributed to one's level of education. The primary goals of education systems around the world include fostering in students' scientific knowledge, creative thinking, analytical thinking, and reasoning (Abdolrezapour and Tavakoli, 2012); (Petrides and Furnham, 2003). Furthermore, these models undoubtedly led to the training of people with high information quotients. However, educational and psychological researchers argue that this is not a flawless or ideal result. Views and attitudes regarding the role of intellect in forecasting human success have been altered by the idea of emotional intelligence. Numerous studies have been conducted and shown that an individual's emotional intelligence quotient accurately predicts their potential in both their professional and personal lives.

Emotions play a key role in the brain's ability to reason and think, according to a neuroscience study. Some Western Nations hold the belief that an increased emotional quotient is related to increased knowledge and professional education. Instead of focusing just on professional knowledge as in the past, tests are now included in the hiring process to assess emotional intelligence (Daniel Goleman, 2007; 2008). Due to this, several studies on emotional intelligence expressions, particularly those of students, have been conducted

<sup>1</sup> Faculty of Economic Information System and E- Commerce, Thuongmai University, Email: vananh.works@gmail.com

<sup>2</sup> Faculty of Economic Information System and E- Commerce, Thuongmai University.

in our nation. According to certain research, most students function at an average or below average level when it comes to emotional intelligence, whereas a select few perform at a high or extremely high level. The fact that pupils' knowledge of emotional intelligence has not been updated is one of the causes of this issue. On the other hand, the existing educational system has not paid much attention to ways to improve pupils' emotional indices during the learning process at school, (Andrea & Ali, 1996; Dulewicz & Higgs, 2000; Daniel, 2008; Bar-On, 2006; Santos et al., 2022; Gurbuz et al., 2016).

As a result, the study of students' awareness of emotional intelligence is both to assess the effectiveness of training and to help students understand the reality of their emotional intelligence. From here, students can plan their study, practice, and develop their ability to think emotionally and apply it to their lives and learning processes, preparing for their future careers (Udayar et al., 2020; Santos et al., 2022)

We settled on the subject of "*Research Factors Affecting Emotional Intelligence on The Results of Studies on Students in Some Universities in Hanoi City*" to identify the impacts of emotional intelligence on the results of studies on students. In this study, the research team used a quantitative method based on four factors: emotional intelligence, self-control, sociability, and happiness, to determine the influence of emotional intelligence or happiness. The emotional intelligence of students towards learning and research results at some universities in Hanoi is based on the collection of actual data from students with different majors in Hanoi combined with analysis using SPSS. The paper included parts: The theoretical foundation, the findings of the research, potential applications, and a conclusion.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Intellect, Emotional and Emotional intelligence**

Intelligence is a person's potential for adaptation. Many psychologists agree that this is the most prevalent definition. Take this example: W. S. Stern says intelligence is the general capacity of a person to deliberately focus his or her mind on new requirements. This is the capability of the general mind to adjust to new tasks and circumstances in life: Gardner sees intelligence as a capacity for problem-solving that results in goods that are valuable in the cultural environment, (Howard, 1999). In conclusion, it may be concluded from the viewpoints of psychologists of mind that: Intelligence is a relatively autonomous cognitive quality of personality, the core of which is the capacity for abstract thought; Cultural and historical restrictions have an impact on intelligence. The main function of intelligence is to ensure proper interaction with its surroundings (Bradberry & Greaves, 2005; Udayar et al., 2020)

Emotions are a person's vibrations toward another person, an event, or any other phenomenon in life. The Vietnamese dictionary defines emotion as a psychological reflection of a direct experience of the life meaning of particular phenomena and situations through the relationship between their objective attributes and the needs of the subject. There is no single definition for emotion. Emotions emerged as a way for organisms to assess the biological relevance of body states and environmental factors during the course of evolution. Fecht Russell, a psychologist, stated in 1996 that "emotions are things that everyone knows but cannot define." (Bar – On, 1997; Bar-On, 2006). This psychologist contends that although we all understand how to communicate our emotions, they cannot be precisely and broadly defined, (Salovey & Mayer, 1997; Dulewicz & Higgs, 2000);

When studying the word and the exercises, there is considerable disagreement over the meaning of emotional intelligence. Emotional intelligence was first defined by (Salovey & Mayer, 1990) as "the ability to monitor one's own and other people's feelings and emotions, distinguish between them, and use this information to inform one's thoughts and actions." The precise concept of this construction is still unclear despite this early definition. They are so erratic, and fields are expanding so quickly, that definitions are

frequently altered by academics since the ability model, the mixed model, and the particular model are the three main models of emotional intelligence in use today.

## **2.2. Effects of Emotions on students**

In addition to examining emotions and their various forms, researchers also look at how emotions impact their subjects. Positive or negative emotions themselves have had favorable or unfavorable results. Even negative feelings, when expressed with the right intensity, can encourage students to take initiative, be positive, and adjust to their learning and training environment (Goleman et al., 2013). Specifically impacting students' psychological well-being, learning and training, and social interactions, positive emotions make learners excited and interested and give better learning results, while negative emotions can lead to an uncooperative state, make the lesson difficult to absorb, or lead to rejection of the lesson (Udayar et al, 2020; Nguyen, 2018; Le, 2021).

Emotional intelligence is essential for students, as it will help them better perceive and manage their feelings and support learning and research in different disciplines. For example, it helps learners increase their ability to recognize and correctly identify their current feelings to help them control their emotions. Studies show that people who are unable to recognize their own feelings are more likely to erupt in violence and have difficulty being receptive to conflicting opinions. (Daniel, 2013; Udayar et al, 2020).

In addition, enhancing emotional intelligence helps learners manage feelings and will help them focus on accomplishing goals better. For example, even though the subject is boring, learners can still try to look at it from a different angle. Maybe a certain topic will interest learners. Students who can organize their work in this way often do well in school, even if they have a low IQ (Daniel, 2013; Udayar et al, 2020; Nguyen, 2018; Le, 2021)

## **2.3. Related works**

When it comes to learning, emotional intelligence has a significant impact on the process, which is particularly evident in the learning attitude. Making progress in learning is impossible or challenging if the attitude toward learning is negative. Due to inadequate family education on emotions or family conflicts that cause children to be emotionally deviant, children who commit crimes, engage in violent behavior, exhibit hostility, or become involved in societal ills are partially caused by emotions. (Gurbuz et al., 2016; (Bradberry & Greaves, 2005; Udayar et al, 2020) said that Emotions are tough to generate if they aren't taught early on and are incapable of being controlled. Students can learn emotional intelligence in a variety of ways, starting at a young age. Relationship between emotional intelligence and other complementary learning activities: high academic achievement requires the ability to listen and focus attention, control impulses, and feel responsible for one's own learning; emotional intelligence facilitates teachers' ability to carry out their teaching duties.

When used in the workplace, emotional intelligence enables individuals to operate with great efficiency, manage tasks skillfully, and produce work of the highest caliber (Santos et al., 2022). Being able to identify emotions, produce them, and manage or control them are all characteristics of a good communicator. People who always live in peace with others and who take their work seriously are more likely to succeed in both work and life, (Udayar et al., 2020). Emotional intelligence is a key component of leadership skills, which enable people to operate more efficiently (Nguyen, 2018; Le, 2021; Ngui and Lay, 2020).

## **2.4. The proposes research model**

First, the authors put together a list of factors included in the emotional intelligence model of domestic studies. From this, the following table can be built:

**Table 1: Summary table of factors in the emotional intelligence model**

Factor 1	Factor 2	Factor 3	Factor 4	Another factor	Model references
Self-awareness	Self-Management	Enthusiasm	Persist	Self motivation	(Andrea & Ali, 1996); (Dulewicz & Higgs, 2000); (Daniel , 2007); (Daniel , 2008); (Goleman et al., 2013)
Self-control	Sympathy	Sociability	Well-being		(Bar – On, 1997); (Bar-On , 2006) (Santos et al., 2022)
Emotional awareness	Use emotions	Understanding emotions	Control your emotions		(Salovey & Mayer, 1990); (Andrea & Ali, 1996); (Gurbuz et al., 2016). (Bradberry & Greaves, 2005) (Udayar et al., 2020)
Sympathy	Self-control	Sociability	Well-being		(Salovey & Mayer, 1997); Dulewicz & Higgs, 2000); (Duong Thi Hoang Yen, 2008); (Hamdy et al., 2014). (Nguyen Thi Thanh Huyen, 2018), (Le Bich Ngoc, 2021) (Ngui and Lay, 2020)

From the (Daniel, 2007; Bar – On, 2006; (Salovey & Mayer, 1990; 1997) we have selected the factors that are most suitable for the study: sympathy, self-control, sociability, and well-being. Because these factors are general and appear in many previous studies.

**Figure 2: Proposed research model**

**3. RESEARCH METHOD**

This study combines qualitative and quantitative research. For qualitative research, it first builds and strengthens a theoretical research model through existing research and behavioral research models. For quantitative research, the study was carried out through the data collection of live survey questionnaires and online questionnaires, and we used a 5-point Likert scale: 1 being completely disagreed, 2 being disagreed, 3 being neutral, 4 being agreed, and 5 being completely agreed.

The research conducted quantitative research by collecting data from surveys and questionnaires, processing it through SPSS software, and using the following technology to evaluate the data: descriptive analysis, Cronbach’s alpha test, EFA exploratory analysis, and regression analysis.

**4. RESULTS AND DISCUSSION.**

**4.1. Descriptive sample statistics**

The study used statistical data from the survey, which was delivered to the survey subjects online as a query on a Google form and then asked straight into the survey form. There are 302 valid responses in the findings. Survey forms are categorized using identifying signals, which demonstrate:

**Table 2: Description of the study sample**

Classification Criteria		Amount of people	Proportion (%)
What year are you a student?	First year	60	19,9%
	Second year	67	22,2%
	Third year	81	26,8%
	Final year	94	31,1%
What is your gender?	Male	142	47,0%
	Female	160	53,0%
Are you a major student?	Economics	80	26,5%
	Technology	61	20,2%
	Education	67	22,2%
	Language	59	19,5%
	Other	35	11,6
What school are you a student of?	Thuongmai University	59	19,5%
	Vietnam National University	71	23,5%
	HaNoi University of Science and Technology	50	16,6%
	FPT University	59	19,5%
	Other	63	20,9%

**4.2. Results**

**4.2.1. Cronbach’s alpha test**

The study will test the scale using the Cronbach’s alpha tool in SPSS software version 20.0 to determine its reliability and the connection between the observed variables and the service quality components before proceeding with factor analysis. The results of the Cronbach’s alpha test are described in the statistical table below for each group of variables’ final test results:

**Table 3: Statistical results of Cronbach’s Alpha test**

No	Factor	Symbol	First observation variable	The remaining observed variable	Cronbach’s Alpha	Discarded variable
1	Sympathy	DC	8	7	0,846	1
2	Self-control	KS	8	8	0,864	0
3	Sociability	HD	6	6	0,843	0
4	Well-being	HP	6	6	0,825	0
5	Academic results	KQ	5	5	0,814	0

*(Source: Analysis results of questionnaires using SPSS)*

All variables have Cronbach’s alpha coefficient higher than 0.8. So put the variables in the EFA factor analysis.

**4.2.2. Exploratory Factor Analysis (EFA)**

EFA analysis for the independent variable: after performing EFA analysis twice, the study obtained results that satisfy the requirements of the proposed research hypotheses.

**Table 4: Final model evaluation results**

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	6.513	27.138	27.138	6.513	27.138	27.138	3.595	14.978	14.978

KQ5	.748
KQ2	.735
Extraction Method: Principal Component Analysis.	
a. 1 components extracted.	

(Source: Analysis results of questionnaires using SPSS)

This is a successful outcome for the scale in terms of ensuring unidirectionality. The observed variables are not omitted since the indexes in the rotation matrix table are adequate.

### 4.2.3. Correlation analysis

The purpose of running Pearson correlation is to test the close linear correlation between the dependent variable and the independent variables because the condition for regression is first to be correlated. In addition, the problem of multicollinearity arises when the independent variables are also strongly correlated with each other. The suspicious sign is based on the Sig value. The correlation between the independent variables is less than 0.05, and the Pearson correlation value is greater than 0.3.

**Table 9. Correlations**

		KQ	DC	KS	HD	HP
KQ	Pearson Correlation	1	.533**	.579**	.556**	.579**
	Sig. (2-tailed)		.000	.000	.000	.000
	N	302	302	302	302	302
DC	Pearson Correlation	.533**	1	.298**	.367**	.328**
	Sig. (2-tailed)	.000		.000	.000	.000
	N	302	302	302	302	302
KS	Pearson Correlation	.579**	.298**	1	.329**	.383**
	Sig. (2-tailed)	.000	.000		.000	.000
	N	302	302	302	302	302
HD	Pearson Correlation	.556**	.367**	.329**	1	.360**
	Sig. (2-tailed)	.000	.000	.000		.000
	N	302	302	302	302	302
HP	Pearson Correlation	.579**	.328**	.383**	.360**	1
	Sig. (2-tailed)	.000	.000	.000	.000	
	N	302	302	302	302	302

\*\* . Correlation is significant at the 0.01 level (2-tailed).

(Source: Analysis results of questionnaires using SPSS)

The Pearson correlation of independent variables DC, KS, HD, and HP with the dependent variable KQ is less than 0.05 (=0.00). The independent variables KS, HP, and KQ have the strongest correlation with the r coefficient of 0.579, and the DC independent variable with the dependent variable KQ has the weakest correlation with the loading coefficient of 0.533.

The pairs of independent variables have a fairly strong correlation with each other, so there is a possibility of multicollinearity.

### 4.2.4. Regression analysis

**Table 10: Coefficients**

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		B	Std. Error	Beta			Tolerance	VIF
1	(Constant)	-.464	.192		-2.415	.016		
	DC	.265	.042	.253	6.355	.000	.804	1.244
	KS	.328	.042	.310	7.750	.000	.794	1.259
	HD	.264	.041	.259	6.390	.000	.776	1.289
	HP	.294	.042	.284	6.969	.000	.767	1.304

Dependent Variable: KQ

Predictors: (Constant), DC, KS, HD, HP

(Source: Analysis results of questionnaires using SPSS)

The sig value of independent variables HP, DC, KS, and HD is less than 0.05; independent variables have an impact on the independent variable. The VIF column is used to check for multicollinearity.

Theoretically, if VIF is less than 10, multicollinearity will not occur. However, in fact, research models using Likert scales have shown that a VIF less than 2 will not have multicollinearity occurring between independent variables. Here, the coefficients of magnification of variance are all less than 2, so there is no multicollinearity.

The regression coefficients of the variables HP, DC, KS, and HD are all larger than 0, so these variables all have the same effect as the dependent variable. Based on the size of the normalized regression coefficient Beta, the order of magnitude of the impact from the strongest to the weakest of the independent variables on the dependent variable KQ is: KS (0.310) > HP (0.284) > HD (0.259) > DC (0.253). The variable that has the strongest impact on the dependent variable is self-control; the second strongest variable on learning outcomes is well-being; the third impact variable is sociability; and the fourth variable is sympathy.

We have the normalized regression equation:

$$KQ = 0.310*KS + 0.284*HP + 0.259*HD + 0.253*DC + e.$$

$$Academic\ results = 0.310*Self-control + 0.284*Well-being + 0.259*Sociability + 0.253*Sympathy + e$$

We obtain the normalized residual frequency histogram and the Normal P-P Plot as Figure 1 and Figure 2. From the graph above, we see a normal distribution curve superimposed on the histogram. This curve is bell-shaped, which is consistent with the graph of the normal distribution. The mean is close to 0, and the standard deviation is 0.993, which is close to 1. It can be said that the distribution is almost normal. Therefore, it can be concluded that the residual distribution assumption is not violated.

With the P-P plot, the percentiles in the distribution of the residuals will cluster into a diagonal. Thus, it does not violate the regression assumption about the residual normal distribution. The scatter plot tests the assumption of linear contact.

### 4.3. Discussion

Firstly, through the results obtained from the SPSS data processing software, the study shows that:

Students should have a positive outlook and be confident in their ability to control their emotions in order to improve their learning outcomes, since the factor “self-control” has the biggest impact on students’ learning outcomes. Students must develop a scientific study plan for themselves, become more engaged in their education, constantly seek out new information, and thoroughly understand what they have learned. Students need to allow themselves time to unwind without being confined in addition to studying. Limits should be set with impetuous thoughts, and students should give themselves time to reflect because doing so

will enable them to reconsider their own behavior from the perspective of others. Spend some time observing and comprehending your feelings so that you can identify times when you are stressed, anxious, or furious. It will be easier for you to control your emotions if you have knowledge of them. Find a method to see the issue positively and come up with workable solutions rather than dwelling on the bad. Be persistent and take the necessary actions to reach your objectives, because success does not happen overnight.

Next, “well-being” is a component that significantly affects how well children study. Students should therefore concentrate on their own moral principles because doing so would help them love themselves more and achieve more success in life. Consider the positive aspects of life while studying. Find ways to be grateful for your triumphs, your favorite items, and your positive experiences. You can maintain a healthy body and mind by exercising frequently, eating well, getting adequate sleep, and minimizing stress. These actions will make you feel happier. Additionally, search for chances to educate and better oneself. Your confidence and happiness might rise as a result of learning new skills, reading a good book, attending courses, volunteering, or engaging in community activities.

“Sociability” is the third component that has an impact on pupils’ learning outcomes. Students should therefore learn to respect others and listen to them. Additionally, if you want to learn more effectively, you need to live a more active life. Students must practice cultivating a positive outlook on life, being more sociable, being perfectionists, expressing their views to others, making friends on their own, and fostering stronger bonds with others. Students should aim to open their hearts and actively communicate with individuals around them, actively disclose their learning challenges to seek helpful guidance, and actively express their desires rather than being self-deprecating. Students should push over their boundaries, overcome themselves, gain greater confidence, dare to speak up and express their opinions, express their opinions when they participate in group activities, and be confident. promote your interests. Many students often surround themselves with a small group of people; they are always private, hesitant to communicate, afraid to express their own opinions, and afraid to stand up for their interests.

Finally, “sympathy” influences how well pupils learn. Students must maintain their composure in the face of any challenges and refrain from overthinking to improve learning efficiency. Students need to participate more in extracurricular activities that will boost their self-esteem and prepare them to express their feelings to friends and other people, consequently lowering stress levels and fostering a sense of community that will help them learn how to encourage themselves. Next, develop your listening skills by concentrating on others while they speak and by probing further into their feelings. Instead of focusing on your own sentiments, learn to feel better about others by concentrating on theirs. Be at ease and naturally converse with others. Additionally, to improve communication and emotionality, pay attention to your feelings, discover what makes you happy, and engage in social events, volunteer work, and other community activities. You can make new friends through these events and learn more about the struggles and obstacles other people face.

## **5. THE IMPLICATIONS AND CONCLUSION**

After the research, the research report met the topic’s research goals, which were to identify the elements of emotional intelligence that could influence and impact students’ academic results at some universities in Hanoi.

The study’s findings have led to the creation of the following specific contents: Briefly describe the theoretical underpinnings of emotional intelligence and how it affects students’ learning activities based on local and international studies and references. Building an integrated research model from the examined

models to identify the characteristics that affect how well students at some Hanoi-area colleges study by incorporating existing emotional intelligence research models

To ascertain the influencing aspects of emotional intelligence on student learning outcomes, conduct surveys and experiments to test them via scales. As a result, the dependent variable (academic results) is positively impacted by each of the four independent variables (sympathy, self-control, sociability, and well-being). We suggest a variety of solutions based on the findings of the research report to assist students in changing their perception of emotional intelligence, creating a study plan, practicing and developing their emotional thinking capacity, and using it in real life. Along with making suggestions on how the school could better assist students in their studies.

Every topic for a scientific inquiry has advantages and disadvantages. As a result, the group's topic has the following restrictions: One is the subject of performing broad research for all students in the city of Hanoi rather than concentrating on a particular group of students. As a result, no one answer is appropriate for each group of students with various majors. Therefore, it is essential to establish distinct study subjects for groups of students with comparable majors to address deeper issues. Second, due to time and space constraints, the study was only able to conduct research in a few different locations, primarily a student-sized university in Hanoi city. This resulted in a lack of diversity in the research samples in terms of majors, academic years, and regions, and the obtained results were not favorable in terms of demographic factors. Third, the study was unable to contact specialists or individuals with psychology-related knowledge; therefore, it was unable to get the information needed to develop the questionnaire's contents and organize the scales.

The fourth involves locating papers. The study team encounters a time-consuming and challenging phase during which they frequently search for papers in an ambiguous manner, discover an excessive number of documents (even unrelated ones), and are unable to locate the required documents. On the other hand, there are still few real records and foreign documents available on the subject. To be able to provide the most beneficial solutions to improve the quality of study for each student across the nation, we will study more about other study levels, broaden the research area, and conduct more extensive research on each particular specialized group in the subsequent study period.

## APPENDIX

### THE SURVEY

*(Used to collect opinions from students of universities in Hanoi city)*

For the goal of examining the influencing elements of emotional intelligence on the learning outcomes of students at some universities in the region of Hanoi City, it is necessary to create a foundation upon which to assess and enhance students' learning efficiency. We will gain a better understanding of the effect of emotional intelligence on students' learning thanks to the insightful remarks in this poll. We reassure you that all of the material provided is solely for research. Please take your time reading and responding to the questions.

Sincerely thank!

#### **A. What is correct for you?**

1. What year are you a student?

First year

Second year

Third year

Final year

2. What is your gender?

Male

Female

Commenting factors affecting emotional intelligence on student results of students in some universities in Hanoi city (check X or bold in the selected circle). *1 = Totally disagree; 2 = Disagree; 3 = Relatively agree; 4 = Agree; 5 = Totally agree*

#### **B. ASSESSMENT OF THE EFFECT OF FACTORS ON STUDENT RESULTS OF STUDENTS IN SOME UNIVERSITIES IN HANOI CITY.**

	Sympathy	1	2	3	4	5
DC1	I don't care to see things from someone else's point of view.					
DC2	Overall, I'm a pretty highly motivated person.					
DC3	Overall, I find it very easy to know exactly how I feel.					
DC4	People close to me often say that I treat them well.					
DC5	I don't find it difficult to express my feelings to those close to me.					
DC6	I can put myself in other people's shoes and experience their emotions.					
DC7	I always keep myself motivated.					
DC8	I find it easy to create bonds with people, even those close to me.					

	Self-Control	1	2	3	4	5
KS1	I often feel like I can regulate my emotions.					
KS2	I don't tend to change my mind often.					
KS3	I often find it easy to adapt to circumstances.					
KS4	Overall, I can deal with stress.					
KS5	I can control my emotions when I want.					
KS6	I tend to get involved in things that I later wish I had done					
KS7	Overall, I can adapt to the new environment.					
KS8	Others see me as an optimist.					

	Sociability	1	2	3	4	5
HD1	I can flexibly interact with people.					
HD2	I often actively speak up to protect my rights.					
HD3	I often actively speak up to protect my rights.					
HD4	I find myself good at communicating.					

HD5	I tend to always move forward because I know I'm supported.					
HD6	I seem to have influence over other people's emotions.					

	Well-being	1	2	3	4	5
HP1	I often find life interesting.					
HP2	Overall, I'm comfortable with my point of view.					
HP3	Overall, I have an optimistic view of most things.					
HP4	Overall, I am satisfied with my life.					
HP5	I feel good about myself right now.					
HP6	I believe everything will go well in my life.					

	Academic results	1	2	3	4	5
KQ1	I have academic results that meet my goals.					
KQ2	I will have better academic results in the next semester than in the previous semester.					
KQ3	I believe I am an effective learner.					
KQ4	My friends rate me as an effective learner.					
KQ5	My teachers consider me to be an effective learner.					

Thank you very much for your cooperation!

## THE IMPACT OF SANITARY AND PHYTOSANITARY MEASURES AND TECHNICAL BARRIERS TO TRADE ON VIETNAM'S TEA EXPORTS

**Author: Do Thi Hong Nhung<sup>1</sup>, Le Thi Hong Tham<sup>1</sup>**

**Advisor: Dr. Nguyen Thi Thu Hien<sup>1</sup>**

**ABSTRACT:** *The study uses a gravity model to estimate the impact of Sanitary and Phyto-Sanitary measures (SPS) and Technical Barriers to Trade (TBT) on Vietnam's tea exports. The results show that SPS measures have hindered Vietnam's tea exports. Each additional SPS measure would reduce Vietnam's tea exports by an average of 0.007%. Meanwhile, the regression analysis of the factor TBTs has a positive value, showing that this factor promotes Vietnam's tea exports. The study also proposes two groups of solutions to promote Vietnam's tea exports.*

**Keywords:** *SPS, TBT, tea, export, gravity model.*

### 1. INTRODUCTION

Tea is one of Vietnam's main export agricultural products. Vietnam's tea has been exported to more than 70 countries and territories with an average turnover of nearly 170 million USD/year. Tea export creates jobs and increases incomes for workers in many rural areas. However, Vietnam still mainly exports raw tea products, low added value, has not exploited the domestic advantages in production.

According to the United Nations Conference on Trade and Development-UNCTAD (2012), NTMs are non-tariff measures, but "can have an economic impact on the exchange of goods between countries". NTBs refer to restrictions due to specific bans, conditions or market requirements that make it difficult and/or expensive to import or export a product. NTBs also include the improper and/or inappropriate application of non-tariff measures (NTMs) such as sanitary and phytosanitary measures (SPS) and technical barriers to trade (TBT). In the WTO framework, NTMs are defined as "Non-tariff measures are measures that are not tariffs, but relate to or may affect the movement of goods between countries". Meanwhile, "non-tariff barriers are non-tariff measures that impede trade without a legal, scientific and fair basis". Therefore, NTBs are a subset of NTMs. Thus, in practical application and research overview, instrumental measures are understood as NTMs when the following basic points are ensured: Firstly, NTMs are types of measurement tools of the non-tariff trade policy, applied to imported goods (some applied to exports); Secondly, non-tariff instruments may or may not affect trade flows; Thirdly, not all measures affecting trade flows are implemented with discriminatory or protectionist purposes, such as trade barriers. NTMs can affect trade flows in terms of trade volume and impact benefits and costs from production to final consumption; Fourthly, NTMs are built on the basis of facilitating market access and regulating imports or providing appropriate protection for sensitive sectors within the framework of the World Trade Organization and regional commitments.

According to the WTO Agreement, SPS measures are laws, regulations, standards and procedures that governments use to protect human, animal or plant life or health from risks associated with them. Risks here refer to the spread of pests, diseases or disease carriers caused by organisms or from toxic additives or contaminants present in food, drink or feed. For example, SPS measures could be products and process-

---

<sup>1</sup> Thuong Mai University

specific standards, requirements for products produced in disease-free areas, quarantine and inspection procedures, sampling and testing. In return, limiting pesticide and drug residues in food and banning some food additives.

+ Prohibit import restrictions for reasons of hygiene and quarantine. This is the country's regulations for products imported from countries and territories with epidemics in order to promptly prevent epidemics and diseases from entering the importing country.

+ Regulations on residues or limits of chemicals used. Many countries use regulations on the list of chemicals banned from use in cultivation, agricultural products processing or regulations on chemical residues, restricting chemicals used to ensure safety and health. of humans, animals, and plants.

+ Prohibit the importation of products from specific low-production areas (due to region-specific pest concerns) and importation of production inputs (e.g. nurseries, seeds).

+ Food additives, residues and contaminants (e.g. Maximum Residue Limits (MRLs) for pesticide residues; veterinary drug residue limits and hormone use in meat production).

+ Product regulations or processing specifications (e.g. Restrictions on the use of antibiotics, sulfur dioxide, sorbic acid, potassium sorbate, biotechnology and genetic material).

+ Regulations on microbiological contamination; Chemical contaminants; Irradiation and other forms of hygiene, including washing meat with antibacterial agents.

+ Regulations of agricultural biotechnology (eg. GM crops on animal cloning); Other perceived health risks. Various overlapping technology requirements such as labeling and standards, including Good Agricultural Practices (GAP) or land use practices, employ third-party auditors.

+ Hygienic requirements related to sanitary and phytosanitary conditions. These provisions are often reflected in national food safety legislation. For example, Japan applies the Law on Food Hygiene and Safety, according to which a shipment of food that does not meet food hygiene and safety standards will not be imported into this market.

+ Regulations on measures to treat and eliminate harmful organisms of plants, animals and disease-causing organisms in the final products. Pests, diseases of plants and animals, and carriers of diseases in food, drink or feed (e.g., blight, brown rot, rot, potato warts and fungi plants).

+ Regulations on hygiene and epidemiology during production, packaging, transportation, storage and distribution; regulations on packaging, packaging and labeling with sanitary and epidemiological information in order to prevent and control harmful effects and diseases to humans, animals and plants.

According to article 2, paragraph 1, of the SPS Agreement of the WTO, the purpose of using SPS measures is to prevent the entry of diseases and protect the health and life of people and animals and plants in the country. water. As follows (Annex A of the SPS Agreement):

Firstly, to protect the life or health of animals or plants in the territory of the Member from the threat of entry, appearance or spread of pests, diseases, pathogens or pathogens.

Secondly, to protect human or animal life or health in the Member's territory from danger from food additives, impurities, toxins or pathogens in food, beverages or beverages eat cattle.

Thirdly, to protect human life or health in the territory of the Member from the risk of diseases caused by animals, plants or products thereof or from the entry, appearance or spread of harmful species.

Fourthly, to prevent or limit other harm in the territory of the Member due to the entry, appearance or spread of pests.

Under the WTO agreement, TBT measures apply to both food and non-food items. TBT measures refer to product specifications, such as manufacturing standards, specifications, product environmental

regulations, and voluntary processes related to health, hygiene and safety biology and animal welfare, as well as testing procedures, product specifications, specifications, approvals and marketing. biotechnology.

+ Import quotas and controls (such as permits) and other administrative requirements (e.g., protocols, risk assessments, exemptions, permits, tolerances, packaging requirements). Those are the regulations for importing businesses and imported goods to comply with in order to be licensed to import.

+ Export restrictions and bans.

+ Food law, including quality standards, food safety, domestic content and blending requirements as well as rules of origin requirements.

+ Certification programs, including organic certification, marketing and eco-labelling requirements, such as health claims and country of origin.

+ Regulations on processes, production methods, methods of storage, transportation, regulations on product quality, regulations related to safety and performance, etc.

+ Regulations on packaging standards and labeling requirements. These are regulations related to packaging specifications, packaging materials, language and content of labeling information (product name, ingredients, instructions for use, expiry date, ...), symbols, necessary codes to guide the transportation and preservation of goods.

+ Ions regulate food and consumer safety (e.g., labeling, packaging, pesticide residue testing, nutritional content labeling, and contamination prevention). These regulations put limits on chemical residues, restricting the use of certain substances. This includes regulations on the maximum limits of chemicals used in the production process or regulations on the use of certain substances as ingredients or materials to avoid risks to users.

+ Measures to prevent consumer fraud (e.g. shipping and financial documents, identity and measurement standards).

The main objective of the TBT Agreement is to ensure that technical regulations, standards and conformity assessment procedures do not create unnecessary obstacles to international trade:

Firstly, to protect the safety and health of people, animals and plants. Countries often control commodities, volume, and quality of goods traded on their markets through NTMs such as import-export bans, import-export quotas, import-export permits, goods. technical barriers, sanitary and phytosanitary measures, regulations on origin of goods, ensuring that the goods purchased and sold do not cause harm, do not affect human health or cause harm, adversely affect the safety and life of plants and animals.

Secondly, to protect the domestic industry. Countries always want to protect domestic industries from competitive pressures of foreign enterprises. The use of non-tariff measures such as intellectual property protection, trade safeguards and subsidies. Trade-related investment measures will help domestic enterprises keep the market.

Thirdly, to protect the environment. Environmental protection is one of the important goals of every country. Manufacturing activities have a negative impact on the environment. Therefore, countries use necessary regulations to limit the negative impact of production and trading of goods on the environment by non-tariff measures such as banning import and export, licensing import and export. regulations on technical regulations, in order to protect the environment against harmful effects from production and business activities of enterprises.

Vietnam's participation in free trade agreements (FTAs) has helped remove barriers to Vietnam's agricultural exports in general and tea in particular. However, countries tend to use more non-tariff measures (NTMs) to control trade. Among non-tariff measures, SPS and TBT measures are the most commonly used. Therefore, besides the basic advantages of enjoying preferential tariffs, there are still many challenges for Vietnam's tea

exports. This study analyzes the current situation of Vietnam’s tea exports from 2001 to 2021 and uses a gravity model to analyze the impact of SPS and TBT measures on Vietnam’s tea exports. In addition, the study also offers a number of solutions to promote mulberry silk exports to 2025 and effectively until 2030.

For developing countries, it is important to assess the trade impact of SPS and TBT due to the significant technological and financial constraints and inadequate market access they face. This study will analyze the impact of SPS and TBT on Vietnam’s tea exports for the following reasons:

Firstly, NTMs are not always easy to identify and have only been sporadically collected for relatively few countries. The availability of information is a key challenge that also magnifies other challenges, such as the national streamlining of NTMs and regulatory cooperation at the regional and multilateral level to reduce any adverse effects of NTMs. Until recently, systematic information about NTMs was not available for a significant number of countries and a significant share of world trade (UNCTAD, the World Bank, 2018). Similarly, SPS and TBT measures have little relevant data. Therefore, our research was born to provide information on SPS and TBT for Vietnamese tea exporters.

Secondly, rising incomes will lead to the introduction of additional NTMs to satisfy consumer demands and to achieve the sustainable development goals. Higher-income countries use technical NTMs more extensively. The coverage of SPS measures in agriculture in developed countries is nearly 100 per cent. Furthermore, developed countries use three times as many TBT measures as developing countries (UNCTAD, the World Bank, 2018). Therefore, Vietnam needs to meet the standards, SPS, TBT set by developed countries to be able to penetrate these markets. However, Vietnam does not have a good quality management system (compliance with MRL regulations) and necessary certifications. That makes it difficult for Vietnam’s tea exports to access markets in developed countries around the world.

Thirdly, compared to the top 10 tea exporting countries in the world in 2020, the price of Vietnamese tea is the lowest, at 27,326 USD/ton compared to 28,897 USD for Japan, 4000 USD for China, and 3,093 USD for Sri Lanka, etc. In general, the price of Vietnamese tea has always been low for many years due to the impact of SPS and TBT which may be the cause of the decrease in the export price of Vietnam’s tea. Because the purpose of these measures is to protect human or animal or plant life. Meanwhile, Vietnamese tea products were tested for having pesticide content exceeding the prescribed standards.

**Figure 1: Price of 1 ton of tea exported by Vietnam compared to the top 10 tea exporting countries in the world**

*Unit: Thousand USD*

*(Source: Author's calculations based on TRADE MAP database)*

Our empirical objective is to estimate whether SPS and TBT imposed by importing countries have a significant impact on Vietnam’s exports of tea products. The remaining question is whether SPS and TBT have facilitated or hindered Vietnam’s tea exports.

We hope that this estimate will contribute to a better understanding of the impact of SPS and TBT on Vietnam's exports of tea products, which is crucial for Vietnam to design and implement policies to strengthen Export better efficiently.

The rest of this article is structured as follows. Part 2 presents the basic theory of the impact of SPS and TBT on exports and briefly summarizes the results of related studies. Part 3 outlines econometric models and data sources, and Part 4 describes empirical results and discusses them. The final section provides conclusions and policy implications.

## 2. LITERATURE REVIEW

Not all SPS and TBT measures have a negative impact on trade. A number of measures can help reduce trade costs by standardizing information regarding product safety, quality and specifications for business partners and information for consumers (UNCTAD, two thousand and thirteen). These measures also have an important function in facilitating international trade, including facilitating greater access to foreign markets for small and medium-sized enterprises (SMEs). TBT measures also enable governments to pursue legitimate goals such as protecting human health and the environment as well as preventing fraud.

However, non-transparent, discriminatory or baseless TBT and SPS measures are significant barriers to trade when they become barriers to agricultural products. This is contrary to the objective of trade liberalization of the Agreement on Agriculture.

+ Increasing export costs and reducing the competitiveness of exported goods. Exporting companies incur compliance costs to develop products that meet new standards and regulations or obtain the necessary certifications for production. These costs can increase export prices, thus underscoring the trade-restrictive effect (Maskus et al. 2000). In addition, indirect costs should be taken into account (e.g. the cost of changing the product structure to conform to the importing country's trademark regulations), the costs of inspection, testing, evaluation, purchasing buy equipment. equipment, costs due to lack of transparency, excessive delays and uncertainty about the conformity assessment process.

+ Limited access to the market of the importing country. Developed countries have monopolistic economic and technological advantages that, through legislation or other optional means, develop some harsh environmental standards and specifications, which limit significantly market access of exporters, especially in developing countries (Bossoma Doriane N'Doua, 2022). Technical barriers to trade will reduce the export output of exporting countries and their share in the world market (K. P. G. L. Sandaruwan et al., 2019). In the extreme, when importing countries set increasingly high standards, agricultural products produced at low technology level are forced to leave the market because they do not meet requirements and standards. In case, companies want to maintain their market share, they have to improve technology and increase investment. This will increase costs, increase costs and reduce international competitiveness.

+ Promoting technological innovation, improving production and business processes for production and export, through improving the competitiveness of export goods (S.A. Neeliah et al., 2012; Rossanto Dwi Handoyo et al., 2012; Rossanto Dwi Handoyo et al., 2012). partner, 2019; Joe Eyong Assoua et al., 2022). One aspect of this impact is that domestic exporters and manufacturers differ in their ability to cope with the new standards. Normally, the importing country will set common standards for goods imported into that country. As a result, not only does the country in question face additional costs to meet the SPS and TBT standards, but other partner countries need to meet these standards as well. In that context, businesses that cannot change to meet high environmental standards will lose their competitiveness and will eventually be eliminated by the market. Enterprises that have experience, often innovate and adapt well will survive

and have a more competitive advantage. Thus, this can be considered an opportunity for exporting countries when competing to export agricultural products to a specific market.

+ Reducing consumer demand in the importing country for imported agricultural products. It can be seen that the limited impact of consumption on exports is because the application of SPS or TBT measures can increase export prices for domestic consumption. import. Thus, as prices rise, the amount of foreign demand for the country’s exports decreases. Then, consumers will search for and switch to consuming domestic goods or goods imported from other countries at cheaper prices (Marina Murina et al., 2014; Jacob Wood et al., 2020).

+ From an impact perspective, SPS and TBT increase the importing country’s demand for imported agricultural products (Olayinka Idowu Kareem et al., 2017; Jacob Wood et al., 2020). On the other hand, they are implemented in the name of protecting human health, animals/plants and the environment. From a positive perspective, even measures that discriminate between imports and domestic products or increase the cost of imports beyond what is necessary can have a positive impact on the main objectives of a country. policies, such as mitigating safety risks and other market failures (Eyal Ronen, 2017; Hea-Jung et al., 2019). Therefore, SPS and TBT measures act as positive catalysts for exports by boosting consumer demand for imports.

### 3. RESEARCH METHODOLOGY

#### 3.1. Estimation model

We use the gravity model (GM) proposed by Jan Tinbergen (1962) and developed by Anderson and van Wincoop (2003) to estimate the impact of SPS and TBT measures on Vietnam’s tea exports. The model is in the logarithmic form as follows:

$$\ln(\exp_{it}) = \beta_0 + \beta_1 \ln(\text{tar}_{it}) + \beta_2 \ln(\text{SPS}_{it}) + \beta_3 \ln(\text{TBT}_{it}) + \beta_4 \ln(\text{impsh}_{it}) + \beta_5 \ln(\text{ireer}_{it}) + \beta_6 \ln(\text{gdp}_{it}) + \beta_7 \ln(\text{dist}_{it}) + \gamma_1 + \gamma_2 + \gamma_3 + \gamma_4 + \gamma_5 + \gamma_6 + \gamma_7 + \gamma_8 + \gamma_9 + \gamma_{10} + \gamma_{11} + \gamma_{12} + \gamma_{13} + \gamma_{14} + \gamma_{15} + \gamma_{16} + \gamma_{17} + \gamma_{18} + \gamma_{19} + \gamma_{20} + \mu_t \quad (1)$$

In which “ln” is the natural logarithm, “i” means the importing country, and “t” refers to the year;

+  $\exp_{it}$ , is a dependent variable, stands for the export value of tea products from Vietnam to 31 countries and territories at time t.

+  $\text{tar}_{it}$  is the average tariff of 31 countries and territories applied to the import of tea products. When tariffs are imposed on imported tea, the price of tea in the importing country increases. This could lead to a decrease in the demand for tea in that country.

+  $\text{SPS}_{it}$  and  $\text{TBT}_{it}$  are applied by 31 countries and territories to tea imported from Vietnam in year t. The impact of tariffs on exports is limited while the impact of SPS and TBT measures cannot be determined. If the importing country adds a SPS or TBT measures, the import requirements will be more stringent and adversely affect tea exports. However, it can also boost tea exports by building consumer confidence in the safety of the product.

+  $\text{impsh}_{it}$  is the share of 31 countries’ imports share in the world trade’s value of tea products in year t. This can be considered as a representative of the market power of the importing country for each specific item. When a new SPS and TBT measure is introduced, the market power of a large importing country may mean higher compliance costs for exporting countries and a larger negative impact on trade because they don’t have many other market options to export. However, assuming a country needs to import a lot of products, in that case it will be difficult for exporting countries to

redirect their products to other markets and lead to more efforts to comply with SPS and TBT. When an importing country has an increased share of imports of a certain commodity, it shows that the import demand of that country for that product in the market increases and will increase the exports of other countries to that commodity with this item.

+  $ireer_{it}$  represents the real effective exchange rate of 31 countries and territories in year  $t$ . We expect the sign of this coefficient to be positive because the stronger currency of the importing country when the exchange rate increases will help importing countries tend to consume more and Vietnam's tea products will be exported export more.

+  $gdp_{it}$  reflects the gross domestic product of 31 countries and territories in year  $t$ . GDP is calculated for the absorption capacity of 31 countries and territories on imported tea products. This factor is expected to have a positive impact on Vietnam's tea exports.

+  $dist_{it}$  is the distance of 31 countries and territories to Vietnam, determined based on the distance from the capital Hanoi to the capitals of 31 countries and territories. We consider the sign of this coefficient to be negative because the growing distance will make it more difficult to export goods. Due to the geographical distance between the two countries affects the freight rates, risks during transportation, etc.

We also add dummy variables from  $y1$  to  $y20$  to the model. These dummy variables are included in the model to increase the reliability of the estimate and control for possible deviations outside the model.

### 3.2. Data sources

Trade data is taken from the Commodity Trade Statistics Database (COMTRADE) and supplemented by the ITC database. This source provides data on the export value of countries to partners by year and by a group of goods detailed to the 6-digit HS code. In our study, we collected data on the export value of tea products with a 4-digit HS code. This source also provides the total value of import and export of goods of each country by year, allowing the author to calculate the share of Vietnam's exports.

Data on SPS and TBT measures for 31 countries and territories are obtained from the WTO website which provides data on SPS and TBT notifications through the Integrated Trade Portal (I-TIP). This data source provides 136 NTMs that WTO members provide for each commodity group (details for products with 6-digit HS codes). In addition, information on SPS and TBT is also published by the International Trade Center (ITC) on its website [macmap.org](http://macmap.org).

Tariff information is available in the Trade Analysis Information System (TRAINS) and WTO Integrated Database (IDB) databases through the World Integrated Trade Solutions (WITS) online platform. The choice of tariff rates included in the regression model is carried out on the basis of following the following rules: The preferential tax rate under the PTA will be considered for selection in advance. In case preferential tariff information is not available or does not apply, the most favored nation (MFN) tax rate will be replaced.

GDP data derived from Basic Data Selection — anaWebClient – United Nations Statistics Division 2015 Real GDP per capita PPP for 31 countries and territories were used in the model for estimation.

The true effective exchange rate ( $ireer$ ) is obtained from Bruegel's website:

<http://www.bruegel.org/publications/datasets/real-effective-exchange-rates-for-178-countries-a-new-database/>

Distance data was collected from Google Maps on the distance from Vietnam's capital Hanoi to the capitals of 31 countries and territories.

## 4. RESULTS AND DISCUSSION

### 4.1. Econometric results

The estimated coefficient for *ltar* is in line with expectations and is significant. This result shows that the higher the import tax imposed by the importing countries on Vietnamese tea products, the lower Vietnam's tea exports will be. Keeping other factors unchanged, with a 1% increase in customs duties, Vietnam's tea exports will decrease by about 0.258% on average. Importing countries' imposition of export tax on Vietnamese tea not only increases the export price of Vietnamese tea to these countries, but also reduces the relative competitive advantage between Vietnam's tea products and other countries (in the case of other countries) cases where these exporting countries are not subject to import duties) or they are subject to a lower import duty rate).

The regression coefficient of *ireer* shows sign of agreement with the expectation. When the value of currencies of importing countries increases, people of these countries will tend to consume more, so these countries will import more, leading to an increase in Vietnam's tea exports. Specifically, a 1% increase in the real effective exchange rate of importing countries will increase Vietnam's tea exports by an average of 0.260%. However, this result was not statistically significant.

The regression coefficient of *impish* has a positive sign and is statistically significant. According to measurement, the higher the import rate of importing countries in the world market, the more promoting Vietnam's tea exports to this country. When other factors are constant, if the import proportion of importing countries increases by 1%, the average export value of Vietnam to this market will increase by about 0.0539%.

The regression coefficient of *gdp* has a positive sign as expected. The higher market size and purchasing power in these countries will increase demand for Vietnamese tea products. If the average GDP of the importing country increases by 1%, Vietnam's average tea exports to this market increase by 0.0154%.

The regression coefficient of *dist* is negative. If the gap between Vietnam and importing countries increases by 1%, the average tea export of Vietnam to this market will increase by 0.0154 %.

Considering the impact of SPS and TBT measures, the results show that SPS measures have a limited impact on Vietnam's tea exports. On average, when an importing country announces additional SPS measure, Vietnam's tea exports will decrease by about 0.00667%. This result is similar to the research results of Nguyen Thi Thu Thuong (2018), Le Thi Viet Nga et al (2019), Nguyen Quoc Thai (2020), Amir Mustafa et al (2022), Sedigheh Alaebakhsh et al (2012), Jason H Grant et al (2015), Yuan Li et al (2011), Sushil Mohan (2021), Rossanto Dwi Handoyo et al (2019), K. P. G. L. Sandaruwan et al (2019), G. H. Udagedara et al (2022) show the negative impact of SPS measures on commodity exports. Meanwhile, the impact of TBT measures aimed at boosting Vietnam's tea exports. However, the level of impact may be small and not statistically significant. According to the calculation results, on average, when an importing country announces additional TBT measure, Vietnam's tea exports will increase by about 0.00950%. This result is also consistent with many previous studies on the impact of TBT measures on commodity exports such as the study by G. H. Udagedara et al (2022), S. M. H. Shah et al (2014), Rossanto Dwi Handoyo et al (2019).

#### 4.2. Discussion

Overall, SPS measures have had a limited impact on Vietnam's tea exports. From that, it can be seen that the SPS measures that the importing country applies to imported tea products are a concern for Vietnamese tea exporters. Vietnam's exports are still raw, with low nutritional value. The investment and care of tea plants in tea areas are still low compared to requirements, especially in areas with slow economic development, the care of tea plants is even worse. In addition, a serious problem affecting compliance with SPS measures is that pesticide residues in tea leaves exceed permissible limit due to arbitrary use of pesticides, wrong dosage, not right type and wrong process. This leads to Vietnamese tea still producing an unhygienic amount of tea, affecting the reputation of Vietnam, causing anxiety to users, and making it difficult for Vietnam's exports.

Meanwhile, TBT measures have a positive impact on Vietnam's tea exports. The reason may be that Vietnamese tea exporters have focused on investing in labels, packaging and technical equipment to meet TBT's requirements.

The market power of the importing country has a positive impact on Vietnam's tea exports. The higher the proportion of tea imports by importing countries in the world market, the more promoting Vietnam's tea exports. This result shows that the greater the market power of the importing country in the international market, the more positive the impact on Vietnam's tea exports.

Tariffs have the effect of limiting Vietnam's tea exports. Therefore, Vietnam actively participates in FTAs, tariff barriers will be removed to zero, which will be a positive factor for Vietnam's exports in general and tea exports in particular.

The average GDP of importing countries has a positive impact on Vietnam's tea exports. Compared with other factors, the influence of GDP on exports is quite large. This result is also consistent with the theory when considering the impact of GDP on consumer income on import demand. In general, the average income of importing countries tended to increase during the study period, thereby increasing import demand.

Geographical distance in international trade has a negative impact on Vietnam's tea exports. The longer the distance between the importing country and Vietnam, the more transportation costs and other risks arise. In fact, domestic logistics costs account for a relatively high proportion of product costs, along with the scarcity of empty containers, which has pushed up international shipping rates and significantly affects competitiveness. of Vietnamese tea products.

## 5. POLICY CONCLUSIONS AND IMPLICATIONS

Firstly, tea exports still face obstacles from SPS measures applied by importing countries. In the coming time, Vietnam's tea industry needs to continue to find measures to meet the regulations on food safety, hygiene and epidemiology that are being applied by importing countries. The government needs to develop a set of national standards for tea exports in harmony with international standards. At the same time, planning the production of tea for export in the direction of clean production. The Government also needs to have policies to support training and capacity building for tea farmers, to practice sustainable tea production using pesticides under the Integrated Pest Management and Nutrition Program (IPM, ICM).

Enterprises need to have a research strategy to improve quality, innovate technology in production, processing, control the quality of input materials such as seeds, fertilizers, especially pesticides.

Secondly, Vietnam needs to better exploit the advantages of FTAs. At the same time, the Government needs to continue to take measures to support businesses to cut costs in production, processing and export. Accordingly, ministries, sectors and localities need to continue to reform institutions, simplify administrative procedures, cut costs, remove obstacles and barriers for export in general and tea export in particular.

From the perspective of export enterprises, it is necessary to continue to improve production efficiency. Exporting enterprises promote the form of joint ventures, association with domestic tea exporters or joint ventures with foreign enterprises to have strengths in technical factors, technology, input materials, etc.

Thirdly, the average GDP has a positive impact on tea exports. Therefore, boosting exports to target market segments with high living standards will make an important contribution to maintaining and improving Vietnam's tea export turnover. In order to promote tea exports to these markets, the Government needs to strengthen trade promotion measures, provide market information as well as organize connection, trade, and gender promotion programs, etc to introduce and promote Vietnamese tea to foreign partners.

Fourthly, geographical distance in international trade has a relatively large impact on Vietnam's tea exports. In fact, domestic logistics costs account for too high a proportion of product costs, along with the scarcity of empty containers, which has pushed up international shipping rates and significantly affected the competitiveness of Vietnamese goods. Therefore, cutting transportation costs is one of the important measures to boost tea exports. To reduce logistics costs, a total solution is needed; which focuses on continuing to invest and develop logistics infrastructure.

## DETEMINANTS OF JOB SEARCH AND JOB SELECTION IN ECONOMICS STUDENTS OF GENERATION Z IN HANOI

**Hoang Thuy Quynh<sup>1</sup>, Nguyen Thi Thanh<sup>1</sup>, Le Thi Tho<sup>1</sup>, Vo Hong Anh<sup>1</sup>, Nguyen Thi Dung<sup>1</sup>**

**Mentor: MA. Kieu Quoc Hoan**

*ABSTRACT: Gen Z, who were born between 1997 and 2012, is gradually becoming the primary workforce in the global economy, with Gen Z students playing an increasingly decisive role. Therefore, researching the factors that affect their behavior in the labor market, such as job search and job selection, is crucial. The research has developed a system of indicators that serves as a scale to measure the impact of these factors on the decision-making process of economics students regarding job research and selection. This scale system is derived from previous studies, with some observed variables adjusted to align with the perspectives of economics students in the recruitment environment of our country, specifically in the city of Hanoi. The findings indicate that social influence, including family, friends, and school; suitable working conditions based on personal circumstances (such as income, training and promotion opportunities, and suitable working conditions for individuals); and the reputation of employers' brands are factors that significantly influence students' decisions.*

*Keywords: job seeking, job selection, Gen Z*

### 1. INTRODUCTION

With increasing global competition, human resources can play a crucial role in establishing a business's competitiveness, particularly during challenging times such as the current state of the global economy, marked by recessions and rapid technological and communication changes. In this context, Gen Z, a group of people born between 1997 and 2012, is gradually emerging as the main workforce of the global economy. With their technological prowess and inclination towards change, this generation's curiosity becomes a driving force in shaping and creating new values for future society. Globally, Generation Z includes about 2.6 billion people worldwide, or about a quarter of the global population. In Vietnam, Gen Z accounts for about 25% of the country's workforce, or about 15 million people.

There are many acknowledged differences in the behavior of Gen Z compared to previous generations. Therefore, it is important to conduct in-depth studies on their working perceptions and behaviors to better understand how they navigate the labor market. Currently, a huge problem for businesses and researchers is to understand how today's young people choose where to work to attract and retain talent (Csiszárík-Kocsír & Garia-Fodor, 2018). Students, who form the most important segment of the Gen Z workforce, receive special attention from businesses, employers and universities. The research question here is what determining factors influence these students' decision to seek and choose a job. Hence, we conducted research specifically focusing on analyzing the factors that influence job search and selection among economics students in Hanoi. The study aims to contribute to our knowledge and understanding of the behavior of this workforce, thereby enabling businesses to gain insights into their potential workforce and universities to better align their activities with the training needs of student human resources.

## 2. LITERATURE REVIEW

Nguyen Thi Kim Phuong (2011) conducted a study titled “The influence of organizational image on the candidate’s intention to pursue a job in the recruitment process,” which identified several factors related to job selection. These factors include: (a) the opportunity to fully utilize one’s abilities in performing job duties, (b) opportunities for skill development and learning new work skills, (c) opportunities for career advancement, (d) maintenance of interest in the job, and (e) interesting job content. The study concluded that interesting jobs have the strongest impact on a candidate’s intention to pursue a job.

Tran Van Man and Tran Kim Dung (2010) focused on factors influencing workplace choices among graduates in their study “Factors affecting the decision to choose a workplace of graduates.” They identified eight factors: employment prospects, availability of open information and procedures, affection for the homeland, preferential policies, location and working environment, people, recreational conditions, and low cost of living.

Regarding job selection, Tran Thi Dieu Huyen (2014) conducted a study aimed at orienting students’ career choices after graduation and identifying factors affecting their career orientation. The study found that the most influential factors in candidates’ choice of employer include: (i) good career development opportunities offered by the company, (ii) opportunities to work in desired positions, (iii) personal suitability for job responsibilities at the company, (iv) appropriate scale of the company’s operations, (v) alignment of job tasks with interests and passions, and (vi) training opportunities.

In a research survey conducted by Heilmann, Saarenketo, and Liikkanen (2013), they emphasized the key factors for an employer branding strategy. These factors include a better employer name and image, improved job satisfaction, better satisfaction at work, active recruitment, and improved work motivation.

Jiří BEJTKOVSKI (2018) from Tomas Bata University in Zlín, Czech Republic, conducted a study titled “Factors affecting job search and choice employment of Generation Y students in the Czech Republic in employer branding context.” The study identified five factors that influence job search and choice in the context of employer branding: job security, income, workplace relationships, working environment, and opportunities for growth and advancement. Candidates frequently investigate information about job positions and working conditions when researching potential employers, along with company ratings and internship programs.

In Vietnam, Pham Ngoc Anh Thu and Tran Nguyen Van Khanh (2021) conducted a study on the perception and job-seeking behavior of Gen Z titled “Recruitment brand in recruiting Generation Z- Research on the perception and job-seeking behavior of Gen Z in Vietnam.” The study emphasizes that the recruitment brand is considered an important factor for Gen Z in their job search.

In the study “Talent Acquisition for Small Medium Enterprise (SME): A qualitative analysis of Generation Zers in Taiwan and Vietnam” by Cao Huynh Hong Phan (2022), it was found that Gen Z places importance on the image and brand of an organization during the initial stages of the recruitment process. Job advertisements that clearly define job duties and industry play a significant role. New graduates expect job advertisements to highlight development and training opportunities, as well as offer flexibility in the work environment, allowing them to create and learn at their own pace.

Base on the reviewed studies, it can be seen that, although Gen Z has received a lot of attention, in Vietnam, research on the behavior of Gen Z students has not been comprehensively studied. There have not been studies focusing on analyzing what factors affect the decision to choose and look for a job, which is almost not paid enough attention. Some studies have mentioned the influencing factors but only stopped

at the brand of the employer, there are many other aspects that have not been mentioned. This is a research gap that needs to be addressed soon.

### **Theoretical framework**

Based on the previous studies reviewed, the behavior of students in job selection and search can be understood and developed based on the following theories:

#### *Theory of Rational Action:*

The Theory of Reasoned Action (TRA), developed by Ajzen and Fishbein, emphasizes that the intention to perform a particular behavior is the most important factor in determining an individual's behavior. Behavioral intention is influenced by two main factors: the person's attitude towards the behavior and the subjective norm associated with the behavior. According to TRA, behavioral decisions are primarily influenced by attitudes and social influences.

#### *Theory of Planned Behavior:*

The Theory of Planned Behavior (TPB), introduced by Ajzen in 1991, builds upon the TRA and addresses some limitations of the previous model. TPB expands on TRA by incorporating an additional component called Perceived Behavioral Control (PBC) alongside Attitude-Ab and Subjective Norm (SN). PBC refers to an individual's perception of the level of control they have over performing a behavior. The TPB has proven to be valuable and effective in various psychological studies related to human behavior by including cognitive control as a crucial element.

Both TRA and TPB are applicable to voluntary behaviors and are supported by rational intentions and thinking. They provide frameworks for understanding the factors influencing individuals' behavioral decisions, including attitudes, social influences, and perceived behavioral control. These theories can be applied to studying students' behavior in job selection and search, providing insights into their decision-making processes and the factors that drive their choices.

#### *Theory of Rational Choice*

Rational-choice theory, also known as the Theory of Rational Choice, emerged in the 18th and 19th centuries from various disciplines. During this period, some philosophers argued that human nature is inherently selfish, always seeking gratification, satisfaction, and avoiding suffering. For example, Karl Marx posited that workers ultimately receive the outcomes they initially envisioned when entering the working process.

From a sociological perspective, George C. Homans generalized the principles of rational-choice theory with an equation: " $C = (P \times V) = \text{Maximum}$ ." In this equation, "C" represents the chosen action, "P" denotes the highest probability of success for that action, and "V" represents the maximum value or reward that the action brings. The optimal action is determined by multiplying the highest probability (P) by the maximum value (V).

Homans' Theory of Rational Choice emphasizes that individuals make decisions based on a rational assessment of the probabilities of success and the anticipated rewards. This theory assumes that individuals aim to maximize their gains and minimize their losses when making choices. In the context of job selection and search, individuals may consider factors such as the likelihood of success in a particular job and the potential rewards, such as salary, career advancement opportunities, or job satisfaction.

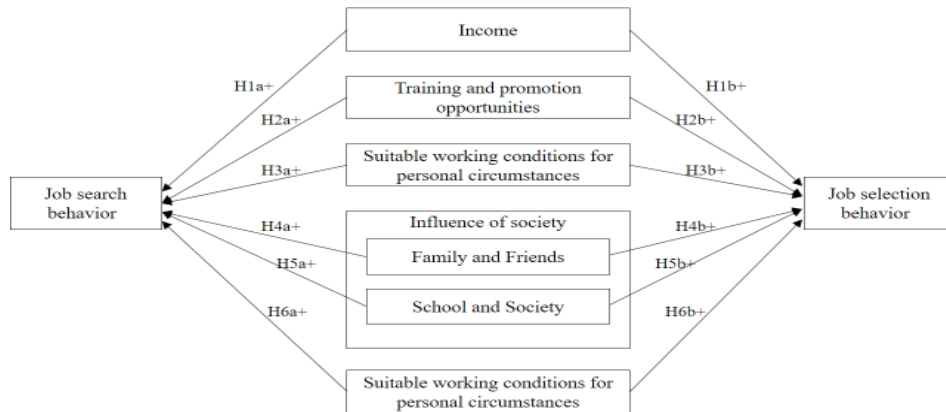

Rational-choice theory provides a framework for understanding decision-making processes based on the perceived probabilities of success and the value individuals attach to different outcomes. It can be

applied to the study of students’ behavior in job selection and search, shedding light on their rational assessments and motivations behind their choices.

**Research model and hypotheses**

Based on theoretical foundations, the research model explaining the relationship between influencing factors and the behavior of job selection and search; and hypothesis system are constructed as follows:

**Figure 1: Research model**

Research hypotheses:

*Hypothesis H1*

H1a: Income affects the job search of students majoring in economics, administration, and management in Hanoi city.

H1b: Income affects the job choice of students majoring in economics, administration, and management in Hanoi city.

*Hypothesis H2*

H2a: Training and promotion opportunities affect the job search of students majoring in economics, administration, and management in Hanoi city.

H2b: Training and promotion opportunities affect the job choice of students majoring in economics, administration, and management in Hanoi city.

*Hypothesis H3*

H3a: Suitable working conditions for personal circumstances affect the job search of students majoring in economics, administration, and management in Hanoi city.

H3b: Suitable working conditions for personal circumstances affect the job choice of students majoring in economics, administration, and management in Hanoi city.

*Hypothesis H4*

H4a: Family and friends affect the job search of students majoring in economics, administration, and management in Hanoi city.

H4b: Family and friends affect the job choice of students majoring in economics, administration, and management in Hanoi city.

*Hypothesis H5*

H5a: School and societal factors affect the job search of students majoring in economics, administration, and management in Hanoi city.

H5b: School and societal factors affect the job choice of students majoring in economics, administration, and management in Hanoi city.

#### *Hypothesis H6*

H6a: Reputation and employer brand influence the job search of students majoring in economics, administration, and management in Hanoi city.

H6b: Reputation and employer brand influence the job choice of students majoring in economics, administration, and management in Hanoi city.

#### **Research method**

A scale system is developed to measure the factors representing the influencing factors and behavior of Generation Z economics students. To accomplish this, a pilot research is conducted with the following steps: (i) Referring to previous studies and conducting face-to-face interviews with experts to explore factors and construct questionnaires; (ii) Conducting a pilot survey with a sample size of  $n = 76$  to refine the scale, eliminate inappropriate observed variables, and develop the final survey questionnaire. Then a official investigation is then conducted with a sample size of  $n = 212$  to test the research hypotheses and evaluate the influence of independent variables on the dependent variable.

The collected data is processed and analyzed, including screening observed variables, determining scale components and values, assessing scale reliability, and testing the theoretical model. The analysis utilizes SPSS and AMOS software, involving descriptive statistical analysis, Cronbach's alpha analysis to assess scale reliability and eliminate inappropriate variables. Exploratory Factor Analysis (EFA) is conducted to extract factors, and based on the EFA results, inappropriate variables are removed, the reliability of the new factor group is tested, and a re-run of EFA is performed to check the rotation matrix and extract new factors. Once new factors are obtained, they are included in the Confirmatory Factor Analysis (CFA) to validate the factor structure. Finally, a linear structural model analysis is conducted, transforming the CFA results into a Structural Equation Model (SEM) to examine the multidimensional structure among variables, determine the level of impact of each factor on the two dependent variables, and provide explanations for each influencing factor.

#### **Empirical results**

##### Scale test results

The research consists of 2 dependent variables: Job search behavior (TK) and Job selection behavior (LC), and 3 independent variables after adjusting the model: Job conditions suitable for personal conditions (DKCV), Social influence (AHXH), and Reputation, employer brand (NTD). All variables meet the conditions for analyzing scale reliability using Cronbach's Alpha coefficient (Cronbach's Alpha  $> 0.6$ ) and total correlation  $> 0.3$ , as suggested by Nunnally (1994).

The results of the Exploratory Factor Analysis (EFA) for both the independent and dependent variables show that the Kaiser-Meyer-Olkin (KMO) measure is greater than 0.5, and Bartlett's test is significant (Sig. =  $0.000 < 0.05$ ), indicating that the data used for factor analysis is appropriate and there are correlations among the variables. The extracted variance is  $62.529\% > 50\%$ , with Eigenvalue = 1.104, indicating that the EFA model is suitable. The factor loadings of all measured variables are greater than 0.5 (ranging from 0.571 to 0.929), demonstrating practical significance according to Hair et al. (2009).

**Table 1: Evaluation results of model scale with Job search behavior**

	Scale	Reliability		Convergent Validity		Discriminant Validity
		Cronbach's Alpha	Composite Reliability	Standardized Factor Loading	AVE	HTMT
		> 0.6	> 0.7	> 0.5	> 0.5	< 0.9
Working conditions	Income	0.911	0.911		0.596	Yes

	TK7			0.753		
	TK8			0.822		
	TK9			0.82		

**Table 2: Evaluation results of model scale with Job search behavior**

	Scale	Reliability		Convergent Validity		Discriminant Validity
		Cronbach's Alpha	Composite Reliability	Standardized Factor Loading	AVE	HTMT
		> 0.6	> 0.7	> 0.5	> 0.5	< 0.9

Working conditions	Income	0.911	0.906		0.582	Yes
	TN1			0.813		
	TN2			0.771		
	TN3			0.871		
	Working conditions					
	CN1			0.784		
	CN4			0.745		
	Training and promotion opportunities					
	DT3			0.678		
	DT4			0.655		
Social influence	Friends and family	0.842	0.844		0.523	Yes
	GB2			0.678		
	GB3			0.571		
	School, society					
	XH1			0.739		
	XH2			0.785		
	XH3			0.820		
Reputation and employer brand	NTD1	0.874	0.886	0.718	0.609	Yes
	NTD2			0.822		
	NTD3			0.807		
	NTD4			0.793		
	NTD5			0.758		
Job choice behavior	LC1	0.846	0.842	0.591	0.572	Yes
	LC2			0.751		
	LC3			0.795		
	LC4			0.776		
	LC5			0.699		

The CFA confirmatory analysis of the scales showed that the model indicators fit well, specifically: With the dependent variable model Job search behavior has:  $\chi^2/df = 2.277 < 3$ , CFI index = 0.910, GFI = 0.810, TLI = 0.894 all  $> 0.8$ ; RMSEA = 0.08 (Hair et al., 2009). Therefore, this model responds well to the collected data. The normalized loading coefficients of the observed variables are all greater than 0.5 (ranging from 0.587 to 0.929).

The composite reliability (CR) ranges from 0.842 to 0.940, all  $> 0.70$ , so the scales are reliable (Hair et al., 2009). The mean extracted variance (AVE) ranges from 0.524 to 0.636, all  $> 0.50$  (Bagozzi, Yi, & Phillips, 1991; Fornell & Larcker, 1981; Hair et al., 2009), ensuring the convergence condition. strong. The analysis results show that the correlation coefficient between each pair of concepts is  $< 0.9$ , significant with P-value  $< 0.05$ . Therefore, the discriminant validity of these concepts is reached (Steenkamp & Van Trijp, 1991).

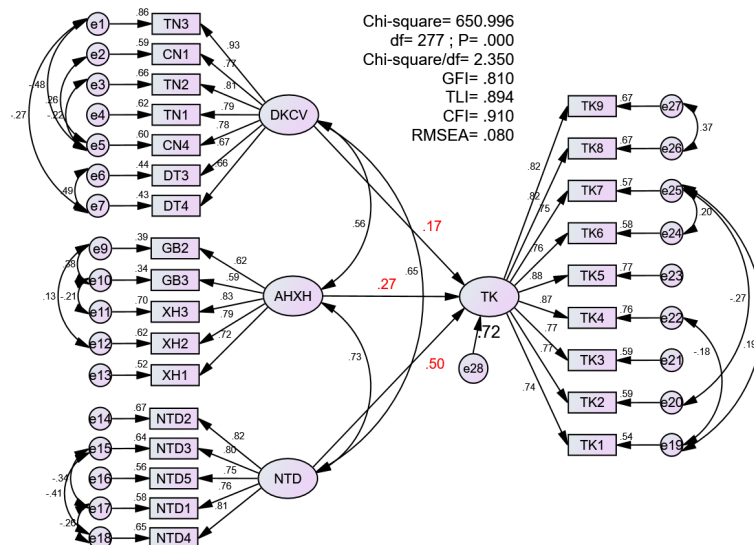

The results are similar to the dependent variable model. Job selection behavior is appropriate and satisfactory. Reliability indices like  $\text{Chi-square}/df = 2.352 (< 3)$ ,  $\text{CFI} = 0.913$ ,  $\text{GFI} = 0.836$ ,  $\text{TLI} = 0.896$  all  $> 0.8$ ;  $\text{RMSEA} = 0.08$ . The normalized loading coefficients of all observed variables are  $> 0.5$  (ranging from 0.571 to 0.871). All scales are reliable with composite reliability (CR) ranging from 0.842 to 0.906, all  $> 0.70$ , so the scales are all reliable. The average extracted variance (AVE) ranges from 0.523 to 0.609, all  $> 0.50$ , ensuring strong convergence conditions. The analysis results show that the correlation coefficient between each pair of concepts is  $< 0.9$ , significant with  $P\text{-value} < 0.05$ . Therefore, the discriminant validity of these concepts is reached.

The above results show that the model and construction scale are completely consistent with the data file, reliable enough to conduct a linear structural model test.

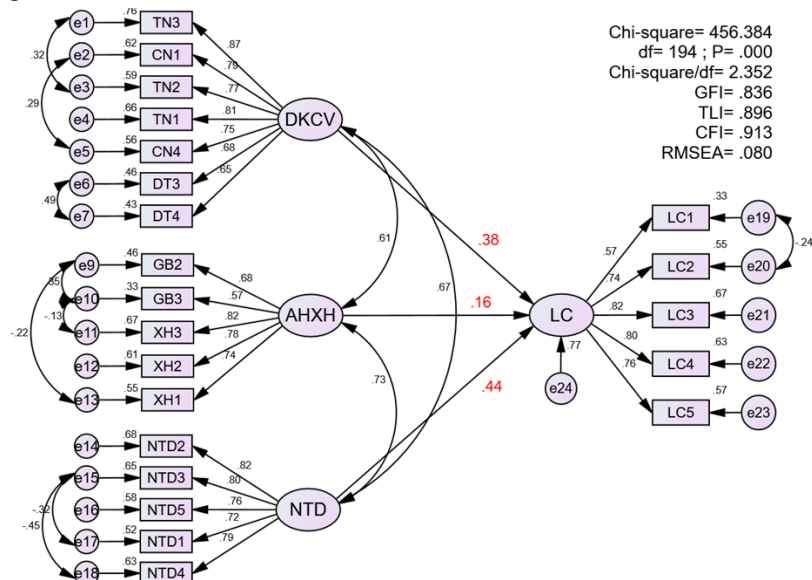

**Research finding and discuss**

The measurement model test was conducted to evaluate the linear structural model using Structural Equation Modeling (SEM) for the two dependent variables, as illustrated in Figure 2 and Figure 3. The fit indicators of the model demonstrate satisfactory results, indicating that the model is suitable for the survey data.

**Figure 2: SEM results of research model of Job seeking behavior (normalized)**

**Figure 3: SEM results of research model of Job selection behavior (normalized)**

The results indicate that all three independent variables have a positive impact on both Job seeking behavior and Job selection behavior, as evidenced by their respective normalized regression coefficients. Consequently, all six hypotheses of the new model are accepted.

The revised model includes six factors that influence the job search and job choice of economics students in Hanoi, namely Income, Training and promotion opportunities, Working conditions suitable to personal conditions, Influence of family and friends, Influence of school and society, and Reputation and recruitment brand. The findings reveal that three factors have a significant positive influence:

**Working conditions suitable for personal conditions:** This factor encompasses motivations related to income, opportunities for training and skill development, and favorable working conditions. The surveyed students express a desire to earn more money to fulfill their living needs and achieve financial independence, reflecting their independent attitude. They also prioritize training opportunities to enhance their professional knowledge and skills, recognizing that academic knowledge alone is insufficient for career success and advancement. Moreover, the convenience and flexibility of work arrangements, such as flexible working hours and the ability to work remotely, are important considerations for Gen Z students in their job search and selection process.

**Social influence:** This factor includes the influence of family, friends, school, and society on the job-seeking behavior and job selection of students. The results indicate that social influence plays a significant role in both job search behavior and job selection behavior. Students are influenced by the opinions and advice of their family, friends, and the broader social environment when making decisions about job opportunities. This underscores the importance of social networks and support systems in shaping students' career choices.

**Reputation and employer brand:** The reputation of a company or employer brand also influences students' job search and selection behavior. Students consider the reputation and brand image of a potential employer as factors of significance when deciding on job opportunities. A positive reputation and strong employer brand can attract and appeal to Gen Z students.

Regarding the specific impact of the factors on job-seeking behavior and job selection behavior, there is a notable difference. For job-seeking behavior, the factor "Social influence" has a relatively higher impact (normalized regression coefficient = 0.173) compared to the factor "Working conditions suitable for personal conditions" (0.272). Conversely, for job selection behavior, the impact of "Working conditions suitable for personal conditions" is stronger (0.377) compared to "Social influence" (0.183).

It is worth mentioning that the evolving work landscape, accelerated by the Covid pandemic and technological advancements, has led to changing attitudes and preferences among Gen Z students. They value flexibility in terms of working time and location, and they seek a balance between their academic commitments and work responsibilities. The ability to work remotely and have control over their time is highly desirable to this generation. Additionally, some comments suggest that Gen Z individuals may have a preference for independent work rather than traditional office settings and fixed working hours, which may impact their job choices and behaviors.

Overall, the results indicate that the revised model aligns well with the collected data, providing reliable insights to understand and explain the job search and job selection behavior of economics students.

However, it is worth noting that other factors such as the working environment and relationships with colleagues and leaders were not considered in the research model regarding their impact on the job search and job selection behavior of economics students. In reality, there are various opinions and discussions,

including some prejudices, about Gen Z's behavior in the workplace from other generations, colleagues, and employers, as well as from Gen Z individuals themselves. These issues involve conflicts in working styles, relationships, and communication between Gen Z employees and their superiors, colleagues, and future generations. Many opinions suggest that young people may be more prone to quitting their jobs immediately in case of disputes, disagreements, high ego, or when they feel that the generation gaps hinder their progress. Therefore, the relationship with colleagues, superiors, and the overall working culture can significantly impact a large portion of Gen Z employees. This factor might have been excluded from the research model due to non-standardized data collection. It is possible that the survey participants did not respond seriously or honestly. Moreover, as the survey sample primarily consisted of students, who may lack practical work experience, they might not fully appreciate the significance of this factor as individuals who have already entered the workforce.

On the other hand, the "Social influence" factor includes the influence of family, friends, and school on the job search and job selection behavior of students. Students believe that the university and its connections with businesses can benefit their job search and selection process. They often refer to job directories associated with their schools and seek advice from professors and instructors, expecting to find more opportunities through their academic networks. Gen Z students no longer perceive family relationships and external pressures (such as having a prestigious job) as significant factors affecting their decision-making. Generally, Gen Z students are more self-reliant and independent in their thoughts and considerations regarding their careers and job search behavior. However, the opinions and experiences shared by employees who have worked or are currently working in companies might not hold much influence on the behavior of Gen Z individuals. This might change if a wider research sample were employed, involving a larger number of surveys and subjects who are officially employed.

The "reputation and employer brand" factor has the most substantial impact on the job-seeking and job selection behavior of economics students, with standardized beta coefficients of 0.499 and 0.446, respectively. The reputation and brand image of an employer have been extensively studied, considering various aspects such as awareness, attitude, aspirations, and employment behavior among employees, including current and potential ones, especially among Gen Z individuals. Students tend to learn more about a business if they feel satisfied and interested in its products or services. Additionally, they aspire to work for large and renowned companies. Job postings and introductions from major companies always attract their attention and interest. They believe that such companies provide favorable working conditions, learning opportunities from experienced and specialized individuals, clear career pathways, and promotion prospects. Moreover, they assume that large and well-known companies offer higher salaries and attractive bonus schemes. Therefore, they trust and seek more information about renowned companies or groups. Moreover, information about various aspects of these large companies, including business operations, finance, administration, social activities, stock market performance, and employee experiences, is readily available on the internet. Furthermore, when it comes to human resources, Gen Z individuals tend to place higher trust and reliability in larger companies, making them more inclined to pursue job opportunities within such organizations.

For candidates in general, and specifically for candidates studying economics, the "prestige and brand of the organization" not only provides a guarantee of a recognized job and relative stability, but also instills a sense of pride in individuals. Naturally, no one wants to join a business with a poor reputation or no future prospects. Being an employee of a reputable organization also brings recognition from friends and acquaintances. Given that the majority of respondents in the sample had university and graduate

degrees, they are highly concerned about their personal brand. Consequently, the prestige and brand of an organization play a significant role in shaping their intentions and decisions. This aligns with the need for esteem, as outlined in Maslow's hierarchy of needs.

Furthermore, the research team discovered some differences between demographic groups in the job search and selection process, which have not been extensively discussed or deeply explored in previous studies. Graduates who have entered the labor market tend to have higher evaluation criteria compared to those who have no prior work experience. They may be more open to learning and working in fields unrelated to their academic training, but they scrutinize factors that align with their personal preferences more extensively. Consequently, the job search and selection behavior of these two groups of students differ in terms of frequency and the perceived importance of various factors. Similarly, the significance of job search and selection behavior in the career development process of economics students was found to vary among income groups.

## CONCLUSION

Through analysis, measurement, and research results have also demonstrated that the factors have a positive impact on job search behavior and job selection behavior of candidates. In particular, for job-seeking behavior, the survey results show that the job-seeking behavior of economics students is positively influenced by the following factors and the degree of decreasing from: Reputation, brand Employers to Social Influence and then to Working Conditions. For job selection behavior, the level of positive influence of the factor Reputation, employer brand is still the largest, followed by Working conditions, then Social influence. This is completely consistent with the reality and trend of choosing the current workplace.

Another goal achieved after surveying the research sample is that the group has learned some trends, actual job-seeking needs and behavioral characteristics while searching and choosing jobs of students. Economists are different from previous generations. As follows:

Finding 1: Gen Z students prefer flexibility in the post-pandemic work environment. They questioned whether the company allowed teleworking and how remote work works in the workplace. For them, the future of work is flexibility. More than three years of Covid-19 familiarize them with learning and working remotely. That's why they want to know if the job offers flexible and remote working.

Finding 2: Unlike the old generation, Gen Z students have a higher independent attitude than previous generations, they do not want to depend on their family and have a high self-esteem.

Finding 3: Students now no longer think that family relationships and work are too important to their job search and decision. Gen Z students are now more independent and independent in their thought, thinking about career and job search and choice behavior.

Research using convenience samples should limit the ability to generalize. The sample size was small and the scope of the study was narrow. If the survey is conducted over a wider area, the generality and reliability of the research results will be higher. The study only considers students studying economics, administration and management in general, but has not gone into specific industry groups, so the influencing factors found are still general and not representative when considering. Specifically in a branch, majoring in the economic sector. In order to confirm the difference in influencing factors as well as the degree of influence of these factors on job search and choice between candidates who have studied or are studying economics with candidates who do not Studying economics majors, research can continue to develop in the direction of studying the factors affecting job search and choice of non-economics students. From there, compare the two research results to confirm the difference (if any) between the candidates studying the

economics major and the remaining group of candidates and find a separate research model for the target group. Economics.

Therefore, the future research direction can be to expand the scope of the survey more broadly, to include more target groups, or to localize subjects belonging to a specific discipline in the economic sector, or to take a closer look. More than the impact of factors affecting students' search and choice between two groups of people studying economics and non-economics students.

## EXAMINING THE IMPACT OF PEER PRESSURE ON CAREER CHOICE INTENTION AMONG HUMAN RESOURCE MANAGEMENT STUDENTS IN VIETNAM: THE MEDIATING ROLE OF ACADEMIC SATISFACTION

**Author: Pham Thi Dung<sup>1</sup>, Le Hai Tam<sup>1</sup>, Vien Thi Trang<sup>1</sup>, Nguyen Tuong Vy<sup>1</sup>, Nguyen Thi Tuoi<sup>1</sup>**

**Mentor: Nguyen Hong Chau Linh (MA)<sup>1</sup>**

*ABSTRACT: This study investigates the influence of peer pressure on the academic satisfaction and career choice intention of Vietnamese students specializing in human resource management. The study employs a quantitative research approach with a sample size of 258 participants. Descriptive statistics analysis, scale testing, exploratory factor analysis (EFA), and mediation model testing were conducted using SPSS 22 and Jamovi 2.3.21. The findings indicate that peer pressure positively affects both academic satisfaction and career choice intention among students studying human resource management. Furthermore, the results demonstrate that peer pressure significantly influences students' career choice intention through the mediating role of academic satisfaction. Based on these findings, the study provides practical implications for students, educational institutions, lecturers, and employers, offering guidance on managing peer pressure, enhancing career choice intention, and promoting academic satisfaction.*

**Keywords:** Academic satisfaction, career choice intention, human resource management, peer pressure

### 1. INTRODUCTION

Peer pressure among students is a prevalent and significant psychological issue that deserves heightened attention. In today's rapidly changing socio-economic landscape, students face various psychological pressures that have a substantial impact on their academic pursuits and future career choices. These pressures can arise from different sources and greatly affect students' emotions, thoughts, and behaviors.

In the context of the COVID-19 pandemic, the field of human resource management (HRM) has experienced profound transformations. The uncertain working environment has presented challenges for HR operations, with a reduced number of HR staff requiring remaining professionals to adapt and ensure optimal and flexible operations. Consequently, the demand for skills and knowledge in HR positions has increased, posing both opportunities and challenges for students in this field. Peer pressure can manifest during career orientation and job search while students are still in school, leading many to make career choices based on majority opinions or the advice of friends and family, rather than considering their own passions, capabilities, and quality. Therefore, it is crucial to investigate the influence of peer pressure on students' academic satisfaction and career choice intentions in the current circumstances.

While numerous studies have explored peer pressure within specific age groups and its correlation with academic satisfaction or career choice intentions, there has been limited focus on university students, particularly those majoring in management or HRM. Previous research has predominantly examined the negative consequences of peer pressure, such as substance use and alcoholism, with less attention given to the positive influence of this social phenomenon on the academic satisfaction and career choices of undergraduate students. Therefore, this study contributes novelty to the field by highlighting the positive effects of peer pressure in this context. The following research questions are proposed:

---

<sup>1</sup> Thuongmai University

- How does peer pressure affect the academic satisfaction and career choice intentions of students majoring in HRM in Vietnam?
- Through the mediating role of academic satisfaction, how does peer pressure influence the intention to choose a career among students majoring in HRM in Vietnam?

## **2. THEORETICAL FRAMEWORK**

### **2.1. Peer pressure**

#### **2.1.1. The definition of peer pressure**

According to the American Psychological Association (APA), peer pressure occurs when an individual is influenced by others belonging to the same social group. This “group influence” can compel them to alter their attitudes, values, and behaviors to align with the standards and expectations of the group. Peer pressure often arises from feelings of inferiority or insecurity when individuals perceive that they lack or have not achieved the same things as their friends. Ryan (2000) defines peer pressure as the act of friends encouraging or urging someone to do something, regardless of their personal desires. However, Clasen and Brown (1985) argue that peer pressure involves the pressure to think or behave according to guidelines set by a peer group, which requires modifying one’s behavior to meet perceived expectations from others (Burns and Darling, 2002). Poonam and Rajesh (2017) explain peer pressure as the desire of individuals to engage in the same activities as others in their age group and social circle. This social group can exert direct or indirect pressure, often causing discomfort to those influenced.

To conclude, peer pressure is a condition in which an individual is psychologically influenced by people of the same age or a peer group in society, forcing them to change their attitudes, values, and behaviors to accordance with the group’s standards and expectations.

#### **2.1.2. Is peer pressure positive or negative?**

Clasen and Brown (1985) conducted a study with 689 students from grades 7 to 12, finding a strong correlation between peer pressure and five behavioral tendencies: conformity to peer norms, peer involvement, school involvement, family involvement, and misconduct. Similarly, Brown et al. (1986) proposed that adolescents’ perceptions of peer pressure are influenced by four domains: social involvement, conformity to peer norms, misconduct, and pro-adult behavior. The impact of peer pressure can be positive or negative, depending on the behaviors exhibited by peers. In this study, we anticipate that positive peer behaviors will have positive effects on students.

Social Learning Theory (Bandura, 1977) is closely related to peer pressure. Individuals tend to adopt behaviors they observe in trusted role models, particularly those with high status within the peer group. Bandura’s concept of self-efficacy is also relevant, as adolescents who believe socially learned behaviors are effective are more likely to adopt them.

Research conducted by McConchie et al. (2019) on positive peer pressure aligns closely with this theory. The authors define positive peer pressure as the beneficial impact of peer influence on the attitudes, beliefs, and behaviors of certain individuals, highlighting two main dimensions. First, positive peer pressure can enhance the quality of adolescents’ friendships and lead to positive experiences rather than increasing conflict and competition (Berndt and Keefe, 1995). This concept is evidently connected to social learning theory (Bandura, 1977). Second, individuals perceive and respond to peer pressure differently based on internal and external factors (Berndt, 1979; Krosnick and Judd, 1982; Steinberg and Monahan, 2007). For instance, peer compliance is higher among sixth and ninth graders (Berndt, 1979), as they are adjusting

to a new learning environment. In contrast, adolescents in grades 10 to 12 appear to be less susceptible to peer influence (Steinberg and Monahan, 2007). Therefore, the perception of peer pressure can yield varying outcomes among different age groups.

## 2.2. Management students

Research on management students has become increasingly diverse, exploring various aspects such as job readiness of management graduates (Brown and Scase, 1994; Cranmer, 2006; Griesel and Parker, 2009), the relationship between personality characteristics of students in this field and their employability after graduation (Potgieter and Coetzee, 2013; Potgieter, 2012), and the intention to start a business (Jena, 2020).

In addition to examining the connections between students and their careers or entrepreneurship, there is also significant attention given to the mental health of students in this major. Several studies have demonstrated that management students exhibit more negative attitudes towards mental health issues and are at a higher risk of depression compared to medical students (Vijayalakshmi et al., 2013; Dahlin et al., 2011). Research conducted by Lounsbury et al. (2009) identified key personality traits among this group of students, including lower levels of openness, agreeableness, and a high degree of extroversion. The authors explain that lower levels of openness correspond to shyness or shamelessness, low agreeableness is linked to reduced compassion, and high levels of extroversion are associated with a strong need for extrinsic motivation. Building upon the work of Lounsbury et al. (2009), Kotera et al. (2019) further investigated students in business and management majors and found that they tend to be highly concerned about their self-image, which increases their vulnerability to feelings of shame (Kotera et al., 2019).

## 2.3. Peer pressure and academic satisfaction

Understanding peer pressure within the university setting is crucial for enhancing productivity and designing effective learning systems. It is as important as teacher quality, available resources, and active learning methods in improving student outcomes and fostering motivation to learn (Choi and Yang, 2011; Gurpinar et al., 2010). Educational economists emphasize the relevance of peer groups in relation to student academic satisfaction, with peer pressure motivating students to strive for learning opportunities provided by the school (Hoxby, 2000; Akhtar, 2011). Peer relationships play a vital role in students' development, enhancing their competence and self-control, leading to positive long-term behavioral outcomes (Ryan, 2000; You, 2011).

Vietnamese studies have shown the positive influence of peer pressure on students' learning outcomes. Friends, who are easily accessible and of the same age, provide effective platforms for exchanging learning knowledge (Dang Thi Lan Huong, 2013; Vo Van Viet and Dang Thi Thu Phuong, 2017). Students perceive their friends as sources of learning motivation, leading to enhanced study skills, exploration of new ideas, and increased creativity, resulting in satisfaction when their learning expectations are met.

The argument that peer pressure has a positive effect on academic performance aligns with social learning theory (Bandura, 1977). Students tend to learn from and emulate outstanding individuals. When students have high expectations of their own abilities, they exert greater effort, which, when accompanied by positive results, leads to a sense of satisfaction in their learning journey. Therefore, the following research hypothesis is proposed:

**Hypothesis 1 (H1):** Peer pressure has a positive impact on the academic satisfaction of HRM students in Vietnam.

## 2.4. Peer pressure and students' career choice intention

According to Rani (2013), career decision making is an ongoing and dynamic process influenced by various factors such as self-knowledge, values, interests, characteristics, financial needs, and external

circumstances. The intention to choose a career is linked to the Theory of Planned Behavior (Ajzen, 1991), which suggests that individual behavior is driven by intention. Intentions are translated into actions only when they are within the individual's control and aligned with their will.

Research on the impact of peer pressure on career choice intentions among Asian students, particularly in Vietnam, is still relatively limited. In Vietnam, individual career choices are often influenced by parental desires, while societal expectations continue to shape the thoughts, lifestyles, and decisions of many individuals. Nguyen Thi Kim Nhung and Luong Thi Thanh Vinh (2018) found that among high school students in Nghe An, the influence of friends on career orientation was statistically insignificant, while the family factor emerged as a strong influencer of students' career intentions. Similarly, research conducted by Arif, Iqbal, and Khalil (2019) on factors affecting career choices of Pakistani students revealed that society and family exerted the most significant impact on students' career intentions.

On the other hand, studies by Naz et al. (2014), Ogutu et al. (2017), and Mtemeri (2017) suggest that friends do play a certain role in students' career decisions. Through interactions with friends, students gain valuable information about different career options. Additionally, Kaur (2020) found a significant relationship between peer pressure and career decision-making among adolescents, although the correlation coefficient for positive peer pressure was -0.14, while negative peer pressure exhibited a higher correlation coefficient of 0.25.

Therefore, it is evident that peer pressure always has an impact on students' career intentions. Based on this understanding, the following research hypothesis is proposed:

**Hypothesis 2 (H2):** Peer pressure has a positive influence on the intention to choose a career among students majoring in HRM in Vietnam.

## **2.5. Academic satisfaction and career choice intention**

Academic satisfaction can be described as the contentment derived from accomplishing learning goals and aspirations (Kumar and Dileep, 2006). In essence, academic satisfaction is viewed as field-specific satisfaction, wherein students perceive the curriculum as a resource provided by the institution to help them pursue their career objectives (Lent et al., 2009). Research with undergraduate students has shown that satisfaction is closely linked to academic achievement (Graunke and Woosley, 2005) and the certainty of career plans (Ware and Pogge, 1980).

Bandura (1986) concluded that students with higher satisfaction are more likely to achieve better performance in career decision-making. This is because academic achievement and emotional stimulation serve as fundamental sources for self-efficacy expectations. Those who have succeeded in previous career decision-making tasks, such as selecting a major, are likely to feel more effective in making decisions in the future.

On the other hand, a qualitative study conducted by Hallier and Summers (2011) with 24 students majoring in HRM and related disciplines in the UK revealed that HRM is a topic that generates significant debate in both theory and practice. Consequently, the curriculum is often designed to incorporate a balance of theory and practical application, aiming to equip students comprehensively with knowledge and increase their satisfaction with the field. However, students' direct exposure to human resources professionals is often limited before graduation, which can result in a mismatch between their career expectations and their desired first company of employment. Nevertheless, Hallier and Summers (2011) also confirmed that students' career choice intentions in HRM remain consistent throughout their university studies. Thus, within the scope of this research, which focuses on undergraduate students majoring in Human Resource

Management, and considering the evidence from the aforementioned studies, the research team aims to explore the relationship between satisfaction in learning and career choice intentions, and therefore testing a mediating role of academic satisfaction between peer pressure and career choice intention. Consequently, the research team proposes a hypothesis regarding the mediating role of satisfaction in learning:

**Hypothesis 3 (H3):** Academic satisfaction has a positive influence because peer pressure will positively affect the intention to choose a career among students majoring in HRM in Vietnam.

**Figure 1. Proposed research model**

### 3. RESEARCH METHODS

#### 3.1. Quantitative methods

Quantitative method was employed in this research due to its relevance to the field of educational psychology and the novelty of the topic in Vietnam. The use of quantitative methods ensures the safety and confidentiality of participants and allows for easy access to data, thereby ensuring the objectivity of the research. Quantitative methods have been widely used in educational psychology research, including studies on peer pressure such as those conducted by Mtemeri (2020), Ogutu et al. (2017), Naz (2014), and Naz (2014).

#### 3.2. Research sample

According to Hair et al. (1998), the sample size should be greater than or equal to 100, and the minimum sample size should be  $n=5*k$ , where  $k$  represents the number of observed variables corresponding to the research questions. Roger (2006) suggests a minimum sample size of 150-200 for practical research. Considering that, this study involves 25 observed variables, the minimum sample size is calculated as  $25*5=125$ . A total of 259 students majoring in HRM at Thuongmai University participated in the survey, which was conducted online through Google Forms (164 responses) and through direct surveys (94 responses). However, there was one invalid response, resulting in a total of 258 valid responses.

#### 3.3. Data collection

The questionnaire was designed based on synthesized research materials from previous studies. After the survey was completed, a total of 259 students from Thuongmai University participated and completed the questionnaire.

#### 3.4. Measures

The research team adopted scales from previous studies and self-translated them into Vietnamese to suit students majoring in HRM in Thuongmai University.

##### 3.4.1. Peer pressure scale

The peer pressure scale was based on the Peer Pressure Inventory scale by Clasen and Brown (1985) and the Peer Pressure Index by Brown et al. (1986). After comparing the two scales, the research team selected 12 representative questions to create a concise peer pressure scale. The observed variables related to negative behaviors (such as drug use, alcohol, and pre-matured sex) were excluded from the scale, as they were more appropriate for Clasen and Brown's scale targeting students from 7th to 12th grade. For university students, the research team included the observed variable "Using stimulants, addictive

substances (alcohol, beer, tobacco...)” (P11- see Appendix A) as an indicator of conformity to peer norms. The Peer Pressure scale was measured using a 5-point Likert scale and coded from PP1 to PP12.

**3.4.2. Academic satisfaction scale**

The scale for academic satisfaction was derived from the study by Chau and Cheung (2018). It consisted of 9 observed variables, reflecting students’ interest and engagement in learning activities (Ryan and Deci, 2000), and representing faculty expectations regarding the depth, breadth, and diversity of learning measures. The Academic satisfaction scale employed a 5-point Likert scale and was coded from AS1 to AS9.

**3.4.3. Career choice intention scale**

Career choice intention scale was adapted from the study on career goals by Tsaour et al. (2015), with a reliability of 0.85. This scale was chosen to capture students’ career intentions, as it clearly reflected their will and goals when selecting a career. While the original scale by Tsaour et al. (2015) focused on hotel and restaurant students in China, the research team modified the content to better suit the target group of this study, which consists of students in the field of Human Resource Management. The scale comprised 4 questions, coded from CG1 to CG4, and was measured using a 5-point Likert scale.

**3.5. Data analysis**

Data analysis was performed using SPSS 22 and Jamovi 2.3.21 software. The analysis involved descriptive statistical analysis, scale analysis and validation, exploratory factor analysis (EFA), the mediation model testing.

**4. RESEARCH RESULTS**

**4.1. Descriptive statistics**

**4.1.1. Descriptive statistics by gender**

The analysis of the survey participants’ gender revealed that out of 258 participants, 32 were males (12.4%) and 226 were females (87.6%).

**4.1.2. Descriptive statistics by university level**

Regarding the university level, the majority of participants were 2nd and 3rd year students. Specifically, 99 participants were in their 2nd year (38.2%), and 97 participants were in their 3rd year (37.5%).

**4.1.3. Descriptive statistics of peer pressure, academic satisfaction and career choice intention**

**Table 1. Descriptive statistic of peer pressure, academic satisfaction and career choice intention**

	N	Minimum	Maximum	Mean	Std. Deviation
PP	258	1	5	2.37±3.78	1,000±1.390
AS	258	1	5	3.05±3.84	0.095±1.004
CG	258	1	5	3.32±3.93	0.984±1.039
Valid N (listwise)	258				

*Source: Synthesized results from SPSS 22*

Analyzing the levels of agreement for different variables, it was found that for the Peer Pressure (PP) variable, PP5 had the highest level of agreement (3.78), while PP11 (alcohol, beer, tobacco...) had the lowest level of agreement (2.37). For the Academic Satisfaction (AS) variable, AS6 had the highest agreement level (3.84), and AS1 had the lowest agreement level (2.37). In terms of the Career Choice Intention (CG) variable, CG4 had the highest agreement (3.93), and CG2 had the lowest agreement (3.32).

## 4.2. Scale reliability

### 4.2.1. Cronbach's Alpha reliability analysis

**Table 2. Cronbach's Alpha coefficients**

No.	Variable	The number of observed variables remaining	Cronbach's Alpha (last run)	Correlated Item-Total Correlation (minimum-maximum)	Number of eliminated variables
1	PP	12	0.866	0.310; 0.661	0
2	CG	4	0.886	0.642; 0.828	0
3	AS	9	0.865	0.502; 0.670	0

Source: Synthesized results from SPSS 22

Cronbach's Alpha coefficient was calculated to test the reliability of the scales. The variable PP, AS, and CG all met the requirements, with correlation coefficients greater than 0.3 and Cronbach's Alpha coefficients greater than 0.6. This indicates that the variables have good and reliable scales.

### 4.2.2. Exploratory Factor Analysis (EFA)

#### 4.2.2.1. Peer pressure (PP) variable

We used the Kaiser-Meyer-Olkin (KMO) measure of sampling adequacy to examine whether the number of items per factor were adequate. According to theory, the KMO coefficient must reach a value of 0.5 or more ( $0.5 \leq \text{KMO} \leq 1$ ). In which, from the processed data, the coefficient  $\text{KMO} = 0.855$  has meet the conditions of the test ( $0.5 \leq \text{KMO} \leq 1$ ).

**Table 3. KMO and Bartlett's Test of PP scale**

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.855
Bartlett's Test of Sphericity	Approx. Chi-Square	1319.377
	df	66
	Sig.	.000

Source: Synthesized results from SPSS 22

The total extracted variance was 64.769%, exceeding the 50% threshold, indicating the suitability of the EFA model. The Eigenvalue of 1.145 also met the criterion of being greater than 1. Three factors were extracted from the 12 original factors, which accounted for 64.769% of the observed variables.

**Table 4. Total Variance Explained of PP scale**

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %

The factor rotation matrix showed satisfactory convergence and discriminant values, with most variables having loading coefficients greater than 0.3. The three factors were named as follows:

PPa: Peer and school involvement (PP1, PP3, PP5, PP6, PP7)

PPb: Pro-adult behavior (PP4, PP8, PP9, PP10)

PPc: Conformity to peer norms (PP2, PP11, PP12)

**Table 6. Comparison of PP scales**

Variables	Clasen and Brown (1985)	Brown et al (1986)	Research results
PP1	Conformity to peer norms	Conformity to peer norms	PPa
PP2	Conformity to peer norms	Conformity to peer norms	PPc
PP3	Peer involvement	Social involvement	PPa
PP4	Peer involvement	-	PPb
PP5	School involvement	Pro-adult behavior	PPa
PP6	School involvement	-	PPa
PP7	School involvement	-	PPa
PP8	School involvement	Social involvement	PPb
PP9	School involvement	Social involvement	PPb
PP10	Family involvement	Pro-adult behavior	PPb
PP11	Misconduct	Misconduct	PPc*
PP12	Conformity to peer norms	Conformity to peer norms	PPc

Source: Compiled by the authors

From the comparison table, it can be seen that the observed variable PP11 belongs to the conformity to peer norms group. This factor indicates that university students tend to imitate and follow certain behaviors that are considered standards, enhancing their image in the eyes of peers of the same age. The comparison table also shows that the significance of the variable group PPa and PPb does not vary significantly compared to the original scale.

4.2.2.2. Academic satisfaction (AS) variable

The coefficient KMO = 0.860 of AS has meet the conditions of the test ( $0.5 \leq KMO \leq 1$ ).

The total extracted variance is 61,725% > 50%, showing that the EFA model is suitable. Eigenvalue is a commonly used criterion to determine the number of factors in the EFA, the Eigenvalue of 1,178 > 1 is satisfactory. Thus, out of 9 factors, only 2 factors can be considered satisfactory in the test with the best summary information. Thus, 2 factors are extracted to summarize 61.725% variation of observed variables.

The above matrix has ensured the conditions of convergence and discriminant values and the most important thing is that there is no variable loading in both factors or no variable without loading coefficient, most of them have load is greater than 0.3.

#### 4.2.2.3. Career choice intention (CG) variable

The coefficient KMO = 0.816 of CG has satisfied the conditions of the test ( $0.5 \leq \text{KMO} \leq 1$ ).

The total extracted variance is 74.556 % > 50%, showing that the EFA model is suitable. Eigenvalue is a commonly used criterion to determine the number of factors in the EFA, the Eigenvalue of 2.982 > 1 is satisfactory. Thus, out of 4 factors, only 2 factors can be considered satisfactory in the test with the best summary information. Thus, one factor is extracted to condense 74.556% of the observed variables.

#### 4.2.3. Pearson correlation analysis

**Table 7. Correlations**

		PPa	PPb	PPc	ASa	ASb	tb_CG

*Linear correlation between the “Peer and school involvement” (PPa), “Pro-adult behavior” (PPb) and “Conformity to peer norms” (PPc) and “Career choice intention” (CG)*

The correlation relationship between the independent variable PPa and the dependent variable CG has sig.<0.05 and has  $0 \leq r = 0.300 \leq 1$ . This shows that the independent variable PPa has a linear correlation with the dependent variable CG with the level average correlation .

The correlation relationship between the independent variable PPb and the dependent variable CG has sig. <0.05 and have  $0 \leq r = 0.281 \leq 1$ . This shows that the independent variable PPb has a linear correlation with the dependent variable CG with a weak correlation .

The correlation relationship between the independent variable PPc to the dependent variable CG has sig.>0.05 and has  $0 \leq r = 0.098 \leq 1$ . This shows that the independent variable PPc has no linear correlation with the CG variable.

Linear correlation between “Academic satisfaction” (AS) and “Career choice intention” (CG)

The correlation relationship between AS and CG has sig.<0.05 and has  $0 \leq r = 0.553 \leq 1$ , showing that AS has a linear correlation with the CG with a strong degree (determined on r).

Linear correlation between “Peer and school involvement” (PPa), “Pro-adult behavior” (PPb) and “Conformity to peer norms” (PPc)

The independent variables PPa, PPb and PPc are linearly correlated with each other with sig. <0.05; where r of PPa and PPb, PPa and PPc and PPb and PPc are 0.601, 0.368, 0.396, respectively. The correlation level of PPa and PPb is strong correlation, the correlation level of PPa and PPc, PPb and PPc is the average correlation.

Linear correlation between “Peer and school involvement” (PPa), “Pro-adult behavior” (PPb) and “Conformity to peer norms” (PPc) with “Academic satisfaction” (AS)

PPa, PPb and PPc all have a linear correlation with AS with sig. <0.05; where r of PPa and AS, PPb and AS, PPc and AS are 0.466, 0.451, 0.272, respectively. The correlation level of PPa and AS, PPb and AS is moderate correlation and the correlation level of PPc and AS is weakly correlated.

**4.2.4. Model testing**

Note. Confidence intervals computed with method: Standard (Delta method)  
 Note. Betas are completely standardized effect sizes

Source: Synthesized results from Jamovi 2.3.21

The mediating model was performed to evaluate the role of the mediating variable AS based on the impact of the independent variable PPa; PPb; PPc with dependent variable CG. The results show that the total impact of variable PPa and variable PPb on CG is significant.

Total direct impact of variable PPa on variable CG with  $\beta = 0.2143$ ,  $t = 2.862$ ,  $p = 0.004$ . Total direct effects of variable PPb on variable CG with  $\beta = 0.1721$ ,  $t = 2.269$ ,  $p = 0.023$ . Total direct impact of variable PPc with dependent variable CG with  $\beta = -0.0495$ ,  $t = -0.759$ ,  $p = 0.448 > 0.05$ .

Indirect impact of variable PPa on variable CG through variable (AS) with  $\beta = 0.1546$ ,  $t = 3.864$ ,  $p < .001$ . Indirect impact of variable PPb on variable CG through variable AS with  $\beta = 0.1326$ ,  $t = 3.365$ ,  $p <$

.001. Indirect impact of variable PPc on variable CG through variable AS with  $\beta = 0.0348$ ,  $t = 1.102$ ,  $p = 0.271 > 0.05$ .

From the above results, it can be seen that the impact of PPc on CG is not significant, either directly or indirectly through AS. Through the above table, we can see the direct impact of variables PPa, PPb on CG; In addition, it also showed the role of AS mediator when showing the indirect impact of PPa, PPb on CG.

Figure 2. Research model

## 5. DISCUSSION AND IMPLICATIONS

### 5.1. Discussion

#### 5.1.1. Impact of peer pressure on academic satisfaction

The research findings indicate that the independent variables, “Peers and school involvement” (PPa) and “Pro-adult behavior” (PPb), have a positive impact on the mediating variable “Academic satisfaction” (AS). However, the variable “Conformity to peer norms” (PPc) does not have any impact on AS.

Among the independent variables, PPa has a stronger impact on AS compared to PPb, as evidenced by a higher beta coefficient ( $0.2914 > 0.2499$ ).

Therefore, hypothesis H1, which states that peer pressure has a positive impact on the academic satisfaction of students in the HRM major in Vietnam, is partially supported. These findings align with previous research by Wentzel and Brophy (2014) and Tope (2011), which suggest that students who receive support and care from friends tend to have higher motivation and satisfaction in their learning.

#### 5.1.2. Impact of peer pressure on career choice intention

The results demonstrate that the independent variables “Peers and school involvement” (PPa) and “Pro-adult behavior” (PPb) directly impact the dependent variable “Career choice intention” (CG). Specifically, PPa has a stronger impact on CG compared to PPb, indicated by a higher beta coefficient ( $0.0598 > 0.0395$ ).

Thus, hypothesis H2, which posits that peer pressure positively affects the career choice intention of students majoring in HRM in Vietnam, is partially supported. These findings suggest that for students in the HRM field, factors related to friends and school, such as participating with friends and attending school, have a strong positive influence on their career choice intentions. These results align with the research conducted by Ogutu, Odera, and Maragia (2017), who found that peer pressure significantly influences students’ career decision-making. It is recommended to raise awareness among students about the role peer pressure plays in career decision-making.

However, these findings are not consistent with the results of Nguyen Kim Nhung and Luong Thi Thanh Vinh (2018) and Seema Arif et al. (2019), who argue that the influence of friends is not statistically

significant when assessing factors affecting career choice. Instead, they suggest that family factors have a stronger impact on students' career choices.

### **5.1.3. The mediating role of academic satisfaction**

The study findings indicate that the mediating variable “Academic satisfaction” (AS) has a significant impact on the dependent variable “Career choice intention” (CG), as reflected by a Beta coefficient of 0.5304.

This result demonstrates the mediating role of academic satisfaction in the relationship between peer pressure and career choice intention. However, the mediating role of academic satisfaction is only partial. Both the independent variables “Participating with friends, attending school” (PPa) and “Professional behavior, maturity” (PPb) directly influence career choice intention without being mediated by academic satisfaction.

Furthermore, the variable “Academic satisfaction” (AS) does not mediate the relationship between the variable “Compliance with the standards of friends” (PPc) and the variable “Career choice intention” (CG).

Therefore, hypothesis H3, which suggests that academic satisfaction has a positive influence on career choice intention as peer pressure positively affects the intention to choose a career for students majoring in HM in Vietnam, is partially supported. However, these findings differ from the study conducted by Hallier and Summers (2011), who found that the intention to choose a career for students majoring in HRM remains unchanged during their university studies..

## **5.2. Implications**

### **5.2.1. Theoretical implications**

The present research theoretically emphasizes the positive aspects of peer pressure, a social phenomenon that is commonly perceived as negative. Existing literature has limited studies evaluating the significance of peer pressure's positive influences. Therefore, this research fills a gap in the literature by examining a new group of participants, specifically university students. The research findings also demonstrate that peer pressure does indeed have impacts on their academic lives and prospective careers. The outcomes, whether negative or positive, depend on the behaviors they perceive and imitate. This concept, is again closely related to social learning theory of Bandura (1977) and needs to be examine further in future peer pressure and higher education research. Furthermore, based on this research, there is a critical need to develop a new scale that effectively defines and measures the behaviors of university students.

### **5.2.2. Practical implications**

Based on the research results, the research team proposes several solutions to help students majoring in HRM in Vietnam overcome the influence of peer pressure and enhance academic satisfaction and career choice intention effectively:

#### **5.2.2.1. For students**

Firstly, it is important for students to build motivation and self-discipline in their studies. This can be achieved by setting clear and specific learning goals, creating detailed learning plans, and understanding their own abilities and limitations. By doing so, students can transform the pressure they feel into positive motivation, driving them to become better versions of themselves.

Creating an inspiring learning environment is also crucial. Students should be encouraged to learn together, share their perspectives, and grow collectively. It is important for students not to force themselves into activities that they are not suited for or that go against their true interests, simply because their peers excel in those areas.

Balancing listening and sharing is another effective approach to reducing peer pressure in both academic and personal environments. By actively participating in discussions and exchanging experiences with others, students can alleviate the pressure they feel and gain a broader perspective on their own choices and decisions.

#### *5.2.2.2 For lecturers*

In terms of the role of lecturers, it is essential for them to incorporate interactive activities and games related to the subject matter to make the learning process more engaging and enjoyable. They should also provide opportunities for students to express their opinions and apply theoretical knowledge to practical situations. Additionally, teachers should adopt teaching methods that make students feel comfortable and provide guidance and career orientation to assist students in making informed decisions about their future careers.

#### *5.2.2.3. For the school*

At the institutional level, schools can establish a psychological counseling department to provide support and guidance to students in expressing their thoughts, addressing difficulties, and managing stress and fatigue. It is also beneficial to organize events and projects that allow students to develop themselves and acquire new skills. Furthermore, schools can develop training programs and seminars, particularly for final-year students, with the participation of businesses. Extend the duration of internships and provide more opportunities for practical experience to aid students in making career choices.

Based on the research by Hallier and Summers (2011) on building professional “identity” in the HRM field, the research team suggests incorporating additional career planning and management methods to help students establish themselves in their chosen profession. This will contribute to the availability of high-quality human resources in the labor market and support the growth of the profession.

#### *5.2.2.4. For employers*

First and foremost, establishing collaborations between enterprises and educational institutions is crucial. This collaboration can involve developing criteria for evaluating internships, leading to an improved assessment process for student performance. Additionally, it is important to focus on creating suitable career paths, diversifying training methods, and offering competitive employee benefits. These measures will contribute to the enhancement of both professional and soft skills development for students.

Furthermore, organizing supplementary programs such as team-building activities, exchanges, and training sessions can play a significant role in fostering excitement and facilitating the acquisition of professional knowledge and soft skills. These programs provide valuable opportunities for students to develop their abilities and improve their overall competence. By implementing these proposed solutions, it is anticipated that students in the field of HRM will be better equipped to navigate peer pressure, experience increased academic satisfaction, and make well-informed career choices.

It is important to emphasize that the success of these initiatives relies on the collaboration and collective efforts of students, lecturers, schools, and employers. By creating a supportive and conducive environment that promotes cooperation and mutual understanding, all stakeholders can contribute to the holistic development of students and prepare them for successful futures in the field of HRM.

### **5.3. Limitations of the study and suggestions for future research**

#### ***5.3.1. Limitations of the study***

The study has a number of limitations that should be acknowledged. Firstly, the sample size was small, comprising only 259 students from the Faculty of Human Resources Management at Thuongmai

University. This limited sample size may affect the generalizability of the findings. Additionally, the scales used in the study were self-translated from English to Vietnamese by the research team, potentially leading to translation errors or discrepancies from the original scales. Moreover, the study did not comprehensively define and explore specific behaviors representing misconduct among university students, which may limit the understanding of peer pressure within this age group. Furthermore, the influence of gender on the relationship between peer pressure, academic satisfaction, and career choice intention was not clarified in the study.

### **5.3.2. Suggestions for developing topics for future research**

For future research, it is suggested to address these limitations and expand the research scope. Firstly, further studies can delve into the personality characteristics of students in HRM and related fields in economics and business. Secondly, exploring the relationship between peer pressure and specific social behaviors, such as procrastination, motivation loss, social media addiction, and substance abuse, can provide valuable insights. Thirdly, focusing on the impact of peer pressure on mental health and emotional intelligence of Vietnamese students, while considering the influence of gender and regional cultural factors, would be beneficial. Lastly, expanding the research to include students from various industries and regions across the country would contribute to a more comprehensive understanding of peer pressure dynamics.

## APPENDIX A. MEANING OF OBSERVED VARIABLES

### 1. Peer pressure scale (PP)

PP1	Join one or more groups (famous or unpopular) at school
PP2	Have the same hairstyle, wear the same clothes, or listen to the same music as my group of friends
PP3	Active in extracurricular activities (parties, sports, concerts, ...)
PP4	Spend a lot of free time with friends
PP5	Study hard and get good grades
PP6	My performance at school reflects my personality/ability
PP7	Participate in training sessions, improve experience, knowledge and skills
PP8	Do not skip class, skip school
PP9	Trying to finish college
PP10	Get along with your parents
PP11	Using stimulants, addictive substances (alcohol, beer, tobacco...)
PP12	Have actions and words like friends around

### 2. Academic Satisfaction scale (AS)

AS1	I enjoy studying more than most of my friends
AS2	I discover myself through learning
AS3	I feel proud to study at this university
AS4	My academic results are assessed objectively
AS5	Unbiased scoring process
AS6	Studying helps me get a lot of information and experience
AS7	The curriculum requires a lot of homework
AS8	The program gives me many topics to discuss and share thoughts on
AS9	I feel happy to take a class

### 3. Career choice intention scale (CG) in human resource management

CG1	After I graduate, I will definitely try to find a job in HR
CG2	No matter the difficulties, I will persistently pursue the job I want with the HR industry
CG3	I will definitely work in HR after I graduate
CG4	If a potential employer offers me a job in HR, I will gladly accept it

## **FACTORS IMPACT ON GREEN INNOVATION, COMPETITIVE COMPETITION AND OPERATION EFFICIENCY IN VIETNAM BUSINESSES IN DIGITAL ENVIRONMENT**

**Author: Nguyen Thi Quyen<sup>1</sup>, Nguyen Hoang Anh<sup>1</sup>**

**Mentor: Dinh Thi Huong (PhD)<sup>1</sup>**

*ABSTRACT: This study aims to analyze the impact of green innovation on the competitive advantage and organizational performance of Vietnamese enterprises. Data was collected from 625 questionnaires received from 32 Vietnamese enterprises. The data was then processed through SPSS 26 & AMOS 24 software. After that, descriptive statistics, EFA analysis, CFA analysis, SEM analysis, and Bootstrap test were used. The research results indicate that the factors affecting green innovation are technology, organization, and environment. In particular, factors related to the organization have the most decisive impact. Besides, green innovation impacts competitive advantage and performance within Vietnamese firms. In today's businesses, business performance takes into account the impact on the environment. Therefore, innovation of green processes and products has a positive impact on the performance of businesses.*

*The study also proposes some implications for managers to boost green innovation to achieve competitive advantages and operational efficiency of Vietnamese enterprises in the digital environment.*

*Keywords: Green innovation, operational efficiency, Vietnamese enterprises, digital environment*

### **1. INTRODUCTION**

In the present day, green innovation in the digital environment is becoming one of the models targeted by many businesses, in order to respond to new requirements, in line with the general development trend of the world, and at the same time improve the position of enterprises. Thus, increasing the competitiveness of enterprises in both domestic and foreign markets. Green innovation in the digital environment, especially green production, is a production process that is environmentally friendly from input materials to output products and does not cause harm to human health. According to the Department of Domestic Market - Ministry of Industry and Trade (2022): “In the face of the impacts of climate change, in the context of a heavily polluted environment, resources are gradually being exhausted, etc., a wave of consumption. Green production is spreading globally, green production is an inevitable trend and an important link in the green growth strategy. In Vietnam, green innovation is an important link to help Vietnam move towards a green and sustainable economy. Participating in the campaign of environmentally friendly green production and ensuring the health of consumers, in recent years, many Vietnamese businesses have been paying more attention to using natural materials, fuels and chemicals. non-toxic substances; invest in modern machinery, technology and equipment according to international standards to improve processes, towards green production. At the same time, invest in and install renewable energy systems to actively use clean energy, in addition to solutions to save electricity and water in the production process... as well as install a management system. Quality, safety and hygiene management and waste treatment system, aiming at green and clean production criteria” . Vietnamese enterprises in the digital environment are taking green innovation seriously at Vietnamese enterprises. This is evidence that promoting green innovation, competitive advantage and operational efficiency at Vietnamese enterprises has helped their human resources “shift from volume to substance”. Nevertheless, DARA (2020) indicated : “Economics

<sup>1</sup> Thuongmai University.

is decrease 15 billions USD every year, equally 11% GDP because of climate changes”. Green innovation has received considerable attention, but it is still a modest number and has not really created a driving force for the economy. Thus, promoting green innovation in the digital environment to enhance the operational efficiency of Vietnamese enterprises will be an inevitable development trend, one of the top priorities to become the “life saving” methods. “The decision is a “golden opportunity” to make a breakthrough in labor productivity, competitive advantage, sustainable development in sustainable development, green economy development in the digital environment.

## **2. THEORETICAL BASIS, HYPOTHESIS AND RESEARCH MODEL**

### **2.1. Theoretical basis, hypothesis**

#### **Green innovator**

Weng & Lin (2011) suggested :“Green innovation is an effective way for businesses to solve problems of environmental impact. Based on stakeholder theory, businesses operate according to new standards to satisfy their key stakeholders. Weng et al., (2015) evaluated: “Company managers are interested in understanding the internal and external factors to promote green innovation implementation; For example, consider customer requirements or government environmental regulations as a key driver of green innovation, the way in which a company can comprehensively address stakeholders’ concerns. relevant to achieve business goals”. As such, green innovation aims at general purpose, pollution reduction, energy productivity, waste reduction, replacement of limited resources with sustainable and recyclable ones based on eco-friendly technologies. environment, operating processes towards greening and implementing sustainable development

Thus: “Green innovation of enterprises is the creation of technological innovation, using environmentally friendly technologies to help enterprises use energy most effectively, contribute to environmental protection, in order to increase labor productivity. , bringing operational efficiency and competitive advantages of enterprises”.

#### **Factors affecting green innovation**

##### **(i) Technological factors:**

According to Lin & Ho (2011): “Technological factors are often interested in green innovation technical documents of enterprises ”. Frambach & Schillewaert, 2002; Jeyaraj et al., 2006; Rogers, 2003 evaluated: “Some of the technological factors of innovation increase relative advantage, compatibility, complexity, reliability, observability, usefulness, information intensity.” Along with that, in the current new context, ever-evolving technology will create conditions to promote green innovation activities of enterprises faster and more effectively. From the research results, we make the following hypothesis:

##### **Hypothesis 1 (H1): Technology has a positive impact on green innovation of enterprises.**

##### **(ii) Organizational factors:**

Bambang et al (2020) nhận định: “Organizations can also be viewed as internal factors that have an impact on the adoption of green practices. Organizational factors are often analyzed in related research on environmental protection and technical innovation. There are many studies that have discussed the factors affecting the organization such as human resource quality, top leadership skills, organizational support, organizational culture and organizational size in terms of technical innovation. Business owners need to balance economic, environmental, and social issues in their business. In the era of sustainable development and enhanced environmental awareness, enterprises need to accept the green market orientation and

implement green innovation to achieve better business performance.” With Lee (2008); Lin & Ho (2011); Weng et al. (2015), Lin & Ho (2011); Lee et al. (2005), Phạm Anh Nguyễn (2022) also recognized that organizational factors have a positive impact on green innovation of enterprises. On that basis, the study proposes the following hypothesis:

**Hypothesis 2 (H2): Organization has a positive impact on green innovation of enterprises.**

**(iii) External environmental factors:**

Lin & Ho (2011); Weng et al. (2015); Guo et al. (2018), Phạm Anh Nguyễn (2022) suggested: “Influence of stakeholder pressures, in particular, customers and regulations, government support factors, and market changes as these are factors that are Previous research confirms the influence on the implementation of green innovation in enterprises.

**Hypothesis 3 (H3): External environmental factors have a positive impact on green innovation of enterprises.**

**Operational Efficiency**

According to the research results of Ar (2012): “Green product innovation has a significant positive effect on both the efficiency of the enterprise and its competitiveness. In other words, environmental management only plays a role in moderating the relationship between green innovation and enterprise efficiency. Financial performance is defined as a parameter that describes a company’s financial or quantitative performance, which is then used for comparisons against financial reporting standards and shows the company’s performance. company in the recent period in terms of financial aspect will be evaluated as a basis for other activities”. In today’s businesses, business performance takes into account the impact on the environment. Therefore, innovation of green processes and products has a positive impact on the performance of businesses.

From the research results, we put forward the following research hypothesis:

**Hypothesis 4 (H4): Green innovation has a positive impact on the performance of enterprises.**

**Competitive advantage**

Barney (1991) & Phạm Anh Nguyễn (2022) said that: “Businesses from green innovation can come up with policies suitable to the actual conditions of their organizations to develop businesses quickly and effectively. and sustainable, contributing a part to sustainable development. Green innovation helps businesses develop and maintain a competitive advantage, leveraging resources and competitive advantages for superior performance.” As such, businesses have realized the importance of environmental protection, which also brings a number of benefits to businesses besides environmental protection. With green applications both in products and processes, businesses have a cost advantage or gain special customer attention in effectively dealing with the environmental issue. From there, green innovation develops not only the operational efficiency of enterprises but also provides a competitive advantage.

From the research results, we put forward the following research hypothesis:

**Hypothesis 5 (H5): Green innovation has a positive impact on competitive advantage of enterprises.**

**Hypothesis 6 (H6): Competitive advantage has a positive impact on the performance of enterprises.**

## **2.2. Research Model**

From 6 hypotheses of the research model of factors affecting green innovation, competitive advantage, operational efficiency, in Vietnamese enterprises in the digital environment with the proposed research

model, there are 3 independent variables: technology, organization, external environment, 1 intermediate variable is green innovation, The 2 dependent variables are operational efficiency and competitive advantage. Research scales are inherited and developed by Lai et al. 2003; Wen and Chen, 1997, Chen 2008 and Chen et al. 2006, Lin & Ho, 2011, Kousar et al. 2017, Pham Anh Nguyen 2022, Ehr Gott et al., Lopez-Gamero et al., 2010; Liu, 2009, Zhao et al., 2015, Cooper et al. 1994, Avlonitis et al. 2001, Pham Anh Nguyen 2022.... The Likert scale is 5 points: where 1 is strongly opposed and 5 is strongly agreed.

The Green Innovation Capacity Scale is inherited and developed from studies by Lai et al. 2003, Wen and Chen, 1997, Chen 2008 and Chen et al. 2006, Pham Anh Nguyen 2022... The scale is encoded from DM1→DM7 with 7 observation variables: DM1-DN prioritizes the use of materials that consume less resources and energy, DM2-DN will consider the reuse of products, DM3-DN applies energy conservation technologies; DM4-DN applies renewable resource technologies; DM5-DN applies technologies in pollution prevention process.

Technology scale inherited and developed from studies by Lin & Ho 2011, Kousar et al. 2017, Pham Anh Nguyen 2022... The measurement scale is encoded from CN1→CN7 with 7 observation variables: CN1-Green technology innovation suitable to current production and business activities of enterprises, CN2-Green technology innovation in accordance with the orientation of enterprises, CN3-Green technology innovation is easy to practice, CN4-Knowledge of green technology innovation is easy to share, CN5-Easy to evaluate green technology innovations, CN6-Green technology innovation takes time to become familiar, CN7-It takes less cost to be able to gradually get used to green technology innovation.

The organizational scale is inherited and developed from the studies of Lin & Ho, 2011; Lee et al., 2005, Pham Anh Nguyen 2022... The measurement scale is coded from TC1→TC6 with 6 observations including: TC1-DN encourages employees to learn knowledge about green innovation; TC2-DN considers the application of green innovation as an important strategic activity of the company; TC3-DN strongly supports employees' environmental protection efforts; TC4-Employees have the ability to learn new technologies easily; TC5-Employees trained in green knowledge; TC6-Employees are able to provide ideas on green innovation for enterprises

The environmental scale is inherited and developed from studies by Lin & Ho 2011, Lopez-Gamero et al. 2010; Liu, 2009; Zhao et al. 2015, Pham Anh Nguyen 2022... The scale is coded from MT1→MT7 with 7 observations including: MT1- enterprises will be sanctioned if they violate environmental regulations; MT2- enterprises feel pressure from monitoring environmental activities of local governments; MT3- Predicting competitor behavior is difficult; MT4-Client requests enterprises to improve environmental performance; MT5- Clients prefer businesses with strong environmental protection responsibilities, MT6- Clients request detailed information about environmental protection of other enterprises, MT7- Clients will stop supporting if enterprises do not produce green products.

The performance scale is inherited and developed from studies by Cooper et al., 1994, Avlonitis et al., 2001 Pham Anh Nguyen 2022... The measurement scale is encoded from HQ1→HQ6 with 6 observations including: HQ1- enterprises increase sales revenue, HQ2- enterprises increase profits significantly, HQ3- enterprises increase market share, HQ4- Financial value of enterprises is increased, HQ5- enterprises achieve customer loyalty/loyalty, HQ6- Enterprises increase employee loyalty.

The competitive advantage scale is inherited and developed from studies by Cooper et al., 1994, Avlonitis et al., 2001, Pham Anh Nguyen 2022... The measurement scale is encoded from LT1→LT5 with 6 observations including: LT1- Green technology innovation helps businesses feel an increased reputation/

brand, LT2- Green technology innovation helps businesses feel more creative products, LT3- enterprises have competitive advantages over direct competitors, LT4- The image of the enterprise is better than the image of direct competitors, LT5- The reputation of the enterprise is better than the reputation of competitors, LT5- The reputation of the enterprise is better than the reputation of competitors.

From 6 research hypotheses, the research model has a total of 38 observed variables, of which 3 independent variables are technology (CN), organization (TC), external environment (MT), 1 intermediate variable is green innovation (DM); The 2 dependent variables are operational efficiency (HQ) and competitive advantage (LT). The proposed model is below (see figure 1).

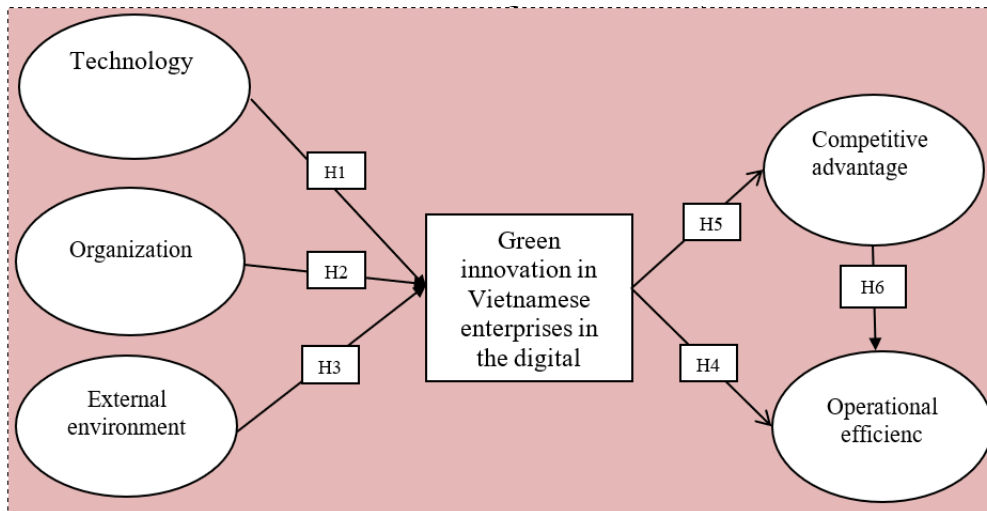

Figure 1. Proposed research model

Source: Compilation of authors

3. RESEARCH METHODOLOGY

The study was carried out through 2 qualitative and quantitative steps with 2 different groups of subjects. Respondents for qualitative research are experts and managers at 32 Vietnamese enterprises. The survey subjects of the quantitative study are managers and employees, who are implementing green innovation where they are working. From the synthesized theoretical basis, the observed variables are built on a 5-point Likert scale (from 1 = strongly disagree to 5 = strongly agree) reflecting 6 complete research concepts. Qualitative research through in-depth interviews with 10 experts with knowledge of green innovation of Vietnamese enterprises in the digital environment to supplement and adjust the above observed variables to be easy to understand and suitable to the context at Vietnamese enterprises. Qualitative research results help to form a quantitative questionnaire consisting of 38 observational variables, of which 3 are independent are technology, organization, external environment, 1 intermediate variable is green innovation; The 2 dependent variables are operational efficiency and competitive advantage. Summary of variables in the proposed model:

Table 1. Summary of variables in the model

Sequence number	Factors	Author
1	Technology	Lin & Ho, 2011, Kousar et al., 2017, Pham Anh Nguyen (2022)
2	Organization	Lin & Ho, 2011; Lee et al., 2005, Pham Anh Nguyen (2022)
3	External environment	Lin & Ho (2011), Ehr Gott and associates, Lopez-Gamero et al., 2010; Liu, 2009; Zhao et al., 2015, Pham Anh Nguyen (2022)

4	Green Innovation	Lai et al., 2003; Wen and Chen, 1997, Chen (2008) và Chen et al. (2006), Pham Anh Nguyen (2022)
5	Operational efficiency	Cooper et al., (1994); Avlonitis et al., 2001 Pham Anh Nguyen (2022)
6	C o m p e t i t i v e advantage	Cooper et al., (1994); Avlonitis et al., 2001, Pham Anh Nguyen (2022)

*Source: Compilation of authors*

According to Hair et al. (1998), as a rule of thumb, the sample size should be greater than or equal to 100 and the smallest sample should have the desired ratio and  $n = 5*k$ , where  $k$  is the number of observed variables equivalent to the number of questions studied. On the other hand, according to Roger (2006) the minimum sample size applied in practice research is 150-200 observations. Thus, this study has 34 observations so the minimum sample size is  $38*5 = 190$ . To ensure the representativeness of the study, the team tried to collect the largest number of questionnaires possible. Quantitative research was conducted immediately after with a sample size of 750 from managers and employees at 32 enterprises, including 06 textile and garment enterprises, 03 fishery enterprises; 05 Electronic enterprises; 09 Commercial banks; 06 Information Technology Enterprises, 03 Telecommunications Companies. These enterprises are in Hanoi, Bac Ninh, Nam Dinh, Thai Nguyen, Bac Giang, Hai Phong, Nghe An, Hue, Da Nang, Nha Trang, Ho Chi Minh City, Dong Nai ... in Hanoi, Bac Ninh, Da Nang, Ho Chi Minh City. The period is from 1/08/2022-1/09/2022. Reach survey subjects in 2 ways: (i) Send surveys designed on Google doc to email addresses of employees and managers at enterprises; (ii) Send the survey directly to employees and managers at enterprises. Then 671 votes were obtained after screening the answer sheets, eliminating 46 invalid votes (due to lack of information) and the remaining 625 valid votes used by the author group to enter and process data. The survey data is then imported into an Excel file, then analyzed the data using SPSS 26 and AMOS version 24 software. Specifically, SPSS software is used for descriptive statistical analysis, reliability analysis of Crobach's Alpha scale, AMOS software is used for EFA, CFA factor analysis, SEM linear structure analysis, Bootstrap test.

## 4. RESEARCH RESULTS

### 4.1. Characteristics of the study sample

Out of 625 questionnaires collected from 32 Vietnamese enterprises, 54.88% were female, 45.12% were male; In terms of age, respondents were mainly between the ages of 35-45 years old, accounting for 52.16%, while the age group from 23-35 years old accounted for the remaining 35.84% and over 45 years old. Thus, the main subjects of the investigation are managers and employees who have working experience and are quite knowledgeable about the factors affecting green innovation, competitive advantage, and operational efficiency in Vietnamese enterprises. in the digital environment; Regarding the level of survey subjects, mainly university and postgraduate is 58.88%. Thus, most of the survey subjects are qualified to deeply understand the factors affecting green innovation, competitive advantage, and operational efficiency in Vietnamese enterprises in the digital environment; Regarding the working position, the survey results show that 19.04% of respondents are managers and 80.96% of respondents are employees. In particular, employees will be the main subjects of green innovation, along with that, managers will also assess the factors affecting green innovation, competitive advantages, operational efficiency, in enterprises. Vietnam; Regarding the type of enterprises, the survey showed that 19.52% are large-scale enterprises, 80.48% are small and medium-sized enterprises. This is consistent with the characteristics of Vietnamese enterprises in the digital environment, mainly small and medium sized enterprises.

**4.2. Check the reliability of the scale**

According to Nguyen Dinh Tho & Nguyen Thi Mai Trang (2009): “The purpose of the scale analysis is to see if the scale has discriminatory value and reliability. The scales are evaluated through the main tool which is Cronbach’s Alpha coefficient. Before conducting EFA factor analysis, we will use Cronbach’s Alpha reliability coefficient method to eliminate some inappropriate variables. When evaluating the reliability of the scale, it is necessary to satisfy: Select the scale when the reliability Alpha is greater than 0.6. The larger the alpha, the higher the intrinsically consistent reliability”; Hoang Trong and Chu Nguyen Mong Ngoc (2005) research: “The value of Alpha: greater than 0.8 is a good scale; from 0.7 to 0.8 are usable; from 0.6 or more can be used and the observed variables have small variable-total correlation coefficient, specifically less than 0.3”. Thus, the reliability of the scales JR, TD, ER, CI, OE, SD satisfies the requirements used for EFA factor analysis (see Table 2).

**Table 2. Cronbach’s Alpha coefficient of the scales**

	Element	The number of observed variables remaining	Cronbach’s Alpha	Total variable correlation coefficient (minimum-maximum value)	Number of variables eliminated
1	CN	7	0,857	0,423; 0,692	2
2	TC	6	0,825	0,521; 0,637	1
3	MT	7	0,802	0,435; 0,616	1
4	DM	7	0,859	0,496; 0,655	1
5	LT	6	0,778	0,437; 0,693	2
6	HQ	6	0,826	0,412; 0,628	1

Source: Summary of results from SPSS 26 and Amos 22

**4.3. EFA exploratory factor analysis**

The criteria used when running EFA are: KMO coefficient >0.5, significance level sig <0.05, principal axis factoring extraction method with promax rotation is used and the breakpoint when extracting factors with Eigenvalue > 1 is used. use.

**Table 3. KMO and Bartlett’s Test**

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.850
Bartlett’s Test of Sphericity	Approx. Chi-Square	3896.556
	df	231
	Sig.	.000

Source: Analysis results from SPSS 26

KMO coefficient = 0.850 > 0.5, Significance level sig = 0.000 < 0.05, Data suitable for EFA factor analysis, significance level sig <0.05, so it can be concluded that observed variables are correlated with each other. Besides, the proposed factors explain 59.87% of the variables with the stopping method used with Eigenvalues reaching 3,176.

**Table 4. Pattern Matrix<sup>a</sup>**

	Factor					
	1	2	3	4	5	6
TC1	.726					
TC6	.702					
TC5	.701					
TC2	.645

MT5				.758		
MT1				.630		
MT6				.622		
MT3				.602		
CN5					.844	
CN7					.728	
LT5						.673
LT4						.568
LT6						.562

Source: Summary of results from SPSS 26

Through the first 3 regression runs, a total of 22 observations were accepted and the remaining 8 observed variables were removed, including: organization (TC1, TC6, TC5 TC2, TC3), operational efficiency (HQ2, HQ3, HQ5, HQ1), green innovation (DM5, DM2, DM1, DM6), external environment (MT5, MT1, MT6), technology (CN5, CN7), competitive advantage (LT5, LT4, LT6). Observed variables: CN1, CN2, MT2, MT4, LT1, HQ4, DM4, DM7 with weight < 0.5 do not satisfy the condition, so they are excluded from the model.

#### 4.4. The results of confirmatory factor analysis CFA

Is the CFA analysis to see if the measurement model of the concepts used in the study is satisfactory? Do the scales meet the requirements of a good scale?

Steiger (1998) said that: The evaluation criteria include: unidirectionality, convergent value, discriminant value and theoretically related value. Criteria from 1 to 3 are evaluated in the critical scale model, while the theoretical correlation value is evaluated in the model". Therefore, the CFA test group with 6 factors includes 25 observed variables to consider the fit of the model with market data.

The results of CFA analysis show that this model has 194 degrees of freedom. Figure 2 shows the value of the Chi-squared index = 446,427 with a p=000 value. Other indicators: Chi-squared/df = 2.301, GFI, TLI, CFI are all higher than 0.9 (Bentler & Bonett, 1980), RMSEA = 0.050 < 0.08 (Steiger, 1998), this can be model is considered to be consistent with market data.

Evaluation of composite reliability (PC), total variance (PVC) and Cronbach's Alpha coefficient. PC and PVC must meet the requirements  $\geq 0.5$ , Cronbach's Alpha coefficient must be  $\geq 0.6$  and the total variable correlation coefficient must be higher than 0.3.

Unidirectional/monad: CFA analysis for this model has 194 degrees of freedom. Figure 2 shows the value of the Chi-squared index = 446,427 with a p=000 value. Other indicators: Chi-squared/df = 2.301, GFI, TLI, CFI are all higher than 0.9 (Bentler & Bonett, 1980), RMSEA = 0.050 < 0.08 (Steiger, 1998), -> This gives us the necessary and sufficient conditions for the set of observed variables to be unidirectional (Steenkamp & Van Trijp, 1991).

Convergence value: For the weights (normalized) all > 0.5, it proves that the scale of concepts all achieve convergent value (if there is any observed variable with weight < 0.5, it is necessary to turns out but this model is not available)

Discriminant value: The correlation coefficient between the research concepts in the model is positive and < 1 and different from 1 (based on the above table), the P-value is very small and < 0.05, so The correlation coefficient of each pair of concepts is different from 1 at the 95% confidence level. Therefore, the research concepts in this model have gained discriminant value.

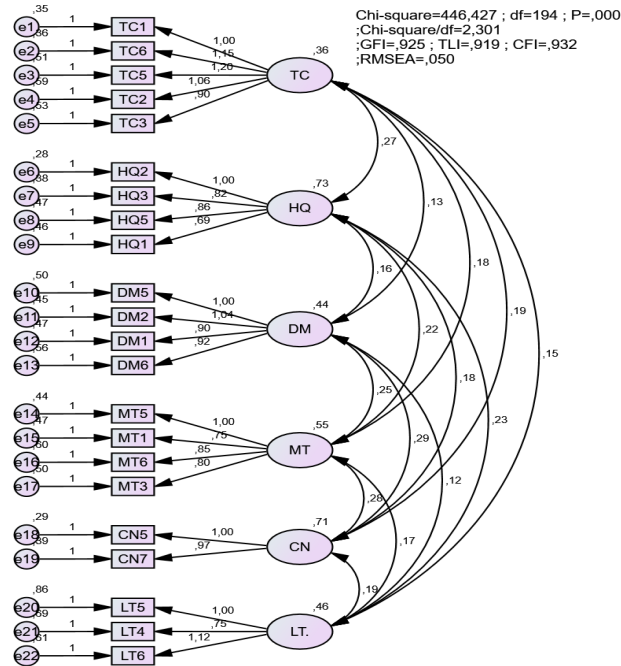

Figure 2. Confirmatory factor analysis (CFA) results (normalized)

Source: Synthesized results from the analysis of SPSS 26 and Amos 24

#### 4.5. The results and suppositions of the study

The results of the SEM model analysis of regression weights for THE elements TC, HQ, DM, MT, CN, are all of a statistical significance of 5%. However, LT’s regression weight of more than 10% does not meet the requirement. Thus, the SEM model analysis revealed that there are factors such as organization, technology and an external environment that impact green innovation of Vietnamese enterprises in the digital environment. These factors are statistically significant at 95% reliability. The regressive weights of the above table all bear positive marks that show the organization, technology and external environment concepts, and co-dimensional influence on green innovation at Vietnamese enterprises. In addition, green innovation impacts competitive advantage and performance within Vietnamese firms. These elements in the model explain 59 percent of the variation in variables that depend on green innovation, competitive advantage, and performance at Vietnamese businesses in the digital environment.

Table 5. Regression Weights

		Estimate	S.E.	C.R.	P	Label
DM	<--- TC	,496	,078	1,273	***	
DM	<--- MT	,450	,127	3,547	***	
DM	<--- CN	,216	,056	3,723	***	
LT.	<--- DM	,404	,081	5,017	***	
HQ	<--- DM	,389	,086	4,523	***	
HQ	<--- LT.	,365	,083	4,629	,203	

Source: Summary of results from SPSS 26 and Amos 24

The first SEM model analysis showed that the value of the chi-squared index = 550,532 for P =,000. The other indicator is: Chi-square/DF = 2.753, GFI, TLI are all higher than 0.9 (Bentler & Bonett, 1980), RMSEA = 0.058 < 0.08 (Steiger, 1998) has a set set of conditions: E1 - E5, E2 - E3, E2 - E5, E11 - E12, E11 - E15, E14 - E16, E15 - E17, E15 - E17. The final CFA result of the scale model was shown in FIG 4.2. This model has 270 degrees of freedom. Figure 3 shows the value of the chi-squared indices = 436,635 for p =,000. The other quackage: Chi-square-Df = 2,298, GFI, TLI, CFI are all 0.9 (Bentler & Bonett, 1980), RMSEA = 0.050 < 0.08 (Steiger, 1998), which inferred to be a model that would be consistent with market data.

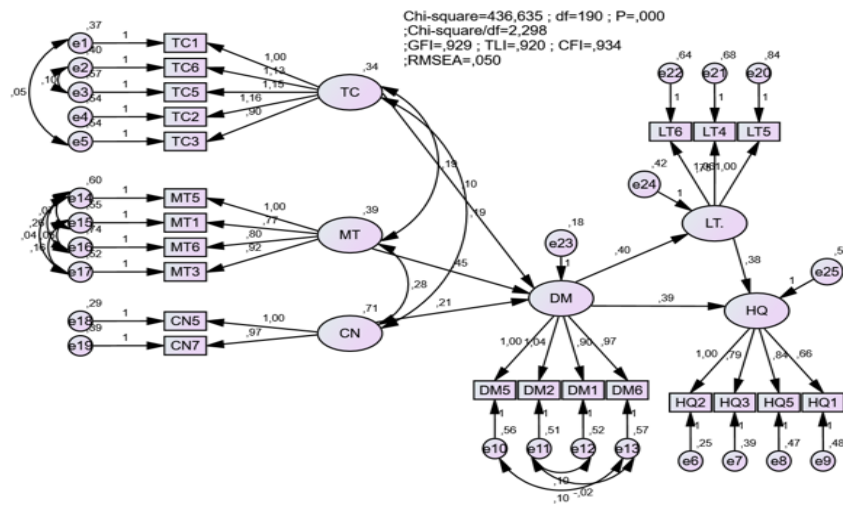

Figure 3. Results of analysis of Linear structure model SEM (Normalized)

Source: Summary of results from SPSS analysis and Amos 22

The study found that 5/6 of the initial hypothesis was accepted and that factors such as the most influential organization, the second and final external environment were the technological factors. The normalized SEM model is shown below (figure 3). The linear regression equation for factors affecting green innovation at Vietnamese enterprises in the digital environment is as follows:

$$DM = 0,496.TC + 0,450. MT+ 0,216. CN$$

4.6. Test Model using Bootstrap Analysis

Schumacker & Lomax (2010) stated: “To evaluate the reliability of estimates, in quantitative sampling methods we would typically divide the sample as two subtypes. Another way is to repeat the study with a different sample. Both of these approaches are often impractical because the structural method often requires large samples, so it is time - and - cost.” In such cases Bootstrap is the appropriate alternative (Schumacker & Lomax, 2010) for the original n = 625 sample, the Bootstrap is an alternative method for repeated sampling, with the initial crowdcasting of 1000 and more.

Table 6. Testing Bootstrap

Parameter	SE	SE-SE	Mean	Bias	SE-Bias	CR
DM <--- TC	0,116	0,006	0,103	0,004	0,008	0,500
DM <--- MT	0,177	0,009	0,476	0,015	0,012	1,250
DM <--- CN	0,081	0,004	0,2	-0,010	0,006	-1,667
LT. <--- DM	0,143	0,007	0,424	0,020	0,015	1,333
HQ <--- DM	0,172	0,009	0,428	0,009	0,012	0,750
HQ <--- LT.	0,107	0,005	0,367	-0,007	0,008	-0,875

Source: Summary of results from SPSS 26 and Amos 22

As such, the table shows: “The Estimate is normal with the method of maximum trends in ML the remaining columns being calculated from the Bootstrap method. The Mean column gives an average of Bootstrap estimations. Bias (deviation) is equal to the Mean column minus Estimate column. Composite reliability columns self - Excel by sharing the LATTER - Bias column by the SE - Bias column. In view of the above table, it is found that the absolute rule of CR is small compared to 2, so it can be said that the deviation is very small, not statistically significant, to 95% confidence “=> Estimates in the SEM model are reliable.

## **5. DISCUSS THE FINDINGS AND SUGGEST A NUMBER OF SOLUTIONS**

From the linear regression equation represents the relationship of factor affecting green innovation, competitive advantage, operational efficiency, at Vietnamese businesses in the digital environment. Among other factors, the most powerful organizational factor is 0.496, followed by an external environmental factor of 0.450 and technology factor of 0.216. H1, H2, H3, H4, H5 are all accepted and H6 is rejected. This result is consistent with the study by some authors that externality, environment, and technology (Lai et al., 2003; Wen and Chen, 1997, Chen 2008 and Chen et al. 2006, Pham Anh Nguyen, 2022. In addition, green reform impacts on competitive advantage, operating efficiency at Vietnamese enterprises. Indeed, Vietnamese enterprises in the digital environment are taking green innovation seriously at Vietnamese enterprises. This is evidence that promoting green innovation, competitive advantage and operational efficiency at Vietnamese enterprises has helped their human resources “shift from volume to substance” in the development of digital economy and sustainable development in the new context. As a result of quantitative research and data research collected, some of the key implications for enhancing green innovation are:

### **5.1. Organizational solutions**

For businesses that innovate green in the digital environment are replicated and diversified in many different fields such as: innovating green business models, developing green business strategies, innovating green products, using resources efficiently and producing cleaner, Greening supply chains, greening logistics systems, green procurement, building green brands... Therefore, in order to effectively promote green innovation in Vietnamese enterprises, it is necessary to: Strengthening financial capacity, human resources as well as green innovation is a basic and vital requirement for the development of enterprises; Focus on renovating organizational management for sustainable development; Promote corporate culture, business ethics, social responsibility. Along with that is green innovation on the basis of advanced technology, creating a core factor for competition and sustainable development.

In order to effectively innovate green in the digital environment, Vietnamese enterprises need to implement digital transformation in human resource management according to the innovation competency framework including 7 groups of competencies: (i) Improving the efficiency of equipment and software operation with the operation of digital equipment, operate digital software and services; (ii) Optimizing information and data extraction with identification of information needs, information search, information evaluation, management of information storage and use; (iii) Innovate communication and cooperation in the digital environment with communication of behavioral norms, understanding the public, effective community participation, exercising rights and services through digital platforms, behaving in the network environment in accordance with ethical and legal standards; (iv) Improve digital safety and wellbeing with digital footprint control, digital identity and privacy protection, digital security maintenance, and environmental protection; (v) Green innovation with innovative thinking practices in the digital environment, creating digital content, applying legal foundations in building and developing digital content, participating in the process of building and developing applications on digital platforms; (vi) Innovating ways to practice and develop digital skills,

recognizing trends and opportunities of online training, digital learning, however open to learning resources; (vii) Solutions to use digital competencies for careers with the use of digital technology for specific jobs, identification and evaluation of specific content and data, use of technology in green innovation.

### **5.2. Solutions for the external environment**

To affirm the importance of green growth in national sustainable development, on the eve of COP 26, the Prime Minister approved the “National Strategy on Green Growth in the period of 2021-2030, vision to 2050” in Decision No. 1658/QĐ-TTg, dated October 1, 2021, in which, setting out the goal of promoting economic restructuring associated with renovating the growth model, to achieve economic prosperity, environmental sustainability and social justice; towards a green economy. The Government has specific priority policies: “Enterprises develop human resources and green jobs, Vietnam encourages the development of human resources for green industries, creating green jobs; attach importance to training and fostering knowledge, skills in governance and administration in the green economy, green production and green innovation for public administrators and enterprises, especially focusing on leaders, managers and policy-makers”

According to CIEM (2020): “The Government needs to create policies to adjust social security and train green human resources to apply AI education technology and information technology infrastructure, develop action plans for internet development combined with artificial intelligence; launching Vietnam’s green innovation strategy with Industry 4.0, digital economy in which people are used as the core. With the main directions are Big Data technology, network system platforms, artificial intelligence and conducting research investment in key scientific projects, universities and research centers work closely with businesses to put green innovation projects into practical application”.

### **5.3. Technology solutions**

Enterprises focus on regularly organizing short-term training programs on green innovation in general as well as digital transformation, digital skills to promote green innovation for the workforce in their businesses, specifically:

Leaders need to attach: “Training digital transformation knowledge, digital skills to promote green innovation in businesses, including management contents in the digital age, accessing digital markets and digital customers, analyzing data to make appropriate decisions and calculating green products, Green services meet customer needs, organize production activities, provide services, optimize costs, manage smart finance, manage customer care continuously, maintain commitment, improve the quality of products and services, expand markets to promote green innovation”.

Target technical staff: Training on digital transformation, digital skills to promote green innovation in enterprises, steps to implement digital transformation. Digital technology (AI, Blockchain, BigData, Cloud Computing Service) how to apply, and governance in enterprises promotes green innovation.

Workers need to focus: “Information and data literacy promotes green innovation; Digital communication and communication skills promote green innovation; Skills in creating digital content/products that promote green innovation; Skills in data protection in the digital environment to promote green innovation; Skills in handling situations, how to fix them, and finding help in cyberspace promotes green innovation.”

### **5.4. Promote green innovation capacity in the use of AI and cloud computing to enhance competitive advantage and operational efficiency**

Artificial Intelligence (AI): Ministry of Science and Technology (2020) said that “Businesses need to promote green innovation by harnessing the power of AI artificial intelligence to process and analyze this huge volume of data to extract actionable insights and provide a better customer experience, improve

operations and increase revenue through new products and services, increasing the competitive advantage of businesses.” Thus, AI with the ability to help manage, optimize and maintain at the same time infrastructure and customer support activities, applying artificial intelligence to promote green innovation in enterprises.

Cloud computing and cybersecurity need to be taken seriously: “Promoting green innovation to improve internal efficiency, cloud computing technology enables the transition from a product-based model to a service-based model. The software-based service model can apply the features of existing Vietnamese enterprise infrastructure, to manage transactions and services, bringing significant benefits in terms of flexibility, delivery time, and reduced operating costs.” From here, Vietnamese enterprises also need to promote green innovation in terms of security and security.

## 6. CONCLUSIONS

The research results show that the factors affecting green innovation in Vietnamese enterprises in the digital environment are technology, organizations and the environment. In which the organizational factor has the strongest impact. In addition, green innovation also affects competitive advantages and operational efficiency in Vietnamese enterprises. At the same time, the study also proposes a number of policy implications for managers at Vietnamese enterprises to enhance green innovation to promote competitive advantages and operational efficiency at Vietnamese enterprises in the digital environment. However, historical research.

Using data from 625 questionnaires from Vietnamese enterprises, the survey of the study sample has not really been covered.

## STUDY OF FACTORS AFFECTING TOURISTS' SATISFACTION IN SAPA, LAO CAI

**Author: Pham Thi Huyen Diep<sup>1</sup>, Tran Thi Tuyet<sup>1</sup>, Nguyen Duy Uyen<sup>1</sup>**

**Mentor: Hoang Thi Thu Trang<sup>1</sup>**

**ABSTRACT:** *This study was conducted to assess the satisfaction of tourists in Sapa, Lao Cai. Based on survey data of 247 tourists, the study model was validated through regression analysis. The results show 4 factors has a positive impact on tourists' satisfaction in Sapa, Lao Cai include: (1) Service prices, (2) sightseeing environment, (3) Natural attractiveness, (4) Destination accessibility. In which, the factor considered by customers to have the strongest impact is destination accessibility. The results of this study contribute to helping managers and businesses understand the factors affecting tourists' satisfaction in Sapa, Lao Cai. From there, the research team gives suggestions to help tourism businesses improve business efficiency in tourist destinations Sa Pa, Lao Cai in the near future.*

**Key words:** *factors affecting; tourists' satisfaction; Sapa, Lao Cai.*

### 1. INTRODUCTION

The tourism industry plays an increasingly important role in creating positive changes for Vietnam's economic, social, cultural and international integration development. In recent years, Northwest tourism has developed strongly, attracting tourists with many different types of tourism. With the advantage of close proximity to the border, diverse national culture, as a key locality of Lao Cai tourism, Sapa has emerged as an ideal land for those who are passionate about exploring and relaxing tourism, this place attracts millions of tourists every year. In order to promote the development of the tourism industry as well as attract more visitors to Sapa as well as Vietnam's tourist resorts, it is important to focus on improving tourist satisfaction.

Sapa is a highland district of Lao Cai province. This place with abundant natural resources, both majestic and dreamy, cool climate all year round, diverse unique culture of ethnic minorities in the Northwest. Sapa has become one of the world's leading destinations, attracting a large amount to the domestic and international tourist market. According to statistics of the Vietnam National Administration of Tourism, the number of tourists to Sapa is constantly increasing after the Hanoi - Lao Cai expressway system and Sun Group's Fansipan cable car project came into operation from the end of 2015.

However, after two years of the impact of the Covid-19 pandemic, tourism was restored, Sapa welcomed a large number of tourists back, leading to many overcrowding conditions, insufficient conditions of facilities compared to the current situation. Along with that, the quality of service has decreased, the professionalism is not high, it does not meet the needs and desires of tourists, the general intangible reduces the satisfaction of tourists with the destination, the rate of tourists returning decreases. The restrictions manifest themselves in the types of tourism in tourist areas such as accommodation, dining, sightseeing and relaxation.

The satisfaction of tourists with a destination is always a topic that receives a lot of attention from researchers not only in Vietnam but also in the world. In terms of aspects of satisfaction, there are three related issues that are mentioned and the most studied are studies on service quality; research on the overall level of tourists' satisfaction; research on tourists' satisfaction at a destination.

---

<sup>1</sup> Faculty of Hospitality - Tourism, Thuong Mai University

The famous study by Thuy Huong Truong and Brian King (2009) “An evaluation of satisfaction levels among Chinese tourists in Vietnam” (2009) was also explored by the research team. What is new about the study is that there is a comparison to assess the importance of different destination attributes to traveler satisfaction. The authors also found that travelers’ perceptions of destination behaviors supported predictions of satisfaction of loyalty to a destination.

At the same research site, authors Bui Thi Thanh Huong and Lorna T. Grande (2022) also conducted a study on Sa Pa, Lao Cai with the topic “Tourists’ Satisfaction and Behavioral Intention in Eco-Tourism Sites of Sa Pa (Lao Cai Province)”. The study is mainly conducted on ecotourism here, although the study has clearly identified the factors affecting Sapa ecotourism and their behavioral intention to travel to eco-tourism destinations of Sapa for the Year 2020. The study recommended the following policy recommendations to improve the service of Eco tourism destinations in Sapa about Ecosystem health and cultural attraction; Amenities; Accommodation, food, people, safe and security and some other policy recommendations.

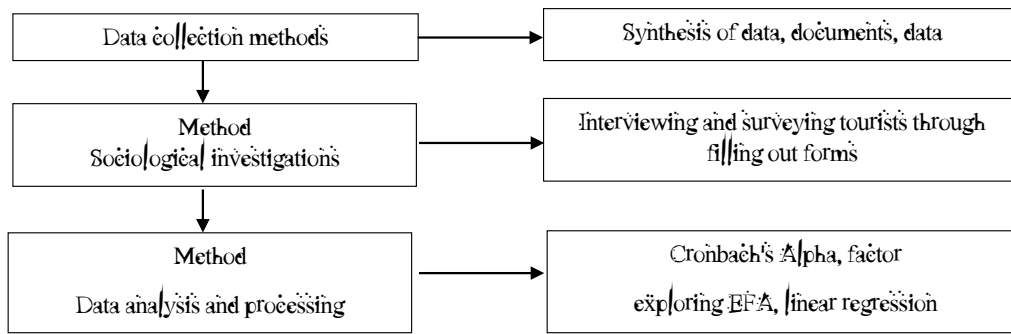

For the study in the Northwest region, author Nguyen Cong Vien in his research pointed out that the quality factors of community tourism destinations affecting the satisfaction of community tourists are: sightseeing environment, infrastructure, price, indigenous culture, natural attraction. While the magnitude of the impact factors varied, they were all positive and statistically significant factors for this study. Sapa is also one of the locations in the Northwest, so the elements of the research by author Nguyen Cong Vien are absolutely necessary for the research topic of the group.

Another study with a specific study location is Ta Xua, Ta Xua commune, Bac Yen district, Son La province, the research team built from the models of John et al. (1998), Pizam et al. (1978), and Hoang Trong Tuan (2015) and adjusted into 5 elements (according to Sharron 1997’s view): (1) accessibility; (2) the attractiveness of tourism resources; (3) amenities; (4) accommodation; (5) attitude (awareness); (6) Safety. The authors found that there are two factors in which visitors are not satisfied, making the satisfaction of tourists with the destination low. Considering that the factors are of great importance, but in terms of the “Security and safety” factor in practice, the research team learns through the actual situation that the level of safety in Sa Pa, Lao Cai is always guaranteed in the best way. Local authorities always coordinate with mass departments to proactively come up with drastic solutions to ensure security, safety, friendly and hospitable people in Sapa, so this factor can be removed from the research topic.

An overview of national and international studies, studies with different approaches and the application of different methods to understand the factors affecting tourist satisfaction. Many works compare the importance of attributes of destinations with tourists’ satisfaction to create novelty for research. However, previous studies have only been conducted on ecotourism examples and have not really comprehensively assessed the satisfaction of tourists in Sa Pa, Lao Cai. For tourism businesses in Sa Pa, there should be a study to show the influence of factors on tourist satisfaction. And through that, this study makes suggestions to better exploit factors to improve tourist satisfaction in the next time.

## **2. METHODOLOGY**

Quantitative research methods are used to validate research scales and models. The scales are evaluated through the following tools: Cronbach’s Alpha confidence coefficient test; exploratory factor analysis (EFA) and descriptive statistics, regression analysis.

**Fig.1: Research process**

In terms of sample size, the concept of “representativeness” or “sample size” is based on a minimum sample size ratio of 5:1. According to Hair & ctg (2006), the minimum sample size is 50, the ratio of observations/items is 5:1, meaning that a measurement variable needs a minimum of 5 observations, preferably a ratio of 10:1 or more. The scale of this study has 21 variables, so the minimum number of observations (votes answered) is  $21 \times 5 = 105$  observations. However, with a scientific topic, to ensure more objectivity and accuracy, the research team issued 260 questionnaires. In particular, the research team distributed 210 vouchers for domestic tourists and 50 vouchers for international tourists. The reason why the research team collected mainly domestic tourists and only 1 part of international tourists is because Sapa is mainly a domestic tourist destination, so it attracts many domestic tourists. Moreover, this is a topic of student scientific research, the ability of the research team is limited, so it is natural to mainly choose domestic tourists. If more international visitors are collected, it may bring many difficulties and inadequacies to the research team.

The research team sent Google Forms links to tourists who have come to Sapa through communication channels, groups on Facebook forums, Tik Tok. Travelers respond to the survey by filling out the information directly on Google Forms. With the secondary data, the team used meta-analysis and systems analysis methods.

### 3. RATIONALE

#### 3.1. The concept of satisfaction and tourists’ satisfaction with a destination

There are many concepts of satisfaction, each researcher has different concepts and definitions. According to Kotler (2001), “Customer satisfaction is the degree to which a person’s sensory state stems from comparing the results obtained from the consumption of the product/service and the expectations of the customer.” As authors Yang & Peterson (2004) and Chen & Tsai (2008) once mentioned, customer satisfaction is a concept that measures all levels of satisfaction that customer has with the organization providing the service after all interactions and interactions with the customer.

After all, according to research and inherited from previous studies, the research team thinks that satisfaction is an internal emotional state, determined on the basis of customers’ objective assessment of the realities of experience compared to their expectations when using the service, The better the quality of the experience, the more satisfaction is valued.

Tourists’ satisfaction is the difference between the expected and perceived value that tourism products have impacted on a traveler’s emotional state (Yoon & Uysal, 2005). Chen and Tsai (2007) affirm tourists’ satisfaction as the positive perception or feeling that travelers have when engaging in leisure and leisure activities and is indicated by the level of enjoyment from those experiences.

From the above-mentioned concepts, the team approaches the concept of tourists’ satisfaction as the perceived value of tourist expressed by the level of satisfaction gained when participating in tourism activities organized in the destination.

### 3.2. The relationship between destination quality and tourists' satisfaction

Tourists participating in tourism activities often have the opportunity to have access to many different services in a destination and therefore it is quite complicated to assess the perception of the quality of service (Marcjanna Augustyn, Samuel K. Ho, 1998). Therefore, researchers often use the concept of "Destination Quality" to indicate the attributes of services introduced by service providers in a locality, namely: The quality of roads, airports, ports, hotels, restaurants, bars, communication systems, etc parks, amusement parks, sports activities, museums, historical sites, safety levels, political stability, commodity prices, air environment, weather, noise pollution, traffic congestion. Meanwhile, when researching tourism in mountainous provinces, in addition to the destination service quality components mentioned above, factors belonging to mountainous tourism resources also play a very important role in creating destination attractions and attracting tourists back.

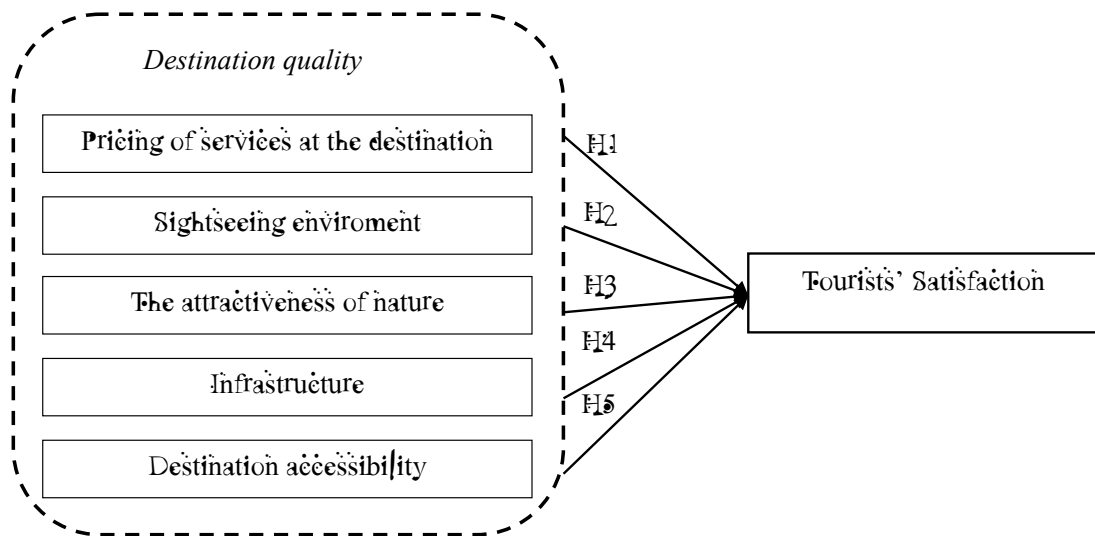

The study by Baker et al. (2000) looked at the correlation between destination quality and visitor satisfaction in the context of visitors participating in festivals. The authors' analysis indicates that perceived quality has a strong impact on visitor satisfaction. However, most studies only approach the concept of the general perceived quality of travelers towards destinations without examining the various components of destination quality and visitor satisfaction. The study by Lee et al. (2004) explores the relationships between service quality and satisfaction, and their effects on behavioral loyalty among primary forest visitors. They found that service quality is a direct influence on satisfaction and that satisfaction plays an intermediary role between service quality and behavioral intent. Furthermore, quality of service was also found to have a direct effect on behavioral loyalty. Thus, the authors concluded that the impact of quality of service on behavioral intent is as important as the impact of satisfaction on behavioral intent. In addition, several other studies in the field of tourism have shown that traveler satisfaction is measured by their perception of the components of destination quality (Dwayne A. Baker, John L. Crompton, 2000). In addition, destination quality plays an important role in behavioral decisions including: influencing the decision-making process of destination selection, post-travel decision-making, and future behavioral intentions; such as return intent and word-of-mouth intent (Bigne and Sanchez, 2001; Chen and Tsai, 2007; Lee 2005).

Travelers' destination quality assessments can be considered primarily based on trip quality perceptions through comparisons between expectations and performance (Chen and Tsai, 2007). However, the influence of destination quality on behavioral decisions has been neglected in previous studies, with the exception of the study of Bigne et al. (2001) and Lee et al. (2005). From a marketing point of view, Lee et al. (2005) argue that individuals who rate a destination well are more satisfied and therefore share their positive experiences on websites, expressing their intention to visit again. Research into the effect of different components of destination quality on visitor satisfaction remains limited and debated. Specifically, previous studies have identified perceived quality as well as destination quality as a general concept and have a direct impact on visitor satisfaction (Crompton and Love, 1995). Meanwhile, other studies have looked at quality through a variety of components, using the SERVQUAL (Tangible, Reliable, Responsive, Reassuring, and Empathetic) service quality scale proposed by Parasuraman et al. (1988) and developed in 1991. 1993 for evaluation. For example, Bojanic and Rosen (1994) used the SERVQUAL scale in restaurant service research; Saleh and Ryan (1992) studied lodging services; Pizam et al. (2004) studied travel services in a destination (Chi and Qu, 2008). In particular, the research of Chi et al. (2008) has approached different components of destination quality such as: (1) Visiting environment; (2) The attractiveness of nature; (3) Recreational and recreational activities; (4) The attractiveness of historical sites; (5) Infrastructure; (6) Convenience in the transportation system; (7) Relaxation services; (8) Outdoor activities; (9) Quality of accommodation and

food services. However, the author considers them to be component indicators of destination quality and impact on satisfaction and loyalty without considering them as standalone components. Finally, the above studies approach the context of western culture where the development of tourism services is too modern and overexploitation of natural resources and resources for tourism development (Truong and King, 2009). While the problem in the development of Vietnam’s mountainous tourism is the close connection between development and preservation and preservation of indigenous cultural values. The question is how do you assess the effects of destination quality on visitor satisfaction? Which of the components constituting the quality of mountain tourism destinations (e.g., accommodation, catering, tours; entertainment services; shopping services; attractiveness of mountain tourism resources; indigenous culture; transportation; local people...) needs to be invested in exploitation or needs to be preserved is a matter of concern heart? Therefore, conducting research to verify whether different components of destination quality have an impact on traveler satisfaction is essential.

**3.3. Research framework and Hypothesis development**

From the previous research model and characteristics of Lao Cai tourism, the authors proposed the research model as shown below:

**Fig.2: Research framework and Hypothesis development**

Based on the research model, the team focused on the influence of factors (Fig.2) on tourists’ satisfaction in tourist areas in Sa Pa, Lao Cai. The elements in the research model are presented as follows:

Service prices: The price of travel services or the price of services at the destination is all the costs that tourists have to pay during the journey: travel costs, accommodation, accommodation, tour guide costs,... and some other expenses. Tourists will be satisfied with the tourist destination if and only if the price of services or costs that tourists spend will be commensurate with the quality of services that tourists experience. Therefore, the research team proposes this factor into the research model of the topic.

Sightseeing environment: Sightseeing environment or tourist environment is an environment consisting of natural, socio-economic and human factors, including the existence and development of tourism activities. Nguyen Trong Nhan (2013) said that “The tourist sightseeing environment is an environment that includes natural, socio-economic and human factors, including the existence and development of tourism activities”. He emphasized that tourism has a close relationship with the sightseeing environment at the tourist destination. The characteristics and elements of the sightseeing environment are optimally utilized, serving tourism

activities such as attracting tourists and developing the tourism economy in that destination. On the contrary, tourism activities also contribute to the reciprocal impact on the visiting environment, changing more or less the existing characteristics of the environment. Tourism activities that have a close relationship with the environment, the impact of the tourism environment or the impact of the “Sightseeing environment” factor are considered factors that have a direct impact on the satisfaction of tourists in Sa Pa, Lao Cai. Therefore, The research team proposed the element of “Visiting Environment” into the research model of the project.

Natural attractiveness: Tourism resources or all things natural and cultural values created by man. The richer, more diverse, spectacular and especially unique and strange tourism resources are, the more attractive it is to tourists, which also positively impacts the satisfaction of visitors. Rittichainuwat and Mongknonvanit (2002), “Natural attractiveness is one of the important factors for evaluating tourism resources and building the image of tourist destinations”. The team also said that the attractiveness of nature is the attraction between nature in the tourist destination for tourists. This attraction includes: the suitability of natural resources for tourism activities; material and technical foundations for tourism; capacity; the development of various types of services for tourists in tourist destinations; the diversity and uniqueness of resources for organizing various types of tourism. On the basis of inheriting previous researches, in order to improve the satisfaction of tourists in tourist destinations, the research team proceeded to propose the factor “Attractiveness of nature” into the research model of this research topic.

Infrastructure: These are facilities and technical facilities to meet the needs of not only tourists but also local people. In order to ensure tourism development in general and ensure the satisfaction of tourists in particular, the element of tourism material and technical infrastructure or the element of tourism infrastructure - “Infrastructure” needs to be invested and facilitated for development. According to Bui Thanh Thuy (2010), “Tourism infrastructure systems consist of many components, they have certain functions and implications for creating and satisfying tourists. In order to improve the quality of destinations, tourist attractions need to build corresponding tourism infrastructure such as hotels, restaurants, canteens, shops, petrol supply stations, health stations, sports venues ...”

Destination accessibility: Pham Hong Long, Phan Thi Quynh (2020) mentioned accessibility which is the level of ease and convenience to reach the destination through the transportation system, different means of transportation. Or it can be roughly understood that a tourist destination must be convenient for visitors to access by many types of transportation. It is the level of ease and convenience that tourists can reach the destination through the transportation system, various means of transportation,... No matter how attractive and attractive a destination is, but the problem of accessing the destination is still difficult, tourism activities will not be exploited and developed in the best way. The development of “destination accessibility” contributes to improving tourists’ satisfaction with the tourist destination. Therefore, the research team proceeded to propose the “Destination Accessibility” factor into the research topic.

Based on the theoretical overview and research model, the hypotheses proposed are as follows:

Hypothesis H1: Service prices have the same impact as tourists’ satisfaction in Sa Pa, Lao Cai.

Authors Muchapondwa & Pimhidzai (2011), Pham Hong Manh (2009), Croes (2000), Uysal & Crompton (1984), Loeb (1982), Stronge & Redman (1982) and Archer (1980) identify cost factors that affect travel demand. So, the more reasonable the cost, the more demand for tourism increases, thereby creating the satisfaction of tourists for the destination. (Tosun and Timothy, 2013).

Hypothesis H2: The sightseeing environment has the same impact on tourists’ satisfaction in Sa Pa, Lao Cai.

The authors Bui Thi Hai Yen (2010), Nguyen Trong Nhan (2013) all commented on the sightseeing environment with a close relationship with tourism activities. Tourism activities have an impact that changes the characteristics of the environment, and the more attractive the visiting environment, the more satisfaction will be created for tourists by increasing the quality of the destination.

Hypothesis H3: The attractiveness of nature has the same effect as tourists' satisfaction in Sa Pa, Lao Cai.

The richer, more diverse, spectacular and especially unique and strange tourism resources are, the more attractive it is to tourists, which also positively impacts the satisfaction of visitors (Pham Hong Long, Phan Thi Quynh, 2022). In research, the attractiveness of nature includes landscapes, landscapes, biodiversity,...

Hypothesis H4: Infrastructure has the same impact on tourists' satisfaction in Sa Pa, Lao Cai.

Infrastructure has always been important in the development of the national economy as well as the development and improvement of service quality. The infrastructure element meets the needs of tourists, the satisfaction of tourists will be enhanced. "In order to ensure the improvement of destination quality, tourist attraction needs to build corresponding tourism infrastructure such as hotels, restaurants, canteens, shops, petrol supply stations, health stations, sports venues ..." (Bui Thanh Thuy, 2022).

Hypothesis H5: Destination accessibility has the same effect as tourists' satisfaction in Sa Pa, Lao Cai.

A highly rated travel destination not only stops at the above factors, but it is also judged through the accessibility of a destination. If visitors have difficult access to tourist destinations, of course, the level of satisfaction of visitors will be affected. Accessibility is of particular importance to the decision on point selection come because it affects the time, distance, and cost of the trip (Chi and Qu, 2008)

## **4. RESULTS AND DISCUSSION**

### **4.1. Results of analysis of research models**

#### **4.1.1. Sample descriptive statistics**

In terms of age, visitors aged 18 to 25 accounted for the largest proportion with 58.7%; the age group from 26 to 45 years accounted for 34.8%; Under 18 accounted for only 1.2%.

In terms of gender, there were 122 fill-in ballots for female respondents and male respondents for 50.6%.

In terms of income, the majority of tourists here have quite high incomes, specifically visitors with incomes from 10 million to less than 20 million accounting for the majority with 37.2%, followed by tourists with incomes below 10 million at 30.4%, from 20 million to 30 million accounting for 18.6%, the rest visitors with incomes over 30 million.

Regarding the number of times that tourists have been to Sapa, it can be said that the demand to return to Sapa is relatively large. Because through the survey, up to 37.7% of tourists have been to Sapa 2 times, 9.7% of tourists have traveled 3 times, and 8.1% of tourists have been to Sapa more than 3 times.

#### **4.1.2. Results and dicusion**

The scale is assessed for reliability using Cronbach's Alpha coefficient. The results of the scale's reliability assessment show that most Cronbach's Alpha values are greater than the required value of 0.65 (table 1). Cronbach's Alpha values if the variable type are all lower than Cronbach's Alpha values. The total variable correlation values are all greater than 0.3. Therefore, the scales used are highly reliable.

**Table 1: Cronbach's Alpha Coefficient**

Factor	Number of observed variables	Cronbach's Alpha
Service prices (PRI)	5	0.748
Sightseeing environment (ENV)	4	0.844
The attractiveness of nature (ATT)	4	0.774
Infrastructure (INF)	4	0.833
Destination accessibility (ACC)	4	0.724
Tourists' satisfaction (TS)	3	0.730
Sum	24	

Next, the research team conducted EFA factor analysis. The EFA results obtained 24 observed variables that measure the extraction into 05 independent variables and 01 dependent variable, which were extracted into 06 factors as suggested by the research model with Initial Eigenvalues greater than 1. Total method The explanation error when taking the factor group is 64.934% (> 50%). Five independent variables all have the same independent factor load observation variables corresponding to the required Factor Loading value greater than 0.3.

The results of the quantitative analysis showed that corrected<sup>R2</sup> = 0.5224 and corrected R2 = 0.514 meant that 51.4% of the variation in traveler satisfaction was explained by independent variables in the study framework. In addition, the results of ANOVA variance analysis show a value of F = 66.086; the value Sig. = 0.000 (< 0.05) represents a correlation between independent variables and dependent variables that ensure reliability. As such, the research model fits the dataset and is usable. Regression coefficient result for the Sig. value of the independent variable Service Price at the destination; Visiting environment; The attractiveness of nature; Destination accessibility is equally equal to 0.000 (< 0.05). This represents variables that have an impact on Traveler Satisfaction for Sa Pa, Lao Cai. Reliability, Pricing of services at the destination; Visiting environment; The attractiveness of nature; Destination accessibility positively impacted Satisfaction (Betas received positive values of 0.283; 0.092; 0.268; 0.339, respectively). The regression equation was determined as follow:  $TS = 0.253 + 0.283 PRI + 0.092 ENV + 0.268 ATT + 0.339 ACC$

Thus, the results of multivariate regression analysis show that, of the 5 factors included in the analysis model, 4/5 factors have a positive impact on the satisfaction of tourists in Sa Pa, Lao Cai. Thus, according to the results of testing the research model, there are sufficient grounds to support the hypothesis H1, H2, H3, H5.

**Table 2: Conclusion about the research hypothesis**

Hypothesis	Content	Result Accreditation
H1	Hypothesis H1: Service prices have the same impact as the satisfaction of tourists in Sa Pa, Lao Cai	Accept
H2	Hypothesis H2: The sightseeing environment has the same impact on the satisfaction of tourists in Sa Pa, Lao Cai	Accept
H3	Hypothesis H3: The attractiveness of nature has the same impact on the satisfaction of tourists in Sa Pa, Lao Cai	Accept
H4	Hypothesis H4: Infrastructure has the same impact on Tourists' satisfaction in Sa Pa, Lao Cai	Not accepted (Due to variable type)
H5	Hypothesis H5: Destination accessibility has the same impact on Tourists' satisfaction in Sa Pa, Lao Cai	Accept

With the obtained linear regression model, it can be concluded that:

The factor that has the strongest impact on tourist satisfaction is the accessibility to the destination (0.339). The main reason is that recently the transportation system has been improved, tourists can easily access the tourist destination Sapa.

The next factor is the price of the destination with a beta of 0.283. Because in recent times, the price management of this destination is quite good. Service providers shall publicize their prices and have pricing methods suitable to the quality of services provided.

The attractiveness of nature is also one of the factors considered to have a large influence, with a beta coefficient of 0.268. Although it is one of the tourist destinations exploited early, it can be said that SaPa is still an attractive destination in terms of nature.

The sightseeing environment has the smallest impact on tourists' satisfaction with a beta coefficient of 0.092. Thus, this is a factor that has been accepted by tourists and does not change the satisfaction of Sapa tourists.

On the other hand, descriptive statistics the observed variables, the research team obtained the following results in table 3. Through the above summary table, it can be seen that visitors have different feelings, but most of the satisfaction of tourists is rated at a fairly high level. Travelers in Sa Pa, Lao Cai are most satisfied with the factor "Attractiveness of nature" (average score of 4.31 on the Likert scale of 5 points), satisfaction with "Destination accessibility" at a relatively high score of 4.04 points, followed by "Sightseeing environment" with 3.92 points and "service prices" with 3.91. Tourists' satisfaction was lowest in terms of "Infrastructure" with 3,87 points. The results of the descriptive analysis are a good sign for the tourism business units in Sa Pa, because the major influencing factors are being highly appreciated by tourists.

**Table 3: Descriptive statistics on the level of tourists' satisfaction with the factors of the destination Sa Pa, Lao Cai**

Variables	N	Lowest	Highest	Average
Service prices	247	1	5	3.91
Sightseeing environment	247	1	5	3.92
The attractiveness of nature	247	1	5	4.31
Infrastructure	247	1	5	3.87
Destination accessibility	247	1	5	4.04
Tourists' Satisfaction	247	1	5	4.10

In summary, the factor accessibility to the destination has the strongest impact of the four factors included in the model of visitor satisfaction analysis in Sa Pa, Lao Cai; Next is the service price factor; The attraction of nature is the third influencing factor and the sightseeing environment has the least impact on visitor satisfaction in Sa Pa, Lao Cai. The study has not assessed the impact of infrastructure factors on tourist satisfaction. Therefore, in order to improve tourist satisfaction, the study will give some suggestions to improve the factors that have a stronger influence on tourists.

## 5. SOME SUGGESTION

The results of the study show that travelers are still not really satisfied with some of the factors surveyed. Based on the above research results, the research team made some suggestions to improve the satisfaction level of tourists in Sapa, Lao Cai.

### 5.1. Flexibility in pricing and adjusting service prices at the destination

It can be seen that in emerging tourist destinations recently, the situation of increasing prices, arbitrarily raising selling prices is always a painful problem, causing disfavor for tourists, reducing the level of satisfaction of tourists. Therefore, in order to increase the satisfaction of tourists in Sapa, tourism businesses need to have directions to set reasonable prices. Price must go hand in hand with quality, and at the same time must be commensurate with the quality of service that tourists experience.

When there are incentives and promotions, tourism businesses can use the media to promote to attract tourists and improve revenue. Ministries and departments must regularly cooperate with local authorities to strictly handle violations of arbitrarily raising and inflating commodity prices to attract customers. Thereby creating a service space for guests, increasing visitor satisfaction.

### **5.2. Create a friendly destination environment**

In order for Sapa to become an attractive destination for tourists, it is essential to bring a green, clean and beautiful environment. Limiting the use of materials that can cause pollution and disposing of garbage in the right places are the leading solutions to this problem. Develop investment projects for the protection, preservation and development of diverse cultural traditions of ethnic minority communities, because this is the strength of Sa Pa.

It is necessary to coordinate with local authorities and construction management agencies to strictly control new construction projects, ensure they do not disrupt the environmental landscape and have adequate water and waste treatment options in accordance with environmental protection standards. Travel businesses need to understand and take responsibility for training guides as pioneers in environmental culture protection. For local communities: organize propaganda widely through mass media, talks, panels, posters, posters to promote people to understand that indiscriminate exploitation will lead to depletion of resources, directly affecting the lives of them and their descendants, damaging the long-term ecological environment at the tourist spot, leading to the degradation or even loss of the exploitability of the tourist spot.

### **5.3. Enhance the natural appeal of the destination**

Sapa is facing many problems in maintaining growth along with ensuring sustainable development. However, reality shows that Sapa develops without control, lack of sustainability makes this place gradually lose its inherent natural beauty, there are too many constructions, concrete, plastic waste leading to pollution. The rapid urbanization process makes Sapa is gradually losing ecological balance, the landscape is violated and degraded.

To increase the attractiveness of natural resources, Sapa should differentiate itself from other localities and take advantage of the available tourism potential of the town. It is recommended to add crops that are local specialties in eco-tourism areas for guests participating in the garden. Invest more in quality facilities for roads in Sapa and build a number of medical stations to support visitors when facing difficulties. There should be more plans to improve, refurbish, change and decorate holiday-themed destinations, or seasons of the year, causing excitement, newness, not being boring to attract more guests. Promote the advantages of terraced fields in the current period for socio-economic development, tourism development, strengthening cultural exchange, promoting the image of Vietnam in general and Sapa in particular to international friends.

### **5.4. Enhancing access to Sapa destinations for tourists**

Upgrade the system of roads and means of transport to create convenient and safe travel conditions for tourists. Enhance the application of science and technology, reduce costs and improve efficiency in investment in transport infrastructure construction. Regularly strengthen the quality inspection of the road surface, set convex bridge mirrors, design safety barriers; Build permanent berths and parking lots to encourage private garages to operate more conveniently. It is necessary to arrange more reasonable boards and signboards so that visitors can access the destination more easily and conveniently, avoiding getting lost, wasting time of tourists, affecting the level of satisfaction of tourists at the destination.

## 6. CONCLUSION

In general, the research results have partly shown the relationship between the influencing factors and the satisfaction of tourists in Sa Pa. Visitors' satisfaction about Sapa has contributed to promoting tourism here, creating jobs for redundant laborers in the countryside, contributing to increasing incomes and improving people's lives. However, it must be said that visitor satisfaction in Sa Pa still has some points to improve towards sustainable development in the future.

Within the scope of the research, due to limitations in time, capacity, etc. Therefore, the research only stops at determining the factors affecting the satisfaction of tourists in Sa Pa, Lao Cai. Although the research has been focused on previous documents, the research models are still limited, leading to not showing all the factors affecting tourist satisfaction. Therefore, further studies still need to add more variables in the research model, this is a further research direction of the topic.

## OPTIMAL FISHERY MANAGEMENT IN VIETNAM UNDER THE IMPACT OF CLIMATE CHANGE

**Author: Nguyen Huu Dung<sup>1</sup>, Nguyen Huyen My<sup>1</sup>, Do Phuong Yen Linh<sup>1</sup>, Ngo Thi Phuong Trang<sup>1</sup>,  
Ngo Thi Kim Chi<sup>1</sup>, Dong To Ha Phuong<sup>1</sup>**

*ABSTRACT: This study discusses how Vietnam should manage its fisheries in the face of climate change, following the three scenarios which will be discussed further in this document. Scenario 1 is described as the action of maintaining the current harvesting effort (Status Quo). Scenario 2 suggests closing the sea for fishery biomass conservation (Closure). Scenario 3 pursues the maximum economic yield in the Vietnamese fisheries (MEY). The fishery yield function is based on the sea surface temperature affected by global warming, which is expected to rise at an annual rate of 0.01°C, starting from 26.35°C, starting from the base year 2013. The bioeconomic model is used. For the model regression, secondary data for the years 1990 to 2020 were used from Statistic Bureau and World Bank data. The findings indicate that if Vietnam keeps up its current harvesting efforts (scenario 1), global warming and current fishing intensity may eventually cause the Vietnamese fisheries to collapse. In contrast, the stock may rebound if Vietnam outlaws fishing (scenario 2), but no profit will be made in the sector. The MEY (scenario 3) strategy, where both the stock and profit are positive even under the influence of global warming, is the most practical one. The execution of such a program, however, necessitates the integration of climate change mitigation policy because the unforeseen result of MEY is a decline in fish production and profit. Currently, a workable solution to rebuild the fishery ecosystem and maintain economic value can be found in the establishment of various conservation zones for fish recovery in conjunction with ongoing harvesting in the other areas under the transferable quota system and climate change adaptation institutions.*

*Keywords: fishery management, climate change, global warming.*

### 1. INTRODUCTION

Vietnam has been recognized as having significant potential for improving fisheries development and the national economy as a coastal country with more than 3260 kilometers of coastline, a number of protected bays, and other profitable natural conditions. The Vietnam Marine Strategy to 2030, with a vision to 2045, asserts that aquaculture and fishing is one of the top priorities with an aim of developing the nation's marine economy (The Central Committee of the Communist Party of Vietnam, 2018)

About 99% of the fishing boats in Viet Nam are small wooden boats, however a small number of steel and composite boats have lately been constructed in accordance with Government Decree No. 67 but comprise only a negligible number. By 2019, the number of fishing vessels was 109,762 vessels, of which 33,173 vessels had capacities of more than 90 HP and 96,827 vessels of less than 90 HP capacity (Figure 1). This indicates that small boats have a propensity to operate close to shore whereas there are very few large capacity vessels operating farther offshore. Typically, coastal fishing involves the overfishing of small, immature, and spawning fish,...easily to encroach on aquatic resources and ineffective, whereas offshore fishing along routes will result in more efficiency.

---

<sup>1</sup> National Economics University.

**Figure 1. Number of fishing vessels in Viet Nam in 2014-2019 by engine capacity**

The fishery industry generates revenue for the populace, which helps to reduce poverty. The fishing industry employs more than 4 million people, or 5.6% of all employed people in the country and 17% of all agricultural workers (General Department of Fisheries, 2020). Currently, there are around 40 different types of marine fishing gears in Viet Nam that may be divided into six main groups, including gillnet, trawl, purse seine, hook and line, stick-falling net, and others (Figure 2).

**Figure 2. Proportion of marine capture fishing gears in Viet Nam**

Recent years, the impacts of climate change influence many different elements of human and animal existence globally, of which the fisheries sector is considered the most affected (Brander, 2010). Changes in physical, biological brought on by climate change affect aquatic species' growth, reproduction, migration, and dispersion (Sumbly et al., 2021; Yasumiishi et al., 2020). Climate change indirectly impacted food intake, competitors, predators, and pathogen issues through ecosystems (Williamson & Guinder, 2021). In many places, particularly in regions with high water temperatures, climate change decreases the revenue and profits that businesses and families make from fishing activities. Cheung et al. (2009) predicted that between 2005 and 2055, the tropics' fishing potential could decrease by up to 40% as a result of climate change. Because Vietnam is a tropical country, the fisheries industry may suffer as a result of climate change. This phenomenon is still growing since the fishing business expands on its own, the regulation of fishing boats is still insufficient, and there are too many fishing boats for each sea area's fish stock size, particularly in the near-shore waters.

**Figure 3: Changes in total boat capacity and fishing productivity**

Decree 67/2014/ND-CP on supporting loans for new offshore fishing vessels, supporting fuel costs, supporting insurance, supporting to reduce post-harvest losses, supporting to overcome risks, and supporting information equipment to monitor the activities of fishing vessels at sea are a few of the policies that Vietnam has released to support and encourage offshore fishing, increasing production and aiding in the development of the offshore fishing fleet (Government, 2014).

The number of coastal ships has not dropped, nevertheless, and coastal fishing is more competitive, which lowers productivity. Fishermen frequently alter factors of the fishing process that the government cannot regulate, such as the number of boats they possess, the number of people that participate in the fishing operation, or the engine capacity. On the other hand, because of the diversity in the fisheries sector in Vietnam, the management organizations have encountered numerous challenges in determining the resources and regulating the catch by each type or different industry. The annual operational plans, five-year plans, and even plans covering more than ten years (such as the Master plan of fisheries sector) identify fishing targets based on aggregated data by water area and in accordance with administrative boundaries rather than the output of each type of fishery. Since then, there has been no discernible basis for issuing quota-based fishing licenses to ship owners and other organizations. The Fisheries Law of 2017 states that fishing will be managed and controlled with varied levels of restriction for each species, although this restriction system has not yet been implemented. Vietnam's policymakers have been looking for better management techniques and procedures to accomplish both economic and ecological objectives in this context.

## 2. THEORETICAL FRAMEWORK

### 2.1. The Bioeconomic Model

Beginning with the natural growth function, various functions have been estimated incorporating determined environmental conditions through the sea surface temperature. We have specifically estimated the most used functions in the literature on natural resource economics (Logistic, Ricker, Cobb-Douglas and Cushing function, respectively).

(1)

$$X_{t+1} = aX_t - bX_t^2 + cT_t - h_t$$

$$X_{t+1} = ae^{bX_t + cT_t} - h_t$$

$$X_{t+1} = aX_t^b T_t^c - h_t$$

$$X_{t+1} = aX_t^{b+cT_t} - h_t$$

where X denotes the fish biomass, t the time (year), h the catches, a, b and c are the parameters that collect biological information and T denotes the sea surface temperature.

In general, the functions shown in (1) result in significant parameters to the accepted levels usually found in the contrasts of statistical inference hypotheses, except for the first expression. In order to compare these expressions, we have used selection criteria of models based on the explicative capacity of the model. We have used the adjusted coefficient of determination,  $(\overline{R})^2$  (the maximum value for all of them), and the criteria based on the error prediction, the AIC Akaike statistic (minimum value for all of them).

With respect to fishing industry technology, the function usually used in the economic literature concerning fisheries is of the type Cobb-Douglas:  $H_t = \alpha X_t^{\beta_1} E_t^{\beta_2}$ , where  $\alpha$  denotes the catchability coefficient and  $\beta^1$  and  $\beta^2$  represent stock and effort elasticity, respectively.

With these premises and in a context of centralised resource management (the European Commission in our study case), the economic problem consists of choosing the total catches (h), which maximise the profits that are generated in the fishery (ph-wE) discounted at the initial moment, and taking into account the fish population growth. The bio-economic model applied to the European sardine fishery is represented by the following expression:

$$\text{s.a. } \dot{X} = \frac{dX}{dt} = X(t+1) - X(t) = aX(t)^{b+cT(t)} - X(t) - h(t)$$

$$X(t) > 0$$

$$0 \leq h(t) \leq h_{\max}$$

Using the optimum control theory (Kamien & Schwartz, 2012) for solving the above problem, the solution for the above is represented by the following expression:

(2)

$$\beta_1 A X(t)^{\frac{\beta_1 + \beta_2}{\beta_2}} (aX(t)^{b+cT(t)} - X(t)^{\frac{1}{\beta_2}} + \left( p - A X(t)^{\frac{\beta_1}{\beta_2}} (aX(t)^{b+cT(t)} - X(t)^{\frac{1-\beta_2}{\beta_2}} \right) \times (a(b+cT(t))X(t)^{b+cT(t)-1}) - \delta \left( p - A X(t)^{\frac{\beta_1}{\beta_2}} (aX(t)^{b+cT(t)} - X(t)^{\frac{1-\beta_2}{\beta_2}} \right) = 0$$

$$\text{Where } A = \frac{w}{\beta_2 \alpha^{\frac{1}{\beta_2}}}$$

From the above expression and substituting the respective parameters, the value of the sardine biomass is estimated.

One should note that these values will depend on the sea surface temperature levels (T) in each instant of time. Once the biomass has been estimated, the catch levels can be obtained from the natural growth expression and the corresponding effort level from the fishing technology expression.

## 2.2. Maximum Economic Yield Strategy

Fisheries have the potential to generate another type of income related to common (community) ownership of fishery resources, known as resource returns, which is income from fisheries after production costs and ordinary profits have been removed.

According to the above indicators, the resource returns of fisheries using a sustainable fishing model is represented by the following expression:

$$\ln(E) = TR(E) - TC(E)$$

The resource returns of fisheries is the revenue that removed all costs, therefore, it depends on the fishing effort. Assuming that the objective of fisheries management is to generate the greatest resource return, we calculate the fishing effort used to achieve this goal.

For the most efficient calculation of effort, it can be assumed that only one owner has full control over the fishery (Gordon, 1954) were the first proponents of this approaches. Necessary condition for maximum resource returns,  $\ln(E)$ .

$$\frac{d(\ln E)}{d(E)} = MR(E) - MC(E) = 0$$

Therefore, we have the following conditions to maximize resource returns:

$$MC(E) = MR(E)$$

The marginal effort cost  $MC(E)$  on the left side is the same in both rules, but the right side is different. Open-access fisheries have increased fishing effort and declining stocks until the average revenue  $AR(E)$  equals the marginal effort cost at the bioeconomic equilibrium. For maximum resource returns, fishing effort needs to be reduced to a level where marginal revenue  $MR(E)$  equals marginal cost.

Resource returns reach their maximum value when fishing with maximum economic yield, abbreviated as MEY (maximum economic yield). Reducing fishing effort relative to that of open-access fisheries can help reduce production costs or increase revenue. Fishing requires two main inputs: fishing effort and stock, as shown in the production function. In order to catch a large amount of fish, it is possible to use a lot of effort and choose a small stock of fish, or a little effort and choose a large stock of fish. From here, we distinguish between two different equilibrium points, without considering the time required to transfer from one stock level to another. The sustainable yield curve and the above analysis allow the comparison of different bio-economic equilibrium states regardless of the time dimension. From the above analysis, the low-effort and large resource reserves state is better than the high-effort and small-resource state.

### 3. RESEARCH METHOD

#### 3.1. Data collection methods

Sea surface temperatures were taken from NASA's MEaSURES program

Secondary data were collected from 2007 to 2022, from the following sources:

- World Bank data (website: <https://data.worldbank.org>)
- Intergovernmental Panel on Climate Change (IPCC)
- Directorate of Fisheries – Ministry of Agriculture and Rual Development of the Socialist Republic of Vietnam.

#### 3.2. Calculation and analysis model

##### 3.2.1. Species Growth Functions

Although the Logistics function is widely used in many fisheries economic documents, other functions can also be considered (Anderson & Seijo, 2010). Therefore, we calculated and compared four reserve populations function with integrated effects of SST (Sea Surface Temperature) to find the most realistic reserve function, including: Cobb-Douglas, Logistic, Ricker, and Cushing function summarized in Table 1.

**Table 1: Species Growth Functions of Vietnam**

	Formula		Reference
Cobb-Douglas	$S_{t+1} = mS_t^{a_1}K_t^{a_2} - Q_t + v_t$	(1)	(Diop et al., 2018)
Logistic	$S_{t+1} = mS_t + a_1S_t^2 + a_2K_t - Q_t + v_t$	(2)	(Diop et al., 2018)
Ricker	$S_{t+1} = mS_t e^{a_1S_t + a_2K_t} - Q_t + v_t$	(3)	(Diop et al., 2018)
Cushing	$S_{t+1} = mS_t^{a_1 + a_2K_t} - Q_t + v_t$	(4)	(Diop et al., 2018)

Where  $S_t$  = fishery stock in year  $t$ ;  $Q_t$ = yield at time  $t$ ;  $K_t$  = sea surface temperature (SST) at year  $t$ ;  $v_t$  is the errors, which is assumed to follow a Gaussian normal distribution:  $N(0, \sigma_5)$ ; Parameters  $m$ ,  $a_1$  và  $a_2$  represent different biological and environmental sensitivities.

Using SPSS software with time series data between 1990 and 2020 to determine the coefficients of the stock functions in Table 3.

**3.2.2. Production Function**

In this study, The Production Function used is the Cobb-Douglas function, as in (Rahim et al., 2019).

$$Q_t = nS_t^{b_1} E_t^{b_2} + u_t Q_t = nS_t^{b_1} E_t^{b_2} + u_t \quad (5)$$

Where  $E_t E_t$  = fishing effort at time  $t$ ;  $u_t$  = errors between estimated fishing yields, assumed to follow a Gaussian standard distribution; Parameter  $nn$  = fishing skills; The coefficients  $b_1$  and  $b_2$  represent the elasticity of the ability to catch  $Q_t$  tons of fishery under the condition of biomass  $S_t$  and fishing effort  $E_t$  respectively; Random variable  $u_t$  follows a Gaussian normal distribution; The level of effort is assumed to correspond to the total number of boats per year.

Using SPSS software with data from 1990 to 2020 to calculate the parameter of equation (5), if  $P > 0.05$ , the coefficient is not statistically significant, and if  $P < 0.05$ , the coefficient is statistically significant. The results are shown in Table 4.

**3.2.3. Fishing management and Climate secario**

This section finds out the optimal capture fisheries management strategy, the article calculates and compares three possible management strategies including: (i) Maintaining the status quo, (ii) Closure (promulgation of fishing ban), and (iii) Maximun Economic Yield (MEY)

The total catch depends on fishing efforts ( $E_t$ ), and fish stocks. Therefore, the first step is to calculate the natural reserve of fishery products and the production of fishery products. However, the fishery stocks studied are located in the sea, so they will be affected by the sea surface temperatures ( $K_t$ ). Then, the bioeconomic model is calculated based on the three management strategy scenarios summarized in Table 2. Since then, these management strategies are calculated under the impact of climate change affecting fishery stocks through changes in sea surface temperature.

**Table 2: Strageic scenarios of Fishery Management and the Rate of Sea Level Warming**

Fisheries management strategy	The annual rate of sea level warming is 0,01°C (minimum)
Maintaining the status quo	Management Strategy 1
Closure (promulgation of fishing ban)	Management Strategy 2
Maximun Economic Yield (MEY)	Management Strategy 3

These three management strategies were calculated in the context of climate change proposed by the IPCC. The author calculated the data based on the SST database system provided by NOAA.

## 4. RESULT AND DISCUSSION

### 4.1. Result

#### 4.1.1. Climate scenario

The following three strategies for management are estimated in the context of the IPCC's (Intergovernmental Panel on Climate Change) recommendations about climate change: Since the base year 2013 was 26.350°C, the rate of warming every year is at least 0.01°C (Solomon et al., 2007). This is the minimal global warming scenario with the highest probability (Sumaila et al., 2011). According to Sanz et al. (2017), the growth function of the fisheries will be impacted by the warming of the sea surface.

The annual change in sea surface temperature is represented by the following function:  $K_{t+1} = K_t(1 + \Delta_{min})$ , with  $K_t = 26.35^\circ\text{C}$  (the average SST temperature recorded over the most recent period, 2009–2013).

#### 4.1.2. Species Growth Functions

The results are summarized in Table 3, which utilizes the formulas in Table 1 to calculate the stock functions' coefficients using time series data for the years 1990 through 2020.

**Table 3. Estimated parameters of fish stocks**

	<b>Cobb-Douglas</b>	<b>Logistic</b>	<b>Ricker</b>	<b>Cushing</b>
$m$	.555 (0.034)	3.89 (0.527)	2.21 (0.007)	0.27 (0.648)
$a_1$	1.100 (0.007)	-3.24E-05 (0.726)	-2.33E-05 (0.631)	2.82 (0.030)
$a_2$	.468 (0.031)	-192.98 (0.372)	-0.34 (0.579)	-0.19 (0.103)
R <sup>2</sup> adjusted	0.73	0.82	0.52	0.39

Note: p-values are in parentheses

In contrast to the other functions, which do not satisfy the Cobb-Douglas function's coefficients with statistical significance ( $P > 0.05$ ), Table 3 demonstrates that the Cobb-Douglas function's coefficients are significant at the 5% level ( $P < 0.05$ ). As a result, fish production is described using the Cobb-Douglas function. The fact that the elasticity for sea surface water temperature (SST) is relatively high ( $a_2 a_2 = 0.468$ ) indicates that the effect of sea surface temperature is notable.

#### 4.1.3. Production Function

Table 4 provides the results of the parameter calculation for equation (5) following the execution of SPSS using the 1990–2020 data. The function can be utilized to represent the output of exploitation because the coefficients are statistically significant ( $P > 0.05$ ) and  $R^2$  is relatively high. It is noteworthy to observe that the elasticity with respect to fishing effort ( $b_2$ ) is almost as strong as the elasticity with respect to stock ( $b_1$ ).

**Table 4. Estimation results of fishing yield**

	$Q_t = nS_t^{b_1} E_t^{b_2}$
n	1.209 (0.024)
$b_1$	0.485 (0.010)
$b_2$	0.622 (0.008)
R <sup>2</sup>	0.89
R <sup>2</sup> adjusted	0.92

Note: p-values are in parentheses

**4.1.4. Fishery Management**

To figure out the best management strategy for Vietnam’s fisheries, three different scenarios are calculated.

**a. Fishing Status Quo**

The first strategy, termed ‘Status Quo’, consists in maintaining the fishing effort at its current level.

$E_t = 91.716$  ships, where  $t = 2020, \dots, 2050$  (the number of ships remains unchanged)

“What is most likely to occur?” will be figured out by the result of this scenario.

**b. Closure**

The second pattern, denoted as ‘Closure’, relates to a ban for this fishery.

$E_t = 0$  where  $t = 2020, \dots, 2050$  (years where the catch was zero)

In order to address the question, “What might happen if we stopped fishing?” this hypothetical scenario takes into account an “extreme” future.

**c. Maximum Economic Yield Strategy**

Here we investigate a more normative management strategy based on the intertemporal optimisation of the rent derived from fishing, which is called MEY (maximum economics yield) (Clark, 1974). This strategy is frequently used when fishing grounds, some collaborative groups of fishers, or specialist fishing associations are controlled by the government. In more mathematical terms, the bioeconomic program is to maximize the discounted value of the profit while maintaining with a constrained relationship between the maximum sustainable yield, the sea surface temperature due to climate change, and fishing effort:

$$\pi = pQ_t - cE_t \tag{6}$$

Where p represents the unit price of harvest while c represents the unit cost of effort. Adopting a risk neutral attitude in the sense that random fluctuations of stock and harvest are not considered in the regulator’s computation, the bioeconomic program can thus be written as:

$$\max_{E_t} \sum_{t=2020}^{\infty} \frac{\pi_t}{(1+r)^{(t-2020)}} \tag{7}$$

st: 
$$S_{t+1} = mS_t^{a_1}K_t^{a_2} - nS_t^{b_1}E_t^{b_2} \tag{8}$$

Where K is the sea surface temperature.

The solution of the above problem requires the use of optimum control theory (Kamien & Schwartz, 2012). Assuming for a while that the temperature  $\theta$  is at equilibrium, it can be proved that the long-term optimal equilibrium is given implicitly by the relation:

$$\left[ p - AS_*^{\frac{-b_1}{b_2}} (mS_*^{a_1}K_*^{a_2} - S_*)^{\frac{(1-b_2)}{b_2}} \right] \times (mnS_*^{a_1-1}K_*^{a_2} - 1) / \left[ p - AS_*^{\frac{-b_1}{b_2}} (mS_*^{a_1}K_*^{a_2})^{\frac{1-b_2}{b_2}} \right] + p^T \nabla \mathcal{L}^*_{p^S} \frac{(\nabla \mathcal{L}^*_{\theta^T} K_{\theta^S} - \mathcal{L}^*)_{p^S}}{-(p^T + p^S)} \setminus \left[ b - \nabla \mathcal{L}^*_{p^S} \frac{(\nabla \mathcal{L}^*_{\theta^T} K_{\theta^S})_{p^S}}{(r - p^S)} \right] = 1. \tag{9}$$

Where  $r = \delta - 1 - 1$  is the discount rate and  $\delta$  stands for the discount factor ( $0 < \delta \leq 1$ ), while parameter A equals  $= c \left( \frac{1}{b^{b_2} b_2} \right)^{-1}$ .

The above first order condition obtained in the steady state, when the fisheries economy is structured to strike a balance between growth and environmental integrity. This function gives an implicit solution for

the stock under MEY, which can be understood as a rule: we should should invest into the resource up to the point where the economic return of marginal investment (Marginal Utility) is equal to the social discount rate (marginal stock) (Lara & Doyen, 2008). In the above formula, we see that the optimal biomass level ( $S_*$ ) depends on the sea surface temperature ( $K$ ) and therefore we will hereafter denote this optimal biomass level as  $S_*(K)$ . According to the optimal control theory, and in the steady state, from equation (1) we deduce:

$$Q_*(K) = mS_*(K)^{a_1}K^{a_2} - S_*(K) \tag{10}$$

From the two formulas (10) and (5), we have the fishing effort:

$$E_*(K) = \left[ \frac{H_*(K)}{nS_*(K)^{b_1}} \right]^{\frac{1}{b_2}} \tag{11}$$

Regarding the numerical values based on the Viet Nam case study, the unit price of landings is set at  $p = 138,000$  đong/kg (mean output price over the period studied), while the cost per unit of effort is fixed at  $c = 10,000,000$  dong/day, which corresponds to the mean cost per day at sea. The discount rate is first set at  $r = 7\%$ . The parameter values are summarized in Table 5.

**Table 5. The value of the parameter about Growth parameters, Production parameters, temperature variation and economy**

	Parameters	Value
Growth parameters	$m$	0.555
	$a_1$	1.100
	$a_2$	0.468
Production parameters	$n$	1.209
	$b_1$	0.485
	$b_2$	0.622
Mean output price (dong/kg)	$p$	138,000
Mean cost per unit day (dong/day)	$c$	10,000,000
Discount rate (%)	$i$	0.07
Minimum rate of temperature rise ( $^{\circ}C/n\grave{a}m$ )	$\Delta_{(min)}$	0.01

Using SPSS with the input data as the parameters in Table 5 to estimate the species growth functions [function (1)], the production function [function (5)], and the profit function [function (7)] of each management strategy under climate conditions will increase  $0.01^{\circ}C$  per year, with  $t = 2020-2050$ . The results are described in Table 6.

**Table 6. The result about biomass, catches, and profit of fishing effort strategies under the climate scenario.**

2050	2,064,875	2,479,532	-942,220,455,672	7,301,260	0	0	6,163,063	3,550,178	2,066,999,705,439

Table 6 shows the status quo strategy will reduce the stocks, catches, and profits in fishing. If the status quo is maintained, the fishery situation is reaching alarming levels: by the end of 2047, both the quantity in stocks and catches will decline, profits will fall to negative.

With a strategy based on the closure of the fishery (no fishing), the prospect of fishery reserves will be more positive, as the results show that the first recovery phase appears, after that is the period of stabilization in 2045.

Notably, the Maximum Economic Yield (MEY) is ecologically feasible. Although there is a decline in biomass similar to the status quo strategy, but less pronounced. The profitability of the MEY is still completely positive, while the total reserve is greater than 0, indicating that Vietnam should consider applying this strategy to ensure the simultaneous achievement of both ecological and marine economic goal.

The results also demonstrate that even the slightest amount of global warming (an increase of 0.01°C per year) is quite concerning, at least in the late 1940s. This is because biomass production captures and revenues both fell, irrespective of the management strategy that was utilized. The status quo strategy (which maintains the fishing intensity recorded in 2020) has the worst effects on fisheries since it prevents stocks from ever recovering, which leads to a reduction in catches and negative profit from 2047. Fishery stocks can be rebuilt thanks to the sea closure policy up until 2035, but after that, the effects of global warming start to be felt, even if reserves usually start to stabilize by the end of 2050. The Maximum Economic Yield (MEY), in contrast to the status quo strategy, provides for a positive return during the whole forecast period, even though the return profits will be low but stable in the 2050s.

#### 4.2. Discussion

According to the research results (Figures 4 and 6), the current fishing method will eventually cause fish stocks to collapse. This is a consequence of the long-term drop in fishery production that has been

seen (Nghiep & Luong, 2019; Vĩnh et al., 2006). The two mechanisms underlying this bioeconomic vulnerability are as follows: First, the production function (Equation 5) states that the decrease in harvest is significantly influenced by the decline in stocks. This is because the catch elasticity for stocks ( $b_1 = b_1 = 0.485$ ) is not much difference to the yield elasticity to effort ( $b_2 = b_2 = 0.622$ ), despite the fact that fishing effort has significantly increased over time. Secondly, the adverse effects on stock dynamics of global warming scenarios through the increase in SST are very high since the elasticity ( $a_2 = a_2 = 0.468$ ). In other words, a temperature increase drastically changes the rate of stock renewal. When fishing effort is maintained at its current level, the combination and interaction of the two aforementioned negative mechanisms strongly explains the long-term bioeconomic collapse of the fishery as well as the significant drop in both fish catches and stocks.

Figure 4. Forecasted fish biomass under climate change impacts

Figure 5. Forecasted fish harvest under climate change

Figure 6. Profits under different catch management scenarios under climate change

An environmental vulnerability in the closure strategy (fishing ban) can be observed: after a brief period of shrimp biomass recovery, the stock starts to decline again from 2036. The fact that such erosion occurs even under the IPCC's least climate warming scenario (just a 0.01°C increase per year) is particularly highlighted. Given that the IPCC projects a potential warming of more than 0.04°C annually (Solomon et al., 2007), the reduction in fish biomass may really be worse than expected. Notably, recent research on the habitat traits of some aquatic species with high economic values, such as shrimp, has demonstrated that environmental parameters like sea surface temperature have an impact on shrimp productivity (Lopes et al., 2018). This implies that biological processes including growth, maturation, and survival are currently impeded and that this trend might get worse in the future. The catch will be permanently negative by 2047 if current fishing efforts are kept up; hence, a modification in current fishing tactics may be required to buck the trend.

The MEY strategy for management may contribute to lessening the adverse effects of climate change on the fisheries industry, as shown by Figures 4 and 6. Even if there is a chance that reserves, output, and profits could decrease due to climate change, the maximum economic yield still makes reserves and profits viable. It can successfully combine economic and ecological factors. The results of the MEY change over time depending on the temperature and the relevant stocks. In that sense, a strategy like that represents an effective response to climate change. These findings highlight the necessity of institutional systems to facilitate the management of climate change adaptation.

The maximum economic yield may have certain benefits in terms of sustainability (both ecologically and economically). But managing strategy The MEY has a number of drawbacks. First of all, as stressed by (Kompas et al., 2010), this strategy is a changing objective because it alters in response to forecasts regarding costs, prices, and temperature. In addition, market fluctuations in seafood prices make it challenging to calculate MEY, particularly given the recent steep rise in inflation and fuel prices (which account for 25% of all transportation-related costs). Overall, the three strategies discussed in this study may seem a little severe or strict and leave little room for citizen engagement. In contrast to the two other tactics (Status Quo and MEY), only the technique of simply terminating the fishery allows for the stock to be preserved (profits with MEY are also quite modest). An alternative intermediate strategy, as suggested by (Dichmont et al., 2010), could be to partially close the fishery and manage the closed portion as a marine protected area while continuing to exploit the remaining portions of the fishery using the MEY strategy. In addition, a transferable quota system can be applied at the same time as emphasized by (Sanz et al., 2017).

## 5. CONCLUSION

In this study, three fishing strategies are investigated under a minimal climate change scenario (0.01°C increase every year). Strategy 1: To maintain the status quo. Strategy 2: The closure of fishery . Strategy 3: Maximum Economic Yield (MEY). The findings indicate that fisheries will eventually collapse if fishing intensity are maintained at current levels (Strategy 1). Contrarily, the second strategy to stop fishing will assist sustain production but not profit. Due to the fact that both output and profits are stable, albeit at a low level in the context of global warming, the best economic output approach (approach 3) is feasible. To enhance approach 3, it should be paired with initiatives to reduce climate change to boost fishing productivity. To enhance approach 3, it should be combined with initiatives to reduce climate change to boost fishing productivity. Additionally, implementing MEY is difficult because the goal is unstable at all times. As a result, Vietnam may think about carrying out an alternative intermediate strategy that includes partial closure (creation of a marine protected area) while continuing to exploit the remainder with assistance. It additionally provides for the creation of a transferable quota system that can be used to simultaneously pursue ecological and economic objectives.

## RESEARCH ON THE IMPACT OF GREEN HUMAN RESOURCE MANAGEMENT ON EXTRA-ROLE GREEN BEHAVIOR OF FIRMS IN VIETNAM

**Author: Ha Nguyen Ngoc Linh<sup>1</sup>, Nguyen Thi Hoang Yen<sup>1</sup>, Tran Minh Vu<sup>1</sup>**

**Mentor: Nguyen Thi Lien Huong<sup>1</sup>**

**ABSTRACT:** *This study examined the impact of HRM (performance management & appraisal; rewards & payment; employee involvement & leadership) on extra-role green behaviors. At the same time, the mediating impact of green knowledge sharing. The study was conducted in Vietnam with the participation of a survey of employees at enterprises applying the environmental management system ISO 14001. The research results indicate that employee involvement & leadership and green knowledge sharing have direct positive in on extra-role green behavior in the Vietnamese iso 14001 certificates. This paper also confirms that employee involvement & leadership display indirect impact on extra-role green behavior via green knowledge sharing. There is no evidence to prove the statistically significant relationship between reward & payment and extra-role green behavior. However, reward & payment doesn't display extra-role green behavior via green knowledge sharing. Finally, this paper found no impact of performance management & appraisal direct and indirect on extra-role green behavior.*

**Keyword:** *Performance management & appraisal; Rewards & payment; Employee involvement & leadership; Extra-role green behavior*

### 1. INTRODUCTION

For the government, government green development behavior is closely linked to the institutional environment (Li et al., 2022) and also is a mainstay of driving the development of the green buildings industry (Fu et al., 2020). Within an organization, workplace pro-environmental behavior refers to a series of behaviors within the organization that are related to environmental sustainability or contribute to environmental sustainability, which includes in-role green workplace behavior and extra-role green workplace behavior (volunteer and self-starter) (Zhang et al., 2019). In general, green workplace behavior is a form of pro-environmental behavior (Safari et al., 2018 cited by Sabri et al., 2022). The extra-role green behavior of individuals contributes to improving and protecting the environment. Therefore, in this study, the authors focus on the study of promoting the engagement of green employees in practice related to performance management & appraisal, reward & payment, employee involvement & leadership and green knowledge sharing. At the same time, there is no specific study on the extra-role green behavior as well as research on the effects of green knowledge sharing. Along with that, extra-role green behavior outside the scope of employees' work still has much to be explored. waterfall. This is also a gap that needs more research focusing on understanding the relationship between underlying elements of green HR practices and extra-role green behavior.

Extra-role Behaviors were introduced early in the 1960s, Katz (1964) noted the behavior as an employee's willingness to contribute extra efforts for the attainment of organizational outcomes. While Organ (1977) came up with the construct of extra-role behavior as the contribution, which was not reflected in the measurement of the individual outputs but generally support the enterprise operation. Later then in the 1980s, Organ (1988) continued to have deeper analysis and develop his concept of ERB, drawing upon the notions of Katz (1964) cited by Brief & Motowidlo (1986), as the behavior that embraces the effectiveness and boosts the functioning of the organization without being recognized explicitly by the formal reward

<sup>1</sup> Faculty of business management.

system. In the middle of the 1990s, Van Dyne et al., (1995) proposed their concept of ERB as “behavior which benefits the organization and/or is intended to benefit the organization, which is discretionary and which goes beyond existing role expectations”. Becker & Kerman (2003) also emphasized that ERB is discretionary, but overall improves the organizational efficiency.

With the necessity of green innovation these days, employees become better aware of their responsibility to take actions in which to ameliorate the global environmental problem beyond the requirement of the organizations. Norton et al. (2015) define extra-role green behavior as actions involving personal initiative that exceeds organizational expectations. According to Islam et al. (2021), ERGBs are not included in employees’ job descriptions because these are as simple as employees’ suggestions to protect the environment. Furthermore, due to Zhang et al. (2019), green behaviors are mostly voluntary, which are referred to as extra-role green behaviors. In previous studies, different aspects of GHRM practices have shown their impact on green behavior in the workplace, overall creating values for corporations. Due to limited time and resources, however, authors focus on evaluating the following HRM practical performance management & appraisal, reward & payment and employee involvement & leadership.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Social identity theory**

Social Identity Theory (SIT) is a psychological theory developed by Tajfel & Turner in the 1970s. It focuses on how individuals define and perceive themselves in relation to social groups, and how group membership influences their behavior, attitudes, and self-concept. According to Tajfel & Turner (1979), “Social identity is the individual’s knowledge that he belongs to certain social groups together with some emotional and value significance to him of the membership in these groups”. This definition highlights that social identity is a sense of belonging and identification with particular social groups, and it carries emotional and personal value for individuals.

Based on Social identity theory suggests that individuals derive part of their identity and self-esteem from their group memberships. When organizations adopt GHRM practices that prioritize environmental sustainability, it can create a shared group identity among employees who support and identify with these practices. This group identity fosters a sense of collective environmental concern and responsibility. SIT proposes that individuals are motivated to maintain a positive social identity and conform to the norms and values of their group. When organizations promote green initiatives and values through GHRM, employees who identify with these practices are more likely to engage in pro-environmental behaviors. This can include actions such as reducing waste, conserving resources, or advocating for sustainable practices within and outside the organization. According to, GHRM aim to support employees’ green behavior so that employee feel they are part of an important change in the environment. Besides, We suggest that Green Human Resource Management plays a role in reducing social uncertainty for employees by providing them with guidance on how to behave, what to expect, and the level to which they should identify with their colleagues in relation to green knowledge-sharing and green service behavior. Employees who are committed to upholding this organizational culture are more likely to be motivated to engage in green knowledge-sharing behavior and green service behavior. These motivations serve as a bridge between GHRM, green knowledge-sharing, and green service behavior.

### **2.2. Performance management & appraisal**

Performance appraisals are a form of providing feedback, deciding promotions or termination, determining compensation, identifying strengths and weaknesses or areas for change and identifying development needs

that can help with career planning (Wessel, 1985) - the quality of an individual's (Macwan & Sajja, 2013). On the other hand, performance appraisal was considered the process of assessing the performance and progress of an employee or a group of employees (Fletcher, 2001) and is a key tool for organizations to make the most of their human resources (Armstrong & Baron, 2005). According to McAfee & Champagne (1993), Performance management, in essence, is a system which combines, clarifies, and strengthens the relationship between corporate goal setting and planning, employee development programmes, and performance review and appraisal. Authors DeNisi & Smith (2014) provide a similar definition. In simpler terms, Performance management is a broad set of activities aimed at improving employee performance (DeNisi & Pritchard, 2006) for improving organizational performance (Armstrong, 2006).

The findings of Pinzone et al. (2016) suggested that including environmental aspects in performance management increases employees' willingness to put extra effort into EM (Environmental Management). In addition, green management of organizational culture is the most used method to increase employee commitment and awareness toward the environment, followed by green performance management & appraisal (Masri & Jaaron, 2017). When employees are given opportunities for involvement in environmental issues and are motivated by green performance management policies, this significantly encourages them to acquire and utilize training in green knowledge and skills to contribute to hotels' environmental protection activities (Pham et al., 2019). Therefore, recent research such as Saeed et al (2019); Chaudhary (2019); Ojo, Tan & Alias (2020); Islam et al (2020); Muisyo & Qin (2021)... supported that performance management & appraisal, part of GHRM, have a positive relationship with employee's extra-role green behaviors.

The authors expect that performance management & appraisal positively impacts extra-role green behavior within Vietnam's organizations from the above analysis. Therefore, the following hypothesis is proposed:

*H1: Performance management & appraisal have direct positive effect on employees' extra-role green behavior.*

### **2.3. Reward & Payment**

The reward & payment could be any type of compensation/incentive program that is used to support the accomplishment of specific objectives (Rubino, 1997; Newman et al, 2016) or it is defined as those objects, which employees will work to acquire through the allocation of time, energy, or effort (Arias-Carrión et al., 2010). Therefore, in general, the reward is generally understood as the total amount of financial and non-financial compensation or total remuneration provided to an employee in return for labor or service rendered at work (Anku et al., 2018; Jeni et al., 2020).

In the environmental field, the green reward & payment is a system of financial and non-financial, being created to reserve and stimulate employees' pro-environmental behaviors (Jabbour et al., 2013; cited by Saeed et al., 2018). Due to Jabbour et al. (2008; 2011), employees become more inspired by nonfinancial rewards through green pay and reward, such as praise and recognition. Renwick et al. (2013) also pointed out employee green performance would be motivated as they received appreciation and support. Drawing upon previous research, a reward system should be added as a well-promoted factor which improves the efficiency and frequency of employees' green behaviors. Thus, recent research such as Dumont et al. (2017), Zhang et al. (2019) and Chaudhary (2019) supported that reward systems, as a part of GHRM, have a positive relationship with employees' extra-role green behaviors.

The authors expect that the reward system positively impacts extra-role green behavior within Vietnam's organizations from the above analysis. Therefore, the following hypothesis is proposed:

*H2: Reward & payment have a direct positive effect on employees' extra-role green behavior.*

#### **2.4. Employee Involvement & Leadership**

Early involvement was defined as the “cognitive belief states” of employees and was distinguished from satisfaction and behavior (Kanungo, 1982). In the study of Kearney (1997), employee involvement has been conceptualized as the process of developing the feeling of psychological ownership among organizational members and has been implemented via the participation of employees in information processing, decision-making and/or problem-solving. Employee involvement is an important enabler for strengthening individual commitment and voluntary behavior towards the environment at work and the hotel's environmental performance (Pham, 2010)

Currently, there is no exact definition of employee leadership in enterprises. The terminology usually calls by the nearest term is employee empowerment. Conger & Kanungo (1988) defined empowerment as a process of enhancing feelings of self-efficacy among organizational members through the identification of conditions that foster powerlessness and through their removal techniques by both formal organizational practices and informal of providing effective information. Besides, Wilkinson (1998) points out that empowerment is regarded as providing a solution to the age-old problem of Taylorised and bureaucratic workplaces where creativity is stifled and workers become alienated, showing discontent through individual or collective means.

Literature review shows that employee involvement has a direct impact on extra-role green behavior (Chaudhary, 2019; Chen et al., 2021; Purba & Tikurura, 2022). According, Chaudhary's (2019) research on green human resource management in the Indian auto industry emphasizes that to reap more benefits, employees also need to be allowed to participate in the organization's green initiatives because this will encourage them to come up with more creative ideas and make meaningful contributions to the achievement of green goals. Besides, Zhang et al (2019) also pointed out that employee empowerment (set up of green champions/task force/green team, etc.) allows employees to improve environmental behavior in a hands-on manner. Employee empowerment directly impacts on extra-role green behavior (Zhang et al., 2019). From the above analysis, the authors expect employee involvement & leadership to have a positive impact on extra-role green behavior within Vietnam's organizations. The authors propose the following hypothesis:

*H3: Employee involvement & leadership have direct positive impact on employees' extra-role green behavior.*

#### **2.5. Green knowledge sharing**

Green knowledge sharing in a green supply chain refers to the exchange and dissemination of green marketing and technological knowledge among the manufacturer and its supply chain partners (Song et al., 2020). The objective is to foster the development of innovative techniques and opportunities that effectively reduce the negative environmental impacts associated with supply chain activities. This process involves the sharing and transfer of knowledge related to sustainable practices, environmentally friendly technologies, and strategies for minimizing ecological footprints. By promoting the sharing of green knowledge, organizations aim to enhance their collective understanding and capabilities in implementing environmentally conscious practices throughout the supply chain. In the study of Chang & Hung (2021), green knowledge sharing is defined as the behavior that members of a company who are keen to pass on information and knowledge about green issues to others, promote learning opportunities and encourage others to learn, and create new knowledge for each other.

Some previous study points out that, green knowledge sharing have direct effect on (Rubel et al., 2021) Green knowledge sharing increased knowledge and empowers employees to engage in extra-role

green behavior, which refers to voluntary actions taken by employees that go beyond their formal job responsibilities to contribute to environmental conservation and sustainability. In their study, Saeed et al. (2019) argue that environmental knowledge reduces the impact of GHRM on extra-role green behavior.

From the above analysis, the authors expect employee involvement & leadership to have a positive impact on extra-role green behavior within Vietnam's organizations. The authors propose the following hypothesis:

*H4: Green knowledge sharing have direct positive impact on employees' extra-role green behavior.*

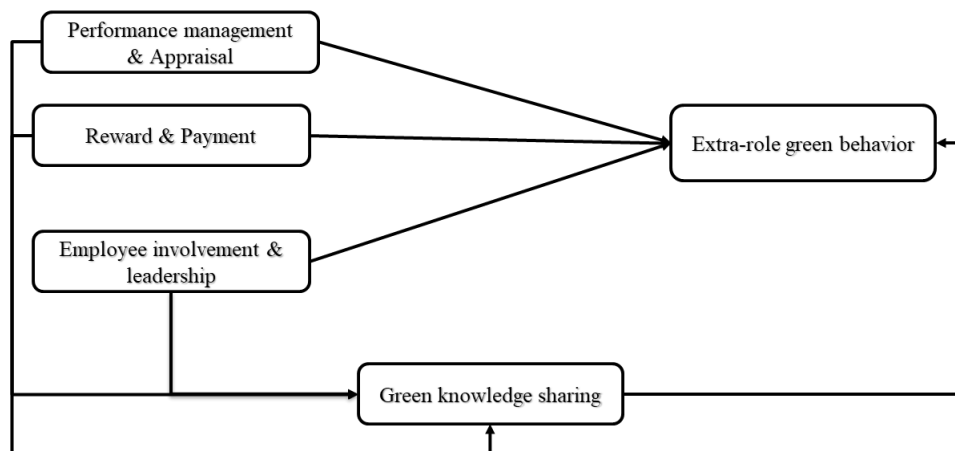

## 2.6. GHRM and Green Knowledge sharing

Research suggests that there is a positive relationship between GHRM and green knowledge sharing. When organizations prioritize and support environmental sustainability initiatives through their HR practices, employees are more likely to engage in knowledge-sharing related to green practices. The positive relationship between GHRM and green knowledge sharing can be explained by several factors. Firstly, when organizations demonstrate their commitment to environmental sustainability through GHRM practices, it signals the importance of green initiatives and encourages employees to participate and contribute. Secondly when employees perceive that their organization values and rewards green knowledge sharing, they are more motivated to engage in such behaviors. The literature also agrees that GHRM in the organization is positively related to green knowledge sharing (Rubel et al., 2021). As mentioned above, in this study, the author focuses on human resource management activities including performance management & appraisal, reward & payment and employee involvement & leadership. So, we proposed the hypothesis:

*H5: Performance management & Appraisal have direct positive impact on Green Knowledge sharing*

*H6: Reward & Payment have direct positive impact on Green Knowledge sharing*

*H7: Employee Involvement & Leadership have direct positive impact on Green Knowledge Sharing*

**Figure 1: Research Model**

## 3. RESEARCH METHOD

The study was carried out in Vietnam and involved firms applying ISO 14001. 47 out of 332 enterprises on the list of enterprises applying ISO 14001 accepted to participate in the survey. HR departments choice randomly select 15-20 willing employees to participate in the survey. Given that the participants were Vietnamese, the questionnaire was translated from English to Vietnamese by members of the research team. A pilot survey was also conducted with 30 employees to obtain feedback and resolve any wording issues that arose, to ensure the questionnaire's ease of use. The survey questionnaire is composed of two parts: i) General information (age, gender, educational background, department, company size); and ii) survey

questions relating to variables (performance management & appraisal, reward & payment, employee involvement & leadership, green knowledge sharing, and extra-role green behavior).

**Table 1: Origin of scales**

Construct	Code	Item	Citation source
Performance management & appraisal	PMA1	HR department of our company establishes clear objectives of green practices for each employee	Muisyo & Qin (2021)
	PMA2	Our company evaluates employee performance based on the achievement of environmental objectives	
	PMA3	Individual environmental performance is monitored by the HR manager in our company	
Reward & payment	RP1	Non-monetary rewards such as public recognition, praises, gifts and leaves are given to employees with high environmental performance	
	RP2	Monetary rewards such as cash, premiums and bonuses are given to employees for their high environmental performance	
	RP3	Employees with eco-initiatives are promoted to motivate other employees	
Employee Involvement & Leadership	IL1	Employees are involved in Environmental Management in our Company	
	IL2	Employees are engaged and empowered to make environmental suggestions	
	IL3	Employees' tacit knowledge is tapped by management through promoting them to basic-level leadership	
Green Knowledge sharing	GKS1	I always share green knowledge obtained from newspapers, magazines, journals, television and other sources	Rubel, Kee & Rimi (2021)
	GKS2	I enjoy sharing environment-friendly knowledge with my colleagues	
	GKS3	In my organization, people share expertise from work experience with each other	
	GKS4	Sharing my knowledge with colleagues is pleasurable	
	GKS5	I believe that knowledge sharing can benefit all parties involved	
Extra-role green behavior	EGB1	I took a chance to get actively involved in environmental protection at work	
	EGB2	I took the initiative to act in environment-friendly ways at work	
	EGB3	I did more for the environment at work than I was expected to	

The authors of the survey conducted a sample collection and were able to eliminate any invalid surveys, resulting in a total of 272 surveys (27.2%) being collected. The data collected from the surveys were analyzed using SPSS, which included various techniques such as reliability testing, EFA, CFA and SEM.

**4. RESULT AND DISCUSSION**

**4.1. Results**

*Descriptive statistic*

The results show that the equal ratio of male and female are 49.63% and 50.37%. Most employees have university diplomas accounting for 41.5%, followed by masters, others and high school/vocational school respectively at 33.8%, 12.9%, and 11.8%. The main ages of the study sample are 31-40 years old (32.4%) and 20-30 years old (30.9%); the other age groups have the following proportions: above 50 years old (16.2%), 41 - 50 years old (12.5%) and less than 20 years old (8.1%). 68.0% of respondents are living in Northern Vietnam, the South (14.35%) and the Central region (17.65%). Applicants are mainly employed and working in the public sector (36.4%), followed by private (29.4%), foreign (21.0%) and

finally joint ventures (13.2%). The size of enterprises that the survey collects the most is above 1000 employees (28.7%), the second is 100 - 499 employees (26.1%), the third is 50 - 99 employees (19.5%); enterprises with less than 50 employees and 500 - 1000 employees have the same rate of 12.9%. The detail of the sample presented in the table below.

**Table 2: Sample descriptive characteristics**

Sample characteristics	Frequency	Weighted (%)
Gender	272	100
Male	136	49.63
Female	136	50.37
Educational Qualification	272	100
High school/vocational school	32	11.8
Undergraduate	113	41.5
Masters	92	33.8
Other	35	12.9
Age	272	100
Less than 20 years	22	8.1
20-30 years	84	30.9
31-40 years	88	32.4
41-50 years	34	12.5
Above 50 years	44	16.2
Current living area	272	100
North	185	68.0
Central Region	48	17.65
Southern	39	14.35
Sector	272	100
State sector	99	36.4
Private	80	29.4
Foreign	57	21.0
Venture	36	13.2
Firm size	272	100
Less than 50 employees	35	12.9
50-99 employees	53	19.5
100-499 employees	71	26.1
500-1000 employees	35	12.9
Above 1000 employees	78	28.7

*Reliability of the scale*

The test results show that performance management & appraisal (PMA), reward & payment (RP), Employee involvement & leadership (IL), and Extra-role green behavior (EGB), Green knowledge sharing (GKS) all achieved good reliability values with Cronbach's Alpha > 0.7. However, the Green knowledge

sharing (GKS) measurement scale has the difference between Corrected Item-Total Correlation and Cronbach’s Alpha if the Item Deleted of the observed variable is significant (>0.3) leading to removing GKS5 to analysis a second time. The detail is presented in Table 3.

**Table 3: Result Cronbach’s Alpha, EFA, CFA**

Variables	Corrected Item-Total Correlation	$\alpha$ if deleted	Factor loading
Performance management & appraisal	.899		
PMA1	.787	.868	.838
PMA2	.843	.820	.950
PMA3	.778	.875	.804
Reward & payment	.770		
RP1	.562	.741	.646
RP2	.660	.631	.851
RP3	.594	.700	.689
Employee Involvement & Leadership	.789		
IL1	.720	.787	.777
IL2	.739	.769	.846
IL3	.695	.811	.788
Green Knowledge sharing	.820		
GKS1	.661	.765	.757
GKS2	.699	.751	.799
GKS3	.565	.810	.590
GKS4	.654	.768	.763
GKS5			
Extra-role green behavior	.887		
EGB1	.778	.842	.829
EGB2	.794	.828	.843
EGB3	.771	.850	.867

Source: SPSS analysis results

*Exploratory factor analysis (EFA)*

The results of the EFA show that the KMO coefficient is  $0.5 < 0.814 < 1$ , and the sig Bartlett’s Test is  $0.000 < 0.05$ . There are 5 factors extracted based on the criterion of eigenvalue greater than 1, so these 5 factors summarize the information of 16 observed variables included in EFA in the best way. The total variance explained by these 5 factors is  $64.350\% > 50\%$ , thus, the 5 factors explain 64.350 % of the data variation of 16 observed variables participating in EFA. In addition factor loadings all of the items  $> 0.5$  (Table 3). Therefore, the independent variables are suitable for aggregation.

*Confirmatory factor analysis (CFA)*

The test results show that the fit indices of the model meet the required standards:  $\text{Chi-square/df} = 1.126 < 3$  is good;  $\text{GFI} = 0.953 > 0.95$  is very good;  $\text{CFI} = 0.994 > 0.95$  is very good;  $\text{TLI} = 0.994 > 0.9$  is good;  $\text{RMSEA} = 0.022 < 0.06$  is good;  $\text{PCLOSE} = 0.997 > 0.05$  is good (Hu & Bentler, 1999). Details

are presented in Table 3 and Figure 2. Furthermore, the quality of the observed variables in the model is good and statistically significant with  $p$ -value  $< 0.05$  and factor loadings ( $\lambda$ )  $> 0.5$ . Therefore, all observed variables are suitable for SEM analysis (Hair et al., 2010).

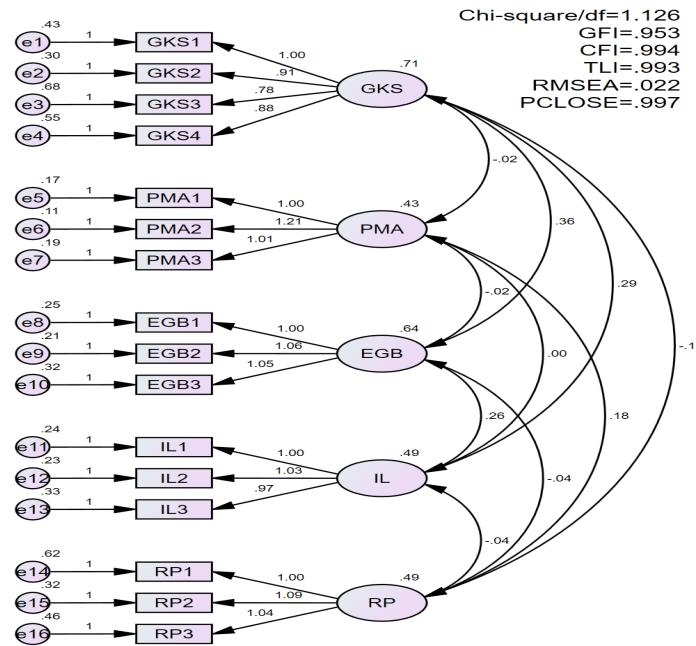

Figure 2: CFA analysis results

Source: AMOS analysis results

The average variance extracted (AVE) of all variables is  $> 0.5$ , the composite reliability (CR) is  $> 0.8$ , and the square root of AVE for each structure is higher than the correlations between structures, indicating that the reliability and validity of each measurement scale in terms of convergent and discriminant validity meet the required standards (Hair et al., 2010). Therefore, the observed variables are retained and subjected to hypothesis testing through structural equation modelling (SEM). Detailed results are presented in Table 4.

Table 4: Results of Fornell-Lacker

### Model Validity Measures

	CR	AVE	MSV	MaxR(H)	GKS	PMA	EGB	IL	RP
GKS	0.824	0.542	0.291	0.839	<b>0.736</b>				
PMA	0.901	0.753	0.155	0.914	-0.030	<b>0.868</b>			
EGB	0.888	0.725	0.291	0.890	0.540***	-0.038	<b>0.852</b>		
IL	0.850	0.653	0.244	0.853	0.494***	-0.008	0.456***	<b>0.808</b>	
RP	0.776	0.538	0.155	0.788	-0.186*	0.394***	-0.074	-0.088	<b>0.734</b>

#### Validity Concerns

No validity concerns here.

#### Structural equation modelling analysis results

The SEM test results presented in Figure 3 show that the fit indices of the model meet the required standards:  $\text{Chi-square}/df = 1.126 < 3$  is good;  $GFI = 0.953 > 0.95$  is very good;  $CFI = 0.994 > 0.95$  is very good;  $TLI = 0.994 > 0.9$  is good;  $RMSEA = 0.022 < 0.06$  is good;  $PCLOSE = 0.997 > 0.05$  is good (Hu & Bentler, 1999)

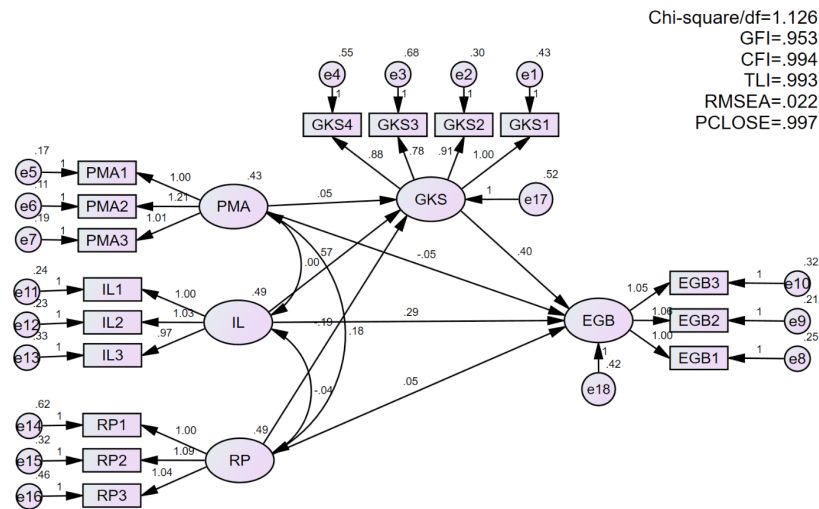

Figure 3: SEM analysis results

Source: AMOS analysis results

Table 5: Results of hypothesis testing using SEM

Variables	Hypothesis	p-value	Standardized Regression Weights	Result
PMA → EGB	H1	0.539	-0.040	Rejected
RP → EGB	H2	0.554	0.042	Rejected
IL → EGB	H3	0.000	0.251	Supported
GKS → EGB	H4	0.000	0.422	Supported
PMA → GKS	H5	0.610	0.036	Rejected
RP → GKS	H6	0.041	-0.157	Rejected
IL → GKS	H7	0.000	0.480	Supported

The results of the SEM test in Table 5 indicate that IL (p-value=0.000) and GKS (p-value=0.000) have a direct positive impact on EGB, while RP (p-value=0.554) and PMA (p-value=0.539) have no impact. Besides, IL direct impact on GKS but RP negative impact on GKS and PMA does not impact GKS. Therefore, hypotheses H3, H4, and H7 are accepted, while hypotheses H1, H2, H5, H6 are rejected. The independent variables in the research model explain 34.1% of the variance in EGB.

The indirect results show that IL and RP indirect effect on EGB through GKS. But RP has a negative effect on green knowledge sharing.

Table 6: Results of indirect relationship

Variables	p-value	Standardized Estimate	Results
RP --> GKS --> EGB	0.013	-0.066	Negative indirect
IL --> GKS --> EGB	0.001	0.203	Positive indirect

4.2. Discussion

The result shows that *Employee involvement & leadership have direct positive impact on employees’ extra-role green behavior*(p-value=0.000;β=0.251). The results of the study are similar to those of previous studies Chaudhary, 2019; Wiradirja & et al., 2020; Anwar et al., 2020; Chen et al., 2021. When employees are actively involved in environmental initiatives and decision-making processes, they develop a sense of ownership and empowerment. They feel that their opinions and contributions matter, which motivates them to go above and beyond their regular job responsibilities and engage in extra-role green behavior. Employee involvement and leadership in green initiatives can enhance job satisfaction and commitment.

When employees are actively engaged in meaningful work that aligns with their values and contributes to a greater cause, they experience a sense of fulfilment and purpose. Employees are more willing to invest their time and energy in extra-role green behavior when they feel a deep sense of connection to the cause.

*Green knowledge sharing has a direct positive impact on employees' extra-role green behavior (p-value=0.000;  $\beta=0.422$ ).* The result is similar to the research of Rubel et al., 2021. That means green knowledge sharing allows employees to access and exchange valuable information and best practices related to environmental sustainability. By sharing knowledge about green initiatives, strategies, and solutions, employees become more informed and equipped to engage in extra-role green behavior. Green knowledge sharing helps raise awareness and understanding among employees about the importance of environmental sustainability and the impact of their actions on the environment motivates employees to go beyond their job responsibilities and actively contribute to green initiatives. Green knowledge sharing fosters collaboration and encourages employees to work together to develop innovative solutions to environmental challenges and establishes social norms within the organization, where extra-role behaviors are encouraged and valued.

*Reward and payment have a direct negative impact on Green knowledge sharing (p-value=0.041;  $\beta=-0.157$ ).* While Chaudhary (2019) points out that reward & payment have direct positive impact on extra-role green behavior. This difference in results can be attributed to the fact that firms in Vietnam often use rewards & payment to prioritize short-term outcomes and achievements, such as meeting specific targets or deadlines. Green knowledge sharing, on the other hand, requires a long-term perspective and continuous learning and improvement. When reward & payment are to immediate outcomes, employees may be tied to invest time and effort in sharing and acquiring green knowledge that may not yield immediate results. This can impede the development of a sustainable knowledge-sharing culture within the organization.

Reward and payment systems primarily operate on extrinsic motivation, where individuals are motivated by external incentives such as bonuses, promotions, or salary increases. When green knowledge-sharing is solely driven by extrinsic rewards, employees may engage in knowledge-sharing activities for the sake of the reward rather than a genuine commitment to sustainability. This can lead to a superficial sharing of information without a true understanding or passion for environmental issues. In addition, reward and payment systems advantageously operate on extrinsic motivation, where individuals are motivated by external incentives such as bonuses, promotions, or salary increases. When extrinsic rewards solely drive green knowledge-sharing, employees in firms in Vietnam may engage in knowledge-sharing activities for the sake of the reward rather than a genuine commitment to sustainability. This can lead to a superficial sharing of information without a proper understanding or passion for environmental issues.

*Employee involvement & leadership has a direct positive impact on Green knowledge sharing (p-value=0.000;  $\beta=0.480$ ).* The result is similar to the research of Rubel et al., 2021, which shows that involvement & leadership – part of GHRM have direct impact on green knowledge sharing. This implies that when employees are actively involved and have high leadership, they tend to share knowledge, experience and information related to environmental sustainability. Employee involvement means active interaction and contribution to environmental sustainability-related activities, projects and initiatives within the organization. Employee leadership demonstrates their ability to motivate, inspire, and guide colleagues toward sustainable goals and values. Employees with high leadership can make a positive impact on their workgroup, encourage participation and interaction on environmental sustainability and recommend green activities and processes.

*Green knowledge sharing mediates the relationship between reward & payment and extra-role green behavior. (p-value=0.013;  $\beta=-0.066$ ).* This means that increasing green knowledge sharing of employees, reward & payment has a negative effect on extra-role green behavior. This finding highlights the importance

of recognizing the intrinsic motivations and non-monetary factors that drive employees to engage in extra-role green behavior. While reward & payment may still play a role in motivating employees, their influence is diminished when employees are already intrinsically motivated to share green knowledge and participate in environmentally responsible actions.

The statement *Green knowledge sharing mediates the relationship between employee involvement & leadership and extra-role green behavior* ( $p\text{-value}=0.000$ ;  $\beta=0.203$ ) suggests that the act of sharing green knowledge plays a mediating role in the link between employee involvement & leadership and their engagement in extra-role green behavior. In other words, when employees are actively involved in sustainable initiatives and exhibit effective leadership in promoting green practices, their engagement in sharing green knowledge acts as a mediator that influences their subsequent participation in extra-role green behavior.

## 5. CONCLUSION

Through the research process and the final report, the research team research has achieved certain tasks. *Firstly*, conducting an overview of the previously published research works in the direction of the research topic from which the authors identify research gaps to determine the research content. *Secondly*, the authors have identified independent and dependent variables, thereby forming a research model to assess the impact of human resource management measures on extra-role green behavior. *Third*, have conducted data collection using research methods such as surveys, and document analysis to collect data using statistical measures and data analysis to find out the relationship between green human resource management measures and extra-role green behavior. However, this study still has a limitation that needs to be overcome to increase the scientific and practical value of the research results.

## IMPACT OF TOP MANAGEMENT COMMITMENT AND SELECTED HRM PRACTICES ON EMPLOYEE IN-ROLE GREEN BEHAVIOR

**Author: Nguyen Pham Hai Dang<sup>1</sup>, Do Thanh Long<sup>1</sup>, Nguyen Thao Phuong<sup>1</sup>**

**Mentor: Dr. Nguyen Thi Lien Huong<sup>1</sup>**

**ABSTRACT:** *This study examines the influence of Top management commitment, Performance Management & Appraisal, and Employee Training on employees' green behaviors in the workplace (namely, In-role Green Behavior hereafter). The survey was conducted in Vietnam, with 1,000 invitations sent to about 50 firms from the VCCI enterprise list and received 476 responses. Our research revealed that Top Management Commitment (TMC), Performance Management & Appraisal (PMA), and Employee Training (ET) directly impact employees' In-role Green Behavior (IGB). Moreover, TMC also positively impacts PMA and ET in which the impact from TMC is the strongest, then PMA and ET with the strength of impact in the exact order respectively. In addition, this paper also found the positive mediation effects of PMA and ET on the relationship between TMC and IGB, in which PMA can transmit a better impact on TMC than ET. Overall, the impact strengths are ranked from TMC to PMA, then TMC to ET, then TMC to IGB, then PMA to IGB, then TMC to IGB via PMA, ET to IGB, and finally TMC to IGB via ET, respectively.*

*Keywords: Top management commitment, Performance Management and Appraisal, Employee Training, In-role Green Behavior.*

### 1. INTRODUCTION

As climate change becomes more and more intense, its effects will likely be profound and can have significant impacts on natural resources, leading to their reduction or alteration. Numerous scientific studies and observations support these impacts on resources. For instance, research has shown decreasing water availability in regions like the Mediterranean and parts of Africa (Xanke & Liesch, 2022), reduced crop yields in various agricultural regions, increasing forest fires in places like the Western United States and Australia (Jones et al., 2022), and coral bleaching events in the Great Barrier Reef (Datte et al., 2022) and other worldwide.

Like other organizations, any initiative, including green-related trends, must be supported by top management. TMC is the terminology that has come to the academic world's attention recently in many different fields, such as quality management, HRM, implementation of innovation, and new system... Especially in a culture like Asia, where employees are mostly "boss followers," the role of top management is vital. Top management will issue supporting policies, allocate adequate resources, conduct internal communication for implementation, etc. Therefore, it is expected that TMC will have a particular impact on employees' green behavior within the organization. Moreover, previous research in the HRM field already proves the impact of TMC on different HRM practices and HR practices in shaping employee behavior in many different aspects. Employee green behavior has been divided into employee in-role and extra-role green behavior (Aboramadan, 2022) because of the difference in the organization's expectations of their green behavior (Paillé & Boiral, 2013). Literature review shows that HR practices can initiate and accelerate in-role and extra-role behavior of employees toward more environmentally friendly practices in the workplace.

Alongside the trend of the green movement worldwide, Vietnam has also started to pay attention to research, policy, and implementation of specific environmental practices in big organizations and firms. The

---

<sup>1</sup> National Economics University.

investigation to understand what factors in different HRM practices better impact employees' behavior toward green trends becomes important and has practical meaning. Due to limited time and resources, this paper can only explore HRM practices (PMA, ET) and their impacts on one dimension of employees' green behavior (IGB). To the authors' best knowledge, there is still minimal research in Vietnam on the same topic, and this paper attempts to fill in this gap and provide further empirical evidence for this literature field.

## 2. THEORETICAL FRAMEWORK

Researchers have taken notice of addressing environmental challenges by explaining how humans make their decisions to perform their behavior related to environmental problems (Klößner, 2013). Previous research has attempted to study what are some of the key drivers and processes behind the behaviors that are causing or are trying to decrease the negative impact of these environmental issues, forecast employee behavior development over time to build the foundation for strategic managers and policymakers to change the system to minimize adverse outcomes (Rayner & Morgan, 2018). Many different theories have been developed in the hope of shedding light on the underlying issue, including Value Belief Norm theory (VBN) (Stern et al., 1999; Stern, 2000), Norm activation theory (NAT) (Schwartz, 1977), Social Cognitive theory (SCT) (Bandura, 1977), theory of green purchase behavior (TGPB) (Han, 2020),...etc. These theories have been used to explain various dimensions in the green movement context (Choi et al., 2015; Han & Hyun, 2017; Phipps et al., 2013; Han, 2020). Of all the mentioned frameworks, Ability Motivation Opportunity (AMO) theory (Appelbaum et al., 2000) and Resource-Based View (RBV) are among the most popular theories, and their validity was proved in many previous HRM and behavioral topics (Boselie et al., 2005).

According to the Resource-Based View theory, each organization is believed to be a combination of numerous resources, including human, tangible (physical), and organizational resources (Barney, 1991; Teece et al., 1997; Memon et al., 2022). These resources are a historically determined collection that is attached to be the "semi-permanent" assets of the firm (Wernerfelt, 1984). This collection represents the antecedents of the firm, which managers should consider to maximize the utility and gain a competitive advantage for their organization (Wernerfelt, 1984; Lockett et al., 2014). Hence, TMC should be clear and dependable to effectively manage these unique resources that can capture the improvement of competitive advantage and imply the long-term and sustainable development of the organization (Lockett et al., 2009). Under the Resource-Based View, the managers' responsibilities are to keep the organization's strategic planning in alignment with the available resources (Lockett et al., 2009). According to this, managers must be both adaptive and proactive; in another way, they must be "enactors" (Lado & Wilson, 1994). In general, managers, specifically managers, play a vital role in coordinating central elements of the Resource-Based View. In the view of HRM, employees are considered to be one of the important resources in the organization who will be in charge of implementing all the policies and fulfilling all the objectives as set by management (Bombiak et al., 2018; Battaglia, 2018; Yuriev et al., 2020). Therefore, it is advisable for any organization to set up and pursue it (Paillé et al., 2013; Memon et al., 2022), including green behavior. In this paper, TMC is perceived as the essential driver since the top manager's commitment will ensure the organization's direction and adequate resources to support the change in the IGB of its employees.

More recently, AMO theory has been widely used to explain and constitute employees' green behavior (Rayner & Morgan, 2017). There are three important elements in AMO theory, namely Individual Abilities, Motivation, and Opportunity, that can be used to determine the high performance of employees (Appelbaum et al., 2000). To boost the performance of the firm, there are some requirements. Firstly, the employees need certain skills and abilities to perform their tasks. Secondly, motivation shall arise from employee participation in various decision-making and skill enhancement opportunities and from the view to create appropriate tasks by their managers. Since AMO theory has been considered the center of Human Resource Management (Katou & Budhwar, 2010), HRM practices constructed in line with this

theory (ability, motivation, opportunity) can form and improve individuals' discretionary behavior (Boxall & Purcell, 2003; Katou & Budhwar, 2010; Pham et al., 2019). In this paper, employee training is one of the variables included in the ability factor of AMO. Employee training provides employees with the required skills, knowledge, and attitudes to perform their related tasks (Pham et al., 2019; Jabbour et al., 2010). On the other hand, motivation in the AMO model is displayed in HRM practices via the PMA tool. The goal of such motivation is to create a suitable and inspiring system to encourage and engage employees toward the firm environmental activities (Renwick et al., 2013). Moreover, with this environmentally focused appraisal system, managers can give feedback that might help improve employees' knowledge, skills, and abilities (Masri & Jaaron, 2017), which motivates them to perform given tasks better (Govindarajulu & Daily, 2004) and withdraw some lesson-learned that might be helpful in their next environmental missions. Lastly, regarding the opportunity, TMC is considered the most vital factor in providing sufficient resources for creating a dynamic working environment toward a green prioritized atmosphere to meet their job description requirements at the best quality.

Employees' green behavior is generally pro-social (Chou, 2014; Dumont et al., 2017). With the development of the green movement, organizations have proven to have outstanding performance in terms of brand image, which in turn will further improve company sales (Wee & Quazi, 2005; Yang et al., 2011; Dumont et al., 2017) as well as trigger preferable green outcomes from their employees (Salem et al., 2012). Since the green movement can support the performance of firms from both operational and sustainable perspectives, recent organizational policies have favored the green trend. As mentioned above, this paper investigates the relationship between TMC, HRM practices, and IGB. Employee IGB is the performance of environmentally friendly activities that follow organizational or governmental policies as part of the job requirements (Norton et al., 2015; Dumont et al., 2017; Chaudhary, 2020) or job description (Borman & Motowidlo, 1997). Recently, Li et al. (2023) defined IGB as "green formal tasks that are an integral part of an employee performance assessment." Although empirical research has shown that this variable has different antecedents, such as Green Work Engagement (Aboramadan, 2022), Organizational Identification (Chaudhary, 2020), Psychological Green Climate (Li et al., 2023), etc., HRM practices are still known for its significant relationship with IGB (Aboramadan, 2022; Dumont et al., 2017; Zhang et al., 2019). More specifically, this paper will empirically test the impact of ET, PMA, and TMC on IGB.

Throughout three decades of research, the definition of ET holds some expansion, but the core part of developing competencies (Goldstein, 1980; Latham, 1988) in knowledge and skill (Kitching & Blackburn, 2002; Dessler, 2008), in capabilities (Anlesinya, 2018) and attitudes (Goldstein, 1980; Latham, 1988; Anlesinya, 2018) to safely (Dessler, 2008), effectively and efficiently (Dessler, 2008; Anlesinya, 2018) carry out their job tasks and responsibilities. With the prosperity of science and technology, ET emerges with more types and is suitable for more purposes of the organization. Recent studies have shown that ET impacts employees' green behavior. The results of these studies indicate a positive and direct relationship between ET and IGB within the scope of work (Saeed et al., 2019; Zhu et al., 2021; Karatepe et al., 2022). Multiple empirical studies have confirmed a direct positive impact of ET as a green HRM practice on environmentally friendly behavior in the workplace (IGB) in Australian multi-national companies, Chinese intermediary manufacturing companies (Dumont et al., 2017), and businesses in operational sectors of across industries (Zhang et al., 2019). Therefore, this research expects to find the same impact in this research context and proposes the following hypothesis:

*H1: ET has a direct positive impact on employee IGB.*

The keyword "performance management" began to gain prominence in the late 20th century. One of the earliest definitions of performance management showed a broad connection between setting and planning corporate goals, implementing employee development initiatives, and conducting performance

reviews and appraisals (McAfee & Champagne, 1993). Over time, performance management began to aim to improve individual and organizational performance by aligning employee efforts with strategic priorities (Tool, 2012). In this work, the authors defined this term based on the research of Armstrong (2021) as a structured approach aiming at enhancing performance at the organizational level through improving individual and team levels. It involves developing and managing performance within an established framework of predetermined goals, standards, and competency requirements.

The assessment of people's performance at work—performance appraisal—has been of interest to scholars and practitioners for literally hundreds of years (DeNisi & Murphy, 2017). Ilgen et al. (1993) defined performance appraisal as the process of assessing information and evaluating an individual's performance and productivity. This process includes three critical sets of operations which are (1) acquisition of information about those to be evaluated, (2) organization and storage of this information in memory, and (3) retrieval and integration of the information in a fashion that leads to the recording of an evaluation of the person being appraised (Feldman, 1981; Ilgen & Feldman, 1983; DeNisi et al., 1984). In addition, Fletcher (2001) believed that the focus has shifted towards evaluating past performance and enhancing employees' skills, improving performance, and allocating rewards. Nowadays, performance appraisal is considered a formal rating feedback (DeNisi & Murphy, 2017) or a formal record (Grote, 2011) of the employees' work quality (Grote, 2011) or their performance by the supervisor (DeNisi & Murphy, 2017). To sum up, performance appraisal is a systematic and formal process conducted by supervisors, managers, or human resources professionals that involves assessing, measuring, and evaluating an individual employee's job performance, productivity, and overall contribution to the organization.

In recent research, various conclusions have emerged regarding the relationship between performance management, performance appraisal, and IGB. Research findings indicate that the implementation of green PMA systems has been shown to exert an influence on employees' behavior inside the company, leading to environmentally responsible actions and practices within their job responsibilities (Dumont et al., 2017; Zhang et al., 2019; Islam et al., 2020). On the other hand, research in Malaysia by Kuan et al. (2022) did not find any impact of PMA on employees' IGB. Since there is still debate on the final impact of PMA on IGB, there exists a need to conduct further empirical research in a new research context to provide more evidence. Therefore, the following hypothesis is proposed:

*H2: PMA has a direct positive impact on employee IGB.*

Management research shows that the success of any effort targeted at changing the organization's operational philosophy has a strong connection with the TMC. Digalwar et al. (2013) stated that TMC is essential for effective environmental improvement as top management is responsible for setting up policies and communicating them thoroughly across the organization. TMC also refers to the emphasis that top managers place on developing the capabilities of an organization (Gavronski et al., 2011). In a nutshell, it represents the TMC in emotion, intention, and attitude in pursuing the organization's goals (Bagozzi, 1992), the lack of which will lead to failure to achieve these goals (Baetz & Bart, 1996). Besides, Yusliza et al. (2019) regard TMC as one of the critical organizational capabilities that assist in developing and implementing corporate environmental practices.

Implementing HRM practices within an organization requires commitment from its management team or top managers (Green et al., 2012). The same thing happens in employee training. HRM focuses on developing a state-of-the-art workforce to achieve its goals continuously. This can only be achieved through the proper and systematic implementation of employee training and development programs. Training employees on an ongoing basis is important because training familiarizes employees with their job-related duties as well as the values and beliefs of the organization (Kusluvan et al., 2010). Thus TMC is expected to have a positive

impact on ET. In addition, a well-designed PMA plays an important role in making decisions for a company’s promotion and employee development. Specifically, PMA is managers’ official assessment tool when making promotion or financial rewards decisions. Management by objective uses performance appraisal results to measure the effectiveness of workers and link it with salary or bonus increases (McKinney et al., 2013). In theory, these activities also play a role in motivating employees and raising organizational productivity levels. Given the importance of an effective performance appraisal system and managers’ clear role in company decision-making, TMC is expected to impact employee PMA positively.

Scholar research showed little evidence about the relationship between TMC and IGB. Most available empirical research confirmed a direct positive relationship (Cairns et al., 2010; Connelly et al., 2011; Graves et al., 2019; Karatepe et al., 2022). While Cairns et al. (2010) direct relationship focused on how the strength of senior management commitment to environmental sustainability can serve as role models for other employees to act in the same way, Graves et al. (2019) proposed a positive impact of TMC on employees’ green behavior. On the other hand, the Signaling Theory (Connelly et al., 2011) proved that a manager’s commitment affects employees’ green practices. Karatepe et al. (2022) also confirmed that TMC positively affected task-related IGB.

From the above findings, this research expects to find out similar relationships and proposes to examine the following hypotheses:

*H3: TMC has a direct positive impact on employee IGB.*

*H4: TMC has a direct positive influence on ET.*

*H5: TMC has a direct positive impact on PMA.*

**Figure 1: Proposed research model**

### 3. RESEARCH METHOD

#### 3.1. Data collection and sample characteristics

The survey was conducted in Vietnam, with 1,000 invitations sent to about 50 firms from the VCCI enterprise list to meet the minimum sample size requirement. The research team asked the HR departments of agreed companies to choose at least 20 employees from their employee list to participate in the survey, using the help of a random number-picking app online.

This questionnaire used a 5-point Likert scale and was translated from English to Vietnamese using a backward translation procedure. First, the original version will be sent to a qualified translation service provider. Then, the received Vietnamese version will be sent to a researcher with a background in the same field of study to convert it back to English. This ensures that the true meaning is kept through translation. After that, a survey was sent to a pilot sample of 30 participants for comments. Several wording issues were fixed to ensure the user-friendliness of the questionnaire. The table below demonstrates the characteristics of the research sample.

**Table 1: Sample characteristics**

Sample characteristics	Quantity	Ratio (%)
Gender	476	100
Male	122	25.6
Female	354	74.4
Age group	476	100
<18	54	11.3
From 18 to 30	315	66.2
From 31 to 45	44	9.2
>45	63	13.2
Living area	476	100
North	403	84.7
Central	39	8.2
South	34	7.1
Education	476	100
<High school	67	14.1
High school	355	74.6
Intermediate/Vocational school	6	1.3
College/ University	48	10.1
Monthly Income	476	100
<5Mio	115	24.2
From 5 to 15 Mio	345	72.5
>15 Mio	16	3.4
Time	476	100
<3 years	127	26.7
From 3 to 5 years	249	52.3
>5 years	100	21.0

### 3.2. Scales' measurement

This research uses items inherited from previous studies and adapted to fit the context of Vietnam. These scales were selected from published studies in reputable academic journals with a high volume of citations, which proves the support of later scholars to the original studies. Some studies were also conducted in developing countries such as Mexico (Jun et al., 2006) and China (Muisyo & Qin, 2021), thus having similar characteristics to Vietnam that would help the questionnaire. Table 2 below illustrates the sources of inheritance.

**Table 2: The inherited scales**

No	Variable name	No of items	Inherited from
1	Performance Management and Appraisal	3	Muisyo & Qin (2021)
2	Top Management Commitment	3	Jun et al. (2006)
3	In-role green behavior	3	Bissing-Olson et al. (2013)
4	Employee Training	3	Muisyo & Qin (2021)

### 3.3. Analysis

The data is collected and processed using SPSS and AMOS. In order to test the reliability of the measurement scales, Cronbach’s Alpha ( $\alpha > 0.7$ ) and Corrected Item-Total Correlation ( $> 0.3$ ). Then EFA and CFA are run to test the discriminant and convergent validity of the variables. Finally, the structural equation model (SEM) explores the relationships between model variables and concludes the hypotheses.

**4. RESULTS AND DISCUSSION**

**4.1. Results**

Scales’ ET, PMA, TMC, and IGB reliability are demonstrated in the table below. Research results indicated that all scales achieved acceptable thresholds because they have Cronbach’s Alpha (CA)  $> 0.8$  and Corrected Item-Total Correlation (CI-TC)  $> 0.3$ .

**Table 3: Reliability test**

Variables	CI-TC	CA if deleted	Factor loading
Employee Training	0.825		
ET1	.640	.805	0.698
ET2	.740	.704	0.923
ET3	.672	.769	0.736
Performance Management & Appraisal	0.926		
PMA1	.842	.897	0.844
PMA2	.866	.878	0.950
PMA3	.837	.901	0.754
Top Management Commitment	0.879		
TMC1	.771	.824	0.769
TMC2	.768	.829	0.934
TMC3	.763	.833	0.612
In-role Green Behavior	0.939		
IGB1	.886	.903	0.926
IGB2	.891	.899	0.977
IGB3	.846	.933	0.818

EFA was run with Principal Axis Factoring and Promax to test the construct validity between the model’s variables. Results show that KMO is  $0 < 0.908 < 1$ ; Bartlett’s sig. is  $0.000 < 0.05$ ; Total Variance Explained is  $75.203\% > 50\%$ , and Factor loadings are all greater than the acceptable threshold of 0.5 (Hair et al., 2009).

**Table 4: CFA results for convergent and discriminant validity**

Variables	CR	P value	$\beta$
CMIN/DF	2.835		
GFI	0.954		
CFI	0.981		
TLI	0.974		
RMSEA	0.062		
PCLOSE	0.050		
IGB1 <- IGB	0.940	0.000	0.930
IGB2 <- IGB		0.000	0.934
IGB3 <- IGB		0.000	0.884

PMA1 <- PMA	0.926	0.000	0.888
PMA2 <- PMA		0.000	0.913
PMA3 <- PMA		0.000	0.893
TMC1 <- TMC	0.877	0.000	0.828
TMC2 <- TMC		0.000	0.806
TMC3 <- TMC		0.000	0.882
ET1 <- ET	0.831	0.000	0.723
ET2 <- ET		0.000	0.852
ET3 <- ET		0.000	0.787

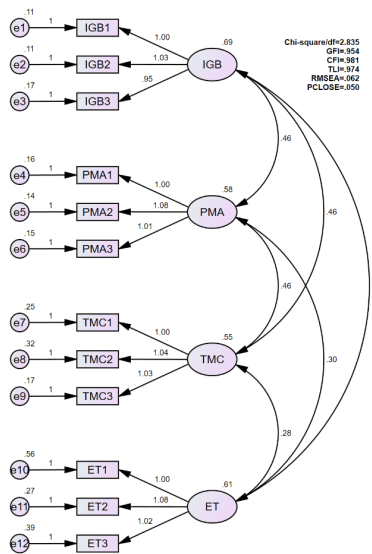

Figure 2: CFA result

Consequently, all items were retained for the subsequent analysis of CFA. The model fit met all requirements, reliability was confirmed again by CR, the p-value of almost all items is  $0.000 < 0.05$ , and factor loading rounded up achieved the minimum threshold of 0.5, which confirms the discriminant and convergence of the model’s items. The Fornell and Lacker results were tested using the Validity plugin in AMOS and showed no validity concerns.

	CR	AVE	MSV	MaxR(H)	IGB	PMA	TMC	ET
<b>IGB</b>	0.940	0.840	0.550	0.944	<b>0.916</b>			
<b>PMA</b>	0.926	0.807	0.668	0.927	0.727***	<b>0.898</b>		
<b>TMC</b>	0.877	0.704	0.668	0.883	0.742***	0.817***	<b>0.839</b>	
<b>ET</b>	0.831	0.622	0.257	0.843	0.507***	0.506***	0.479***	<b>0.789</b>

**Validity Concerns**

No validity concerns here.

- \* p < 0.050
- \*\* p < 0.010
- \*\*\* p < 0.001

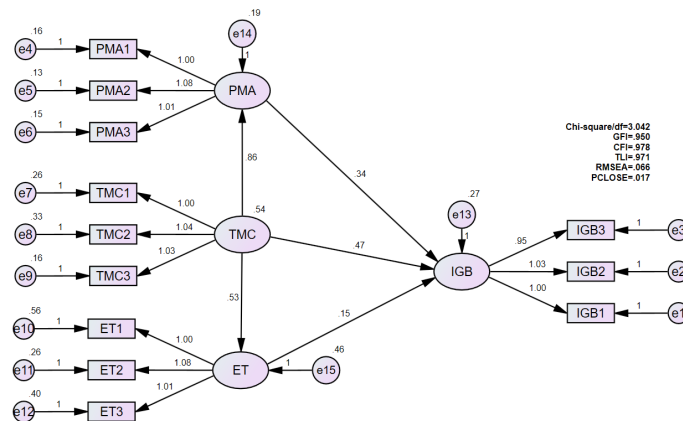

Figure 3: Fornell Lacker validity test

SEM analysis was conducted to test the model fit and the hypotheses. Results showed that the path coefficient from TMC to both PMA and ET is significant as a p-value <0.05. Similarly, TMC, PMA, and ET all have positive relationships with IGB (-value <0.05).

**Table 5: SEM for hypothesis testing**

Variables	Status	P value	$\beta$
CMIN/DF		3.042	
GFI		0.950	
CFI		0.978	
TLI		0.971	
RMSEA		0.066	
PCLOSE		0.017	
IGB <- ET	Accept	0.000	0.143
IGB<- PMA	Accept	0.000	0.310
IGB<-TMC	Accept	0.000	0.422
ET<TMC	Accept	0.000	0.504
PMA <- TMC	Accept	0.000	0.826
IGB<- PMA <- TMC	Accept	0.001	0.256
IGB <- ET <- TMC	Accept	0.001	0.072
R <sup>2</sup>			
IGB		0.610	

More specifically, the strength of these relationships rank from TMC to PMA ( $\beta=0.826$ ), TMC to ET ( $\beta=0.504$ ), TMC to IGB ( $\beta=0.422$ ), PMA to IGB ( $\beta=0.310$ ), and finally ET to IGB ( $\beta=0.143$ ). The independent variables can explain roughly 61% of the variance in IGB. All proposed hypotheses are supported in this case.

**Figure 3: SEM results**

The indirect relationships were tested using the Indirect Effect plugin in AMOS. Results showed that PMA has a mediating effect on the relationship between TMC and IGB (P-value< 0.05), and ET has a mediating effect on the relationship between TMC and IGB (P-value< 0.05). Besides, both PMA ( $\beta=0.288$ ) and ET ( $\beta=0.081$ ) have a positive mediate role, enhancing the relationship between TMC and IGB. Last but not least, PMA made a more significant indirect impact than ET.

**4.2. Discussion**

The research results show a direct positive relationship between ET and IGB. This result aligns with previous studies (Chaudhary, 2019, 2020; Goswami & Upadhyay, 2020). In addition, according to our results, PMA also makes a direct positive impact on IGB, which is also similar to the research of Zhang et al. (2019),

Chaudhary (2020), and Pham et al. (2020). The results of this paper emphasize that PMA plays an essential role in shaping employee IGB. Furthermore, the authors find out that TMC not only has a direct positive effect on ET (Yusliza et al., 2019; Memon et al., 2022; Haldorai et al., 2022) but also directly impacts PMA (Yusliza et al., 2019; Haldorai et al., 2022). Research results also show that TMC positively influences IGB. These results highlight the importance of TMC in shaping HRM practices and promoting environmentally friendly employee behavior. Some previous studies have also proven this view (Graves et al., 2019; Karatepe et al., 2022).

The fact that these findings have met the research team's expectations demonstrated in our hypotheses shows that the Vietnamese context and the view of organizations doing business in Vietnam have been quite in line with international practice. Vietnam has dealt with many environmental problems lately, as people have been severely depleted of natural resources. This condition has occurred due to the lack of people awareness and appropriate policy. After some initial suffering from the damage of biodiversity loss and understanding how sustainable development can positively enhance firms' benefits in particular and social welfare in general, Organizations and policymakers have recognized the necessary demand in building up well-structured training programs closely attached to green orientation. Therefore, employees in the organization can perceive the value of going green and accompany their organization to fetch sustainable development. In addition, the performance management and appraisal system are proven to have a certain positive impact on motivating employees to follow those green behaviors that are required by the extent of the job description. This practice's more substantial impact can be explained by the Vietnamese government encouraging companies to develop based on sustainable orientation. For instance, Vietnamese Communist Party Congress Resolution 4<sup>th</sup> has been approved by the Vietnamese National Assembly, states that government and state governors have to "Support key and focal businesses, anticipating new business trends; developing new business models based on innovation, digital economy, sharing economy, circular economy, green economy, and sustainable business; promoting the formation of leading enterprises in potential industries and fields to create new growth momentum and achieve sustainable goals." According to this, the performance management and appraisal for IGB of employees need to be closely coordinated with the reality of the organization and correctly perform the green behavior of employees. Also, top management commitment is undoubtedly vital in beginning the effort of going towards green orientation in the organization and connecting every practice to gain desired outcomes.

Theoretical implications of the study include integrating the Resource-Based View theory and the Ability Motivation Opportunity theory in explaining the relationships between TMC, selected HRM practices (PMA, ET), and IGB. The study provides empirical evidence for the direct effects of TMC, PMA, and ET on IGB. Additionally, the study demonstrates the mediation effects of PMA and ET on the relationship between TMC and IGB. The study's practical implications suggest that organizations should emphasize TMC towards environmental sustainability and incorporate green HRM practices into their human resource strategies. The urge to become committed starts with awareness of the positive outcomes and impact of constructing green employee behavior. Organizations should maintain, provide and further extend training programs to equip employees with the necessary knowledge and skills for environmentally friendly behavior. PMA systems should also be designed to encourage and recognize IGB at the right time, at the right place, and to the right person. By implementing these practices, organizations can foster a culture of sustainability and promote employees' engagement in green activities, eventually gaining benefits from it. On the other hand, the government needs to encourage people and organizations further to develop sustainably by passing policies that raise awareness and instruct how organizations simultaneously achieve their environmental and business goals.

This current study has some existing limitations and would like to address certain directions for future research. *Firstly*, the present study only researched several HRM practices and their impacts on IGB due to a scarcity of time and resources. Therefore, the study suggests the scope of future studies to focus on more practices of HRM such as reward and payment, recruitment and selection, employee engagement, etc. *Secondly*, the surveyed respondents mainly live in the northern region of Vietnam. Hence, future research could develop and expand surveys nationwide. *Thirdly*, this paper mainly focuses on IGB, limits the general understanding of employees' green behavior only, and does not examine its remaining dimension – extra-role green behavior. Future researchers can further extend their research to gain more comprehensive knowledge about how different HRM practices impact each dimension and propose more valuable suggestions to organizations to build up suitable policies in a green context.

## 5. CONCLUSION

This research paper aims to test the relationship between selected HRM practices and IGB, using AMO theory and Resource-Based View theory to build the theoretical framework. After analyzing 476 responses, the research found that TMC, PMA, and ET have a positive direct relationship with IGB. Moreover, TMC also positively impacts ET and PMA. According to these results, some suggestions were made for organizations and governments to improve the green behavioral outcomes of employees. As the independent variables in this study can only explain 61% of the IGB variance, other impact factors were not included in this research. Future studies in the same field can further expand this research to deepen the underlying issue's meaning and comprehension.

## THE EFFECTS OF BLOCKCHAIN TECHNOLOGY ON FOOD - PURCHASING INTENTIONS OF CONSUMERS IN HANOI OF VIETNAM

**Author: Do Thi Hien Mai<sup>1</sup>, Tran Thi Ngoc Diep<sup>2</sup>, Hoang Thi My Linh<sup>2</sup>, Nguyen Dang Nhat Minh<sup>2</sup>**

**Mentor: Nguyen Thi Phuong Linh<sup>3</sup>**

**ABSTRACT:** *In the 21st century, food-related issues have been a topic of interest among consumers worldwide. In this regard, blockchain has emerged as a promising technology that allows users to track and monitor food through the supply network, ensuring its origin. This study explores factors such as Blockchain's traceability, product quality, supply chain transparency, safety, anti-counterfeiting, trust, perceived usefulness, and perceived risk are all positively related to purchase intentions in Hanoi, Vietnam. After in-depth interviews, the authors have found that these factors directly or indirectly encourage consumers to purchase food products in the surveyed area.*

**Keywords:** *Blockchain features in the buying process, consumer awareness, purchase intention..*

### 1. INTRODUCTION

In recent years, the safety and quality of food products has become the dominating concern of the whole society. An estimated 600 million – almost 1 in 10 people in the world – fall ill after eating contaminated food and 420 000 die every year, resulting in the loss of 33 million healthy life years (DALYs) (World Health Organization 2022). This directly puts enormous pressures and challenges on the global food market such as the enforcement of bans on unhealthy foods, plastics, the pervasiveness of e-commerce, and the transfer of advanced technologies. Additionally, there is an increasing demand in the food sector to collect and share substantial volumes of data to ensure the reliability and trustworthiness of the supply chain. Moreover, customers have become progressively more demanding when it comes to the quality and safety of food items. In this regard, blockchain has emerged as a promising technology that allows users to effectively and efficiently track and trace the sources of foods from food retailers and mitigate or even eliminate harmful food fraud. For instance, Walmart has successfully started using Blockchain to trace the import process of pork from China. With the support, Walmart understands the manufacturing, logistics, storing as well as transacting processes of any products.

From now, there are numerous studies on the effect of Blockchain on purchasing intention in countries around the world. In the context of developing countries such as VietNam, however, there are no studies that put emphasis on the effects of Blockchain on food-related areas. Therefore, the aim of this paper is to identify Blockchain factors affecting consumers' intention to purchase food products in Hanoi through in-depth interviews. In this study, we will investigate three main points: (i) review the Stimulus-Organism-Response (S-O-R) Model; (ii) develop a research framework for purchasing intention; (iii) determine the impact of factors that affect purchasing intention of consumers.

## 2. LITERATURE REVIEW

### 2.1. The Stimulus-Organism-Response (S-O-R) Model

The SOR model is employed as the conceptual foundation for this study. It suggests that various aspects of the environment (S), such as physical and nonphysical elements of the food - related field, can affect peoples' internal states and organismic experiences (O), such as perceptual, physiological, feeling, and thinking activities, which in turn drive their behavioral responses (R), such as satisfaction, patronage, intention, number of items purchased, and amount of money spent in the store (Mehrabian and Russell, 1974).

Stimuli (S), according to Lin and Lo (2016) refers to the influencing factor of the external environment which can affect the mental and cognitive state of the organism. In this study, we adopt some factors, including Traceability, Food quality, Supply chain transparency, Safety, and Anti-Counterfeiting. In the study of Gotel and Finkelstein (1994), traceability is defined as “the ability to describe and follow the life of a requirement, in both a forwards and backwards direction”.

Organism (O) refers to the internal processes and structures that intervene between external stimuli and final actions, reactions, or responses emitted by individuals, “which consist of perceptual, physiological, feeling, and thinking activities” (Bagozzi, 1986). This study adopts few notions, namely perceived usefulness, perceived risk and trust, to demonstrate customers' internal processes.

Our study considers Food-purchasing Intention as the response (R) to the stimulus and organism discussed in the preceding section. It is associated with customers' behavioral reactions, often termed a “behavioral intention.” Purchase intention is defined as the likelihood of a consumer to purchase a service or product in the future (Richardson et al., 1996). We, in this study, adopt the argument of Halji (2014), which states that purchase intention can be used to anticipate a customer's possible actions. Therefore, our research model indicates food-purchasing intention as the response to describe consumers' intentions to buy food in relation to Blockchain traceability.

### 2.2. Development of hypotheses

#### 2.2.1. Blockchain feature in Buying process (S)

Food safety and quality assurance has become increasingly difficult in times of growing global flows of goods (Creydt and Fischer, 2019). Moreover, with increased quality of life, food consumers are highly concerned not only about the taste of food but also quality, cleanliness and authenticity (George et al., 2019). Correspondingly, the demand for traceability has been increased due to food-related safety hazards and scares (Opara, 2003). This drives organizations to adapt the latest technologies in the quality control systems which ensures traceability right from post-harvest to serve consumers with the maximum value addition possible. According to George *et al.* (2019), the potential value of the index of food quality as a nutrition education tool for the public will be realized only when food profiles are readily available. In addition, the adoption of food traceability systems enables companies to ensure food safety through early detection of deficiencies, and to efficiently withdraw and reduce the volume of unsafe products on the market (Kher *et al.*, 2010; Thakur *et al.*, 2010). A typical example of implementing Blockchain's traceability is Walmart which ensures food safety for products like pork and mango by capturing data from various nodes, starting from the farm, packing house, and transportation to the final consumer. Thus, we hypothesize the following:

#### **H1: Blockchain's traceability exert a positive influence on food quality**

In the context of supply chain management, two terms “Transparency” and “traceability” are wrongly used interchangeably. Supply chain transparency is the practice of disclosing detailed and accurate

information about operations and products, such as their origin and sourcing, manufacturing processes, costs, and logistics (Bai and Sarkis, 2020). However, Sunny *et al.* (2020) proposed that traceability represents the ability to access the granular level information about anything that remains as part of a supply chain. Traceability capabilities allow the observability of supply chain processes (Ringsberg, 2014) and provide insights into the origin, authenticity, chain of custody, and integrity of market offerings (Marucheck et al., 2011). As such, effective and efficient traceability capabilities are essential operational vehicles of supply chain transparency due to their critical role in establishing provenance (Sodhi and Tang, 2019). Sunny *et al.* (2020) suggested that several researchers have incorporated traceability in various supply chain scenarios in order to erect transparency. For example, Kandel *et al.* (2011) presented a Global Positioning System (GPS) enabled traceability system called GPS.LAB to perform tracing and tracking in the context of production planning and supply chain event management to establish transparency in global supply chains. In short, traceability enables transparency through tracing and tracking. Therefore, a following hypothesis is drawn:

### **H2: Blockchain's traceability exert a positive influence on supply chain transparency**

The problem of counterfeit product trading is one of the major challenges in an innovation-driven global economy which also pose broader adverse effects to the economy, public health, safety, and security of the wider community. In order to overcome the issue of counterfeiting, an effective supply chain traceability system is necessary (Gayialis *et al.*, 2022). According to the author, If a product is found to be faulty, the traceability system gives all of the information essential to conduct a successful recall of the problematic product or batch. Thus, it serves as a solution for ensuring the security and sustainability of businesses, their rapid reaction in times of crisis, their protection from malicious activities, and the overall improvement of operations via the discovery of root causes. Aitzhan and Svetinovic (2016) argued that the combination of data tampering and transaction traceability on blockchain can solve the problem of trust in traditional traceability, effectively solve the problem of fake and inferior products during the product circulation process in the supply chain, and protect the rights and interests of consumers. Therefore, implementing Blockchain's traceability features not only track the origin of goods but also identify counterfeiting products, fake transactions... Thus, we put forward a hypothesis:

### **H3: Blockchain's traceability exert a positive influence on safety and anti-counterfeiting**

It has been recognised that there is an increasing need for transparent information on the quality of the entire food chain, supported by modern tracking and tracing methods (Trienekens and Beulens, 2001). Trienekens *et al.* (2012) posited that transparency in the food supply chain is essential to guarantee food quality and provenance to all users of food and food products. Due to recent food crises, product and process quality and safety have become paramount - alongside efficiency - (Babuchowski *et al.*, 2005; Aramyan *et al.*, 2006) and, thus, can be used as indicators of chain performance for measuring the effects of transparency.

In addition, supply chain transparency plays a vital role in verifying counterfeiting products. Certain industries, such as the seafood industry, are vulnerable to fraud, where lesser value fish are commonly labeled and sold at higher value (Astill et al., 2019). Oceana reported that 44% of sampled seafood products from Canadian retail and restaurant locations were mislabelled (Oceana Canada, 2018). This leads to many concerns over the accuracy of properly labeled seafood, as many different species of fish can be grouped under one label, leaving consumers with very little confidence about the veracity of seafood products (Levin, 2018). Therefore, by increasing the transparency of the operations that go into food production, consumers can avoid purchasing fake products, poor quality goods due to the wealth of new data and information, underpinned by evolving technologies that have and will become available. With these considerations, the following hypotheses are proposed:

**H4: Supply chain transparency is positively related to product quality.**

**H5: Supply chain transparency is positively related to safety and anti-counterfeiting.**

### **2.2.2. Influences of Blockchain features (S) on Consumer awareness (O)**

Consumers can access information about the value of food products. This is related to a trade-off in terms of perceived usefulness between quality/benefit and cost/price (Kervenoael et al., 2021). According to the study of Jamal and Sharifuddin (2015), developing advertisement messages that encourage consumers to think about the quality of the halal logo products. These messages can highlight the usefulness of a halal logo by using an advertising format that describes how the logo resolves a typical problem in shopping for halal food products. Additionally, food quality is often presented on the food label. According to Festila *et al.* (2014), food labels served as a versatile tool that helps manufacturers promote and communicate certain qualities of the food products, including nutritional composition, process-related features (such as organic, and traditional), and other relevant information. The increasing presence of a wide range of quality differentiated food (such as healthy, organic, environmental friendly, ...) in the market has helped consumers with more information, then increase their perceived usefulness. Consequently, we put forward a hypothesis:

**H6: Product quality has a positive influence on the perceived usefulness of consumers.**

The absence of transparency in the supply chain of any product prevents supply chain participants and consumers from verifying and validating the actual value of that product (Saberri et al., 2019). Blockchain technology enhances supply chain transparency, enabling supply chain managers to obtain the information that consumers are demanding (Francisco and Swanson, 2018). Supply chain transparency builds trust between consumers and other supply chain participants. This trust contributes to higher perceived usefulness of the product as consumers believe it will effectively fulfill their needs. Supply chain transparency allows consumers to understand the impacts and outcomes of a decision on a product and to promote a better understanding of environmental conditions (Abeyratne and Monfared, 2016). According to Wang *et al.* (2019), Blockchain technology improves supply chain transparency by enabling the development of services like track and trace, Blockchain diminishes the necessity for double-checking as data validation is automated. Additionally, Blockchain technology enables transaction tracing, thereby providing evidence of the origin and authenticity of transactions. As a result, we propose a hypothesis:

**H7: Supply chain transparency has a positive influence on the perceived usefulness of consumers.**

Companies can positively shape the perceived usefulness of consumers by giving priority to safety and anti-counterfeiting measures. Therefore, they influence consumers' perception of the value and usefulness of the products. Blockchain technology has the characteristics: distributed ledgers, data security, anti-counterfeiting, and programmable features... increase flexibility and reliability across various application scenarios (Zhu and Zhou, 2016). In addition, Zhu and Zhou (2016) indicated that Blockchain technology enables a decentralized ledger system, providing data security, transparency, and integrity. Moreover, it offers anti-tampering and anti-counterfeiting characteristics. Thus, it helps platforms to earn consumers' trust and makes themselves a reliable third-party institution. Based on numerous studies (Cranor et al., 2000; Westin and Maurici, 2007; Agarwal et al, 2009...), with the rapid expansion of online products and services, consumers are becoming progressively more apprehensive about security and privacy issues. Therefore, we put forward a hypothesis:

**H8: Safety and anti-counterfeiting have a positive influence on the perceived usefulness of consumers.**

According to Wang *et al.* (2020), numerous food product scandals have erupted in China and have since remained in the spotlight in both local and international societies. As a consequence, trust in the

Chinese food industry has plummeted, and consumers have little confidence in the quality of food products produced or manufactured in China. Jimenez and Martin (2010) mention, trust can be formed by the image of products based on the country of origin of products and also the knowledge of the product or brand. Furthermore, Haslinda et al., (2014), suggest that the indicator of consumer confidence in product COO, are:(1)Consumers trust the quality of the brand products; (2)Reputation of brand is reliable. In addition to the above dimensions, the country of origin of products and technology are the attributes of the product quality perception COO considered by consumers when deciding to purchase a product (Han, 1990). Thus, we hypothesize the following:

**H9: Product quality has a positive influence on the trust of consumers.**

Consumer perception of transparency was a strong factor that positively influenced trust and in addition, general attitude. The results thus suggest that the level of a company's transparency, as perceived by a consumer, can play a valid and significant role in building trust and a positive attitude toward the company. (Kang and Hustvedt 2014). In addition, Francisco and Swanson (2018) indicated that consumers' expectations regarding product origins are continuously increasing, especially for high-value items such as food. According to Ward (2017), pioneering companies recognized the competitive advantage of supply chain transparency, which led to increasing the consumer's trust, and increased purchasing and financial benefits for these companies. Furthermore, consumers often lack awareness of the numerous issues associated with the production of goods. The incidents such as environmental damage, generation of waste at the end of product life, unethical labor, and counterfeit products,... have heightened the demand for transparency in manufacturing supply chains as a means of regaining consumers' trust in products (Abeyratne and Monfared, 2016). Thus, we hypothesized:

**H10: Supply chain transparency has a positive influence on the trust of consumers.**

The importance of farmers building trust has become critical in light of recent concerns about food safety in food consumption (Yee et al 2012). According to a consumer survey conducted by the Institute of Grocery and Distribution (IGD), only 10 percent of respondents expressed trust in farmers (Grocer, 2000). Consumers might develop trust in livestock farmers if their demonstrated competence increased, reflected in their capability to supply livestock free from health hazards throughout the supply chain. (Moorman et al., 1993; Smith and Barclay, 1997). This competence is evident in their provision of safe and clean raw meat and their accurate guidance on food safety. Additionally, there is an inverse relationship between trust and food risks, meaning that individuals who have a greater level of trust in the food system tend to be less concerned about potential risks, and conversely, those who have lower levels of trust may exhibit higher levels of concern regarding food risks (Knight and Warland, 2005). Based on prior research investigations, we hypothesize:

**H11: Safety and anti-counterfeiting have a positive influence on the trust of consumers.**

Transparency can reduce information asymmetry among parties involved in the transaction (Nuengwang et al 2013). The act of seeking information and the utilization of traceability systems are closely linked to transparency. This connection is evident in the findings of Yoo *et al.* (2015), who observed that when consumers perceive a risk, they are motivated to proactively seek additional information. This pursuit of information is facilitated by transparency, which allows consumers to access and evaluate relevant data through traceability systems. Thus, transparency serves as a fundamental factor in enabling and supporting the process of seeking information and utilizing traceability systems in response to perceived risks (Yoo et al., 2015).

Perceived transparency is expected to alleviate the information asymmetry between the users (principal) and a website (agent) (Wang et al 2007), thereby reducing their perceived risk. Information transparency in the supply chain is an effective approach to mitigate information asymmetry between the principal and the agent, thereby reducing consumers' perceived risk and increasing their intention to purchase. Given that transparency enhanced consumers' purchase intention by directly providing them with information benefits (i.e., reduce search cost and increase search efficiency) or by indirectly helping them reduce potential losses/risks (i.e., risk of purchasing a dysfunctional product or transacting with a fraudulent trader) (Zhou et al 2018). On the basis of these reasons, the following hypothesis is proposed:

**H12: Supply chain transparency reduces the perceived risk of consumers.**

Safety and anti-counterfeiting measures focus on maintaining food safety standards and preventing unauthorized alterations or frauds. Risks related to food fraud are for the most part low probability and high impact and characterized by a lack of controllability by individuals. During the process of transitioning to an information society, it has been observed that consumers have become more conscious of their purchase attitudes. Therefore, in addition to the above-mentioned factors, well-informed and conscious consumers tend to develop their own risk-mitigation process for purchase activities of goods and services (Köprülü, 2013). This indicates that consumers' perception of risk is significantly influenced by the implementation of safety practices. Yeung and Morris (2001) suggest that as the concern about food safety is growing, the demand for problematic food falls as consumers perceive a risk impact on their health. Therefore, when food is unequivocally established as safe, consumers can confidently make their purchases. Thus, we make a hypothesis:

**H13: Safety and anti-counterfeiting reduces the perceived risk of consumers.**

**2.2.3. Influences of Blockchain features (S) and Consumer awareness (O) on Intention (R)**

Consumer risk perceptions evolved from the consumer beliefs concerning complexity and unpleasant events that may occur during the online purchase scenarios (Tham et al., 2019). However, trust can play an essential role in mitigating the impact of risks that are associated with the consumer's perception of risk. (Pappas, 2016). When consumers perceive financial risks, such as the possibility of fraudulent transactions or financial losses, time risks, such as delays in delivery or inconvenience, and psychological risks, it undermines their trust in sellers. These perceived risks create doubts and uncertainties, eroding the confidence consumers have in the reliability and credibility of the online seller. (Munikrishnan et al., 2023). After considering those analyses, we propose a hypothesis:

**H14: The perceived risk has a negative influence on the trust of consumers.**

Perceived usefulness has significantly influenced consumers' overall intention to purchase, besides being positively related to consumers' behavior and attitude (Monica et al., 2016). According to Nedra *et al.* (2019), consumers are more likely to consider making a purchase when they perceive a specific system as useful to them. In other words, when a technological innovation provides benefits to the clients, perceived usefulness can generate purchase intention. As stated by Mazzini *et al.* (2016), perceived usefulness refers to users' convictions that utilizing a medium, such as the Internet, a website, or an app, will enhance their performance and productivity, in addition to boosting their satisfaction and improving their overall experience. In addition, consumer satisfaction has been found to have a direct effect on buying intention (e.g. Yi, 1990; Bou-Llusar et al., 2001; Yi and La, 2004; Tsiotsou, 2006). Specifically, in the context of food products, various authors have discovered a positive impact of consumer satisfaction on buying intention (e.g. Mai and Ness, 2000; Calvo, 2001; Hansen and Solgaard, 2001; Sanzo et al., 2003; Grunert et al., 2004; Nowak and Newton, 2006). Hence, we propose following hypothesis:

**H15: The perceived usefulness of consumers has a positive influence on the intention of purchasing food from consumers.**

Blockchain adoption process of traceability raises awareness among consumers, leading to their trust in food products which are purchased. Trust is one of the most effective methods of reducing consumer uncertainty (Hart and Saunders, 1997). Wang et al (2020) indicated that consumers hold different levels of trust in different labels, depending on the food certifying body, and that international bodies receive the highest confidence level, influencing the total purchase intention of certified food. In the context of liquid milk (Hoque and Alam, 2018) and organic food (Nuttavuthisit and Thøgersen, 2017; Teng and Wang, 2015), it is projected that trust will signify the consumers- attitudes and purchase intentions. Thus, the consumers - perspectives on trustworthiness are likely to determine the final purchase decision between a buyer and a seller (Gupta et al., 2009). We accordingly proposed a reasonable hypothesis:

**H16: The trust of consumers has a positive influence on the intention of purchasing food from consumers.**

Several studies suggest that the risk perception with regard to food can strongly impact purchase intention (Klerck and Sweeney, 2007; McCarthy and Henson, 2005; Tsiros and Heilman, 2005; Park et al., 2005). In addition, Ariff et al (2014) asserted perceived risk is significantly associated with a customer's purchase intention. Nok et al (2017) revealed the negative relationship between perceived risk and buying intention, implying that an enterprise should reduce the perceived risk of products and boost consumer trust of products to enhance the purchase intention. According to Jun (2020), risk perception has been suggested as one of the most significant determinants of consumer buying intention. Chen *et al.* (2016) stated that the more perceived risk of consumers would reduce the purchase possibility; consumers would reduce risks by collecting information before buying. Therefore, we hypothesize that:

**H17: The perceived risk of consumers has a negative influence on the intention of purchasing food from consumers.**

Product quality plays a significant role in influencing a consumer's intention to purchase food. Consumers often associate high-quality products with superior taste, safety, and nutritional value. As such, they are willing to pay more for these products and are more likely to purchase them repeatedly. Iskandar et al (2015) concluded that product quality acting as a satisfaction component variable would significantly lead consumers to a higher propensity for purchases. With regard to organic food, Basha et al (2015) argued that quality of products is one of the most commonly stated motives for pursuing this kind of food. According to Saleem et al (2015), if the quality is high, the purchase intention of the customer is also high. Moreover, consumers engage in purchase by taking into account the quality signals they encounter (Iyer and Kuksov, 2010)). In other words, consumer-perceived product quality plays a significant role in shaping attitudes and buying intentions (Lin et al., 2009). Therefore, a following hypothesis is drawn:

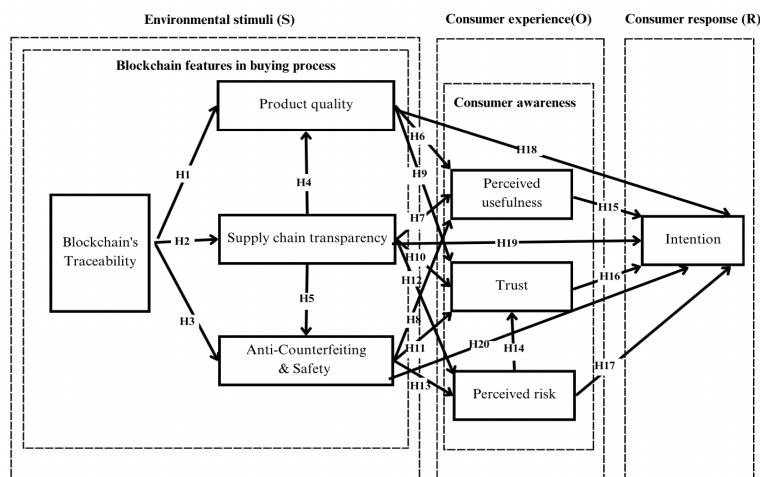

**H18: Product quality has a positive influence on the intention of purchasing food from consumers.**

When consumers have access to information about where their food comes from, how it was produced, and how it was transported, they are more likely to trust the brand and form purchase intentions. Francisco and Swanson, (2018) stated that the supply chain concept of transparency embodies, basically the idea of information readily available to end-users and firms in a supply chain, positively impacts the consumer intentions. The presence of a blockchain label on a product as an evidence of supply chain transparency increases a consumer's propensity to purchase it (Gazzola et al., 2023). Mollenkopf et al (2022) revealed that the signal of supply chain transparency exhibits higher attraction to consumers in buying intention. Thus, boosting consumer intention to purchase food - related products calls for promoting supply chain transparency. We propose a following hypothesis:

**H19: Supply chain transparency has a positive influence on the intention of purchasing food from consumers.**

Safety and anti-counterfeiting are crucial factors for consumers when choosing which products to buy, especially in the food industry. The presence of such elements builds trust between consumers and food manufacturers, which can lead to an increase in purchase intention. Lee and Yun (2015) investigated how consumers perceive organic food attributes including food safety, which in turn influence their attitudes and intentions to buy. According to Sans (2018), there are numerous cases regarding food frauds that have had major social impact, such as the marketing of more eggs sold as free range than there is the capacity to produce, of organic products that are not organic, of animal or plant species labeled as other species, or nuts with a false origin. In addition, wines have been found to be labeled with inaccurate ratings, or have unauthorized flavorings added to them without proper disclosure. Additionally, mechanically separated meat has been observed to be sold without proper declaration, and olive oil is marketed as extra virgin even when it fails to meet the requisite standards. The lack of food fraud control leads to a loss of trust in the food industry among consumers, consequently affecting their intention to buy food. Since Blockchain traceability features including ensuring and enhancing food safety, quickly detecting and solving food fraud, we make a hypothesis that:

**H20: Safety and anti-counterfeiting have a positive influence on the intention of purchasing food from consumers.**

**Figure 1. The effect of Blockchain technology on Purchasing intention research model**

### 3. RESEARCH METHOD

The group of authors utilized a qualitative approach - in-depth interviews to examine the relevance of factors in the research model applied in the context of Vietnam. The participants involved in the in-depth interviews were food consumers in Hanoi, Vietnam, encompassing diverse demographic characteristics in order to achieve the research objectives as follows:

Firstly, the study explored the current status of Blockchain-related factors influencing consumers' intention to purchase food (characteristics of Blockchain, features related to the purchasing process, consumer perception). Secondly, the study investigated the relevance of these factors and the interplay among them in the overall model. The group of authors conducted in-depth interviews with 18 individuals with different demographic characteristics (age, gender, occupation, average monthly income).

The qualitative research using in-depth interviews was conducted over a span of approximately one week, from May 8th, 2023, to May 14st, 2023, through both face-to-face and online meetings, with an

average interview duration of 30 minutes per session. The interview questions were designed by the authors, focusing on the Blockchain-related factors impacting consumers' intention to purchase food.

**Table 1. Characteristics of participants interviewed (n=18).**

Demographics Variables		Frequency	Percent (%)
Age	Old (51 and older)	5	27,8
	Middle-aged (36 - 50)	1	5,6
	Young (18 - 35)	12	66,7
Gender	Male	8	44,4
	Female	10	55,6
Career Fields	Education	4	27,9
	Technology	1	5,6
	Farmer	1	5,6
	Finance and Accounting	2	5,6
	Student	10	55,3
Monthly income (million VND)	<5	11	61,1
	5 - 10	2	11,1
	11 - 15	2	11,1
	16 - 20	1	5,6
	21 - 30	0	0
	>30	2	11,1

## 4. RESULTS AND DISCUSSION

### 4.1. Results

In our research, the authors did qualitative research as well as collecting information from eighteen consumers in Hanoi through an in-depth interview. When asked about Blockchain features, most participants believe that these features have a positive influence on their purchasing intention. The surveyees who joined in the in-depth interviews indicated that there are several factors of Blockchain affecting their purchasing decisions.

#### *Blockchain features in buying process*

The interview results illustrated that Blockchain's traceability exerted a positive influence on food quality, supply chain transparency, safety, and anti-counterfeiting. In other words, all respondents agreed that Blockchain's features play a vital role in the supply chain and indirectly affect the purchase intentions of consumers. Some of the responses collected are as follows:

- *I am strongly of the opinion that traceability requires production units to pay more attention to improving food quality. (Female, 46 years old)*

- *I will feel more secure when using products with clear origins than those with unknown origins. Moreover, Blockchain's traceability helps me to identify fake goods and differentiate them from authentic ones. (Male, 54 years old)*

- *If there is a large volume of information about product quality, and transparent origin, it will be easy for both consumers and manufacturers to monitor processes and discover mistakes. (Female, 20 years old)*

- *Information about the origin, ingredients, and production process of food is stored on a distributed and secure network owing to the decentralized feature of blockchain. This helps mitigate fraud and fake information about products. (Male, 20 years old)*

In addition, regarding in-depth interview results, when asked about the influence of supply chain

transparency on product quality and anti-counterfeiting, sixteen out of seventeen participants believe that transparency is positively related to both factors. Some of the responses collected are as follows:

- *For me, supply chain transparency has a tremendous impact on food quality and anti-counterfeiting because every step of the process is controlled and monitored. (Male, 20 years old)*

- *I suppose that transparency allows all members in the supply chain to be clear about how the product was created in the previous stage, monitor and validate each other, thereby eliminating poor quality products. Therefore, safety and anti-counterfeiting will also be maintained. (Female, 21 years old)*

However, besides the aforementioned ideas, there is a person who has an opposite perspective. She (20 years old) posited that supply chain transparency does not necessarily affect product quality and anti-counterfeiting. She explained that when organizations are clear about the supply chain, they can expose manufacturing processes to competitors, making products easier to imitate, causing counterfeits and poor quality products.

### ***Influences of Blockchain features and Consumer Awareness***

Blockchain features which include product quality, supply chain transparency, food safety and anti-counterfeiting play a major role in building consumer's trust and perceived usefulness, mitigating perceived risk.

In terms of perceived usefulness, the in-depth interviews revealed that food safety and anti-counterfeiting have an impact on the perceived usefulness of consumers. The interviewees believed that unsafe and counterfeit foods could affect their health. Additionally, information about certified and tested foods would be helpful for them in the process of purchasing and using food. Some of the collected feedbacks are as follows:

- *In my opinion, food safety and anti-counterfeiting have a significant impact on my perceived usefulness and trust in food. I am aware that using safe products and genuine items is crucial for my own and my family's health. Genuine products have been tested for food hygiene, ensuring they do not harm consumers' health. (Male, 54 years old)*

- *There are times when I spend a lot of time choosing the right product at the supermarket, and only after using it do I know if my selection was correct. For example, whether the fruits have been genetically modified, or if the fish eyes are clear and not cloudy. Is the apple or banana ripe enough? Is the pomelo suitable for offering prayers? It would be fantastic if technology could help me address these concerns. (Female, 25 years old)*

- *I find that livestock raised with clean ingredients and special processes have a better taste than those sold in regular markets. Transparency would help me eliminate the idea of buying unsuitable products. (Male, 34 years old)*

The exclusion of risks had a significant impact on perceived risk of consumers. Respondents firmly believed that the implementation of the Blockchain had the potential to significantly mitigate and eliminate any potential risks associated with unsafe food. This was particularly noted by individuals with strict lifestyles such as exercise enthusiast:

- *For someone like me who exercises at the gym or for children, product information is extremely important. I often pay attention to the nutritional intake of family members. Any substance that I know can have a negative impact on the health of children cannot be included in our family meals. (Male, 35 years old)*

- *Unsafe and counterfeit food greatly affects health and can cause unwanted illnesses. Therefore, I am concerned about products with anti-counterfeit labels and recognized as safe food. (Female, 20 years old)*

Furthermore, according to in-depth interviews, raising awareness about risks also helped sensitive individuals, such as pregnant women and patients, to shop and consume with a peace of mind:

- *For pregnant women, eliminating factors that could potentially harm the fetus is emphasized. For*

*example, heavy metals in seafood, preservatives and flavor enhancers that have been proven to be harmful to pregnant women should be avoided. (Female, 34 years old)*

The aforementioned elements of Blockchain features contribute to the trust in a brand, manufacturer, or product that applies these technologies. This argument is demonstrated as followed:

- *I frequently purchase aromatic products like Za'atar and Rasel Hanout from overseas because they are often unique and more fragrant compared to domestic products. Utilizing reputable trading channels helps me acquire the desired goods. I aspire for these products not to be counterfeited by other manufacturers. If Blockchain is implemented, it could instill trust in the place where I make my purchases, eliminating the need for extensive sourcing efforts and saving me time. (Male, 34 years old)*

Additionally, during the in-depth interviews, two participants expressed that food sold in supermarkets has a more transparent supply chain, giving them peace of mind when using those products. Some collected responses are as follows:

- *In general, I tend to forget, but I do some research before making a choice (e.g., buying vegetables at WINMART because I know their cultivation process takes place at Ecogreen). (Female, 20 years old)*

- *I feel that purchasing food at a supermarket provides a clearer supply chain transparency compared to buying at a traditional market. Transparency gives me a sense of cleaner products, and I trust them more. I don't worry as much about food safety and the risk of cancer. (Female, 20 years old)*

#### ***Influences of Blockchain features and Consumer awareness on purchase Intention***

When it comes to consumer organisms and intention, most participants revealed that their food-purchasing intentions are influenced positively by perceived usefulness and trust, and negatively by perceived risk. Only one respondent was not sure whether her buying intention is influenced by perceived risk or not. Meanwhile, some interviewees believed that these factors also affect repurchase intention and loyalty towards food products. Some of the responses collected are as follows:

- *I often care about the values that a product will bring to me, so perceived usefulness has a big impact on my purchase intention. (Male, 21 years old)*

- *If a particular brand's rice has multiple certifications and is safe, and I have previously used it without experiencing any negative effects, then I will develop a habit of only buying that type of rice in the future. This creates a sense of trust for me and helps me decide to buy that brand of rice. (Female, 20 years old)*

- *When I buy products that are not fresh and from unreliable suppliers, I am worried about potential health risks to myself and my family. Therefore, I will not make the purchase. (Female, 53 years old)*

Moreover, regarding in-depth interview results, when asked about the influence of perceived risk on the intention of buying food, the interviewees all shared the same opinion that perceived risk has a negative impact on their trust in food. A response is collected as follows:

- *When I become aware of the risks, it makes me more anxious about the product, and will negatively affect my trust. (Female, 20 years old)*

However, besides the same idea as the above, there were some people who had different perspectives. They argued that if the risk of food is under control, they will still believe in that product as the trivial food insecurity would not have a clear impact on their trust on that food.

The respondents also agreed that they will have intentions to purchase food if Blockchain features including product quality, supply chain transparency, food safety and anti-counterfeiting are facilitated by Blockchain's traceability. Besides the particular food considered, some of interviewees intended to purchase other products from the same brand equipped with all these features. Some of the responses collected are as follows:

- *I always have a desire to buy products with good quality, understand the production process, origin, food safety, and avoid food fraud. (Female, 20 years old)*
- *Not only do I buy the food with all these features but I also pursue other products from the same brand. (Female, 46 years old)*

#### **4.2. Discussion**

After the qualitative research process, the research results showed that factors such as Blockchain's traceability, product quality, supply chain transparency, safety, anti-counterfeiting, trust, perceived usefulness, and perceived risk all affect directly and indirectly on consumer's purchasing intention. The authors believe that future researchers should apply the official research model and combine it with quantitative methods to accurately determine the degree of impact of each factor on purchasing intention of consumers in Vietnam, thereby proposing appropriate solutions for decision-makers to promote purchasing decisions and behaviors in Vietnam.

#### **5. CONCLUSION**

The main contribution of this research is to synthesize the factors that both directly and indirectly affect consumer intention to purchase food. This study provides several benefits from Blockchain that should be considered for the development of the food market. Not only are sufficient and reliable Blockchain features significant to the creation of consumer trust and perceived usefulness towards food but they also mitigate and eliminate the potential of risk that poses a threat to consumers' health. Given that food-related issues such as unsafe, low-quality food, food fraud is so popular in Vietnam, providing credible Blockchain features by displaying how products are grown, processed, and handled, and the percentage of fresh or safe ingredients in a product is crucial to stimulate consumer experience to make informed buying intentions. Therefore, the government agencies not only need to take the responsibility to set regulations for agricultural products, but also need to encourage companies in this field to apply Blockchain to their supply chain and use Blockchain labels as a guarantee of safety and quality to boost their consumer purchase intention. Finally, this study was conducted in Hanoi, Vietnam with the aim to shed light on the consumer's perception of Blockchain and its benefits in food in particular as well as agriculture in general.

## FACTORS INFLUENCING GREEN CONSUMPTION BEHAVIOR: IN THE CASE OF TOURISM IN VIET NAM

**Author: Nguyen Thanh Doan<sup>1</sup>, Quach Thu Phuong<sup>1</sup>, Le Thi Thanh Xuan, Do Linh Chi<sup>1</sup>  
Mentor: Ph.D. Nguyen Thi Huyen<sup>1</sup>**

**ABSTRACT:** *The aim of the study is to investigate the determinants of the sustainable consumption behaviors of Viet Nam tourists and their precise impacts on the behaviors by intergrading the Theory of Reasoned Action (TRA), Theory of Planned Behavior (TPB), and Value-Belief-Norm Theory. The data was collected with a total of 201 valid answers from tourists visiting famous destinations within Ha Noi city and imported to SPSS 26.0 for further statistical analysis. Results show that all the hypothesis determinants have impacts on the green consumption behavior of tourists coming to Viet Nam, including Environmental Factors, Availability, Price, Mass Media, Subjective Norms, Social Influence, and Green Beliefs. The first empirical study broadly provides a theoretical framework for the green purchase behavior of tourists within Vietnam's territory. The theoretical and practical contributions to tourists' purchasing green products are discussed.*

**Keyword:** *Green Consumer Behavior, Tourist, Sustainable Development*

### 1. INTRODUCTION

Tourism has undoubtedly become a large and diffuse global industry (Ralf Buckley). On the one hand, moderate and well-distributed tourism plays an important role in the upkeep of the attractions and preserving the environment (Erik Cohen). Furthermore, tourism is also one of the major sources of income for some countries including Viet Nam. Tourism is considered a spearheading industry in Viet Nam with an AAGR of 22.7%, contributing up to 8.5% of Viet Nam GDP in 2018 (Tran Doan Cuong). However, it can also pose environmental threats as a mass industry (Erik Cohen). According to a report conducted by the Institute of Tourism Development (ITDR), a tourist discharges, on average per day, 5-10 plastic bags and 2-4 plastic cans and cartoons excluding one-time used personal items. In the same report, Viet Nam has been stated to welcome about 103 million both domestic and international visitors with, respectively, 3.04 and 7.08 days of staying on average. Based on the previous information, an estimation of 230.110 tons of plastic waste was ejected by the activities of tourism. The impact of tourism in Viet Nam has become huge enough to gain attention from the authorities in the past decade. Several circulars related to protecting the environment were passed by Viet Nam government. Yet, the root of the problem seems to be ignored. Firms have realized that focusing on “sustainability” as a business goal can thoroughly increase the firm’s competitiveness in the market and have been using Green Marketing Strategies to promote green purchases (Raska and Shaw). Abundant of studies have been carried out to examine green consumption behavior from distinctive perspectives in several regions. Chetali investigated different factors such as behavioral flexibility, peer group influence, and price, which determine green consumption behavior in India in the context of two product categories. Yasmin proposed a theoretical framework for the relations between value and identity, using intrinsic and extrinsic motivation as a mediator, to understand sustainable consumer behavior. Jieong Chen et al. have inspected the relationship between the rural tourism experience and post-experience green consumption intention of Chinese People. Closer to home, Hoai et al. examined the factors that influence the green consumption behavior of Gen Z in Viet Nam, including environmental awareness,

properties, price, and availability of green products. Nevertheless, consumer behavior is continuously evolving, demanding further investigations to understand the consumption pattern. Especially when there is insufficient study of Viet Nam tourists' green consumption behavior in Viet Nam, the need to develop a better understanding of tourists' green purchase behavior in Viet Nam has become more and more urgent. Thus, this paper aims to identify the determinants of the behavior, as well as suggest a framework of Green Consumption Behavior of Viet Nam tourists.

**2. LITERATURE REVIEW**

**2.1. Theoretical Orientation**

*\* Theory of Reasoned Action (TRA); Theory of Planned Behavior (TPB)*

TRA was first introduced in 1967 by Fishbein and being developed further in decades later by Ajzen and Fishbein. The TRA model has been used widely to explain the mechanism of human behavior in the decision-making process in a certain direction. The model suggests that the actual behavior of an individual is determined by the behavioral intentions, which is a function of two main factors, accordingly, personal attitude and subjective Norms. Attitude, according to psychology, is a set of feelings, beliefs and behavior toward a specific individual (or individuals), object or event. The attitude is usually the result of the experience or nurturing process and can strongly affect behavior. Although the attitude often lasts long, they can still be changed. Attitude toward behavior can be understood as how an individual feels about the consequences of the behavior. It can be either positive or negative depending on one's beliefs about the consequences. Normative Norms are an individual's perceptions of social pressure, or one's belief about what others think he/ she should or should not perform that act. Subjective norms refer to a smaller and more specific pressure from a group of important people to an individual such as friends or family. Subjective norms are a function of a person's normative beliefs about what important others think they should (or shouldn't do) and their motivation to do so (Ajzen and Fishbein, 1980).

**Figure 1. Model of The Theory of Reasoned Action**

Later, TPB – a more detailed version of TRA was developed by Ajzen in 1985 from the foundation of TRA. While TRA might prove to be effective when applied to voluntary control of an individual, TRA is vulnerable to intervening environmental conditions, in other words, TRA becomes less effective when the behaviors are not fully under voluntary control. TPB was able to overcome the weakness of TRA since the external environmental factors were considered. More precisely, the TPB model suggests that the actual behaviors are also determined by the behavioral intentions, and aside from the two determinants mentioned in TRA model, TPB model referred to perceived behavioral control as a factor controlling the intentions.

*Figure 2. Model of The Theory of Planned Behavior*

Perceived Behavioral Control can be seen as an individual's perception of the difficulty of performing a particular behavior whether it is easy or difficult. This depends on the availability of resources and opportunities to perform the behavior. Ajzen proposed that the perceived behavioral control factor directly affects the propensity to perform the behavior, and that if the individual correctly perceives his or her degree of control, then behavioral control also predicts the behavior. The concept of perceived behavioral control is conceptually related to self-control.

**\* Value-Belief-Norm Theory (VBN)**

Currently, consumers are increasingly interested in smart and sustainable consumption, as well as environmentally friendly products and services right from production to consumption and use of products. Today's consumption requires not only intelligence about product quality, but also a deep understanding of the sociability and humanity of each product. Previous studies have relied heavily on Ajzen's (1991) theory of planned behavior (TPB) to explain issues related to sustainable development. However, Slevitch et al. (2013) propose that consumer green behaviors are particularly associated with self-actualization, ranking highest in Maslow's hierarchy of needs (1970). According to these authors, self-realization can be achieved by doing something that benefits society, thereby meeting the internal development needs of a person. Therefore, when many people realize that their purchasing decisions directly affect the environment, it is essential in any investigation to consider green consumer behavior that is specifically related to personal factors, such as values, beliefs, and norms. One theory that has succeeded in solving this problem is the VBN theory originally developed by Stern (2000). The advantage of VBN theory is that it examines green behavior by considering some of the factors necessary for environmentalism, such as ecological values and worldviews (Stern, 2000). So, VBN theory has succeeded in addressing the pro-social motivations of individuals by considering rational selection models including self-interest motives related to green behavioral intentions in different contexts (De Groot and Steg, 2009, De Groot and Steg, 2010, Kim and Han, 2010, Han, 2015).

Although VBN theory (Stern, 2000) was developed to predict more practically important environmental behaviors than intentions of behaviors, recently, a growing research group has also used VBN theory to explore "behavioral intent," with the assumption that intention is considered the primary determinant of actual behavior (Hansla et al. the, 2008). For example, using VBN theory, Han (2015) investigated tourists' pro-environmental behavior in the context of green accommodation, while using behavioral intent as an outcome variable. Therefore, this study contributes to the literature by proposing and testing VBN theory as a framework for comprehensively understanding consumer decision-making processes in green consumer intent.

This study also attempts to expand VBN theory by combining two important structures: subjective norms and green beliefs. Although personal norms have been extensively dealt with in previous studies, not much has been tested in conjunction with subjective norms. However, Fishbein's earlier statement (1967) proposed that consideration of both personal norms and subjective norms would increase the understanding of behavioral intent for green behavior. In addition, according to Ajzen (1991), individuals' intention to behave in a certain way becomes even stronger when they believe that their family, relatives, friends, and other colleagues will value a particular behavior. There is growing evidence for the existence of a strong social consciousness that directly influences consumer purchase intent and post-purchase behavior (Domina and Koch, 2002, Ogle et al., 2004, Ibtissem, 2010).

## **2.2. Hypothesis and research model**

### **2.2.1. Environmental Factors**

Behavior-oriented personal attitudes are defined as positive feelings or negativity of an individual when committing such behavior (Schiffman and Kanuk, 1987). Attitude will decide one's buying preferences, and that's one of the important predictors most important behavioral intent. Other research also suggests that attitude is one of the important factors influencing behavioral intentions and is the best indicator for predicting behavior (Rana & Paul, 2017). Attitudes toward the environment are recognized as determinants of behavioral intent (Chan & Lau, 2001; Wesley et al., 2012; Law et al., 2017). This study aims to explore the influence of people's environmental consumption attitudes on intentions to buy green goods. According to D'Souza et al. (2007), environmental knowledge can be defined as the consumer's knowledge of the impact of using a particular product on environment. Environmental knowledge is an understanding of whether the product itself has produced in an environmentally friendly way or not (Polonsky, 2011; Lim and Associates, 2014). Many studies suggest that environmental knowledge is an impact factor to consumer behavior in all stages of the buying decision-making process environmentally friendly products. Also, according to Banytne et al. (2010), consumers the more they know about environmentally friendly products, the more motivated they will be product purchasing force. Knowledge of the environment is often cited as the main motivator of action. green microconsumer (Peattie, 2010; Zhao et al., 2014, Laroche et al., 1996, Noor et al. 2012). Based on the above studies, the author noticed a relationship between ants' Actual environmental practices and behaviors persist and are fact-tested in some studies rescue. For further verification, this view will be tested in the hypothesis section below:

**H1:** *Environmental factors positively affect product consumption behavior green.*

### **2.2.2. Subjective norms and the influence on green consumption behavior of visitors to Vietnam**

Subjective norms can be understood as the perception of social pressure to implement a specific behavior (Ajzen, 1991). The subjective norm shows the extent to which an individual feels be morally responsible to others by purchasing green products and creating should have a positive social image (Barber et al., 2014). Large number of studies have claims that social pressure encourages consumers to buy green products and is a among the dominant factors affecting sustainable consumption (Biswas and Roy, 2015; Zhao et al., 2014; Lorek and Fuchs, 2013; Wang et al., 2014; Ritter et al., 2015). Wansink et al. (2017) notes that attitudes, subjective norms, and behavioral control of the individual significantly influencing the intention of purchasing environmentally friendly products of an individual..., therefore, the author proposes the hypothesis that:

**H2:** *Subjective norms positively affect product intent green.*

### **2.2.3. Price and its impact on green consumer behavior of visitors to Vietnam**

Price, according to the Cambridge dictionary, is defined as the amount of money exchanged/purchased for a product or service. In economics, price is considered the main factor directly influencing the demand for a product or service. Specifically, the book "Microeconomics" (Roger A. Arnold, Daniel R Arnold, David H Arnold, 2022) referred to "The Law of Demand", which states that if the price of goods and services decreases, the demand for those goods and services will increase, and vice versa. Meanwhile, the amount of demand for goods and services or the decision to buy Consumer goods and services are thoroughly studied in behavioral theory consumers in which price is considered one of the external stimuli belonging to Marketing that influences the decision to purchase goods or services of the consumer (Susan L.Henry, 1991). Both aspects suggest that the price plays an important role in predicting behaviors. So, the hypothesis that is proposed is:

**H3:** *Prices have a negative effect on the green consumer behavior of visitors to Vietnam.*

#### **2.2.4. The availability and its impact on green consumer behavior of visitors to Vietnam**

The availability of green products is defined as the popularity or ease of the search for green products in the market. Sujay R. Nair and Hari Krishna Mahram argued that the difficulty of finding green products is a factor hindering green consumer behavior. Carmen Tanner and her colleagues found that Swedish consumers dislike spending time looking for green products on the market. Walia and her colleagues have also studied this issue and found that the availability of green products has a significant impact on consumer purchase intent, but the scope of the study is limited to fast-moving consumer goods. So, the proposed research hypothesis is:

**H4:** *Availability has a positive influence on the green consumer behavior of visitors to Vietnam.*

#### **2.2.5. Mass media and the influence on green consumption behavior of visitors to Vietnam**

Mass communication is understood as an opportunity for readers, viewers, and listeners to see a media message in the media (Schultz and Lauterbourl, 1993). So, is there a relationship between mass media that impacts green consumer behavior? The team hypothesized that:

**H5:** *Mass media positively influences green consumer behavior.*

#### **2.2.6. Green beliefs and influence on green consumption behavior of visitors to Vietnam**

Green beliefs are the willingness to depend on partners they trust (Moorman, Deshpande, and Zaltman, 1993). In other words, trust in honesty, the responsibility of the manufacturer, the information on the packaging, the trademark, and the quality assurance of TPAT products (Janssen and Hamm, 2011). Therefore, the team hypothesized that:

**H6:** *Green belief positively influences green consumer behavior.*

#### **2.2.7. Social influence and its impact on green consumption behavior of visitors to Vietnam**

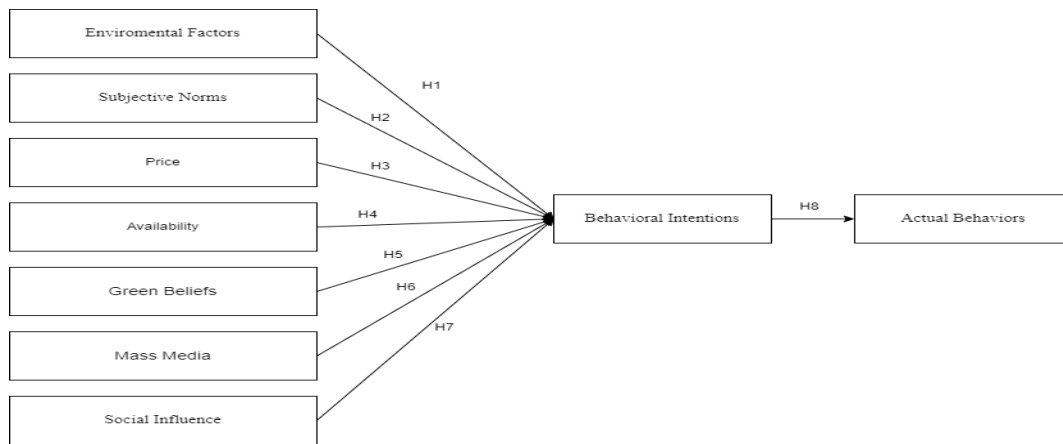

Consumers living in society will be greatly influenced by society, especially for goods such as green products – due to the low awareness and income of people in Vietnam – the influence of society plays a very important role in promoting changes in people's perception of green consumption, thereby influencing consumers' green consumption intentions. Snapping and Rahman (2011), and Hisami and Yousef (2013) also found a positive relationship between social influence on green consumer intentions and behavior.

**H7:** *Social influences have a positive impact on green consumption intentions.*

#### **2.2.8. Behavioral intentions and influences on green consumption behavior of visitors to Vietnam**

Purchase intentions refers to a product category's priority to consumers when they are at the purchase evaluation stage, as those priorities indicate a consumer's intent to purchase a particular product. Buying intent is a step in the buying decision process, which is the course of action that transitions from buying intent to actual buying behavior. Purchase intent is defined as a person's tendency to act on the choice of goods (Bagozzi & Burnkrant, 1979). Behavioral intentions are the most important factor for predicting consumer behavior Ajzen (1985), Venkatesh et al. (2003); some studies indicate that behavior can be determined from intention with considerable accuracy (Ajzen 1991). In many studies, intention is thought to be a strong predictor of behavior, so the author proposes a hypothesis:

**H8:** *Behavioral intent has a positive relationship with green product consumer behavior.*

**Figure 3. Proposed conceptual model of the green consumption behavior of Viet Nam tourists.**

**3. METHODS**

**3.1. Instrumentation**

The convenient sampling method was carried out to save traveling costs and reach more tourists. Since the surveyed subjects are very diverse and distributed over a large area, a convenient sample selection method is suitable for the research process. The survey was conducted by distributing questionnaires when surveying directly at tourist destinations in Hanoi and sending surveys online via social networks. To obtain the most suitable answer from tourists based on their actual observed behaviors, it took more time for the team to simultaneously conduct the survey and observe to check whether the answer is valid or not. Therefore, only a limited amount of 30 valid direct answers was added to the sample along with the results from the online surveys shared in tourists’ social media groups.

The final sample collected 201 valid answers from visitors. The data consists of 141 female (70.1%), 58 male (28.9%) and 2 individuals of other genders (1%). The age group accounting for the highest proportion in 201 samples is from 15 to 20 years old, there are 140 visitors (69.5%), from 21 to 30 years old there are 54 visitors (27%), from 31 to 40 years old there are 6 visitors (3%), from 41 to 50 years old there is 1 tourist (0.5%).

**Table 1: Sample**

	Sample	Frequency	Percent	Valid Percent	Cumulative Percent
Gender	Female	141	70.1	70.1	70.1
	Male	58	28.9	28.9	99
	Other Genders	2	1	1	100
Age	15 - 20	140	69.7	69.7	69.7
	21 - 30	54	26.9	26.9	96.5
	31 - 40	6	3	3	99.5
	5	1	0.5	0.5	100
	Total	201	100	100	

**3.2. Measurement Instrument**

The questionnaire was designed using a five-point Likert scale 1- strongly disagree and 5 - strongly agree. The questionnaire had 2 main parts namely: (1) socio-demographic characteristics of tourists (Age and gender) and (2) factors influencing tourists’ sustainable consumption behaviour during travelling. We have included demographic variables as control variables to reduce the possibility of baseless relationships

based on such personal characteristics. Except for Environmental Factors, which has 6 measurements, the rest of the variables (Subjective Norms, Price, Availability, Green Belief, Mass Media. Social Influence, Intentions and Behaviors) use only 3 measurements, which was all adapted from previous research in the field.

### 3.3. Research models

Answers was imported to SPSS 26.0 and descriptive statistical analysis and other analysis including Cronbach's Alpha Reliability and correlation were carried out; results on the reliability of the scales through Cronbach's Alpha reliability assessment, correlation analysis and the suitability of the research model to the hypotheses and come up with the model and the adjustment hypothesis.

## 4. RESULT

### 4.1. Cronbach's Alpha Reliability Assessment

The result of the scale reliability analysis by Cronbach's Alpha coefficients is quite high, indicating that the reliability of the questionnaire is good.

**Table 3. The result of the reliability test of the scale**

Factor	Cronbach's Alpha
<b>Environmental Factor, Cronbach's alpha = 0,830</b>	
I like the idea of green consumption (EF1)	0,786
Green consumption is a good idea (EF2)	0,785
I have a supportive attitude towards green consumption (EF3)	0,788
The government now encourages consumers to buy green products (SN2)	0,831
Most people around me use green products (SN3)	
<b>Price, Cronbach's alpha = 0,690</b>	
I noticed that the price of green products is clearly listed (p1)	
I noticed that the price of green products is high because of the high cost of production and business (P2)	
I find the price of green products in line with the quality (P3)	
<b>Availability, Cronbach's alpha = 0,745</b>	
I find it inconvenient to find green products as an alternative to regular products (A1)	
Green products are often not available in the regular stores I shop for (A2)	
I really don't know where green products are sold (A3)	
Mass Media, Cronbach's alpha = 0,785	
I see green consumption promotion media information on ads, television, internet, TV game shows... (M1)	
Modern developments are destroying the environment (EF4)	
Environmental pollution can only be improved when we act together (EF5)	0,793
Balancing the natural environment is complex and easy to lose (EF6)	0,827
I see many promotions and incentives when participating in consuming green products (M2)	0,715
I see information about eco-friendly products on travel guides or other travel guides (M3)	0,724
<b>Green Beliefs, Cronbach's alpha = 0,861</b>	
I believe in the honesty of the producer (GB1)	0,742
I believe in the responsibility of the producer (GB2)	0,753

I believe in safety endorsements, green product certification marks (GB3)	0,900
<b>Social Influence, Cronbach's alpha = 0,807</b>	
I want to buy green products to reduce environmental pollution (SI1)	0,717
I regularly introduce friends and relatives to the positive effects of green products (SI2)	0,823
I am willing to buy green products for individuals, families (SI3)	0,672
<b>Behavioral Intentions, Cronbach's alpha = 0,838</b>	
I/my family will buy green products because they cause less environmental pollution (I1)	0,751
<b>Subjective Norms, Cronbach's alpha = 0.670</b>	
My shopping decisions are influenced by my family members (SN1)	0,706
I plan to purchase green products for individuals/families (I2)	0,771
I would consider switching from an existing brand to an eco-brand (I3)	0,802
<b>Actual Behaviors, Cronbach's alpha = 0,867</b>	
I/my family often buy environmentally friendly products/services (B1)	0,878
When I/my family have a choice between 2 products, we usually buy products that are less harmful to others and the environment (B2)	0,820
I/my family buy green products on a regular basis (B3)	0,718

Cronbach (1951) gives a confidence factor for the scale. If a measurement variable has a Corrected Item – Total Correlation  $\geq 0.3$ , the variable is satisfactory (Nunnally, J. (1978), Psychometric Theory, New York, McGraw-Hill). Cronbach's Alpha coefficient value (Hoang Trong, Chu Nguyen Mong Ngoc (2008), Research data analysis with SPSS Volume 2, Hong Duc Publishing House, Page 24):

From 0.8 to close to 1: very good scale.

From 0.7 to close to 0.8: the scale measures good use.

From 0.6 or higher: qualifying scale.

Cronbach's alpha test results have 4 variables excluded from the model including: SN2, SN3, P1 and P3.

#### 4.2. Correlation Analysis

Building a correlation coefficient matrix helps to consider the linear correlation between variables in the model. Specifically, the team can look at the correlation between variables that are independent and the intermediate variable and the intermediate variable with the dependent variable, even between variables that are independent of each other. If the independent variables are closely correlated, we must pay attention to the phenomenon of linear multi-addictiveness. In addition, we can remove any independent variable if it is not correlated with the intention's variable. Pearson correlation coefficient will be used to quantify how close the linear relationship between quantitative variables is. If there is a close relationship between two variables, the problem of linear multiplication must be considered when analyzing regression (when the Pearson correlation coefficient  $> 0.3$ )

$$I = \beta_1 EF + \beta_2 M + \beta_3 P + \beta_4 SI + \beta_5 SN + \beta_6 GB + \beta_7 A + \alpha$$

Andy Field (2009) suggested that although it is possible to evaluate the linear relationship between two variables through the Pearson correlation coefficient, the test result if the test sig  $< 0.05$ , the variable pair is not linearly correlated (assuming a significance level of  $5\% = 0.05$ ). From the results of the above Person correlation analysis, the sig of pairs of independent variables with the intent variable is  $< 0.05$ , showing that the independent variables here are linearly correlated with the intentions variable. The sig coefficients of pairs of variables independent of each other are all  $< 0.05$ , these pairs of variables are linearly

correlated with each other except for 2 pairs of SN – A and SI – A with sig coefficients of 0.087 and 0.114 respectively, these two pairs are not linearly correlated with each other.

The results have shown that environmental factors, mass media, price awareness, subjective norms and green beliefs have correlation coefficients Pearson ranging from 0.3 to 0.5 indicating the correlation of these independent variables with the intermediate variable is a medium-strength. The social influence variable with a Pearson correlation coefficient of  $0.724 > 0.5$  demonstrates the correlation between social influence and intention is strong. As for these variables, the phenomenon of linear multi-additiveness must be considered when analyzing. The availability variable with correlation coefficients of 0.149 greater than 0.1 but less than 0.3 shows that the relationship between availability and intention is weak.

From the results of the above Pearson correlation analysis, the sig coefficient of the intentions variable pairing with the behaviors variable is less than 0.05, showing that the intentions variable has a linear correlation with the behaviors variable. The Pearson correlation coefficient between the intent variable and the dependent variable of 0.211, in the range of 0.1 to 0.3, proves that the pair of behavioral intent variables – green consumer behavior variables are weakly correlated.

### **4.3. Model Fit Test**

#### **4.3.1. R-squared**

After correlation analysis, the team put 7 independent variables (EF to A), 1 intermediate variable I, and 1 dependent variable B into the regression model, then proceeded to test R-Squared. R-Squared shows how much the study hypothesis model fits into the data. The team proceeded to conduct Regression Analysis. There are 3 out of 5 independent variables have a positive impact (with a Beta factor of  $>0$ ) and 2 have a negative impact on the dependent variable. The low Standardized beta coefficients of variables indicated that the variable has weak affection on the model. This may be temporarily acceptable due to objective reasons of resources and bias in the team's analysis. The group tentatively concluded that there are 5 factors affecting the green consumption behavior of visitors to Vietnam, of which social influence and environmental factors have the greatest influence on the model.

#### **4.3.2. T-test**

From the Coefficients table, the sig value of the t-test is used to verify the significance of the regression coefficient. If the sig value of the regression coefficient of an independent variable is less than 0.05, we can conclude that the independent variable has an impact on the dependent variable. If the sig value of the independent variable is greater than 0.05, we conclude that the independent variable has no effect on the dependent variable, and there is no need to remove that variable to run the regression again the second time. On the basis of regression analysis, the sig coefficient of  $t < 0.05$  demonstrates that the model is statistically significant.

#### **4.3.3. VIF**

VIF (Variance Inflation Factor) is used to test the phenomenon of linear multi-additive. Typically, if the VIF of an independent variable is greater than 10, there is linear multi-additive phenomenon occurring with that independent variable. Then this variable will have no value to explain the variation of the dependent variable in the regression model. For research works using the Likert scale, the best VIF coefficient is  $<2$ , ensuring that no linear multi-additive phenomenon occurs. With the results of the analysis in the Coefficients table, the team found that the VIF values were all  $<2$  demonstrating variables without linear polyaddition and that the model was guaranteed statistical significance.

## 5. DISCUSSION

Stemming from the actual research results, the group made a number of proposals for tourism businesses or tourism-related businesses and tourists themselves in Hanoi city in making decisions to buy and consume green products during travel, thereby serving as a premise for improving accessibility to each visitor effectively for tourism businesses and related services.

**As for tourists**, “Environmental Factors” and “Social Influences” have a great influence on the consumption behavior of tourists, they are aware that green consumption should be done to protect the environment, limiting the use of many products that pollute the environment, but due to the short travel time, they often do not care or even have no time to think of green consumption when traveling, they only buy products they prefer at tourist destinations, so it is difficult to change their behavior but there is still a solution that can be solved, which is to change the behavior of selling products at tourist destinations. Local people, tour guides or sellers of products at tourist destinations should be equipped with the knowledge related to green consumption. Whenever there is visitors, event organizers, sellers, guides should regularly propagate about green consumption, protect the environment so that tourists can be aware of in the process of traveling and practice green consumption behavior when traveling in Vietnam.

**As for firms**, first, “Social Influences” and “Environmental Factors” are 2 determinants that have a great influence, promoting consumption intentions and leading to green consumption decisions of tourists in Hanoi city. These two factors include the desire to protect the environment, awareness of the benefits of green consumption, awareness that the environment is being undermined and the willingness of visitors to take action to fulfill that desire. Businesses can promote tourists’ consumption decisions by influencing their desires, increasing their desire to do good deeds for the environment or increasing propaganda about green products to protect the environment, tourism services that come with programs that benefit tourist destinations in particular and the living environment in general or increase awareness of the product/service. Specifically, enterprises can carry out activities to protect the ecological environment when tourists are traveling or at tourist destinations, organize regular environmental protection transmission activities to firmly reinforce tourists’ green consumption intentions, exhibiting green products with many good thoughts for the environment can increase the excitement and fun of green activities, from which visitors can easily consume green products/services with a comfortable mentality.

Secondly, “Green Beliefs” also has a great impact on the green consumption intentions of tourists when traveling in Hanoi city. Enterprises must always focus on the production process from input to output, from raw materials to finished products. Because, only when enterprises produce honestly and responsibly, tourists will have the confidence to consume green products with the meaning of environmental protection. In addition to the other two qualities, green product certification issued by the government is also a strength, a lever that turns tourists’ consumption intentions into green consumer behavior.

Thirdly, today’s society is increasingly developing, there are many social networking platforms that can directly reach tourists, but the mass media of green products/services is still very sparse and fragmentary, making visitors unable to access the deepest, the most complete of green products/services. According to the results of the survey and analysis team, the “Mass Media” is a significant determinant affecting the consumption intentions and consumer behavior of tourists in Hanoi city. Therefore, the group recommends that businesses focus strongly on developing and expanding communication on different platforms and methods to get closer to visitors and customers in general.

Finally, an indispensable factor that also contributes greatly to promoting intentions into green consumer behavior is “Availability”. This factor means presence, or availability around when customers

want to consume. According to the survey results, most visitors find it inconvenient to take time to learn green products to replace conventional products, realizing that not always green products are right next door, can be consumed anytime, anywhere like regular products. Therefore, businesses should focus on distributing products/services more widely and more commonly in many different tourist areas so that visitors can see green products / services anytime they need them instead of using conventional products.

## **6. CONCLUSION**

Research results show that 8 factors strongly influence the green consumption behavior of visitors to Hanoi. Among them, the strongest impact factor was “Behavioral Intentions”, with an average score of 3.986 and Cronbach’s Alpha of 0.838; these include the “Social Influence” factor with an average score of 3.87 and Cronbach’s Alpha of 0.807; followed by the “Green Beliefs” factor with an average score of 3.59 and Cronbach’s Alpha of 0.861, “Mass Media” with an average score of 3.56, and Cronbach’s Alpha of 0.785 1; “Environmental Factors” with a average score of 2.52 and Cronbach’s Alpha of 0.830; finally, “Availability” with an average score of 3.363 and Cronbach’s Alpha with a GPA of 0.745, “Price” with an average score of 3.78, and Cronbach’s Alpha of 0.69; finally, “Subjective Norms” with an average score of 3.326 and Cronbach’s Alpha of 0.676. The green consumption behavior of tourists is also heavily influenced by the factor “Intentions”. Behavioral intentions show a willingness of consumers to consume green products. It is considered the premise of the implementation of the act of consuming green products. This conclusion is also consistent with the opinion of the authors Dr. Pham Thi Huyen, Nguyen Thi Van Anh, Dao Ngoc Han, Tran Trung Kien and Do Tri Tu.

In the context of government agencies and businesses strongly launching incentive programs on green consumption today, it is not necessary for a person to have a pre-existing interest and awareness of environmental issues to know about green consumption and thereby generate green consumption behavior. The biggest impact affecting the green consumer behavior of visitors to Vietnam is the purchase intention with the choice of environmentally friendly or conventional goods.

Besides, if consumers live in a society, they will be greatly influenced by society, especially for goods such as green products. The characteristic of Vietnamese society in general is that people live in a community that is strongly influenced by relationships. If an individual lives in an environment where the surrounding relationships have green consumption intentions and behaviors, that individual will suffer many impacts that lead to green consumption behaviors.

However, we can’t deny the impact of “Green Beliefs”, “Mass Media” and “Environmental Factors” green consumer behavior. Despite of being influenced by society, the person has no faith in the use of green products or does not care about environmental issues or is not aware of the seriousness of environmental problems and the need for environmental protection, they are not likely to care about green consumption and will not intend to consume green products. Along with that, in order for green beliefs to spread to people faster and stronger, mass media also play an important role.

Along with these factors, “Availability”, “Price” and “Subjective Norms” also contribute to influencing the green consumption behavior of visitors to Vietnam. The difficulty of finding green products hinders visitors from consuming green products. Due to low awareness and incomes of Vietnam – the influence of prices plays a very important role in the consumption choices of Vietnamese tourists.

*Abstract: The objective of this research is to identify the impacts of influencing factors on the university choice decisions of high school students in Vietnam and propose recommendations for students, educational institutions, employers, and the government to optimize the university selection process. This study takes place in the current context following the COVID-19 pandemic and the recent wave of studying abroad nationwide. Survey data collected from 662 high school students and 538 university students, including 547 surveys from the Northern region, 439 surveys from the Southern region, and 214 surveys from the Central region, have been analyzed. The results from multiple regression analysis using SPSS software indicate that Student Characteristics, Significant persons, Fixed university characteristics, Social Media, and University Efforts to Communicate with students significantly impact University choice decisions.*

*Keywords: University choice decision, High school students, Covid-19.*

### 1. INTRODUCTION

After 1986, Vietnam witnessed the emergence of private universities alongside the existing public system. By 2022, 60 private universities operated nationwide, and 400 collaborative programs with foreign countries enrolled over 25,000 students (Ministry of Education and Training, 2022). This expansion led to increased competition among universities and a wave of studying abroad. However, the COVID-19 pandemic shifted the trend, favoring domestic higher education due to cost advantages and improved quality. This change offers multiple choices for high school graduates and opportunities for the development of universities in Vietnam.

Vietnamese higher education now benefits students, universities, employers, and the government. Students seek quality education and competitive advantages in the job market. Universities aim to attract capable students to enhance their reputation and attract more high-quality individuals. Employers hope for skilled labor to meet their requirements. The government benefits from a prosperous nation when these interests align. Students' university choices are central, influencing all stakeholders' interests. Making the right choice helps students achieve their goals, benefits employers, and drives universities to improve educational services in line with the labor market's needs.

To further explore the factors influencing the decision-making process of high school students in selecting universities and their impact, research was conducted, surveying over 1200 high school students and university students nationwide. The study aims to determine the influences of these factors on the university choices of high school students in Vietnam and propose recommendations for students, educational institutions, employers, and the government to optimize the university selection process for high school students in the country.

---

<sup>1</sup> National Economic University.

## **2. THEORETICAL FRAMEWORK**

### **2.1. University choice decision**

High school students face uncertainties during the university selection process, particularly regarding their acceptance into a university (Randall G. Chapman, 1986). While students start with complete information about their preferred university, new information can influence their initial choice. Eventually, students make their selection, though some may defer enrollment due to financial or personal reasons. Economists approach the university choice as a human capital investment decision, assuming that the lifetime economic benefits will outweigh the educational costs (Becker, 1993; Ellwood & Kane, 2000; Paulsen, 2001). They believe individuals calculate the total benefits of attending a university and compare them with the expected costs. On the other hand, sociologists view the decision as an interaction between educational aspirations and difficulties. They emphasize the influence of cultural and social capital, like parental educational attainment and family income, on students' educational aspirations. This sociological approach mainly focuses on the early stages of the university choice process, explaining how an individual's social position shapes their educational aspirations and university choice (Bourdieu, 1986; Hearn, 1988; McDonough, 1997; Terenzini et al., 2001). It differs from the economic approach, which concentrates more on benefits-cost analysis at later stages of the university choice process. In conclusion, the university selection process for high school students involves uncertainties and is influenced by both economic and sociological factors, which shape their decision-making and aspirations.

### **2.2. Factors Influencing the university choice decision**

The research on university selection decisions among high school students in Vietnam has identified two main groups of factors that influence their choice: (1) internal factors, which include (i) significant persons and (ii) student characteristics; and (2) external factors, which consist of (i) fixed university characteristics and (ii) university efforts to communicate with students.

#### **2.2.1. Internal factors**

##### *2.2.1.1. Significant persons*

High school students experience pressure from their "reference group" and strive to meet their expectations. Family and friends play a significant role in influencing students' university selection decisions in two ways: (1) by shaping their perceptions of universities and (2) by directly providing advice on which universities to consider (D.W.Chapman, 1981). The influence of individuals around them positively affects students' university choices. Therefore, the hypothesis **H1: Significant persons have a positive effect on the student's choice of university.**

##### *2.2.1.2. Student characteristics*

Personal abilities and interests are crucial factors that impact students' decisions, including their university choices. Student ability and talent are considered major factors influencing the selection of colleges and universities (Manski, C. and Wise, D., 1983). Interests and career goals are also essential factors influencing student choices (Mehboob, Shah, and Bhutto, 2012). The awareness of the match between personal abilities and the university program's requirements significantly influences student decisions (Cabrera & Nasa, 2000). Personal characteristics have a positive impact on high school students' university selection decisions. Therefore, the hypothesis **H2: Student characteristics have a positive impact on the university selection decisions of high school students.**

### **2.2.2 External factors**

External factors that influence university selection decisions include fixed university characteristics, geographic location, costs, facilities, reputation, and the academic program.

#### *2.2.2.1 Fixed university characteristics*

University characteristics play a crucial role in the decision-making process of university selection (Pham Thi Ly et al., 2006). The geographic location of the university is also a significant consideration, impacting students' costs and convenience while studying. Additionally, the cost of studying, encompassing financial, time, and psychological factors, influences the choice of university. University facilities, both physical and non-physical assets, are also important factors affecting university selection (Ivy, 2008). The reputation of the university holds weight as it directly impacts employment opportunities after graduation. Furthermore, the academic program's quality is a key determinant of student satisfaction with their education and future career prospects (Yusof et al., 2008; Ivy, 2010; Sia, 2010). Overall, it can be concluded that external factors significantly influence high school students' decisions when selecting a university. Based on these factors, the author group proposes hypothesis **H3: Fixed university characteristics have a positive impact on high school students' university selection decisions.**

#### *2.2.2.2. University Effort to Communicate with students*

Universities' communication activities significantly influence students' decisions in choosing a school, encompassing advertising, enrollment events, and campus tours (Kee Ming, 2010). Among the various sources of information, the university's website and the "University Admissions Guide" hold the utmost importance and are extensively consulted by students when making their decisions (Nguyen Minh Ha et al., 2011). Information, admission policies, specific activities, and media also play a role in impacting students during the information-gathering stage (Litten, 1982). The effectiveness of communication and admission counseling has a considerable impact on students' university selection decisions. Based on these factors, the author group proposes hypothesis **H4: University efforts to communicate with students influence high school students' decisions in choosing a university.**

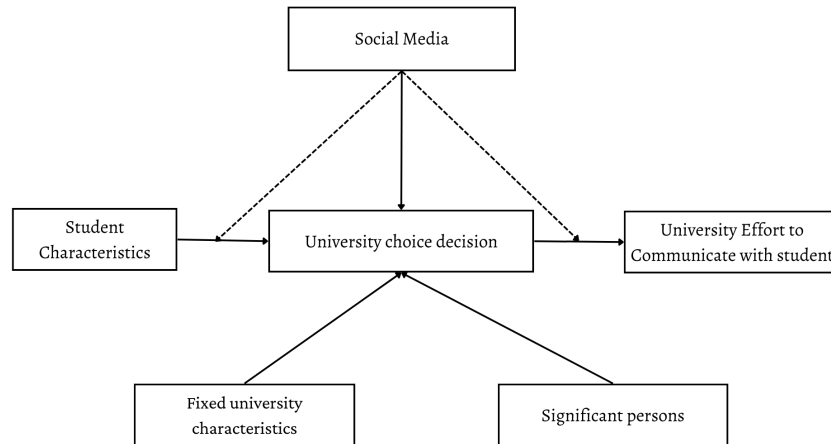

#### *2.2.2.3. Social media*

Social media is a participatory structure that allows individuals to collaborate and share information online. It includes platforms such as YouTube, LinkedIn, Facebook, and Twitter (O'Reilly, Cooke and Buckley, 2008). Social media provides information about different universities, evaluations from experts, and success stories of alumni. It allows users to interact and provide feedback, evaluations, and create differentiation of opinions about a university. Social media has a significant impact on human decisions and actions, particularly in relation to universities. "Media users actively choose specific content based on their needs, and if there is any impact, it is on their awareness or intention to act" (Matei, 2010). Among those surveyed, 68% had used social media to research universities and colleges. Additionally, about 70% of those surveyed believed that social media had a significant, but reasonable, impact on their decision to search for their college or university (The 2014 Social Media Report, Dalfonso, Pratt, and Rogers, 2014). It provides opportunities for universities to present necessary information and can positively influence the behavior, perception, and decision-making process of prospective students. Choudaha (2013) suggests that advertisements about campus life, which can be posted on YouTube and university websites, provide a virtual and effective communication platform for prospective students. With the increasing use of mobile devices, tablets, and the internet, this recruitment strategy has become more effective and important. Therefore, Nurlida (2009) accurately noted that "the satisfaction of prospective students with their choice of university depends on their satisfaction with information related to the university's attributes". Facebook is a good platform for universities to connect with prospective students, as university students often use

this social media platform. However, universities need to ensure that information is conveyed correctly and completely. Based on the factors mentioned above, the research team proposes hypothesis **H5: Social media has an impact on the decision of high school students in choosing universities.**

**2.3. Proposal research model**

The authors propose five factors that influence high school students’ university choices, based on a comprehensive review of previous studies and the current research situation. The research model includes two internal factors: Significant persons and Student Characteristics, and three external factors: fixed characteristics of the university, the university’s communication efforts with students, and social media platforms (Figure 2).

**Figure 2: Research Model**

*Source: Research result*

Specifically, the influence of internal factors is based on Jim Blythe’s reference group theory (2009) and consumer behavior theory by Comegys et al. (2006). The impact of student’s personal factors is based on the theory of planned behavior by Cooke and Sheeran (2004), in which the theory of reasoned action and theory of planned behavior are the basis for the impact of other factors on high school students’ university choices.

The research hypotheses proposed by the authors include:

- H1: Significant persons have a positive influence on their university choice.
- H2: Student characteristics have a positive influence on high school students’ university choices.
- H3: Fixed university characteristics have a positive influence on high school students’ university choices.
- H4: University effort to communicate with students has an influence on high school students’ university choices.
- H5: Social media has an influence on high school students’ university choices.
- H6: Social media has an impact on the relationship between personal factors and university choice.
- H7: Social media has an impact on the relationship between the university’s communication efforts and high school students’ university choices.

**3. RESEARCH METHODS**

**3.1. Research Methods**

The authors used two main research methods called desk research method and field research method:

- **Desk research method:** (i) researching from domestic and foreign research works to determine the theoretical framework, and research model; (ii) analyzing and discussing research findings and suggesting recommendations.

- **Field research method:** conducting in-depth interviews and survey questionnaires for two groups of subjects, students studying at high schools and students studying at universities. The content of the field research method will be described in detail in the context of data collection methods.

### 3.2. Data collection methods

The authors conducted a study in Vietnam to identify factors influencing students' university selection decisions. They used qualitative in-depth interviews and a quantitative questionnaire survey for primary data collection, along with various analytical methods like Cronbach's Alpha, EFA, CFA, and SEM. The authors also gathered secondary data through desk research, reviewing relevant literature and research studies on university selection and decision-making behavior from national and international sources using search engines like Google Scholar and Research Gate.

### 3.3. Sample size and study

After collecting the survey questionnaires, the author team obtained a total of 1263 votes through face-to-face and online surveys. They screened the questionnaires and selected 1200 formal observations for the quantitative study, excluding incomplete responses and those from uncooperative respondents who provided inconsistent answers to synonymous questions.

## 4. RESULTS AND DISCUSSION

### 4.1. Results

#### 4.1.1. Quantitative research findings

##### 4.1.1.1. Descriptive statistics

The study focused on Vietnamese students. 1200 valid questionnaires were collected and analyzed using SPSS 20.0. Demographic information, including gender, family income, geographical region, high school, field of study, and city, is presented in Table 1.

**Table 1. Descriptive statistics of the formal quantitative research sample.**

	Standard	Number of observations	Percent (%)
Total		1200	100
Sex	Female	730	60.8
	Male	470	39.2
Job	Pupil	662	55.2
	Student	538	44.8
High school currently / attended	Public schools	837	69.8
	International Affiliate School	203	16.9
	Private school	157	13.1
	Self-financed public school	2	0.2
The field you want to study	Economy	540	45
	Technique	330	27.5
	Pharmacy	123	10.25
	Language	101	8.42
	Art	50	4.17
	Other Sectors	56	11.6

Regions where you are studying and living	North	547	45.6
	Southern	439	36.6
	Central region	214	17.83
The city where you are studying and living	Hanoi	304	25.3
	Ho Chi Minh City	149	12.4
	Other Cities	747	62.25
Average monthly income of the family (VND)	From 20 million or more	287	23.92
	15 million - less than 20 million	193	16.08
	10 million - less than 15 million	214	17.83
	5 million - less than 10 million	171	14.25
	Under 5 million	185	15.42

Source: Survey result

#### 4.1.1.2. Reliability Test with Cronbach's Alpha

The scale will first be analyzed for Cronbach's Alpha reliability coefficient, variables with item-total correlation coefficient less than 0.3 will be eliminated and the scale will be accepted for analysis in the next steps. according to Cronbach's Alpha reliability of 0.6 or higher (Ha Nam Khanh Giao & Bui Nhat Vuong, 2019).

**Table 2. Results of Cronbach's alpha analysis and variable-total correlation**

The scale	Number of observed variables	Cronbach's alpha	Correlation coefficient of variable - minimum sum
Significant Persons	6	0.878	0.658
Student Characteristics	4	0.800	0.592
Fixed University Characteristics	8	0.913	0.684
University Efforts to Communicate with Students	5	0.838	0.601
Social Media	3	0.878	0.731
University Choice Decision	3	0.867	0.730

Source: Research result

Based on Table 2, the analysis results show that the value of Cronbach's Alpha fluctuates in the range from 0.8 to 0.913, and the minimum coefficient of correlation for each variable is greater than 0.3. Therefore, the scales have gained such confidence and will be used for exploratory factor analysis.

#### 4.1.1.3. Exploratory Factor Analysis (EFA) result

Factor analysis is conducted to examine the potential for reducing a large number of observed variables to a smaller set of variables. This enables the easy assessment of relationships between factors (representing variables if necessary).

**Table 3. Results of the Kaiser-Meyer-Olkin (KMO) test for the observed variables.**

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		0.921
Bartlett's Test of Sphericity	Approx. Chi-Square	18.921.715
	df	435
	Sig.	0

Source: Research result

The initial exploratory factor analysis shows promising results. The KMO coefficient of 0.921 ( $> 0.5$ ) indicates strong correlation among observed variables in the population, making the EFA factor analysis appropriate. Using Eigenvalues greater than 1 and the principal components extraction method with varimax rotation, 6 factors were extracted from 29 observed variables, explaining 57.11% of their variation, meeting the necessary requirements. These 6 factors will be retained in the model.

4.1.1.4. *Confirmatory Factor Analysis*

The authors utilized Confirmatory Factor Analysis (CFA) to assess the model’s fit with the observed data. The CFA results show good alignment, with a significant Relative Chi-square value of 2.940 (below 3). Compatibility tests also yielded positive outcomes: CFI = 0.960, GFI = 0.942, TLI = 0.955, RMSEA = 0.040, and PClose = 1.00. Additionally, the Maximum Likelihood Estimates factor validation analysis confirms the model’s reliability, convergent validity, and discriminant validity. CR values range from 0.801 to 0.912 (all above 0.8), and AVE values range from 0.502 to 0.643 (all above 0.5). Moreover, all MSV values are lower than the corresponding AVE values.

4.1.1.5. *Structural Equation Modeling*

Figure 2. SEM result

Source: Quantitative research results

Table 3 depicts that the P-value of the impact of all indicators on QD is less than 0.5; therefore, the test accepts the hypotheses H1, H2, H3, H4, H5, H6, H7.

Table 3. The result of analyzing SEM

The relationship of indicators			Estimate	S.E.	C.R.	P	Estimate
QD	<---	BTHSA	0.255	0.033	7.818	0,000	0.229
QD	<---	NLA	0.14	0.04	3.46	0,000	0.101
QD	<---	PTTTA	0.216	0.029	7.563	0,000	0.211

QD	<---	DHA	0.168	0.033	5.027	0,000	0.141
QD	<---	DDNTA	0.359	0.032	11.238	0,000	0.362
QD	<---	MOD_PTTT_BTHS	-0.144	0.013	-10.942	0,000	-0.234
QD	<---	MOD_PTTT_NL	0.121	0.011	10.818	0,000	0.231

Source: Quantitative research results

Table 3 shows that DDNTA has the strongest impact on QD with a coefficient of 0.362. BTHSA and PTTTA also strongly influence QD. All positive factors (DDNTA, BTHSA, PTTTA, DHA, and NLA) have a positive influence on university choice. PTTTA moderates the relationship between BTHSA and QD negatively but positively with NLA and QD.

#### 4.1.1.6. One-Way ANOVA Test

**Results of the One-Way ANOVA analysis by region in Appendix 2,3 shows that:**

- DHA: The Northern and Central regions of Vietnam have similar scores, higher than the Southern region. Hence, the Southern region shows less dependence on this factor.
- BTHSA: The Central region has significantly lower scores compared to the Northern and Southern regions.
- DDNTA: The Northern and Southern regions have higher scores than the Central region, indicating more concern for this factor.
- NLA: The Northern region shows slightly higher scores than the Southern and Central regions.
- PTTTA: Interest in social media decreases from the Northern to Southern to Central regions.

**The hypothesis testing for comparing by type of educational institution in Appendix 4,5 indicates that:**

- DHA: Gap year students prioritize this factor more than students in other types of schools.
- BTHSA: Gap year students and students in public and private schools consider their own characteristics when choosing a school more than students in public and international schools.
- DDNTA: Most students and gap year students pay attention to school characteristics, but students from international schools show less interest.
- NLA: Gap year students have a higher average score in terms of the school’s communication effort, while international schools have a lower average score.
- PTTT: There is a slight difference in the average values, with international schools showing a slightly lower interest in social media compared to other groups.

#### 4.1.2. Qualitative research findings

##### 4.1.2.1. Criteria for selecting an ideal university

“ I think the reputation of the university greatly influences future employment opportunities, as businesses are very interested in candidates graduating from reputable institutions.”

*(12th-grade student, Foreign Language Specialized High School)*

“I prioritize the quality of the university’s lecturers. Lecturers need to have solid expertise to train students with good knowledge and skills, effectively serving the needs of businesses.”

*(12th-grade student, Thai Nguyen Specialized High School)*

**Source: In-depth interview results**

**4.1.2.2. The Influence of Significant persons on High School Students' University choice decision.**

“My personal preferences have a significant impact on my decision. I also think that my passion for the chosen field will greatly influence my attitude towards learning at the university. However, I will still balance it with other factors such as the future prospects of the field.”

*(10th-grade student, Tran Phu High School, Hoan Kiem District, Hanoi)*

“Among the factors related to myself, my talent is what I care about the most. I will choose a field that matches my talents.”

*(2nd-year student, British University Vietnam, Hanoi)*

**Source: In-depth interview results.**

The above opinions serve as typical examples supporting the assertion that “the decision-making process of high school students in choosing a university is influenced by personal factors such as academic performance, interests, and career goals” and “interests also play a significant role in university selection,” as discussed by the authors.

**4.1.2.3. The Influence of Fixed university characteristics on High School Students' University choice decision.**

“In my opinion, the reputation of a university and job opportunities are the top important factors when considering what a university has to offer.”

*(10th-grade student, Thai Nguyen Specialized High School)*

“Due to limited financial conditions in my family, the tuition fees of a university are a crucial consideration for me. I have found a university that provides quality education at an affordable and stable tuition fee. The low tuition fee has helped reduce the financial pressure while studying at the university.”

*(2nd-year student, Journalism and Communication Academy, Hanoi)*

**Source: In-depth interview results**

These responses are similar to the following observations: “The reputation of a university is also considered a significant factor as it impacts post-graduation job opportunities,” “Tuition fees are one of the meticulously considered factors, and students need to consider their family’s financial situation,” and “Students often seek universities located in major cities with specialized and career-aligned programs.”

**4.1.2.4. The Influence of University Efforts to Communicate with Students on High School Students' University choice decision.**

Summarizing Opinions on the Influence of University Efforts to Communicate with students:

“I believe that the university’s website is something that universities should invest in heavily. Websites that provide comprehensive information are extremely helpful for us during the research process and making decisions.”

*(3rd-year student, Ho Chi Minh City University of Economics)*

“I have attended some admission counseling events, and I found that these events introduced me to more universities.”

*(12th-grade student, Thai Nguyen Specialized High School, Thai Nguyen)*

Comparing with the factors mentioned in Chapter 2, the authors have identified the following similar factors: University website, Admission counseling activities, Campus tours of universities, and Career guidance activities in high schools. However, the importance attributed to these factors varies among individuals.

**4.1.2.5. The Influence of Significant Persons on High School Students' University choice decision**

Summarizing Opinions on the Influence of Significant Persons with Impact:

“My decision relies heavily on my parents. Since my parents are the ones who pay for my education, I have to follow their decisions.”

*(12th-grade student, Foreign Language Specialized High School, Hanoi)*

“I trust the most in the information provided by previous students because they are the ones who have directly experienced university education.”

*(3rd-year student, National Economics University, Hanoi)*

**Source: In-depth interview results.**

It can be observed that parents have a significant influence on the interviewees.

#### 4.1.2.6. *The Influence of Social Media on High School Students' University choice decision.*

Summarizing Opinions on the Influence of Social Media:

“I frequently use social media to search for information. I believe that social media provides me with diverse information about universities, and I think that information has a significant impact on students. “

*(12th-grade student, Specialized High School, Thai Nguyen Province)*

As discussed, the interviewees affirm that social media has a significant influence on their university choice decision.

## 4.2. Discussion

After conducting quantitative and qualitative research, the influential factors were determined to be Fixed University Characteristics (DDNTA), Student Characteristics (BTHSA), Social Media (PTTTA), Significant Persons (DHA), and University Effort to Communicate with Student (NLA). The study accepted seven hypotheses (H1, H2, H3, H4, H5, H6, H7).

Among these factors, DDNTA had the strongest impact on the university choice decision. BTHSA and PTTTA also significantly influenced the decision. The order of influence was as follows: (1) DDNTA, (2) BTHSA, (3) PTTTA, (4) DHA, (5) NLA.

Furthermore, the research revealed relationships between the factors. The moderating variable, PTTTA, influenced the relationship between BTHSA and QDA, as well as the relationship between NLA and QDA. Additionally, PTTTA had a negative impact on the relationship between BTHSA and QDA, while positively influencing the relationship between NLA and QDA.

## 5. CONCLUSION AND RECOMMENDATION

This research study explores and examines the factors influencing Vietnamese high school students' university choice decisions and provides recommendations for relevant stakeholders. The study employs a mixed-methods approach, combining qualitative and quantitative research, and yields the following results: (1) The relationship between factors influencing university choice decisions, (2) the “Fixed University characteristics” factor has the greatest influence on students' university choice decisions, (3) “Student Characteristics” factor is the second most influential factor, and (4) Social media also significantly influences high school students' university choice decisions.

Based on these findings, the authors offer recommendations to the government and universities, including measures to regulate asymmetrical information, enhance university infrastructure, and create a favorable environment for students to make better choices. Employers should collaborate with universities to offer internship and training opportunities. At the same time, students should carefully explore their interests and career goals when choosing a university, relying on reliable sources of information.

**APPENDIX 01:**

**SURVEY TABLE ON FACTORS INFLUENCING THE DECISION TO CHOOSE A UNIVERSITY FOR HIGH SCHOOL STUDENTS**

Dear Sir/Madam,

Please provide some information about yourself!

**1. Gender:**

<input type="checkbox"/> <sub>1</sub> Male	<input type="checkbox"/> <sub>2</sub> Female
--	--

**2. You are**

<input type="checkbox"/> 1 High school student	<input type="checkbox"/> 2 Students
--	-------------------------------------

**3. Which high school are you currently/ have you attended?**

- 1. Public school
- 2. Private school
- 3. International affiliated school
- 4. Other

**4. Which academic field are you interested in studying?**

- 1. Economics
- 2. Engineering, Industrial
- 3. Arts
- 4. Other

**5. Current family income (average monthly) (VND)**

- 1. Less than 5 million
- 2. 5 million - less than 10 million
- 3. 10 million - less than 15 million
- 4. 15 million - less than 20 million
- 5. 20 million and above

**6. Study and living location**

- 1. Northern region
- 2. Central region
- 3. Southern region

For each statement below, please select the corresponding numeric value that accurately reflects your opinion on the degree of influence of the following factors on your university choice decision.

Each statement is measured on a scale with equal intervals ranging from 1 to 5, where:

1: Strongly disagree; 2: Disagree; 3: Neutral; 4: Agree; 5: Strongly agree.

Or,

1: Never; 2: Rarely; 3: Occasionally; 4: Frequently; 5: Very frequently.

I)	INDIVIDUAL FACTORS					
1	Parental advice influences my decision in choosing a university.					
2	Advice from friends influences my decision in choosing a university.					

3	Advice from classmates influences my decision in choosing a university.					
4	Advice from alumni influences my decision in choosing a university.					
5	Advice from high school teachers influences my decision in choosing a university.					
6	Advice from current students influences my decision in choosing a university.					
II)	STUDENT-RELATED FACTORS					
7	I choose this university because the field of study aligns with my academic strengths.					
8	I choose this university because I believe I am capable of getting admitted.					
9	I choose this university because the field of study aligns with my personal interests.					
10	I choose this university because I want to continue the program after undergraduate studies.					
III)	FIXED CHARACTERISTICS OF THE UNIVERSITY					
11	I choose this university because it has a reputable and prestigious educational address.					
12	I choose this university because it is conveniently located near my home, facilitating commuting and studying.					
13	I choose this university because it offers diverse and attractive academic programs.					
14	I choose this university because it has modern and well-equipped facilities that serve teaching and learning purposes effectively.					
15	I choose this university because its tuition fees are suitable for my family's financial situation.					
16	I choose this university because it provides scholarships and reasonable financial support policies for enrolled students.					
17	I choose this university because it creates employment opportunities after graduation.					
18	I choose this university because it offers high-income job prospects.					
IV)	COMMUNICATION EFFORTS OF UNIVERSITIES					
19	I choose this university because the university's website provides comprehensive information about the institution.					
20	I choose this university because it organizes counseling sessions for high school students in the admission process.					
21	I choose this university because it arranges campus tours for high school students.					
22	I choose this university because it actively participates in career-oriented educational activities at high schools.					
23	I choose this university because it has excellent admission counseling specialists.					
V)	SOCIAL MEDIA COMMUNICATION FACTORS					
24	I choose this university because I find interesting content about the university on social media platforms related to my interests.					
25	I can easily evaluate the universities I am interested in through social media channels.					
26	Using social media platforms to gather information about the university I am interested in is a common trend.					
27	I enjoy sharing information about the university on social media with my friends.					
VI)	DECISION-MAKING FACTORS FOR UNIVERSITY CHOICE					
28	I am satisfied with the university I have chosen/am currently attending (if you are a student).					
29	I would still choose this university if I had the opportunity to change my decision (if you are a student).					
30	I will recommend this university to students (acquaintances) preparing to take university entrance exams.					

**1. In your opinion, which factor has the most significant impact on your university choice?**

- 1. Influence from influential individuals

- 2. Self-related factors
- 3. Fixed characteristics of the university
- 4. Communication efforts of the university
- 5. Social media communication factors
- 6. Other

**2. Do you have any suggestions for domestic universities to enhance their ability to attract prospective students?**

**Thank you sincerely for taking the time to participate in the survey!**

**The research team**

## THE RELATIONSHIP BETWEEN IT STRATEGY, MARKETING STRATEGY, AND OPERATIONAL PERFORMANCE: THE CASE OF TOURISM BUSINESSES IN HANOI

**Author: Nguyen Ha An<sup>1</sup>, Le Viet Ha<sup>1</sup>, Nguyen Thi Thanh Huyen<sup>1</sup>,  
Nguyen Ngoc Nham<sup>1</sup>, Dang Thi Trang<sup>1</sup>  
Mentor: Dr. Hoang Thi Thu Huong<sup>1</sup>**

*ABSTRACT: Nowadays, information technology has a significant impact on all industries, particularly the tourism sector. Significantly, information technology has a close relationship with management activities at some tourism businesses. This paper presents research results on the role of information technology strategy in management activities. This paper examines and evaluates the marketing strategies and operational performance of tourism businesses in Hanoi. The findings further indicated the influence of information technology strategy and marketing strategy on business performance. This result provides useful data for managers to improve their management, thereby enhancing operational performance.*

*Keywords: IT strategy, marketing strategy, operational performance, tourism business.*

### 1. INTRODUCTION

In the scope of Industry 4.0, an increasing number of businesses rely on the massive amount of data and information produced throughout their operations. Traditional methods and platforms, however, are not strong enough to evaluate the structure, identify correlations, and forecast future performance when studying huge data. When making decisions in the real world, where interaction and customer service are key factors, these limitations become challenging (So et al., 2021). The contribution of IT is an effective tool in how to operate, even changing the company model to deal with the enormous amount of data, and the tourism industry is no exception.

According to Greg Oates from Skift, a research firm specializing in economics and tourism, “By integrating IT into online search and booking platforms, hotel and tourism companies are now bringing a lot of real added value to consumers”. Thus, with the development of IT, global tourism activities have undergone great changes. According to statistics, more than 36% of customers can pay more if transactions are easy and there is good interaction, and about 80% of customers prefer to find out information on their own. Understanding and grasping this fact, many travel companies have applied IT technology to find customer sources and improve and enhance the quality of their services. Considering the competitive environment of businesses with huge amounts of data, some businesses find a transition involving corporate strategy that integrates with IT tools. The goal of businesses in the tourism industry is to establish performance and a sustainable competitive advantage.

In reality, IT is considered to be an essential component of a business and is expected to create algorithms to assist travel enterprises in making educated decisions and increase service efficiency.

In recent years, Vietnam has identified tourism as a key economic sector and is taking measures to promote it so that it truly becomes a leading economic sector by 2030. Hanoi, the capital of Vietnam, is always considered one of the most attractive destinations for tourism development because of its existing

---

<sup>1</sup> National Economics University.

potential. Although the tourism industry in Vietnam in general and in Hanoi, in particular, has seen clear growth and achieved important and encouraging results, the pressure of competition and staying firmly in the market always challenges businesses to constantly improve and enhance the quality of their products and services.

Therefore, investigating the relationship between information technology strategy, marketing strategy, organizational culture, and operational performance is a profoundly practical issue, particularly in the case of tourism businesses in Hanoi.

The study will present the following research objectives and questions:

*Research objective:*

- General objective: To investigate and evaluate the operational performance of tour operators and hotels in Hanoi, as well as to examine the impact of information technology strategy and marketing strategy on the performance of these businesses.

- Specific objective:

+ Systematize the theoretical foundation of IT strategy, marketing strategy, and performance measurement

+ Investigate the impact of IT strategy and marketing strategy on the performance of businesses

+ Based on the research findings, propose recommendations to enhance the performance of businesses

*Research questions:*

To achieve the above objective, the research team focuses on answering the following questions:

- What are IT strategy, marketing strategy, and operational performance? How are they expressed/measured?

- Does the IT strategy have an impact on the marketing strategy? If so, what is the direction and degree of impact?

- Does the IT strategy have an impact on operational performance? If so, what is the direction and degree of impact?

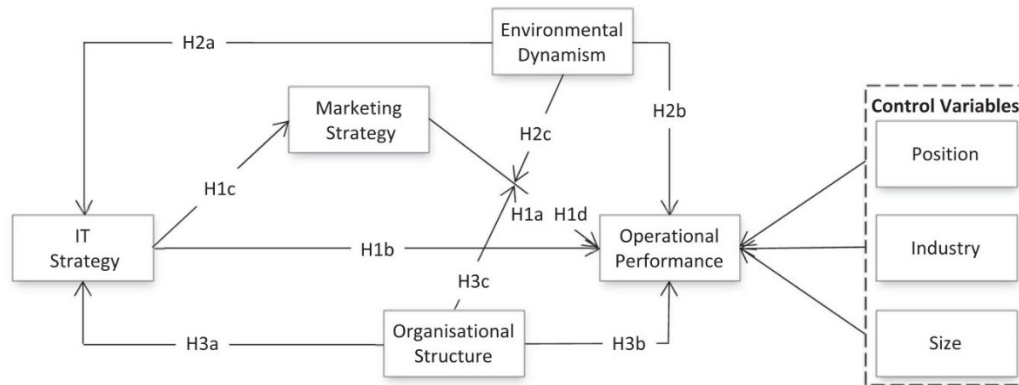

- Does the marketing strategy have an impact on operational performance? If so, what is the direction and degree of impact?

In the following sections, our research team will investigate perspectives on information technology strategy, marketing strategy, and operational performance in tourism businesses in Hanoi. We will also propose a research model based on the examination of theoretical arguments. We will then use data collected from 130 respondents, who are business managers, to test the hypothesis. Subsequently, our research team will discuss the theoretical significance, methodological approach, and practical implications of the findings and synthesize the contributions.

## **2. THEORETICAL FRAMEWORK**

### **2.1. The strategic linkage model to improve Operational Performance of AI - Surmi et al. (2022)**

The strategic linkage model to improve Operational Performance was developed by Al-Surmi et al. in 2022. This study investigates the strategic linkage between marketing strategy and information technology (IT) and provides decision-makers in production and operation with a model to enhance operational performance.

**Figure 1: The strategic linkage model to improve operational performance**

Source: Abdulrahman Al-Surmi et al. (2022)

This model evaluated the linkage between marketing strategy and information technology (IT) in the context of environmental dynamics and organizational structure. The author confirmed that the dynamism of the environment and organizational structure positively impacts operational effectiveness. This is also a different factor of this theory from previous ones (Gartlan and Shanks, 2007; Yeow, Soh, and Hansen, 2018; Al-Surmi, 2016; Cao and Duan, 2019).

## 2.2. IT Strategy

In this paper, we adopted the definition of Gartlan & Shanks (2007): “An IT strategy is a strategic business tool used to structure a future path and addresses the use and management of IT resources, business IT relationships both internal and external and the flow and storage of information throughout the organization”. This definition was synthesized based on the definitions and key IT characteristics from previous studies: Vua, 1978; Henderson & Vankatraman, 1993; Broadbent & Weill, 1993; Gadiesh & Gilbert, 2001...

### 2.1.2. The impact of IT strategy on marketing strategy

According to Henderson (1992) and Venkatraman (2013), regardless of the chosen approach, Marketing and IT need to be coordinated. Literature on information systems (IS) has extensively discussed the necessary fit between the use of IT and the business strategy of the enterprise.

A study in Russia (2018) also showed that IT strategy plays an important role in improving the marketing strategy of enterprises. Technologies such as artificial intelligence, data analytics, digital marketing, and e-commerce have helped enhance the accuracy and predictive capabilities of marketing strategies.

With these positive impacts, the use of IT strategy in marketing strategy is becoming a popular trend and an essential element in modern business, leading to the following hypothesis:

*H1.1: Information technology strategy is positively associated with marketing strategy.*

### 2.1.3. The impact of IT strategy on operational performance

Although technology resources are a prerequisite for IT-supported business processes, IT itself does not directly impact operational performance. According to Melville et al. (2004), operational performance is the effectiveness of business processes. In other words, the presence of technology resources does not lead to increased performance; instead, their utilization will promote performance.”

It can be observed that many studies have shown that IT strategy does not directly impact performance. However, these studies mostly focus on data collection from manufacturing or general businesses.

Conducting research in the service industry, the group found that technology-related decisions have a significant impact on operational performance (Tran Thi Huyen Trang, 2019; Vuong Thao Ly et al., 2022). Therefore, to investigate the relationship between these two factors, we propose the following hypothesis:

*H1.2: Information technology strategy is positively associated with operational performance*

## 2.2. Marketing strategy

In this study, we adopt the definition of Varadarajan (2010): “Marketing strategy can be defined as an organization’s integrated pattern of decisions that specify its crucial choices concerning products, markets, marketing activities, and marketing resources in the creation, communication and/or delivery of products that offer value to customers in exchanges with the organization and thereby enables the organization to achieve specific objectives”. This is a definition that is quite close to the current time and widely used in Varadarajan’s studies (2009, 2015) and by other scholars, such as Morgan et al. (2018).

### 2.2.1. The impact of marketing strategy on operational performance

Varadarajan and Jayachandran (1999), Webster (1992), and Day (1992) affirmed that Marketing strategy is the development of activities and decision-making aimed at building and maintaining a sustainable competitive advantage, bringing superior performance.”

Khaldoon Nusair and colleagues (2019) pointed out that digital marketing strategies such as creating content on social media, online advertising, email marketing, and search engine optimization (SEO) have a positive impact on revenue, profit, and sales growth of businesses. Effective marketing strategies can increase sales revenue, attract new customers (Mohammad Bakhtiar Rana, 2013), and retain existing customers. Therefore, businesses with effective marketing strategies have better financial performance and production efficiency and achieve better competitiveness than those without these strategies (Sabrina Helm, 2015). Therefore, the following hypothesis is proposed:

*H2.1: Marketing strategy is positively associated with operational performance*

## 2.3. Operational performance

In later research, Sanchez and Perez (2001) define operational performance as the changes that occur in performance measures after implementing lean manufacturing practices in an organization. Operational performance is a very important metric because it measures an organization’s problems. From a business perspective, the concept of operating performance is often linked to a company’s financial performance.

Iyer (2011) defines operational performance as the actual outcome measured by metrics of quality improvement, efficiency, cost reduction, customer consistency, and on-time delivery of inventory to the organization.

With the stated research scope, this study is based on the theoretical basis of the relationship between the variables “IT strategy,” “marketing strategy,” and “operational performance”. Therefore, the following research model is proposed:

**Figure 2: Proposed research model**

Source: Synthesis research team (2023)

**Hypotheses**

Based on the theoretical basis and qualitative analysis results, the research team proposed two groups of research hypotheses as follows:

*First hypothetical group*

- H1.1: Information technology strategy is positively associated with marketing strategy.
- H1.2: Information technology strategy is positively associated with operational performance.

*Second hypothetical group*

- H2.1: Marketing strategy is positively associated with operational performance.

**3. RESEARCH METHOD**

**3.1. Data collection methods**

*Secondary data collection*

The secondary data used in this study were collected from sources such as books, newspapers, and websites, and mainly from studies on information technology strategy, marketing strategy, operational performance, organizational culture, and related theoretical knowledge.

*Primary data collection*

At the outset, the research team conducted a qualitative study by interviewing four experts in the field of tourism, such as managers, directors, CEOs & Founders, to identify the fundamental relationships between information technology strategy, marketing strategy, operational performance, and organizational culture in enterprises. The purpose was to refine the definition, identify manifestations, and supplement the measurement scale.

Subsequently, the research team collected primary data through a survey using a questionnaire. The questionnaire was designed with clear and easily understandable questions, using a 5-point Likert scale to allow participants to answer according to their thoughts and ensure an acceptable level of reliability. The questionnaire was distributed to the study participants through social media as an online survey from February 23, 2023, to March 08, 2023. The sample size of the survey was 135; after the filtering process, the number of valid responses was 130 (approximately 96.29%).

**3.2. Data analysis methods**

Collected data will be synthesized, cleaned, and analyzed through Microsoft Excel 2016 and SPSS 25.0 software. This study includes descriptive statistics, Cronbach’s alpha reliability test, EFA exploratory factor analysis, Pearson correlation analysis, and regression analysis. Descriptive statistics were used to examine variables of interest, including demographic variables. Analyze Cronbach’s Alpha coefficients to evaluate the reliability of the scales and eliminate inappropriate observed variables. Exploratory factor analysis (EFA) to discover new groups of factors in case they converge with Varimax rotation. Pearson correlation analysis aims to determine certain correlations between variables. Finally, the research team used linear regression to test the accuracy and influence of the original hypotheses in the model.

**Table 1: Survey sample structure**

	<b>Element</b>	<b>Frequency</b>	<b>Ratio</b>
Gender	Men	53	40,76%
	Women	77	59,24%

Age	From 18 to 25	28	21,5%
	From 26 to 35	55	42,4%
	From 36 to 45	41	31,5%
	Above 45	6	4,6%
Position	Head of department	62	47,7%
	Vice president	24	18,5%
	President	23	17,7%
	Manager	8	6,2%
	CEO&Founder	5	3,8%
	Others	8	6,2%

Source: The analysis results of the research team (2023)

### 3.3. Developing a measurement scale

To test the hypotheses, 22 measurements of IT strategy, marketing strategy, and operational performance were synthesized from reference materials. At the same time, the measurement scales were organized, supplemented, and eliminated to fit the characteristics of the tourism industry.

The measurement scale for the IT strategy used in this study was proposed by Al-Surmi (2016, 2022), as it was deemed suitable in terms of research scope and context for tourism businesses in Hanoi. Additionally, after conducting in-depth interviews for qualitative research, the research team proposed three new measurement scales for the factor.

The scale for measuring marketing strategy was evaluated based on the proposals of Al-Surmi (2022) and Ana Maria, Simone & Fernando (2013). Moreover, after conducting qualitative research, the research team also proposed and included 5 additional scales in the model.

The “Operational performance” measurement scale used in this study is based on the scales proposed by Al-Surmi (2022) and Ana Maria, Simone & Fernando (2013) to measure and observe the “Performance” factor with 6 main observed variables, ensuring reliability and values for testing correlations with other factors in the model.

**Table 2: Summary table of measurable scales**

Ordinal numbers	Factors	Symbol	Content	Source
1	IT Strategy	IT1	Our organization uses IT in business processes	Al-Surmi et al. (2022)
2		IT2	Our organization uses IT to support research and development	
3		IT3	Our organization uses IT to support strategic planning and decision-making	
4		IT4	Our organization uses IT for product marketing and promotion	
5		IT5	The use of IT enables my business to ensure the operational integrity of its work	The research team conducted qualitative research and proposed
6		IT6	IT enables my business to resolve issues quickly.	
7		IT7	IT facilitates the monitoring and supervision of my business operations	

8	Marketing strategy	MS1	My business uses online media channels to reach customers	The research team conducted qualitative research and proposed
9		MS2	My business utilizes information and communication technology (ICT) to enhance the customer experience when using our products and services	
10		MS3	My business develops intelligent search tools	
11		MS4	My business conducts data analysis and predicts customer demand	Al-Surmi et al. (2022)
12		MS5	My business is developing an automated chatbot to answer customer questions	The research team conducted qualitative research and proposed
13		MS6	My business is developing a 24/7 customer support service	
14		MS7	My business analyzes the opportunities and challenges from the external environment	Ana Maria Machado Toaldo et al. (2013)
15		MS8	My business considers options and develops a suitable marketing strategy	
16		MS9	My business always focuses on brand management and image across communication channels	
17	Operational Performance	OP1	The sales growth position is much better	Al-Surmi et al. (2022)
18		OP2	The market share gains are much better	
19		OP3	The net profit position is much better	
20		OP4	The financial liquidity position is much better	
21		OP5	Higher return on investment of the business	Ana Maria Machado Toaldo et al. (2013)
22		OP6	Increased customer satisfaction

#### 4. RESULT AND DISCUSSION

##### 4.1. Result

*Testing the reliability of the measurement scale.*

**Table 3: The reliability assessment table of the measurement scale using Cronbach's Alpha coefficient**

STT	Factors	The number of observed variables		Cronbach's Alpha coefficient		Note
		Initial	After validation	Initial	After validation	
1	IT Strategy	7	7	0,899	0,899	No variable exclusion
2	Marketing Strategy	9	9	0,901	0,901	No variable exclusion
3	Operational Performance	6	6	0,868	0,868	No variable exclusion

Source: The analysis results of the research team (2023)

In general, all scales of the factors included in the analysis have relatively high Cronbach's Alpha coefficients and are all >0.7. This means that all scales are reliable and highly suitable for analysis in further analyses.

*The results of the exploratory factor analysis (EFA)*

**Table 4: Results of the rotation matrix**

Rotated Component Matrix <sup>a</sup>			
	Component		
	1	2	3
IT2	,857		

IT1	,836

The factors retain their original concepts and only remove poor variables, including:

- Operational performance consisting of observed variables: OP1, OP2, OP3, OP4, OP5. Abbreviated as OP.
- Information technology strategy consisting of observed variables: IT1, IT2, IT3, IT5, IT6, IT7. Abbreviated as IT.
- Marketing strategy consisting of observed variables: MS1, MS3, MS4, MS7, MS8, MS9. Abbreviated as MS.

*The result of Pearson correlation analysis*

**Table 5: The correlation between factors**

Correlations				
		IT	OP	MS
IT	Pearson Correlation	1	,514**	,372**
	Sig. (2-tailed)		,000	,000
	N	130	130	130
OP	Pearson Correlation	,514**	1	,472**
	Sig. (2-tailed)	,000		,000
	N	130	130	130
MS	Pearson Correlation	,372**	,472**	1
	Sig. (2-tailed)	,000	,000	
	N	130	130	130
**. Correlation is significant at the 0.01 level (2-tailed).				

Source: The analysis results of the research team (2023)

The correlation coefficients of the variables “IT Strategy” and “Marketing Strategy” with the variable “Operational Performance” are 0.514 and 0.472, respectively, at a significance level of 1%, indicating a fairly strong positive correlation between these independent variables and the dependent variable.

The results of multiple linear regression analysis

**Table 6: The linear regression coefficients of factors affecting marketing strategy (MS)**

Model		Coefficients <sup>a</sup>					Collinearity Statistics	
		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Tolerance	VIF
		B	Std. Error	Beta				
1	(Constant)	2,058	,577		3,570	,001		
	IT	,434	,143	,431	1,634	,000	,663	1,509

a. Dependent Variable: MS

Source: The analysis results of the research team (2023)

The Sig coefficient of the independent variable IT (IT Strategy) is less than 0.01, indicating statistical significance at the 1% level.

**Bảng 7: The linear regression of factors influencing operational performance (OP)**

Model		Coefficients <sup>a</sup>					Collinearity Statistics	
		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Tolerance	VIF
		B	Std. Error	Beta				
1	(Constant)	,665	,335		1,383	,172		
	IT	,159	,077	,165	1,429	,158	,635	1,574
	MS	,231	,067	,243	2,392	,001	,823	1,215

a. Dependent Variable: OP

Source: The analysis results of the research team (2023)

The variable MS (Marketing Strategy) has a significance level of Sig = 0.01 < 0.05, indicating that it has statistically significant meaning at a 5% level of significance. However, the variable IT (IT Strategy) has a coefficient of Sig. = 0.158 > 0.05, indicating that it is not significant in the regression model, or other words, it does not have an impact on the dependent variable OP (Operational Performance).

**Figure 3: Research adjustment model**

Source: The calculations by the research team (2023)

**4.2. Discussion**

Through the synthesis and examination of previous research and the application of research to practical situations in Vietnam, as well as careful attention to the translation, in addition to using a linear regression model, our research team developed a scale of questions to measure the impact of information technology strategy, marketing strategy, organizational culture, and operational performance. The scale ensures reliability and validity, with all question components correlating well with the overall variable, demonstrating the suitability of the scale chosen by our research team. Therefore, the report will summarize the impact of each pair of variables in the research model.

The regression analysis results show that the IT strategy has a positive impact on the marketing strategy. When the IT strategy increases by 1 unit, the marketing strategy increases by 0.431 units. The stronger the IT strategy is applied, the more the marketing strategy is enhanced.

Through the results of the regression analysis, the research team concluded that the IT strategy did not have an impact on operational performance, with a Sig coefficient of  $0.158 > 0.05$ . In the general economic and production sectors, some industries apply IT strategies to production, in which case the IT strategy can have a direct impact on operational performance. However, in the specific tourism industry, this relationship does not have a direct impact but rather relies on other relationships to indirectly impact and increase operational performance, such as marketing strategies.

Based on the table of regression results, the research team concluded that the marketing strategy has a positive impact on performance. For each unit increase in the marketing strategy, the performance increases by 0.243 units. However, the level of impact is the lowest in the model.

## 5. CONCLUSION

Through a comprehensive review of research studies, the study has systematized the fundamental issues of IT strategy, marketing strategy, and performance based on the foundational theory of “strategic link theory for improving operational performance”. As a result, the research team discovered research gaps in identifying influential factors and laying the groundwork for building a research model in the report. By combining two qualitative research methods (in-depth interviews with four experts) and quantitative surveys with a sample size of 130 (analyzing linear regression equations), the research results showed that the model fit the market survey data perfectly and drew conclusions about the hypotheses of the relationships between the factors. Furthermore, the study also identified whether the factors had a positive or negative impact, whether they influenced each other, whether they were in the same direction or the opposite direction, and whether their impact was strong or weak on the operational performance of tourism businesses in Hanoi.

## PEER PRESSURE AND OTHER FACTORS AFFECTING VIETNAMESE PARENTS' INTENTION FOR THEIR CHILDREN TO TAKE THE INTERNATIONAL ENGLISH CERTIFICATE EXAMINATION

**Author: Vu Tien Duc<sup>1</sup>, Pham Ngoc Minh<sup>1</sup>, Vu Hoang Minh<sup>1</sup>,  
Doan Nguyen Tuan Anh<sup>1</sup>, Nguyen Vu Tien Duc<sup>1</sup>  
Mentor: Tran Viet An<sup>1</sup>**

**ABSTRACT:** Vietnamese parents appear to be “rushing” their children to take the International English Certification Exam (IECE), especially in large cities. Is sending the child to take IECs just a social trend or a way to help them access the global learning environment? The purpose of this article is to analyze the factors influencing parents’ decisions to give these exams to their children. The research model was built based on a research overview and adjusted to fit the research problem and context through in-depth interviews and preliminary quantitative research. Analyses using Cronbach’s Alpha, EFA, and linear regression were performed on the formal quantitative research, which included responses from 351 Vietnamese parents. The findings indicate that four factors have an impact on Parents’ Intentions for their children to take the IECE (INT), with Peer Pressure (PP) and the Social Comparison (SC) having the two biggest impacts.

**Keywords:** International English Certification Exam (IECE), peer pressure, intention, parents, Vietnam

### 1. INTRODUCTION

The process of social integration has been penetrating the economy, politics, culture, and society of countries; it affects all aspects of human life and gives us many development opportunities. In that context, English has become an indispensable tool on the tin way of international integration as a means of communication between countries. Especially in the context of growing international trade; investment funds and foreign corporations have flocked to Vietnam, bringing career opportunities for Vietnamese people. Using English fluently will help each develop their professional capacity; creating opportunities to access and exploit the most technological achievements in the world. English is playing an extremely important role, directly affecting the success of many individuals and organizations, and has a close relationship with the development of a country.

More and more people are interested in improving their English ability and actively studying and registering for the International English Language Certificate (IECE). The recognition of many organizations for certificates such as IELTS, TOEIC, TOEFL, SAT, APTIS, Cambridge ESOL... is becoming increasingly obvious. These certificates are not only proof of the exact level and ability to use English, but they are also considered a “golden passport” to help young people exchange and integrate internationally. In recent years, IECE is gradually becoming popular among students and high school students in Vietnam. In addition, the enrollment policy in combination with IECE is becoming a popular trend at the top universities in Vietnam (Anh, 2022). Vietnamese parents are increasingly allowing their children to take IECs in recent years, especially whether they’re in high school or college (Lien, 2023; Quyen, 2022). Many Vietnamese parents desire to create the finest conditions for their children’s development. They expected that if their children

<sup>1</sup> National Economics University.

have IECEs then, they can access advanced education easily, have great advantages in the future such as exemption from national graduation exams, improve their chances of being admitted to higher education institutions, increase their chances of getting a job with good remuneration (Yusupov et al., 2022; Nhat Le, 2021; Anh et al., 2020; Nhut and Vinh, 2014). It shows that Vietnamese society is increasingly interested in learning foreign languages. However, is that just a short-term trend? Does letting children take the IECE come entirely from the objective requirements of society or the subjective point of view of parents?

There are currently a lot of domestic and international studies on the intentions and behavior of students to take IECE, but there is a lack of research on their parents'. Most of the previous studies have focused mainly on students who are about to graduate or are working people who need to take language, computer, or accounting certificates to meet their job needs (Cui et al., 2018; An et al., 2021; Hang and Mai, 2022). Therefore, it is necessary to research parents because they play a crucial role in orienting their children's futures while also serving as the primary source of funding for their children's study and exam needs. The authors chose the research topic "Peer Pressure and other factors affecting the intention of Vietnamese parents for their children to take the International English Certificate Exam". The purpose of this study was to identify the extent to which various factors affected parents' intentions to require their children to take the IECE in Vietnam. Based on an overview to build a research model, in-depth interviews to complete the scale, and a questionnaire, a quantitative study with 351 parents was conducted to test the hypotheses posed in the research model. To better understand the impact of Peer Pressure (PP), and Enrollment Policy (EP) on Vietnamese parents' decisions to allow their children to take the IECE (INT), the conclusions drawn from the research results are presented. The outcomes of those studies are shown in the following sections.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Parents' Intention for their children to take the IECE**

Intentions to invest in children's education, such as studying abroad or taking international English exams, are seen as forms of consumer intent (Chen and Zimitat, 2006). This is an expensive educational option and requires a lot of preparation, including tuition fees, retest fees, and exam fees to be borne by the student's parents and student. As a result, educational decisions always have a significant impact on the lives of families. This is therefore one of the most complex decisions faced by families (Mazzarol, 1998).

Parents play an important role in the educational selection process for their children, especially during the transition from one educational setting to another. Parents are also seen and evaluated from the perspective of those who have a great influence on their children's future educational and career orientation (Sharif et al., 2019). Studies on children's intellectual and occupational development show that children are more likely to be influenced by their maternal (Rani, 2014; O'brien et al., 2000) and paternal (Allen & Daly, 2007; Agarwala, 2008) influences.

Parents' decisions about their children's education are always influenced by many factors, not just the decision to send their children to the exam. These factors may be due to changes in educational policies and social development goals. But it can also come from the parents' level of knowledge, experience, and subjective will.

This issue should have been explored in depth, but studies on the Intention to take the International English Certificate Exam are few and far between. Studies tend to survey students at a young age, on a small scale with a group of university students (Nhut and Vinh, 2014; Vu, 2017), or with international professional and academic certificates (Hang, 2022; An et al., 2021). In the context of the internationalization of education and the current explosive trend of children taking the test, the authors focus on researching and

measuring the impact of factors on Parents' Intentions for their children to take the International English Certification Exams.

## 2.2. Research model

### Peer Pressure (PP)

Several studies have shown that peer pressure is a factor that drives individuals' intentions to do what their friends and colleagues do (Cook & Dayley, 2001). Humans are very social creatures, so they spend most of their lives interacting with each other and building close relationships to compete with each other and thrive together (Brown, 1982). Thus, peer pressure creates the intention to take specific actions to keep up with peers. Peer pressure plays an important role in changing people's behavioral intentions and motivating people to do something.

For parents, peer pressure is understood as pressure from people of parents' age or social class in caring for and educating their children. This causes parents to feel pressure to meet or exceed social standards, place high expectations on their children to meet those standards, and this pressure can even be passed on to their children. From having intentions and making decisions about the parenting and direction of children, and comparing intentions and behaviors with the intentions and behaviors of other parents, parents find out what is best for children (Quyen, 2022). Even if they're not sure it's the right thing for their child, they may still attempt these behaviors under social pressure from friends, to pass a test, or compare themselves to peers. These pressures can influence a parent's intention for their children to take the IECE. Therefore, the authors propose the following hypothesis:

*H1: Peer Pressure has a phase impact on Parents' Intention for their children to take the IECE*

### Enrollment Policy (EP)

Hang (2022) said that Vietnam is gradually using English certificates to consider university degrees and university admissions due to the influence of the demand for international education integration. Using the IECE is not only a basis for assessing a candidate's current English level but also a "door" that opens up excellent study and work opportunities and attracts employers with their profile and skills (Minh, 2021). In addition to the support of the Ministry of Education and Training, the exam organizer will also ensure the quality of training, and the quality of the exam to further promote the use of the IECE for many purposes, and this seems to encourage parents and students to use IECE more often. Hypothesis H3 is proposed:

*H2: Enrollment Policy have a positive impact on Parents' Intention for their children to take the IECE*

### Social Comparison (SC)

According to Festinger's (1954) theory of social comparison, people always tend to compare themselves with others. This is also considered a common and basic feature of collective life. People compare themselves to members of their groups, compare themselves to people in other groups, and compare their groups to other groups. From these comparisons emerge norms, massive groups, group structures, and intergroup relationships, which form a framework for group-based social comparisons. Comparing one to friends and colleagues can create invisible pressures that can influence one's intentions and actions. This is easily seen in the Vietnamese educational environment (Huong, 2019; Anh, 2016). Parents compare their children with other children based on many criteria such as grades, awards, and achievements in extracurricular activities,... When parents realize their child is inferior in some aspects, they may feel pressured and thereby motivate their children to work. That means studying, taking more tests, and investing in learning to improve the score. Therefore, the following hypothesis is proposed:

*H3: Social Comparison has a positive impact on Parents' Peer Pressure on Intention for their children to take the IECE*

**Social Integration (SI)**

Boer et al. (2017) asserts that acceptance in society, especially among friends and colleagues, plays an important role in each person's life. In addition, the fear of social rejection and the desire to express themselves puts pressure on both adolescents and adults. They feel obligated to conform to the standards and expectations of the social group they belong to, the peer group that needs to be cared for, respected, and loved, thereby creating an invisible pressure for themselves. From this theme, the need for social interaction can be explored not only by meeting the standards expected by social groups, but also by the parent's desire to help their children interact better in the international community, job opportunities, and later. This notion puts many parents under pressure when it comes to making decisions about their children's education. Therefore, the authors propose the hypothesis:

*H4: Social Integration has a positive impact on Parents' Peer Pressure on Intention for their children to take the IECE*

With the above hypotheses, the following research model was formed:

**Figure 1: Proposed research model**

**3. RESEARCH METHOD**

The authors created a research model and scale through theoretical analysis and examination of multiple studies. To finalize the scales and survey questionnaire, they conducted qualitative research, consisting of in-depth interviews with six experts in education and psychology. The purpose of these interviews was to enhance the measurement scales and develop a quantitative questionnaire. The authors revised the scales based on the experts' feedback to align with respondents' understanding and adjusted the logic of each scale to ensure students can comprehend the research problem.

After editing the questionnaire based on expert feedback, the research team distributed it to parents at high schools and universities in Ha Noi, Hai Phong, Da Nang, Vung Tau, and Ho Chi Minh City. Using convenience sampling, the survey targeted parents with children attending high schools and universities in Vietnam. Out of the 364 responses received, 351 were deemed objective and provided sufficient information for the next research steps. Interestingly, none of the respondents chose the option "Not intending to let my children take the test," indicating a unanimous intention among parents for their children to participate in the test. 49.9% of parents are preparing their children for the IECE exam, while 31.1% have already sent their children to take the test, and 19.1% have plans but haven't allowed their children to take the test yet. The survey received more responses from mothers (51.3%) than fathers (48.7%), but there was no gender discrimination. The majority of parents (34.5%) fall in the age range of 46 to 50. Age ranges 41 to 45 and 51 to 55 each makeup 25.5% and 19.9% of parents, respectively. Most parents have graduated with a

bachelor's degree (51.6%), followed by those with a graduate degree (23.4%) and a college degree (17.7%). A minority has a high school education or less. In terms of income, the majority of parents (70.1%) earn between 7.5 million and less than 30 million per month. Within this range, 33.9% earn between 7.5 million and less than 15 million, and 36.2% earn between 15 million and under 30 million. 13.1% of parents have an income of over 30 million, and the rest earn less than 7.5 million per month.

Finally, the scales are coded and SPSS 26.0 software is used to perform data analysis steps such as Cronbach's Alpha coefficient analysis, CFA analysis, and multiple linear regression analysis to help understand trends, and the research hypothesis tested.

## 4. RESULTS AND DISCUSSION

### 4.1. Cronbach's Alpha analysis

**Table 1. Results of verifying the reliability of the scale**

Factor	Cronbach's Alpha coefficient	Cronbach's Alpha if the item deleted	Number of variables removed
Peer Pressure (PP)	0.921	0.671 - 0.746	0/9
Social Comparison (SC)	0.893	0.654 - 0.771	0/3
Social Integration (SI)	0.904	0.704 - 0.784	0/6
Enrollment Policy (EP)	0.886	0.677 - 0.788	0/4
Parents' Intention for their children to take the IECE (INT)	0.860	0.623 - 0.720	0/5

*Source: Summary of the research team's results, 2023*

Cronbach Alpha test was performed to remove the scales that are not reliable enough. The findings indicate that all variables have dependable Cronbach Alpha coefficients ( $>0.6$ ), with peer pressure and the need for social integration showing particularly strong coefficients ( $>0.9$ ). According to Nunnally (1978), all the scales met the required level with the correlation coefficients of the total variables in the scales reaching the required level ( $>0.3$ ).

### 4.2. Confirmatory factor analysis (CFA) results

**Table 2: Model Fit Rating Index**

	Index	Access
CMIN/DF	2.358	Good ( $< 3$ )
GFI	0.863	Acceptable ( $>0.8$ )
CFI	0.934	Good ( $>0.9$ )
TLI	0.925	Good ( $>0.9$ )
RMSEA	0.062	Good ( $<0.08$ )

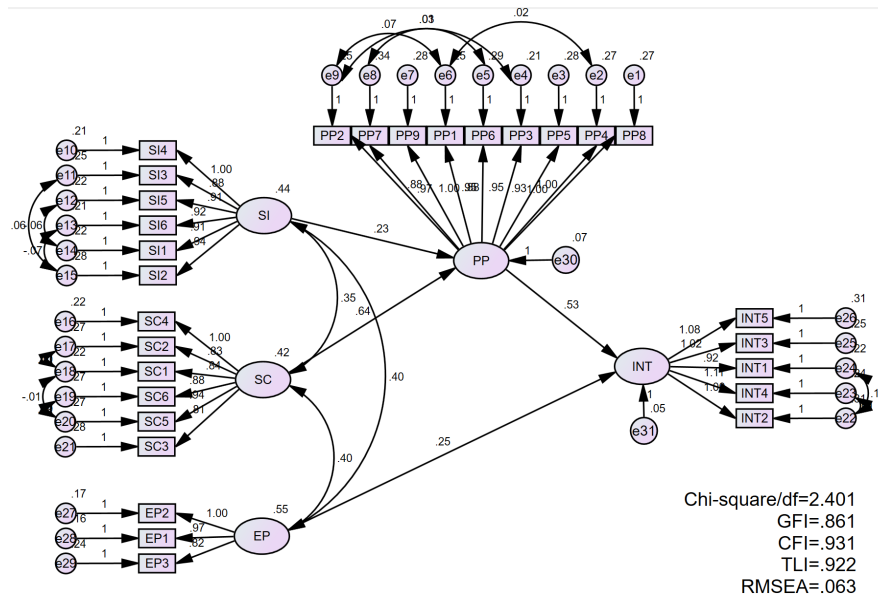

*Source: Summary of the research team's results, 2023*

The above results show that: Chi-Square/df coefficient (CMIN/df) is 2,358 ( $< 3$ ), GFI = 0.863 ( $>0.8$ ), CFI = 0.934 ( $>0.9$ ), TLI = 0.925 ( $>0.9$ ), RMSEA = 0.062 ( $< 0.08$ ). Therefore, the model is suitable for the research data, the values are satisfactory, good, and meaningful for the study.

### 4.3. Structural Equation Modeling (SEM) analysis

The research team performed the SEM Structural Model analysis to analyze the multi-dimensional relationship between the dependent variable "Parents' Intention for their children to take the IECE" (INT) and other variables in the model. The group used a significance level of 5% for this statistical method. The results from the analysis are presented below:

Figure 2: SEM results with the model without control variables

Source: Summary of the research team’s results, 2023

**Evaluate the fitness of the SEM model:**

The Model Fit results in the SEM model once again confirm the appropriate correlation between the research model and the actual data. The research model is completely built according to the theory and has enough grounds to evaluate reality. The indicators are shown in Table 4:

Table 3: Model Fit for SEM Model

	Index	Access
CMIN/DF	2.401	Good (< 3)
GFI	0.861	Acceptable (>0,8)
CFI	0,931	Good (>0,9)
TLI	0.922	Good (>0,9)
RMSEA	0.063	Good (<0.08)

Source: Summary of the research team’s results, 2023

**Test hypotheses and evaluate the impact direction:**

The P-Value index of all variables is < 0.01, reaching a 99% confidence level, so the impact relationships of the independent variable on the dependent variable are all significant. With the results obtained from the SEM analysis, the proposed hypotheses are accepted.

Table 4: Summary of SEM Results

Hypotheses (Hs)		Unstandardized Estimate	P-Value (Sig)	Results
H1	INT ← PP	0.53	***	Accepted
H2	INT ← EP	0.25	***	Accepted
H3	INT ← SC	0.64	***	Accepted
H4	INT ← SI	0.23	***	Accepted

Source: Summary of the research team’s results, 2023

**In terms of the impact relationship**, the Unstandardized Estimate has positive values, showing that the independent variables have a positive impact on the dependent variable.

**In terms of the order of effects**, this coefficient indicates the level of impact from strongest to lowest among variables.

For the dependent variable Peer Pressure (PP), Social Comparison (SC) is the factor that has the strongest impact on this dependent variable, followed by Social Integration (SI).

For the dependent variable Parents' Intention for their children to take the IECE (INT), Peer Pressure (PP) has the strongest influence, followed by Enrollment Policy (EP) which is the factor that has less influence on Parents' Intention for their children to take the IECE.

**In terms of impact level**, Social Comparison (SC) is the factor that has the strongest impact on Peer Pressure (PP) with an impact level of 64%, followed by Social Integration (SI), associated with an influence level of 23%. For the dependent variable INT, Peer Pressure (PP) with the probability of impact is 53%. Another factor that had little impact on Parents' Intentions, the Enrollment Policy (EP) also explained 25% of Parents' Intention for their children to take the IECE.

## **5. CONCLUSION AND RECOMMENDATIONS**

### **5.1. Letting children take the IECE should be an integration promotion instead of a trend**

Firstly, Schools and educational institutions should include international English language certification exams in their language curriculum. This can be achieved by offering preparation courses for these exams or integrating exam preparation materials into existing language classes. Teachers and educators can also motivate students by emphasizing the benefits of certification, such as increased job opportunities and the ability to study abroad.

Parents also play an active role in motivating their children ahead of these exams and encouraging their children to improve their language skills. Parents can support their children by providing opportunities for them to practice their English, such as enrolling them in language courses such as TOEFL or IELTS. This is a useful way to promote integration and enhance opportunities for students in an increasingly globalized world. Or give them access to English resources.

In addition, governments and policymakers support language education, especially in countries where English is not the primary language. This could include increasing funding for language programs in schools, promoting language exchanges between countries, and encouraging certified language teachers to teach international English language certification e.g....

Finally, it's important to remember that these exams should not be viewed as a trend or a contest. Instead, they should be viewed as a tool to help the child achieve academic and career goals. It's also important to make sure that the child is taking the exam for the right reasons and that they don't experience undue pressure or stress in doing so. By implementing these recommendations, we can ensure that taking international English language certification exams becomes a driver for integration and language proficiency, rather than just a trend.

### **5.2. Remaining inadequacies in education policy in Vietnam**

In 2022, the Vietnamese Education Electronic Journal also identified 10 existing issues and shortcomings in education, including:

Inadequate regulations on teacher appointment and salary ranking contribute to complex and costly processes for teachers. Outdated rules still determine their salaries. Nationwide teacher shortages, especially

in early childhood education, amount to 44,000 teachers, posing a significant challenge. Low incomes and unresolved pressures make it difficult to attract education students, hindering the recruitment target of 27,850 teaching positions. Urgent attention is needed for long-term fixed-term contracts with low salaries and a lack of benefits for some teachers.

Despite the teacher shortage, a considerable number of teachers have quit due to heavy workloads and low incomes. Unusually, 29,000 teachers resigned in 2021 and 2022 during the implementation of new programs and experienced teacher shortages. The education sector faces the challenge of simultaneously recruiting and reducing teaching positions by 10%, exacerbating the teacher shortage problem. Integrating teachers is complicated due to the introduction of new subjects and integrated courses, and no effective solution has been found.

The implementation of the new program allowing students to choose subject combinations is impractical. Schools are responsible for creating subject combinations, forcing students to choose from predetermined options regardless of their preferences. This leads to incorrect choices and a lack of guidance on transferring schools or exploring alternative learning options. Documentation and paperwork for the new program remain burdensome, with lengthy attachments and paperwork that have not been streamlined. High school testing methods have become overly formalistic and inappropriate with extensive specifications. Localities set increasingly higher achievement targets each year, resulting in heightened pressure and excessive focus on grades. Moreover, school violence has become more prevalent after a period of online learning, with instances of teacher-on-student incidents.

### **5.3. Being aware of the obligations parents have and what to perform**

**Social Comparison (SC)** was the most influential factor, with the ability to explain about 64% of influence to peer pressure. This was also mentioned by Festinger (1954) in the theory of social comparison, he said that people always tend to compare themselves with others and this can create pressure for themselves. This is also considered a common and fundamental feature of group life. People compare themselves to members of groups, they compare themselves to people in other groups, and they compare their groups to other groups. From these comparisons emerge, normative groups, group structures, and intergroup relationships, which in turn provide a framework for group-based social comparisons. Comparing friends and colleagues can create invisible pressures on parents, thereby affecting an individual's intentions and behavior. Therefore, in the context of the study, the authors found that the more parents tend to compare their children with the children of friends and colleagues, the more pressure they feel. This comparison is shown in such aspects as comparing the child's learning abilities and preparation for the exam with other parents' children; comparing the current English ability of children with other parents; comparing the child's achievements with the children of other parents. Parents are also under peer pressure when trying to find out and compare how other parents have their children review and take the exam to choose the most appropriate method to support their child. In addition, when receiving the results of their child's IECE test lower than that of their peers, parents need to re-evaluate the entire learning process to come up with solutions to "patch" their child's knowledge gaps, help children get better test results next time instead of comparing their scores with other parents' children, leading to pressure and anxiety. Therefore, when they see other students and students taking the exam, they also want their children to study for the exam and achieve the best results.

**Peer Pressure (PP)** is the second strongest factor affecting the Parents' Intention for their children to take the IECE (53%). In essence, this factor can be a form of pressure, but it is also a form of motivation for parents to learn and discover the most effective ways and methods of learning to educate and accompany as well as help their children during the IECE. For these pressures not to become a burden, parents need to:

Receive information frequently about letting children positively take the test from friends, contributing to reducing peer pressure. At the same time, it is necessary to have the right attitude when receiving accurate and regularly updated information from colleagues and friends about letting children take the exam to turn it into motivation to help the process of receiving new information faster and more accurately. When referring to the advice of colleagues and friends about letting their children take the exam, parents should constantly learn and receive information correctly, avoiding the situation of “overeating” information that causes pressure. unnecessary, affecting the process of receiving information transparently.

Parents should consider the ability and learning ability as well as the suitability of their children before making decisions for their children to take the exam to eliminate the possibility of undesirable results and help their children to choose the suitable type of certificate for exam preparation, and achieving the best results. In addition, parents need to understand their children better instead of just caring about what others think about their child’s score results to reduce peer pressure and stress for themselves and spend more time with their children. Spend time focusing and caring for children during the process of giving them the exam.

In addition, it is necessary to carefully access the information about the centers and certificates, avoid following the crowd when getting peer pressure from colleagues as well as from people around, leading to the wrong decision when sending their children to learning centers and taking the IECEs.

Next, **Education Policy (PE)** is the factor that affects the Parents’ Intention for their children to take the IECE at 25%. The scales have all returned feedback that parents find that domestic educational institutions give priority to enrolling candidates who possess international standards, and foreign educational institutions sometimes require candidates to possess IECE for admission. And in addition, all units and agencies give priority to recruiting candidates who possess international standards, from which it is clear that having children with international standards is a great advantage in many levels of education, employment, and society in the future. At present, even if there are no educational policies that require degrees and certificates, it is still necessary for parents to let children study and take English exams - the world’s common language. Parents need to have the right awareness about letting their children take the IECE because it is not only used for enrollment and exchange of points, but more deeply, it helps children have the opportunity to access international languages from early, helps children better integrate into the global environment, and at the same time increase job opportunities and future career development.

**Social Integration (SI)** is the last factor that explains only 23% of parents’ peer pressure. Boer et al. (2017) also confirmed that the acceptance of society, especially friends and colleagues, plays an important role in each person’s life, with parents as an example. In addition, concerns about society’s rejection of children and their children’s desire to express themselves create certain pressures for both adolescents and parents. They feel obligated to conform to the standards and expectations of the social group they belong to and the peer group to be cared for, respected, and praised, thereby creating invisible pressures for the parents. For their children to be able to study in an international quality educational environment, participate in activities of international organizations, or simply easily adapt to a variety of living and working environments in the future, parents need to have an attitude that does not hesitate to let their children take the IECE, to supplement and equip their children with essential skills.

## BEAUTY VIRTUAL TRY-ON: HOW AUGMENTED REALITY INCREASES PURCHASE INTENTION THROUGH ITS IMPACT ON CUSTOMER EXPERIENCE

**Author: Doan Thanh Thien Kim<sup>1</sup>, Huynh Quang Bach<sup>1</sup>, Phan Mai Thuy Trinh<sup>1</sup>, Do Thanh Danh<sup>1</sup>  
Mentor: Nguyen Kim Thao<sup>1</sup>**

**ABSTRACT:** *In the era where the beauty industry has undergone a significant transformation, thanks to technical breakthroughs, Augmented Reality (AR) has evolved rapidly in the past decade as a simple technology to use on practically any device, especially in the context of beauty businesses experimenting with innovative approaches to respond to customer demands through AR solutions (e.g., virtual try-on technology) with an effort to promote brand awareness and consumer interest in the brands. Drawing upon the Stimulus-Organism-Response framework, this study proposes a research model that can explain the chain of effects from the AR experiential attributes (i.e., AR interactivity, AR vividness and AR reality congruence) through customer experience (i.e., perceived personalization and self variety-seeking) towards serial paths of purchase intention of beauty products from customer perspective in the beauty context. Results based on a sample of 300 customers show that the AR attributes positively affect customer experience in using AR beauty try-on applications, in turn enhancing purchase intention of the beauty products illustrated in the apps.*

**Keywords:** *AR beauty try-on applications; augmented reality attributes; customer experience; purchase intention; S-O-R model.*

### 1. INTRODUCTION

Retailing is expanding more quickly as a result of advancements made possible by new technologies (Grewal et al., 2017), from same-day delivery on mobile purchase to AI-powered forecasting as a post-pandemic leverage. Lately, acknowledging digital as the “only door to the world”, with augmented reality (AR), customers now access proactive interactions while saving time for fitting and cash on transportation in daily categories (e.g. sneakers, furniture, make-up products, etc.). Accordingly, with such advancements enhancing AR-based apps, this promising 198-billion-dollar market (Statista, 2022) is estimated to spread this adaptation extensively to industrial manufacturing and even medical treatment. Correspondingly, implementing the AR-based innovations in the beauty industry, yet still a relatively new concept, is potentially gaining extensive traction since users are unlimited to virtually ‘try’ hundreds of beauty products and later make choices owing to preferences. Vietnam, still in the early phases of implementing AR technology in trade, with the pioneering of e-commerce platforms to bridge the online and physical shopping divide, has also witnessed leading beauty companies such as L’Oreal, Estee Lauder or Shu Uemura to use virtual try-on technology for high-end segment products on grand platforms, obtaining results surpassing expectations profitably with a consistent increased traffic, where orders of virtual beauty try-on products had a conversion rate that was three times greater than others (Tran and Nguyen, 2022).

From above arguments, it is evidently stated that AR applications are growing as an accessible yet feasible marketing tool in a wide range of industries, including the beauty sector in Vietnam’s developing market. However, along with the light of customers’ contributions to a growth of 513% in research volume about online shopping (Mendonca, 2022), little research has been done on the impacts of customer experience on purchase intention while using AR-based features in Vietnam. Consequently, this research aims to investigate core experiential attributes of AR beauty try-on applications, examining how purchasing beauty products online compromises consumers’ shopping experience and their perception of items while AR features are

involved through the utilization of Stimulus-Organism-Response (S-O-R) model. More specifically, the study places emphasis on the importance of self-congruence regarding augmented visualizations that reflect one's ideal appearance as an influence on consumers' inclination for self variety-seeking. Through presenting the current users' perceptions of these technologies within the S-O-R framework, this research also attempts to bring new improvement plans and suggestions for this optimizing tool of marketing, later contributing to the literature on the implementation of AR beauty try-on applications in the beauty industry.

## 2. THEORETICAL FRAMEWORK AND HYPOTHESIS DEVELOPMENT

### 2.1. Theoretical framework

#### 2.1.1. Augmented reality (AR) in beauty industry context

With augmented reality, users can virtually “try” hundreds of beauty products and later make choices based on their preferences. This convenience, in accordance with the theoretical assumptions of AR technology enhancing customer buying experiences across a variety of omni-channels (Manis and Choi, 2019), and, a survey of Joshi (2019) indicated that AR emerges in providing a ‘try-before-you-buy’ option for consumer where 40% of people are willing to pay more for a product if they can try it out initially through AR (e.g. e-commerce platforms), it is likely that AR applications are a feasible and successful marketing tool in a variety of industries, including the beauty sector, especially in developing markets like Vietnam.

#### 2.1.1. Theory of S-O-R model

The S-O-R model, as a theoretical foundation for consumer behavior research, does not simply relate to psychological contexts but also contributes as an analysis of a proven theory in management information systems for assessing user behavior. For instance, in the context of consumer behaviors, it is proposed that the S-O-R paradigm can assist retailers in pinpointing the exterior stimuli that need manipulating in order to elicit consumers' internal thoughts and behavioral exhibitions (Hsu et al., 2021). Recently, this framework has been notably applied to research the varied influences of mobile AR app attributes or features on users' behaviors. Correspondingly, the S-O-R model is regularly utilized in this study as an important analytical framework to anticipate the cognitive judgment and subsequent action or intention of a group of specific users in terms of explaining the process of human behavior, particularly in the context of using AR beauty try-on applications, where the S-O-R theoretical framework could be relevantly utilized to investigate experience through AR app features as external stimuli, and examine the role of cognitive and affective responses to experiential AR app features in customers' purchase intention subsequently.

Figure 1. Stimulus-Organism-Response (S-O-R) Model

### 2.2. Hypothesis development

#### 2.2.1. The influences of AR attributes on customer experience

##### The influence of AR interactivity on customer experience

Interactivity, commonly referred to “customizing the user interface and graphics to each user's demand” (Albashrawi and Motiwalla, 2015), is considered a crucial component in the beauty industry context for assisting customers in obtaining more information during the shopping process at ease, thus

promoting the timely exchange of relevant information. Relatedly, this is in consonance with the discussion about the relationship between interactivity features and perceived personalization, which assumes that interactivity and the high levels of personalization can result in favorable consumer reactions (Song and Zinkhan, 2008) since the better performance of interactivity in two-way communication setting consisting of navigation and responsiveness, the higher sense of controllability consumers perceive in the navigation of personalized information, especially in the AR beauty context where consumers' own features (e.g., body ratios, facial features) are highly individually assisted. Thus, the study proposes the following hypothesis:

**H1a: There is a positive relationship between AR interactivity and customers' perceived personalization towards using AR beauty try-on applications.**

According to previous studies, it is indicated that variety seeking can help reduce the degree of uncertainty about future desires by actively obtaining information (Ariely and Levav, 2000). Moreover, a study conducted by Zhang et al. (2022) also found the result implying that "variety seeking will be higher when consumers are making decisions in AI (vs. human) service environment". This finding, as a result, establishes a relatively useful theoretical and empirical connection about the connection between self-variety seeking and interactivity, basing on the previous discussion of how the interactivity in AR beauty context works in comprehending consumers' experience with a solid AI-based background to shape the way consumers would interact in this virtual service environment. Thus, the study proposes the following hypothesis:

**H1b: There is a positive relationship between AR interactivity and customers' self-variety seeking towards using AR beauty try-on applications.**

#### **The influence of AR vividness on customer experience**

McLean and Wilson (2019) demonstrated that vividness, which is the clear, detailed representation of an image in the combination of the actual and virtual world, is one of the most prominent attributes of AR, which can stimulate customers' brand-related responses. Accordingly, it is proposed that vividness plays a crucial aspect of AR when customers want the color shades in virtual makeup to look like the original one since it is the definite purpose of AR, which will ultimately assist customers to contrast and make decisions to acquire the product best suited for their face (McLean and Wilson, 2019). It is therefore suggested that vividness in the shopping environment supported by AR is extensively explored on how it will interact with other Stimulus (S) characteristics in subsequently affecting customers' purchase intention.

In this research context, AR technology combines the sensory experience of actual objects with the non-sensory experience of imaginary objects to create a clear image that is expected to be personalized and tailored to the specific consumer (Smink et al., 2020). For example, the vivid information of visualized products on users' own faces or bodies (e.g., makeup, skincare, hair color products) customizes the experience to that specific consumer. Moreover, perceived personalization elicited by AR vivid information is expected to induce positive consumers' attitudes and evaluations towards the product; thus, ultimately influencing their purchase decision (McLean and Wilson, 2019). As a result, the study proposed the following hypothesis:

**H2a: There is a positive relationship between AR vividness and customers' perceived personalization towards using AR beauty try-on applications.**

According to Kahn (1995), the aesthetic appeal and quality of the product presentation can make consumers more open to exploring and trying out new products, leading to increased variety-seeking. Zhang, et al (2022) supported the same thesis, highlighting the expectation on the AI service environment such as vivid display and the uncertainty it induced will positively influence variety seeking. Ultimately, higher

variety seeking in AR service environments might be motivated by the vividness of product representation to enhance personal control, particularly in the beauty sector, where every individual pursues their own style and looks based on their unique traits. As a result, the study proposed the following hypothesis:

**H2b: There is a positive relationship between AR vividness and customers' self variety-seeking towards using AR beauty try-on applications.**

#### **The influence of AR reality congruence on customer experience**

In the AR context, reality congruence was defined by Kowalczyk et al. (2021) as “the degree to which the realistic virtual presentation fits with the actual product”. In web-based product presentations, 3D dimensions (authenticity, system quality, information quality and entertainment) capture the fit between the virtual and the real products which in turn influence users' perception towards the presented product (Algharabat et al., 2017). Otherwise, if the AR product visualizations are of poor quality or the incorrect size, pixelated, inaccurate, or unrealistic, they do not add value to the users' experience.

AR current applications enable a more direct product experience that provides a combined sensory (by simulating the touch-and-feel of physical products) and give users control over their personalization experience (Hilken et al., 2017; Verhagen et al., 2014). Applied to the AR beauty context, physical and non-physical experiences of simulating beauty products on customers' body parts like cosmetics, hair dye, etc. to personalized and tailored for each individual customer, which consequently are expected to convince positive consumers' attitudes and assessment towards the beauty product; hence, ultimately affect their purchase decision (McLean and Wilson, 2019). Thus, the study proposes the following hypothesis:

**H3a: There is a positive relationship between AR reality congruence and customers' perceived personalization towards using AR beauty try-on applications.**

A research experiment conducted by Poushneh (2018) concurred that 3D product presentations could increase certainty while shopping online since they enable consumers to better evaluate the desired product. Therefore, in the case of being assisted by AR attributes, during the time of trying on AR applications, customers could not only cognitively but also virtually have a try and experience simulating products they are not proprietors of (e.g., a limited collection of lipstick colors from a high-end brand). In accordance with this result, previous studies of Ariely and Levav (2000) brought evidence stating that variety-seeking is referred to as a way of reducing the scope of uncertainty regarding future desires and obtaining information. Accordingly, it is supposed that customers are more likely to increase their self variety-seeking when the virtual presentation and the actual goods match together well since it makes choosing a product easier and reduces the risks involved. Hence, we propose the following hypothesis:

**H3b: There is a positive relationship between AR reality congruence and customers' self variety-seeking towards using AR beauty try-on applications.**

#### **2.2.2. The influences of customer experience on purchase intention**

According to the S-O-R model, customer experiences act as a mediator between technical environmental cues and consumer behavior (Animesh et al., 2011). This study takes two kinds of virtual customer experiences including perceived personalization (Pantano and Timmermans, 2014) and self-variety seeking (Javornik et al., 2021) into account in the research model.

Kim et al. (2013) refers to personalization as linked to tailored information since it appeals to the needs and interests of the customer. Perceived personalization is anticipated to play a crucial role in improving their perceptions in beauty products' online purchase. According to Michael and Thies (2015), personalization leads to a noticeably higher purchasing intention. More precisely, personalized recommendations are seen

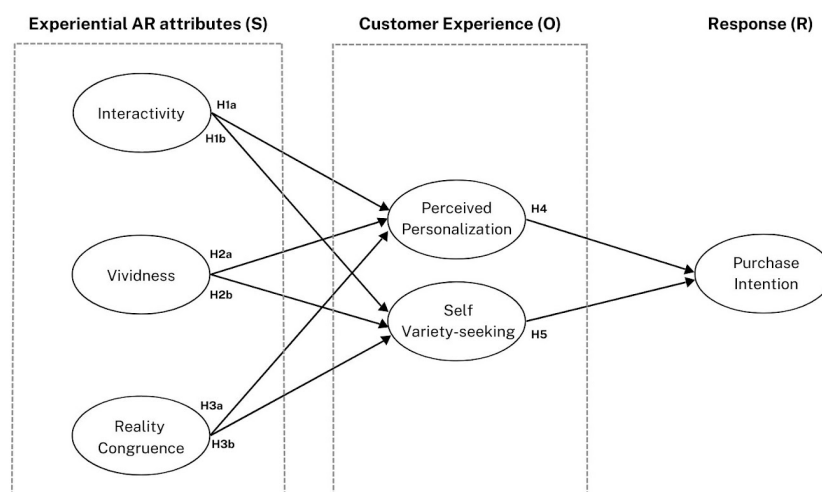

as a one-of-a-kind treat that facilitates their evaluation and decision-making process (Mahapatra, 2017; Zhang et al, 2012). In fact, the AR interface allows users to tailor their experience by selecting various (virtual) beauty products that appear in real-time view of the self or one’s physical world. This results in a more participatory relationship between brands and consumers being formed, consumer demands being satisfied (Ramaswamy and Gouillart, 2008), and enhanced behavioral intention. Thus, the study proposed the following hypothesis:

**H4: Perceived personalization through the experience of AR beauty try-on applications will have a positive effect on purchase intention of beauty products.**

Variety-seeking can be defined as the tendency to diversify choices (Kahn, 1995), which emphasizes that new usage situations or environments can make respondents more open to exploring and trying out new products, and, thus, can lead to increased variety-seeking.

Commonly, in the context of AR beauty applications, users can try hundreds of beauty products (e.g., clothes, makeup, lipstick colors, etc.) and eventually decide according to their choice. (Mendonca et al., 2022). Zhang et al. (2022) also clarified that consumers in the simultaneous-choice condition were more likely to choose a range of goods than those in the sequential-choice condition. Accordingly, the experiment proved that self variety-seeking has a crucial influence on consumer decision-making. These findings play a leading role in demonstrating the wide range customers may test out for several looks to see how cosmetics will seem when worn in real life and finally discover the products that best meet their needs. Therefore, we proposed the following hypothesis:

**H5: Self variety-seeking through the experience of AR beauty try-on applications will have a positive effect on purchase intention of beauty products.**

**Figure 2. Proposed research model**

### 3. RESEARCH METHOD

#### 3.1. Sample and data collection

The data was an analysis of customers in Ho Chi Minh city who have previous experience using AR applications to try on beauty products. This research sample was conducted through interviews and web-based questionnaires. The survey was pre-tested by 25 volunteers with various demographic backgrounds.

After that, the research team developed a web-based survey (Google Form) to collect data from customers. We sent a total of 300 questionnaires, which were used for the last analysis.

Among the respondents, 31 percent were men, and 69 percent were women. Relating to age, results revealed that 88.33 percent of respondents focused on 18 - 25 years old, followed by 26 - 40 years old with 7.67 percent. Considering income, it's almost in the range of low and medium (< 5 mil VND accounts for 59.33 percent and 5 - 10 mil VND accounts for 26 percent). Considering the usage time of AR beauty try-on applications, more than half of respondents (54.67 percent) said that they only used them for less than 10 minutes at a time, followed by 10 - 29 minutes (36.33 percent), and only 4 respondents experienced more than an hour. When asked "the last time they experienced AR beauty try-on", a lot of respondents said that they experienced them recently (<1 recent month accounts for 38 percent, from the last 1-3 months account for 28.67 percent) and only a small percentage (17.33 percent) answered that it was a long time ago, about half a year to 1 year ago. For the last question, only 97 respondents bought beauty products after trying them. The remaining 203 respondents (equivalent to 67.67 percent) said that they do not buy even though they have tried virtual products.

### 3.2. Measurement scale

This research used a 5-point Likert scale questionnaire to measure variables. The measurements for these constructs were adopted from prior studies with some minor modifications to fit the current research context (see Table 1). There are six study conceptions in our research: AR interactivity, AR reality congruence, AR vividness, perceived personalization, self variety seeking, and purchase intention. In general, AR attributes comprise interactivity, reality congruence and vividness, while user experience consists of perceived personalization and self variety-seeking. Interactivity was measured by 4 observed variables, which was adopted and adjusted following the findings of Cyr et al. (2009). The construct of reality congruence consisted of 6 items and was measured based on the study of Kowalczyk et al. (2021). Vividness was assessed based on Babin and Burns (1998)'s single-item construct.

In terms of user experience, the construct of perceived personalization was built with 4 observed variables adopted from the study of Baek and Morimoto (2012); Srinivasan, Anderson, and Ponnavaolu (2002). Four constructs of self variety seeking were adapted from Javornik et al. (2021). Purchase intention was measured based on the scale of Cho et al. (2015).

**Table 1. Measurement scale**

Construct	Measurement	References
Interactivity	<p><b>IN1.</b> When using the AR beauty try-on applications, I was in control of my navigation.</p> <p><b>IN2.</b> When using the AR beauty try-on applications, I had some control over the content that I wanted to see.</p> <p><b>IN3.</b> When using the AR beauty try-on applications, I was in total control over the pace of my visit.</p> <p><b>IN4.</b> The AR beauty try-on applications processed my input very quickly.</p> <p><b>IN5.</b> I was able to obtain the information I wanted without any delay when I used the AR beauty try-on application.</p> <p><b>IN6.</b> This AR beauty try-on application facilitates two-way communication between the visitors and the site.</p>	Cyr et al. ### 3.3. Analytical method

In this study, SmartPLS 4 was used to measure the proposed research model and hypotheses using partial least squares structural equation modeling (PLS-SEM). The PLS-SEM data analysis, according to Henseler and Chin (2010), completes an investigation in two steps: evaluation of measurement model and evaluation of structural model. Additionally, SPSS 25 was also used to process Harman’s single factor test, as well as compute variables and find frequencies of the demographic variables.

## 4. RESULTS AND DISCUSSION

### 4.1. Results

#### 4.1.1. Common method variance (CMV)

If one component can clarify the bulk (typically more than 50%) of covariance in the dependent and independent variables, common method variance occurs. The research must ensure that there is no common method variance before executing the measurement model. To anticipate whether common method variance exists, we used Harman’s single-factor test.

Results of Harman’s single-factor test (Table 2) reveal 30 factors with eigenvalues greater than 1. Approximately 40% of the variance is accounted for by the first factor. These findings suggest that the study does not suffer from the CMV issue.

**Table 2. Total Variance Explained**

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	11.971	39.904	39.904	11.971	39.904	39.904

Extraction Method: Principal Component Analysis.

**4.1.2. Measurement model assessment**

With reference to the mentioned Table 3, most indicators' loadings were higher than the threshold value of 0.708 (Hair et al., 2018), suggesting that more than 50% of the variance in a single indicator can be explained by the corresponding latent construct, confirming indicator reliability (Benitez et al., 2020; Hair et al., 2017a). The IN3 and IN4 variables had loading factors of 0.661 and 0.681 were retained in the measurement model for their contribution to the construct's conceptualization. Furthermore, the removal of these indicators has no effect on the criteria for construct reliability, as indicated by the extracted internal consistency and variance, as well as its discriminant validity; hence, they are regarded as appropriate for the measurement model (Hair et al., 2013).

We applied composite reliability and Cronbach's Alpha for assessing the reliability of the research. As can be seen from the Table 3, the composite reliability ranged from 0.858 to 0.903, which is consistent with the value suggested by Hair et al. (2009), and the Cronbach's alpha results of all latent variables were above 0.7 (Vinzi et al., 2010), indicating a strong mutual association among indicators in describing the intended constructs.

In terms of convergent validity, the AVE should exceed 0.5 to demonstrate that the constructs capture an adequate amount of variance observed by their corresponding items (Hair et al., 2009). In this study, the AVEs were in the range of 0.503 and 0.677, thus were acceptable.

**Table 3. Reliability and convergent validity**

Construct	Items	Indicator Loadings	Composite Reliability	Cronbach's Alpha	AVE
Interactivity	IN1	0.744	0.858	0.802	0.503
	IN2	0.709			
	IN3	0.661			
	IN4	0.681			
	IN5	0.724			
	IN6	0.731			
Vividness	VI1	0.742	0.897	0.857	0.636
	VI2	0.794			
	VI3	0.797			
	VI4	0.820			
	VI5	0.833			
Reality Congruence	RC1	0.764	0.892	0.855	0.580
	RC2	0.801			
	RC3	0.756			
	RC4	0.763			
	RC5	0.752			
	RC6	0.733			
Perceived Personalization	PP1	0.806	0.880	0.818	0.647
	PP2	0.767			
	PP3	0.828			
	PP4	0.815			
Self variety-seeking	SV1	0.791	0.903	0.865	0.649
	SV2	0.783			
	SV3	0.804			
	SV4	0.823			
	SV5	0.826			
Purchase Intention	PI1	0.797	0.893	0.841	0.677
	PI2	0.849			
	PI3	0.835			
	PI4	0.810			

In the measurement model, the concept of discriminant validity is assessed to assure that a concept measure is empirically distinct and captures phenomena of interest that other measures in a structural equation model do not (Hair et al., 2018). The evidence for the discriminant validity of the constructs is shown in Table 4 through the HTMT value. Most of the values are below the threshold of the  $HTMT_{0.85}$  requirements deemed satisfactory for discriminant validity suggested by Clark and Watson (1995) and Kline (2011). Therefore, it indicates that the measurement model possessed adequate validity and discriminant validity.

**Table 4. Discriminant Validity**

	IN	PI	PP	RC	SV	VI
IN						
PI	0.625					
PP	0.613	0.845				
RC	0.740	0.715	0.676			
SV	0.650	0.721	0.676	0.709		
VI	0.649	0.752	0.739	0.715	0.658	

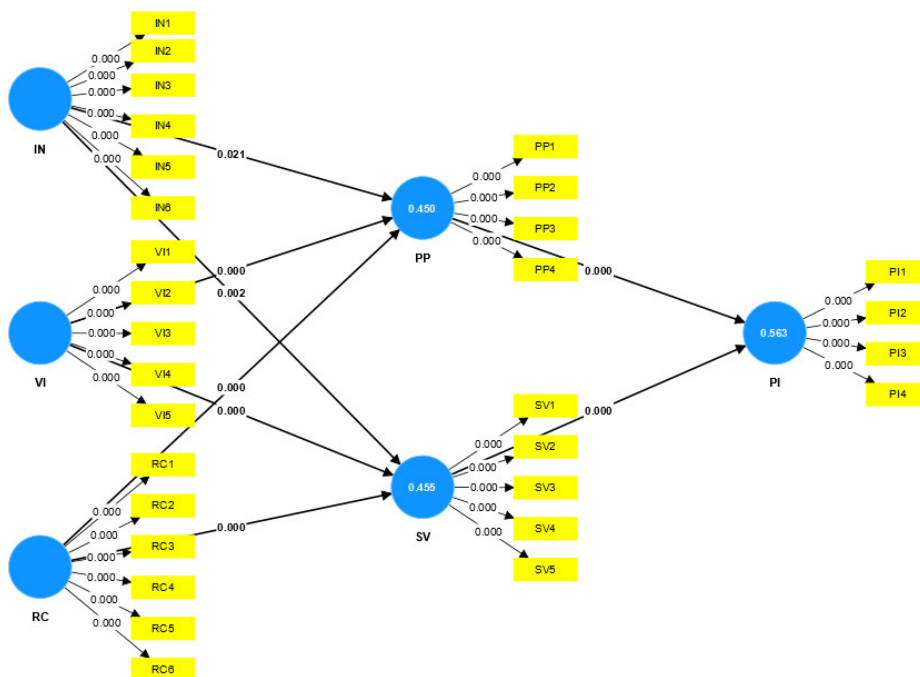

**4.1.3. Structural model assessment**

The results of VIF values (Table 5) are below the common threshold of 5 (Hair et al., 2011), showing that the models do not suffer from multicollinearity.

**Table 5. Variance Inflation Factor**

	IN	PI	PP	RC	SV	VI
IN			1.715		1.715	
PI						
PP		1.479				
RC			1.961		1.961	
SV		1.479				
VI			1.720		1.720	

In this study, PLS-SEM shows all the path coefficient values regarding the variables and factor loadings of each item that it has calculated. Figure 2 shows the values of all items' factors loadings and their path coefficients of PP, SV and PI.

**Figure 3. The structural model after assessing the PLS-SEM**

As suggested by Ramayah et al. (2016), the R2 value measures the goodness of the structural model. The R2 for the generated results of perceived personalization is 0.450, suggesting that 45% of the variance could be explained by the AR attributes and 55% of the variation is explained by other independent variables that are excluded from the model and random error. Moreover, 45.5 percent of the variance of self variety-seeking could be clarified by the AR attributes. As for the R2 coefficient of purchase intention, the value reached 0.563 means that 56.3% of the variation in purchase intention is explained by the mediating variables: perceived personalization and self variety-seeking.

**4.1.3. Hypotheses testing**

The hypothesis testing results are illustrated in Table 6. Bootstrapping outcomes (with 5000 resamplings) for the association between the notions in the suggested study model demonstrated that the t-value of the H1a, H1b, H2a, H2b, H3a, H3b, H4, H5 were higher than 1.96, and these hypotheses were meaningful at a 5% level. As a result, these hypotheses were supported.

**Table 6. Hypothesis testing result**

Hypothesis	Relationship	Standardized beta coefficient	t-value	P-value	Findings
H1a	IN → PP	0.140	2.308	0.021	Supported
H1b	IN → SV	0.204	3.083	0.002	Supported
H2a	VI → PP	0.400	6.245	0.000	Supported
H2b	VI → SV	0.253	3.834	0.000	Supported
H3a	RC → PP	0.235	3.835	0.000	Supported
H3b	RC → SV	0.330	5.244	0.000	Supported
H4	PP → PI	0.521	8.723	0.000	Supported
H5	SV → PI	0.320	5.152	0.000	Supported

## 4.2. Discussions

The study finds that AR attributes positively influence perceived personalization and self variety-seeking, with a stronger effect observed for self variety-seeking ( $\beta = 0.455$ ). This is in line with the findings of Zhang et al. (2022), which suggest that AR attributes enhance the match between virtual presentation and actual goods, simplifying product selection and reducing risks. The findings also confirm the significant impact of AR attributes on perceived personalization ( $\beta = 0.449$ ), supporting the prior theory of Ramaswamy and Gouillart (2008) that highly involved users respond positively to high levels of personalization.

In this study, empirical data-related evidence demonstrates that perceived personalization and self variety-seeking through AR attributes play a significant role in influencing customers' purchase intention. Consistent with the views of Hoyer and Ridgway (1984), variety-seeking orientation was found to be a crucial factor in purchase behaviors. Customers with a higher inclination towards variety-seeking are more likely to have higher purchase intention after experiencing simulated cosmetics through AR. Moreover, similar to Kwon and Kim (2012), perceived personalization is a key factor in purchase intention, as consumer purchases are facilitated through personalization. The more highly accurate, timely, and relevant personalized information is provided, the more enthusiastic in enhancing their intention to purchase an item on its advantages afterwards.

## 4.3. Implication

### 4.3.1. Theoretical implication

Firstly, this study establishes the explanatory value of an established S-O-R model in the context of AR beauty try-on applications. The results show that interactivity, vividness, and reality congruence positively influence customers' experiences. In addition, the study highlights the importance of perceived personalization and self variety-seeking in impacting customers' purchase intentions.

Secondly, this research represents the effort to examine the influence of reality congruence on customers' experiences in using AR beauty try-on applications. This is important considering that previous literature in AR beauty contexts mentioned very less reality congruence as the stimulus in the S-O-R model.

Finally, to examine the relationship between organism and response in the S-O-R model, we introduced another uncommon variable in the AR beauty context: self-variety seeking. In the AR beauty try-on context, relatively few previous studies have focused on self-variety seeking as a part of customers' experiences, as well as its effect on customers' purchase intention for beauty products. Research from Nikhashemi (2021) showed that variety-seeking is a customer response factor, while in our research, we propose it is a part of customers' experiences (Organism).

### 4.3.2. Practical implication

The results firmly support the suggestion of implementing AR beauty try-on applications to increase customer experience through the adaptation of experiential AR features will generate positive responses and influence consumers' intention to purchase beauty products consequently. AR applications appear to be a potentially useful tool in developing successful connections with customers because they are empirically supposed to enhance the sensory richness of the experience, which considerably contributes to the practical implication of this study.

Experiential AR attributes (interactivity, vividness and reality congruence) that relatively lead and enhance positive customer experience. Vividness is found to significantly lead to an increased positive perception of customer experience in shopping, consolidating the background that retailers should make use of images, color, animation, font styles, music, and layout to create a visually appealing AR beauty try-on service experience. Retailers should think about how to convey the try-on platform's architecture and vividness through a strong user interface to interact with customers. In the cosmetics sector, as consumers are usually concerned that the product's color tone and texture do not match the brand's description, it is crucial to optimize virtual products to be as realistic as possible by enhancing the reality congruence features. Therefore, as retailers continually improve the caliber and dependability of their AR tools, ensuring that virtual objects are precisely aligned with the actual environment, even in low-light situations, since a realistic virtual product display can only be realized with good system quality, which in turn boosts the utility of AR (Kowalczyk et al., 2021). Ultimately, the results specifically revealed that since interactivity might result in consumers' excessive usage when performing an ordinary task, "individuals tend to be distracted by irrelevant activities (e.g., playing around the interactivity tools) or be indulged in cognitive laziness", which leads to inferior experiences and attitudes (Tang, F., 2020). Alternatively, customer support regarding AR usage may be incorporated with interactive help features, a search function, or tools for inquiries (Khare et al., 2020). Thus, designers should carefully evaluate the target task with suitable assistance when incorporating interaction features.

### 4.4. Limitation and future development

Beside the contributions of our research, we realized several limitations during the process of implementing. Analytically, the survey could not approach a huge number of possible respondents in other regions to provide an overview of customers' perspectives throughout Vietnam. Besides, the group of authors had difficulties in reaching various demographics leading to the limit in sample objectives and sample size since most of the responses are from 18-24 aged surveyors. Therefore, this study does not generalize the attitude and purchase intention of Vietnamese customers among various age segmentations. As a result, the research responses may differ from each segment, resulting from various experiences and rationales behind the purchase intention of online beauty products. Thus, future studies should extend the sample to include a broader range of research participants, as well as incorporate other theoretical frameworks, to better understand the customers' purchase intention.

## 5. APPENDIX

### Appendix A. Model fit - Coefficient of Determination

# ORGANIC COSMETICS AND ENVIRONMENTAL CONSCIOUSNESS: INVESTIGATING FACTORS INFLUENCING ACTUAL PURCHASE BEHAVIOR OF STUDENTS IN HO CHI MINH CITY

Author: Phan Thi Kim Lan, Pham Nguyen Thuc Tram

Mentor: Nguyen Ngoc Danh<sup>1</sup>

**ABSTRACT:** Consumers are not only increasingly interested in health but also the environment so they are looking for organic and natural products. In Vietnam in general and Ho Chi Minh City in particular, the practice of organic cosmetics in terms of businesses is still underdeveloped. Therefore, this study explores the consumption behavior of organic cosmetics among students in Ho Chi Minh City - a potential market in Vietnam. The study focuses on three main objectives: Firstly, determining the factors affecting students' behavior of using organic cosmetics. Secondly, testing and measuring the impact of these factors on students' behavior of using organic cosmetics. Thirdly, proposing managerial implications as a reference basis for the management of organic cosmetics supply to increase the number of customers using it through the factors tested from the research model. Based on data collected from 500 students, research results confirm the relationship between Health consciousness, Environmental consciousness, Appearance consciousness, Product knowledge, Price consciousness, Subjective Norm, Attitude towards organic cosmetics, Purchase intention and Actual behavior.

**Keywords:** organic cosmetics, environmental consciousness, actual behavior, Ho Chi Minh City

## 1. INTRODUCTION

Society is increasingly developing in the present day. Industrialization and modernization have been and are gradually improving the quality of human life. When essential needs are met, people begin to pay more attention to personal needs, one of which is the issue of aesthetics and beauty. Looking beautiful and being highly regarded by others is a human desire (Kashyap, 2013). One effective means to fulfill this beauty need is through cosmetics. While in the past, makeup cosmetics were often favored by women, nowadays they are becoming more concerned about skincare and the beauty of their skin (Ulfat & colleagues, 2014). Organic cosmetics are becoming increasingly popular and widely used. According to Mintel, Vietnam is evaluated as a large cosmetics consumption market in the Southeast Asia region. The evidence is that the market scale has grown from \$500 million in 2011 to \$1.78 billion per year in 2016, and reached \$2.35 billion in 2018. According to the latest report, in the first half of 2020, the number of cosmetics users increased by 30%. Similarly, research by Statista indicates that the rate of increase in the number of cosmetics stores nationwide has risen by 40%, from 87% in 2021 to 124% in 2022. The market share is also gradually changing as the trend of using high-quality Vietnamese products is spreading. According to market research estimates, the middle class in Vietnam will be the ones to pay for the rapidly increasing consumption of cosmetic products, reaching up to 33 million people. This estimate is based on the results of the high economic growth rate of over 6-7% annually and a young generation that accounts for 60% of the population.

Organic cosmetics in Vietnam are gradually asserting their position in the market, following the global beauty trend. Reports from Euromonitor International also show that the demand for natural and organic cosmetics among Vietnamese consumers is growing stronger. Thanks to their natural production and ingredients such as cucumber, aloe vera, honey, fruit extracts, plant butter extracts, and milk, which

---

<sup>1</sup> University of Economics Ho Chi Minh City

are free from the impact of chemicals, antibiotics, growth hormones, etc., organic cosmetics meet strict organic standards and provide natural nutrients that are beneficial for the health of users. These products contain at least 70% of ingredients sourced from certified organic agriculture. The emergence of organic cosmetics has brought about a revolution in the beauty industry. According to a report by the NPD Group, global organic cosmetics revenue reached \$480 million in 2017, representing a 10% increase compared to 2016, and it is predicted to double in 2018. The global consumer attitude towards organic cosmetics has also become more positive, with an additional 5% of consumers seeking organic cosmetics made from natural ingredients in 2017. Over 80% of people believe that natural ingredients will be even more popular in the next 10 years. Furthermore, natural and organic cosmetics companies currently hold the largest market share in the global cosmetics market. In Vietnam, and particularly in Ho Chi Minh City, the practical aspects of organic cosmetics are still underdeveloped from a business perspective. Although the use of skincare products is currently a trend, Vietnamese consumers still prefer using foreign skincare products. Despite there are some studies and articles on skincare products in Vietnam, there is very little research on the consumption behavior of organic cosmetics. The demand for different types of cosmetics will vary in each region of the country. Vietnamese skincare companies, especially those offering organic products, need to implement appropriate measures to establish a solid position in the domestic market. Similar to other countries, Vietnam also experiences a discrepancy between intention and actual behavior.

Therefore, recognizing the increasing trend of interest in natural and organic products from the Vietnamese market and consumers, the author team conducted this study to investigate the usage behavior of consumers influenced by which factors and evaluate the level of influence of these factors on the usage behavior of organic cosmetics among students. This research serves as a basis for beauty companies to develop suitable products and effective business strategies that meet the market demand for natural, organic, less harmful products.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Overview of organic cosmetics**

Although the term “green” has a strong impact in the cosmetics market, there is no exact definition for it. The easiest meaning of this phrase is the connection to “environmentally friendly” and the use of natural/organic ingredients (Leja & Ross-Fichter, 2014). Natural cosmetic products really only include natural ingredients, with at least 95% of the ingredients used being produced according to the principles of natural agriculture. They also do not contain preservatives, synthetic fragrances or petroleum-derived ingredients, among other non-natural origin ingredients (Kapsnet, 2007; Ethos, 2012). Natural products are often characterized by their green features, as consumers are concerned not only about the end product they will use but also about the entire production process, such as recycling packaging and continuous use of natural resources. In addition, the raw material sourcing process is also being considered, using technologies that are deemed less harmful to the environment (FONSECA-SANTOS et al., 2015, IBD, 2019). According to IFOAM (International Federation of Organic Agriculture Movements), certified natural ingredients are natural substances and substances extracted from nature that are grown under natural conditions and certified by a reputable certification organization (IFOAM, 2018; NATRUE, 2019).

Organic cosmetics provide health benefits such as reducing skin disorders, reducing acne, brightening the skin, and keeping the skin soft. It also helps protect the environment by producing and using cosmetics that do not have negative impacts on the environment. According to the United States Department of Agriculture (USDA), if a cosmetic product contains or is made from agricultural ingredients that can meet the USDA/National Organic Program (NOP) production, processing, and labeling standards, the product

can be certified organic under the NOP regulations. Additionally, the production and processing of organic agricultural ingredients and the manufacturing facility of the final product must be certified by a USDA-accredited organic certifying agent. Due to the large amount of natural ingredients that can be safely used in the final cosmetic products, this field of research is promising (CAVINATO, M. et al., 2017).

## **2.2. Theoretical foundation**

This study examines the formation of purchase intentions for organic cosmetics through the Theory of Planned Behavior (TPB) based on individuals' environmental concerns and the availability of organic cosmetics. TPB addresses situations that activate the cognitive attributes of a person leading to the development of intention and subsequent behavior (Ajzen, 2002). In the initial stage, three discriminant factors, specifically attitude toward the behavior, subjective norm, and perceived behavioral control, form the intention toward behavior (Wu, S. I., & Chen, J. Y. (2014)). TPB, as a social-cognitive framework, has been widely applied to explore large domains of behavioral and social research (Cheung, R., Lau, M. M., & Lam, A. Y., 2015 and Yadav, R., & Pathak, G. S., 2017). Recently, TPB has been applied in the field of green consumer behavior research and has produced significant results. TPB has been exploited not only to explore consumer behavior but also to guide the development of government interventions to facilitate the widespread adoption of green products (Afroz, R., Masud, M. M., Akhtar, R., Islam, M. A., & Duasa, J. B., 2015).

TPB has been used to explore green consumption in low-income households. Attitude and perceived behavioral control are the most important predictors of green consumption (Ghazali, E., Soon, P. C., Mutum, D. S., & Nguyen, B., 2017). Subjective norms appear to be low for low-income households, indicating a pressing need to increase societal acceptance of green products. Therefore, it is reasonable to apply this theory in the study of organic cosmetics consumption behavior.

## **2.3. Research concepts and hypothesis**

### **2.3.1. Health consciousness**

The Oxford Dictionary uses the term "health consciousness" to describe the attitude of a person who is aware of the healthiness of their diet and lifestyle. Health consciousness is defined as "the willingness to engage in health-related actions" (Schifferstein & Ophuis, 1998, p. 122). Health-conscious consumers are those who prioritize their health and engage in activities that enable them to live a healthy lifestyle (Newsom et al., 2005; Kim & Seock, 2009; Kim & Chung, 2011). Kim and Seock (2009) also noted that health-conscious consumers may modify their consumption behavior because they believe it will impact their health. Kim and Chung (2011) also showed that health awareness is the most important factor influencing attitudes towards organic personal care products. Consumers who are more concerned about the safety of the food they consume often view organic food in a positive light and prefer it over other types of food (Roddy et al., 1996). Consumers feel that organic food is right for them because it does not contain harmful organic compounds (Devcich et al., 2007). In addition to health awareness being a progressive topic to focus on for consumers, the convenience and readiness of the product also significantly affect the consumption of organic products (Kouya et al., 2016). Therefore, the authors propose the hypothesis:

*H1: Health consciousness has a positive impact on consumer attitudes towards organic cosmetics.*

### **2.3.2. Environmental consciousness**

Some articles have concluded that customers' environmental knowledge and attitudes play a very important role in purchasing green products, as environmental knowledge activates customers' interest in organic products (Schlegelmilch et al., 1996). Yadav and Pathak also pointed out that individuals'

environmental concerns and attitudes towards green products are identified as key determining factors for the intention to purchase green products among young people in India (Yadav and Pathak, 2016). Customers use their knowledge, overview, and commitment to green products to determine their overall awareness of the environmental benefits, economic benefits, reliability, and value of green products to decide to purchase the product (Maniatis, 2016). The higher customers' environmental awareness, the greater their intention to use green products (Arruda et al., 2017). Environmental attitude, product attitude, social impact, and monetary value are estimated to have a positive impact on the intention to purchase green products (Chen et al., 2018).

Facing environmental destruction issues caused by the harm of toxic substances and animal testing in ingredients and products, the cosmetics industry has developed organic products that are produced without the use of pesticides, synthetic chemicals, and animal testing (Prothero and McDonagh, 1992). Along with the findings that consumer environmental awareness is seen as a prerequisite for green consumption (Dembkowski, 1998; Polonsky and Mintu-Wimsatt, 1995). Therefore, the authors propose the hypothesis:

*H2: Environmental awareness has a positive impact on consumers' attitudes towards organic cosmetics.*

### **2.3.3. Appearance consciousness**

The consciousness of appearance, according to Scandell (2001), is an individual's awareness of themselves within their community, and it relates to a person's concern about what others think of their appearance. Those who are concerned about their appearance will have concerns about expressing or altering their appearance (Lee & Lee, 1997 cited in Park & Kim, 2010). The increasing awareness of health, environment, and appearance has created a demand for green cosmetics and beauty care products among consumers (Newsom et al., 2005; Peattie, 2001; Schlegelmilch et al., 1996; Paladino, 2006; Todd, 2004).

Consumers want products that make their skin look better so they can feel confident about themselves. Therefore, companies have found ways to meet the needs of customers without using harmful chemicals on the skin in the long run by using organic products that make people feel good about their appearance. (Todd, 2004). Some people desire to maintain their youthful appearance and improve their appearance, so they seek out chemical-free personal care products with minimal amounts of chemical substances, and can provide less harmful alternatives compared to conventional products (Tirone, 2007). Since organic skin or hair care products are produced with minimal chemical content, they can provide less harmful products than conventional products. Therefore, the authors propose the hypothesis:

*H3: The perception of appearance has a positive impact on consumers' attitude towards organic cosmetics.*

### **2.3.4. Product knowledge**

The knowledge about a product is defined as the way consumers perceive specific products (Beatty & Smith, 1987). The knowledge that consumers receive about products and services is important in their acceptance decisions of the products (Chyh et al., 2017; Ghazali et al., 2017; Suki, 2016; Assaker, Vinzi, & O'Connor, 2011; Tse & Crotts, 2005; Moorman et al., 2004). According to Park et al. (1992), consumer product knowledge is classified into three types: imaginal knowledge- an individual's self-perceived level of knowledge about a product or service; objective knowledge- information about the product stored in the consumer's memory; and experience-based knowledge- information derived from prior product usage experiences. In this study, product knowledge is understood as consumers' imaginal knowledge about organic cosmetic products.

Several studies support the view that product knowledge has a positive impact on consumers' attitudes towards these products, thereby enhancing organic food consumption (Padel & Foster, 2005; Vermeir &

Verbeke, 2008). Lin (2009) found that individuals with prior experience using organic products demonstrated a higher level of environmental knowledge compared to those who have not used such products. Gracia and de Magistris (2008) found that organic knowledge could influence attitudes not only to increase the likelihood of purchasing organic products, but also to increase the usage level of existing consumers. Therefore, the authors propose the hypothesis:

*H4: Product knowledge has a positive impact on consumers' attitudes towards organic cosmetics.*

### **2.3.5. Price consciousness**

Price is the total amount of money a consumer has to pay to purchase a product or service, and it is also a quality attribute. Typically, consumers consider a reasonable price range for the products they want to buy (Bojanic, 1996). Among many consumers, most look for products with maximum benefits but low prices because the high price of the product is considered too expensive (Marian et al., 2014; Hur et al., 2012). Even though buying green products incurs a higher cost, consumers are still willing to pay a higher price because of the value of the product (Tsay, 2009). Some customers show that they accept the high value of organic products (Davis et al., 1995). Consumers feel satisfied when they have to pay a higher price because they know that green products are worth the money. Older and higher-income consumers tend to buy products with higher prices than younger people (Mohd Suki, 2015; Tsay, 2009). Consumers also use the price to make it easier to choose, find alternative products, and make decisions to buy or not (De Medeiros et al., 2016; Pan et al., 2013). Therefore, the authors propose the hypothesis:

*H5: Price awareness has a positive impact on consumers' attitude towards organic cosmetics.*

### **2.3.6. Attitude towards organic cosmetics**

Azjen (1991, p.188) defined attitude towards a behavior as the extent to which a person has a favorable or unfavorable evaluation or appraisal of that behavior. Attitude is also defined as an individual's affective response to a specific behavior (Ajzen, 2002). Both the Theory of Reasoned Action (TRA) (Ajzen & Fishbein, 1975) and the Theory of Planned Behavior (TPB) (Ajzen, 1985) propose that an individual's action is the result of intention, and intention stems from reasoned thinking. An individual's attitude towards the behavior is a decisive factor in their intention, and in reference materials, attitude is considered the best predictor of intention, and in turn, the best predictor of behavior (Cesareo & Pastore, 2014; Cronan & Al-Rafee, 2008; Fishbein & Ajzen, 1975).

According to Ajzen and Fishbein (1980), when an individual's attitude towards a particular behavior is positive, they may be more likely to engage in that behavior. There is a positive relationship between consumer attitude and intention to purchase environmentally friendly products across cultures and for various product types (Kim & Chung, 2011). The decision to purchase green products is one of the positive indicators on the scale of environmental protection behavior (Liobiki, Grincevi & Bernatonien, 2017). An individual who is environmentally conscious and has positive experience with eco-products is more likely to have the intention to purchase green products due to their green characteristics (Norazah, 2016). Therefore, the authors propose the hypothesis:

*H6: Attitude towards organic cosmetics has a positive impact on the intention to purchase organic cosmetics.*

### **2.3.7. Subjective norms**

Subjective norms are related to the perceived social pressure of an individual to engage in a certain behavior (Ajzen, Icek, 1991). According to Teng and Wang (2015), consumers tend to have a positive intention to purchase a product if they perceive that important others have a positive attitude and opinion

about that product. This individual has normative beliefs about the expectations of others (Boon, Lim Kah, Yeo Sook Fern, and Lee Hue Chee, 2020). Social approval from family, friends, and close colleagues influences a person's decision-making (Mancha, Ruben M., and Carol Y. Yoder, 2015). An individual's perception changes significantly with a suggestion or advice from an important person to them (Yadav, Rambalak, and Govind S. Pathak, 2017).

Subjective norms have a significant impact on the formation of intention to purchase green products (Wu, Shwu-Ing, and Jia-Yi Chen, 2014). Social encouragement is essential in the consumption of green products and services (Barua, Promotosh, and Md Islam, 2011). Tarkiainen and Sundqvist (2005) also emphasize the importance of subjective norms in predicting repeat purchase intention. Additionally, Griskeicius et al. (2010) highlight that social status is considered the most critical factor influencing the purchase of environmentally friendly products compared to environmental and financial considerations. Previous studies have also identified a significant positive relationship between subjective norms and intention to purchase organic food (Al-Swidi et al., 2014; Chen, 2007; Smith and Paladino, 2010), organic cotton clothing (Han and Chung, 2014), and organic skincare/hair care products (Kim and Chung, 2011). Therefore, the authors propose the hypothesis:

*H7: Subjective norm has a positive impact on intention to purchase organic cosmetics.*

#### **2.3.8. Perceived behavioral control**

Perceived behavioral control refers to an individual's perception of the difficulties that may arise when performing a specific behavior, including available resources and opportunities (Ajzen, 1991). While resources and opportunities to perform certain behaviors objectively exist, a person's decision is more influenced by their perceived control over the behavior (Ajzen, 1989). Therefore, when a consumer feels a lack of ability, resources, or opportunity to perform an action, they are unlikely to have a strong intention to do so, regardless of objective conditions (Ajzen, 1989; Schifter and Ajzen, 1985). Perceived behavioral control can be understood from two aspects: the individual's internal efficacy and perceived barriers (Sparks et al., 1997, cited in Yanfeng Zhou, et al., 2013).

Previous studies have revealed that internal locus of control is positively related to the purchase of environmentally friendly products and promotes environmentally friendly purchasing behavior (Wang 2014). According to Ajzen (2005), individuals who perceive a higher degree of personal control tend to have stronger behavioral intentions to engage in a specific behavior. When individuals have more resources such as time, money, and skills, and a higher perception of their control, this increases their behavioral intention (Kim & Chung 2011). Therefore, the authors propose the following hypotheses:

*H8: Control on availability of organic cosmetics has a positive impact on intention to purchase organic cosmetics.*

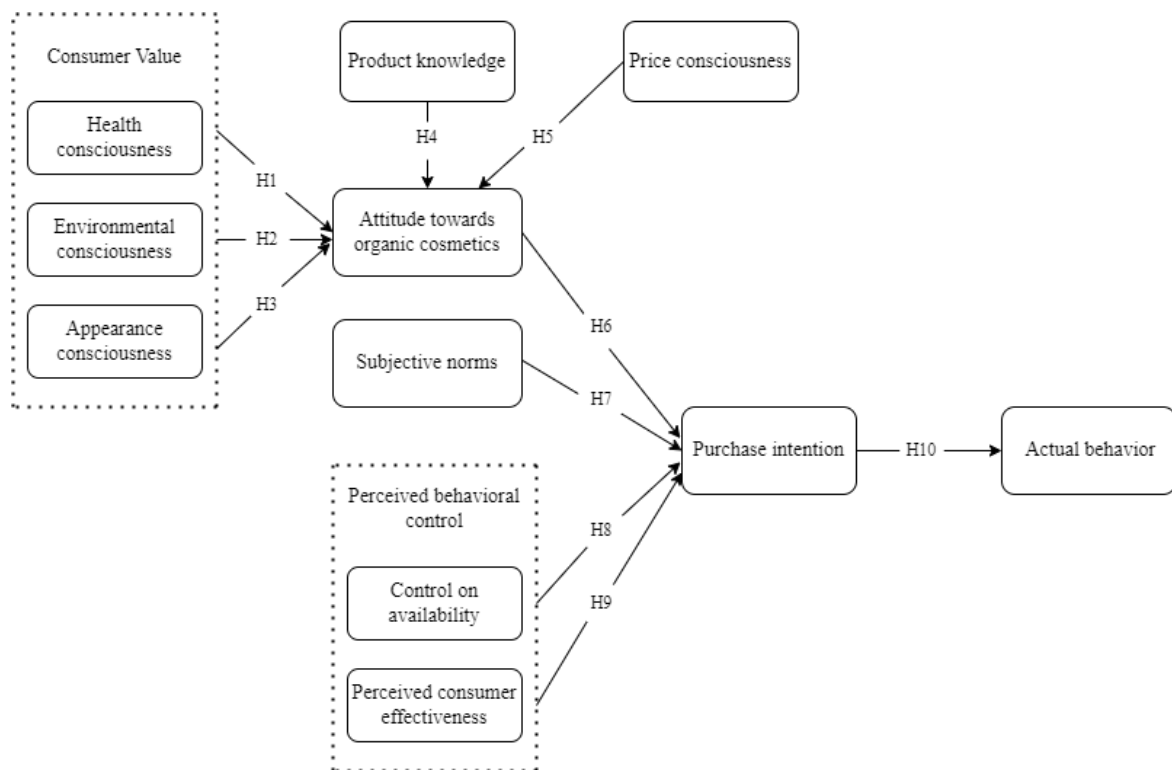

*H9: Perceived consumer has a positive impact on intention to purchase organic cosmetics.*

#### **2.3.9. Purchase intention**

The intention to purchase is defined as an individual's positive attitude and urge to purchase a specific product in a particular situation (Parengkuan, 2017). Customer purchase decision is a complex process that includes the behavior, perception, and attitude of an individual. As stated by Jaafar, Lalp, and Naba (2012, p. 75), purchase intention is an effective tool to predict the purchasing process. Purchase intention can be influenced by perceived quality and value, as well as price. Additionally, people may be influenced by internal or external factors during the purchasing process. Yang, Y. C. (2017) found a strong relationship between purchase intention and the purchase of green skincare products and agreed that consumer purchase

intention significantly affects the purchase of environmentally friendly skincare products. Therefore, the authors propose the hypothesis:

*H10: Intention to purchase organic cosmetics has a positive impact on the actual purchase behavior of organic cosmetics*

**Figure 1. Research model**

### 3. RESEARCH METHOD

#### 3.1. Qualitative research method

The research team carried out a qualitative research method through online discussions with 10 participants in Ho Chi Minh City. Interviews were conducted using the Google Meet application. The interview content was prepared in advance, consisting of open-ended questions about the use of organic cosmetics. Statements were translated into Vietnamese and adjusted for clarity and relevance to the interviewees' cognitive context. Through survey results, discussions, and observations synthesized from theoretical bases, the research team was able to adjust the terms used in the scale and add observation variables to make them suitable for measuring the research definition.

#### 3.2. Quantitative research method

The survey questionnaire used by the research team to collect data was formed based on theory. The content of the observation variables was adjusted to fit the reality of cosmetics users in Ho Chi Minh City. The main content of the survey questionnaire included 44 quantitative questions and 4 customer information questions. The questions focused on exploring the opinions and evaluations of cosmetic users in Ho Chi Minh City. The Likert 5-point scale was used for 44 quantitative questions, with 1 being "strongly disagree", 2 being "disagree", 3 being "neutral", 4 being "agree" and 5 being "strongly agree". The authors used IBM SPSS 20 software to process data. The data, after encoding and selection, will be analyzed through the following: Evaluate the reliability of the scale Cronbach's Alpha, Exploratory factor analysis

(EFA), Discriminant Validity - Heterotrait-Monotrait Ratio (HTMT) and Multivariable regression results.

#### 4. RESULTS AND DISCUSSION

##### 4.1. Results

##### 4.1.1. Descriptive statistical analysis

After completing the sample collection, the researcher removed the survey samples that were not valid as random responses. The number of remaining survey samples is 500 samples.

**Table 1. Statistical table describing survey sample data**

Measure	Item	N	Percent(%)
Gender	Male	46	9.1
	Female	454	90.9
Income	Under 5 million	432	86.4
	5 - 8 million	46	9.1
	Over 9 million	22	4.5

*Source: Author's synthesis*

##### 4.1.2. Cronbach's Alpha reliability test results

Prior to doing the factor analysis, it is necessary to undertake tests to determine the eligibility of the data for the method of factor analysis (Cronbach's Alpha). To be an acceptable measurement model, the total Cronbach's Alpha coefficient should be  $> 0.7$  (Cronbach and Shavelson, 2004) and the inter-item correlation coefficient should be  $> 0.3$  (Clark and Watson, 1995). The results in table 2 show that Cronbach's Alpha and the overall reliability of the factors are all greater than 0.8. Therefore, the overall reliability and factor coefficients of the component measurement scales meet the reliability requirements.

**Table 2. Cronbach's Alpha reliability test results**

Variable	Number of items	Cronbach alpha's value
Health consciousness (HCS)	5	0.899
Environmental consciousness (ECS)	5	0.845
Appearance consciousness(ACS)	5	0.898
Product knowledge (PKE)	4	0.862
Price consciousness (PCS)	5	0.885
Attitude towards organic cosmetics (ATO)	4	0.886
Subjective norms(SNS)	3	0.843
Control on availability(COA)	4	0.812
Perceived consumer effectiveness(PCE)	4	0.858
Purchase intention(PIN)	5	0.859
Actual behavior (ABR)	5	0.884

##### 4.1.3. EFA exploratory factor analysis results

The EFA analysis aimed to evaluate the convergence of observed variables in explaining a factor and the differentiation of groups of observed variables explaining different factors. The KMO coefficient

obtained was  $0.825 > 0.5$ , indicating that the factor analysis was appropriate for the research data; the Bartlett test result was 12520.877 with a significance level of  $\text{sig.} = 0.000 < 0.05$ , demonstrating that the data used for factor analysis was also completely appropriate. At the same time, the Eigenvalue coefficient satisfied greater than 1 for all 11 factors, and the total variance extracted by 11 factors was  $68.526\% > 50\%$ , indicating that these 11 factors explained 68.526% of the variation in the data. The analysis results showed that the observed variables converged and differentiated correctly with the research team's initial proposal.

**Table 3. KMO and Bartlett's Test**

<b>Kaiser-Meyer-Olkin Measure of Sampling Adequacy</b>		0.825
	Approx. Chi-Square	12520.877
Bartlett's Test of Sphericity	df	651
	Sig.	0.000

*Source: Author's calculation*

In table 5, most of the factor loading factors are greater than 0.5 except ECS2, ACS4, PCS1, COA4 whose factor loading is less than 0.5 so it is rejected. In addition, there is no case that any variable can upload both factors at the same time with the load coefficients close to each other, so the factors ensure convergent and discriminant values when analyzing EFA. Thus, we draw the conclusion to reduce the factor ECS2, ACS4, PCS1, COA4.

#### **4.1.4. Discriminant Validity - Heterotrait-Monotrait Ratio (HTMT)**

The HTMT (Heterotrait-Monotrait Ratio) coefficient is a measure used in Structural Equation Modeling (SEM) to assess the discriminant and convergent validity among variables in a model. The results from table 6 indicate that all indices have values less than 0.85. This shows that the observed variable sets used to measure the concepts in the model are weakly correlated with each other. Therefore, the variables

in the model achieve discrimination. Among them, ECS (Environmental consciousness) and ATO (Attitude towards organic cosmetics) have the best discrimination with an HTMT value of only 0.324. Conversely, the variables PIN (Purchase intention) and HCS (Health consciousness) have the strongest correlation with an HTMT index reaching 0.845.

**Table 6. Discriminant Validity - Heterotrait-Monotrait Ratio (HTMT)**

	HCS	ECS	ACS	PKE	PCS	ATO	SNS	COA	PCE	PIN	ABR
HCS											
ECS	0,534										
ACS	0,642	0,531									
PKE	0,689	0,589	0,635								
PCS	0,621	0,494	0,560	0,720

Source: Author's calculation

**4.1.5. Multivariable regression results – Bootstrap 10000 samples**

All independent and intermediate variables: HCS, ECS, ACS, PKE, PCS, SNS, ATO and PIN (except PCE and COA) have a strong correlation with the dependent variable when the Pearson correlation coefficient is smaller than 0.05. Similar to previous studies, the results of hypothesis testing in this study also use the 5% significance level to evaluate. The results are shown in Table 7:

**Table 7. Multivariable regression results – Bootstrap**

Hypothesis	Relationships	Beta value	Standard deviation (STDEV)	P-value	Inspection results
H1	Health consciousness → Attitude towards organic cosmetics	0,362	0,038	0,000	Accepted
H2	Environmental consciousness → Attitude towards organic cosmetics	0,310	0,036	0,000	Accepted
H3	Appearance consciousness → Attitude towards organic cosmetics	0,151	0,022	0,035	Accepted
H4	Product knowledge → Attitude towards organic cosmetics	0,317	0,036	0,013	Accepted
H5	Price consciousness → Attitude towards organic cosmetics	0,446	0,079	0,000	Accepted
H6	Attitude towards organic cosmetics → Purchase intention	0,414	0,018	0,002	Accepted
H7	Subjective norms → Purchase intention	0,279	0,040	0,000	Accepted
H8	Control on availability → Purchase intention	0,265	0,053	0,062	Rejected
H9	Perceived consumer effectiveness → Purchase intention	-0,236	0,019	0,052	Rejected
H10	Purchase intention → Actual behavior	0,390	0,046	0,000	Accepted

Source: Author's calculation and synthesis

The results in table 7 show out of 10 proposed hypotheses. H1, H2, H3, H4 and H5 indicated that Health

consciousness ( $\beta = 0.362$ ,  $p < 0.001$ ); Environmental consciousness ( $\beta = 0.310$ ,  $p < 0.001$ ); Appearance consciousness ( $\beta = 0.151$ ,  $p < 0.05$ ); Product knowledge ( $\beta = 0.217$ ,  $p < 0.05$ ) and Price consciousness ( $\beta = 0.446$ ,  $p < 0.001$ ) were demonstrated to have a positively significant effect on Attitude towards organic cosmetics. Therefore, H1, H2, H3, H5 and H5 were accepted. The results showed that Attitude towards organic cosmetics ( $\beta = 0.414$ ,  $p < 0.05$ ) and Subjective norms ( $\beta = 0.279$ ,  $p < 0.001$ ) positively impact on Purchase intention, therefore H6 and H7 were accepted. The proposed relationship between Attitude towards organic cosmetics. Therefore, H1, H2, H3, H5 and H5 were accepted. The results showed that Attitude towards organic cosmetics, Subjective norms and Purchase intention was tested. Control on availability ( $\beta = 0.265$ ,  $p > 0.05$ ) and Perceived consumer effectiveness ( $\beta = 0.236$ ,  $p > 0.05$ ), so H8 and H9 were rejected. Finally, Purchase intention had a positive impact on Actual behavior ( $\beta = 0.390$ ,  $p < 0.001$ ). Thus, H10 was accepted.

#### 4.2. Discussion

The purpose of the study is to explore the factors affecting the behavior of using organic cosmetics, especially the factors of environmental awareness and consumers' attitudes towards organic cosmetics when the problem of polluting the environment is becoming more and more urgent. Research results show that HCS, ECS, ATO, PCS have the strongest impact on PIN.

The findings demonstrate the research of previous studies by Kim, H. Y., & Chung, J. E. (2011); Al Mamun et al. (2020); Tewar et al. (2021), Shimul et al. (2022) and Chhetri, S., Fernandes, S., & Baby, S. (2021) support the relationship between HCS, ECS and ACS to ATO. As for the relationship of PKE and PCS to ATO, previous studies by Ghazali et al. (2017) and Tengli, A., & Srinivasan, S. H. (2022) showed that they are statistically significant relationships. The results of our study also showed similar results. Next, the relationship between SNS and PIN is accepted with  $\beta = 0.279$ , equivalent to the antecedent studies of Chhetri, S., Fernandes, S., & Baby, S. (2021); Chen, M. F. (2007) and Pop, R. A., Săplăcan, Z., & Alt, M. A. (2020). Finally, the hypothesis of the relationship between COA to PIN in the study supports Nguyen, T. H et al. (2017) but the hypothesis of the relationship between PCE to PIN is not supported. Overall, the researcher's findings provided a thorough explanation of the factors impacting on actual purchase behavior of organic cosmetics. This also supports previous research.

#### 5. CONCLUSION

The research topic on factors influencing the use of organic cosmetics among students in Ho Chi Minh City is a very interesting and highly applicable topic. In today's era, the demand for using organic cosmetics has become a trend that many consumers are interested in. This topic focuses on the factors influencing the use of organic cosmetics among students, including psychological, social, and economic factors. Psychological factors include concerns about health, preference for natural and safe products, confidence when using organic cosmetics, as well as the influence of product information. Social factors include the opinions of friends, family, and relatives about using organic cosmetics, as well as social values related to the use of these products. Economic factors are also an important factor in deciding to use organic cosmetics. The cost, convenience, features of the product, and market selection can also influence the use of organic cosmetics among students. This study also provides many practical contributions to businesses in the cosmetics industry, market managers.

*Firstly*, research results show that attitude towards organic cosmetics emerges as the most important factor in predicting buying behavior of organic cosmetics, followed by intention to purchase organic cosmetics. Individual concern for the environment seems to be the third most important essential factor predicting the

purchase of green skin care products. So administrators or marketers can use the results of this study to better understand consumer attitudes towards organic cosmetic products. The designed advertising strategies can pay more attention to the health and environmental consciousness of consumers towards organic cosmetic products. Two factors should be emphasized for the advertising of organic cosmetic products.

*Secondly*, the study also revealed that product knowledge is the main driver of attitudes towards organic cosmetic use behavior. The public must be made aware of organic cosmetic products through various advertising platforms to improve consumer knowledge. Marketers need to put in place communication efforts to make consumers more aware and increase their knowledge about organic products as well as efforts to reduce pollution and promote eco-friendly behaviors. environment. Marketers should use thumbnails as a marketing tool to create tests. This can be applied when introducing new products or targeting potential consumers. As consumers become more and more aware of the issues of carbon emissions and climate change, there may be more of a shift towards environmentally friendly products.

*Thirdly*, the role of subjective norms and their impact on consumer attitudes and purchase intentions is extremely important. Along with this, individuals' environmental concerns are also important and marketers should aim to create a brand message that impacts individuals and society as a whole.

## DOES THE METAVERSE EDUCATION APPLICATION PLATFORM HAVE THE POTENTIAL TO TRANSFORM LEARNING FORM IN EDUCATIONAL INSTITUTIONS IN THE FUTURE?

Nguyen Thi Thuy Linh<sup>1</sup>, Ho Thi Tam Dieu<sup>1</sup>, Tran Thi Le Na<sup>1</sup>, Le Hieu Ngan<sup>1</sup>, Thai Ngoc Bich Tram<sup>1</sup>  
Supervisor: Dinh Tien Minh (Ph.D.)<sup>1</sup>

*Abstract: Rapidly evolving Metaverse technology has provided significant benefits for online education in recent years. Because empirical studies on user adoption of Metaverse technology in Vietnam, particularly in Ho Chi Minh City, are limited, the current study fills a research gap concerning the Metaverse Education Application Platform. The target objects are the younger generation, who are the most ready to use technology and the internet, and for whom technology has become a part of their daily lives. To predict the factors affecting the intention to use Metaverse as an effective learning aid, this study combined the TAM and PPM models together with the TRA and TPB theories. A survey was conducted on 217 students in Ho Chi Minh City in January and February 2023. The research methods used included Cronbach's Alpha test, EFA, Pearson's correlation test and Linear regression analysis. The research results show that there are four factors that positively affect the intention to use the Metaverse Education Application Platform include Social Influence, Situational Teaching, Social Needs and Personalized Learning in descending order of impact. Meanwhile, no correlation was found between the intention to use and the five factors Learning Convenience, Perceived Usefulness, Perceived Ease Of Use, Task - Technology - Fit and Habit. This study is also limited in terms of space and sample size so further studies will overcome this limitation and provide more convincing evidence.*

**Key words:** Metaverse, Metaverse technology, Metaverse Education Application Platform, Online education, Intention to use

### 1. INTRODUCTION

Because of the 4.0 revolution's modern technological achievements and the emergence of the Covid-19 pandemic, online learning via online platforms is becoming increasingly popular. Since its inception, online education has relied primarily on two system types: asynchronous and synchronous e-learning (Stöhr, Demazière & Adawi, 2020). Both rely on software or web applications in two-dimensional digital environments that span in-plane digital windows with width and height but no depth. Therefore, 2D web-based applications have limitations and inefficiencies that have a negative impact on education: low self-perception, no presence, inactivity, and crude emotional expression (Mystakidis, 2022). All of these constraints can be overcome with immersive 3D spatial environments and this 3D virtual reality is called the "Metaverse".

The term Metaverse first appeared in the novel, Snow Crash (Stephenson, 2003). The word "metaverse" refers to the combination of the prefix "meta," which means "beyond," and the suffix "verse," which means "universe". The phrase was described as "a computer generated world beyond the physical world that is a fully immersive 3D digital environment that reflects the totality of shared online space across all dimensions of representation" (Dionisio & Gilbert, 2013). In 2021 and 2022, the Metaverse received a lot of public attention (Bibri & Allam, 2022). It earned recognition, which shifted the attention of businesses, investors, and customers. Other signs include Facebook changing its name to Meta (Kraus et al., 2022) and Microsoft completing the biggest takeover deal in history by buying a virtual reality (VR) startup for USD 68.7 billion (Bakar et al., 2022). The Metaverse is based on technologies that allow for multisensory interactions with virtual environments, digital objects and people like Extended Reality or Cross Reality (XR) (Mystakidis, 2022). Virtual Reality (VR), Augmented Reality (AR), and Mixed Reality are all parts of XR (MR).

<sup>1</sup> University of Economics Ho Chi Minh city.

In higher education, the use of virtual worlds has been a recurring theme for several years (Reisoğlu et al., 2017; Wood & Gregory, 2018), allowing the teacher and student to explore new methods for the teaching-learning process, where ICTs and emerging technologies play a key role in this regard, maintaining interactivity and immersion as the primary premise, both of which are critical in this process (Díaz, 2017). In recent years, rapidly developing Metaverse technology has provided significant benefits in online education (Kye et al., 2021; Lin et al., 2022). Edu-Metaverse is the twin of the real educational world that uses metaverse technology in the field of education. Meta, Roblox, Zepeto, and other companies have begun to develop the Metaverse Education Application Platform (Wang & Shin, 2022). They incorporate the Metaverse into the teaching project practice and provide users with a better experience. Thanks to Metaverse, educational institutions will be able to provide a 360-degree experience to students and users, as well as much flexibility and adaptability to unforeseen events (Muijs, 2015). However, the use of metaverse technology in the education industry faces some obstacles. For example, there is a significant deviation between the product software and the needs of user groups in the development of the education application platform (Teräs et al., 2020). Although the Application of the Metaverse in Education makes learning more lively and exciting, specifically, it will be possible to take lesson gamification to a new level, to travel without moving to discover the history and culture of other places, and students will be able to learn the laws of physics and enjoy science in ways they never imagined possible (Contreras, 2021), but very few research papers on the level of readiness to apply it in education. Moreover, this concept of “Metaverse Education” is still not familiar to the masses (Julian, Chung & Wang, 2023). However, Vietnam was predicted to place first among the top ten nations in the globe in terms of E-L revenue growth from 2011 to 2016, with an E-L growth rate of 44.3% (Insight, 2011). The Ministry of Education and Training and the Vietnam Government’s efforts to digitize curriculum in schools, the development of online higher education options will all contribute to the extension of education.

Firstly, we have only found the first and only study on Metaverse in Vietnam by Van et al. (2022) with the topic “A Conceptual Framework for Determining Metaverse Adoption in Vietnam IT Enterprises” published at the International Conference on Big Data, Cloud Computing, and Data Science. Therefore, the present research can be considered as pioneering Metaverse topics in the field of education in Vietnam, particularly the case in Ho Chi Minh City. Secondly, the models used in educational technology research in the past were preminent the Technology Acceptance Model (TAM) model or the TAM model combined with Task-Technology Fit (TTF), Integration of Innovation Diffusion Theory (IDT), Integrating Information System Success Model (ISSM) and Expectation-Confirmation Theory (ECT) (Wang & Shin, 2022). A new combination model proposed in this study, TAM and PPM (Push-Pull-Mooring), has been shown to be highly correlated with research on readiness to use educational technology (Wang & Shin, 2022; Granić, 2022; Nayak et al., 2022). The combination of two models TAM and PPM is also considered a new research in the field of technology and has been simulated in our current study.

User adoption and adaptation to these innovations is critical for efficiency and sustainability (Toraman, 2022). Therefore, exploring the factors of user intent on the application platform will thus aid in resolving the issue of a mismatch between the supply of educational technology and the demand of users, as well as the readiness to use then truly bring users into the Metaverse Education ecosystem. We especially focus on students in Ho Chi Minh City, Vietnam because the younger generation are the ones with the highest levels of internet and technology readiness and seem to be part of their daily lives (Wijaya & Afgani, 2021). An online survey was conducted in January and February 2023 at a few high schools/colleges/universities in Ho Chi Minh City through Google Form. The overall objective is research on factors affecting intention to use the Metaverse Education Application Platform. Specific Objectives are as follows:

(1) Identify factors influencing intention to use the Metaverse Education Application Platform of students in Ho Chi Minh City.

(2) Evaluate the impact of each factor on the intention to use the Metaverse Education Application Platform of students in Ho Chi Minh City.

(3) Discuss and recommend solutions corresponding to the research results achieved.

This study was conducted to pave the way for future research on the adoption and application of outstanding features of the Metaverse Education Application Platform. Besides, the study also provides readers with new perspectives on the virtual reality world like Metaverse and the penetration of this platform into the Vietnam market in general and Vietnam education in particular. The obtained research results are the basis for recommending solutions for educational institutions to consider combining the Metaverse Education Application Platform to achieve quality teaching and learning. The study also suggests a number of businesses apply this platform to improve remote working performance or enhance the real-life experience for their customers. Moreover, for technology companies, this research will be a premise for them to develop this application with useful features suitable for different target groups.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Theoretical Background**

The Push-Pull-Mooring (PPM) model is a valuable framework for understanding behavioral intentions related to technology adoption and migration. The model draws from the classical theory of behavioral explanation for geographical relocation (Jung, Han & Oh, 2017). The push effect refers to the negative factors that motivate people to leave the place of origin (economic opportunities, natural disasters, etc.) (Stimson & Minnery, 1998). Pull factors attract people to move in (excellent quality education, political freedom, etc.). Mooring factors are related to migratory behavior, which can hinder or facilitate decision behavior. The PPM model has been extended to explain switching behavior in various domains, in the context of technology switching behavior, push factors motivate users to move away from their current product or platform, while pull factors attract them to adopt new products (Lewis, 1982). Applying the PPM model to this research, conversion behavior refers to users transitioning from a traditional educational platform to a multidimensional educational application platform. Push factors include Personalized Learning, Situational Teaching, and Learning Convenience, while pull factors encompass Perceived Usefulness, Perceived Ease of Use, Social Needs, and Task-Technology Fit. Additionally, mooring factors (Habit and Social Influence) capture personal and social motivations for switching from traditional educational platforms to the Metaverse Education Application Platform.

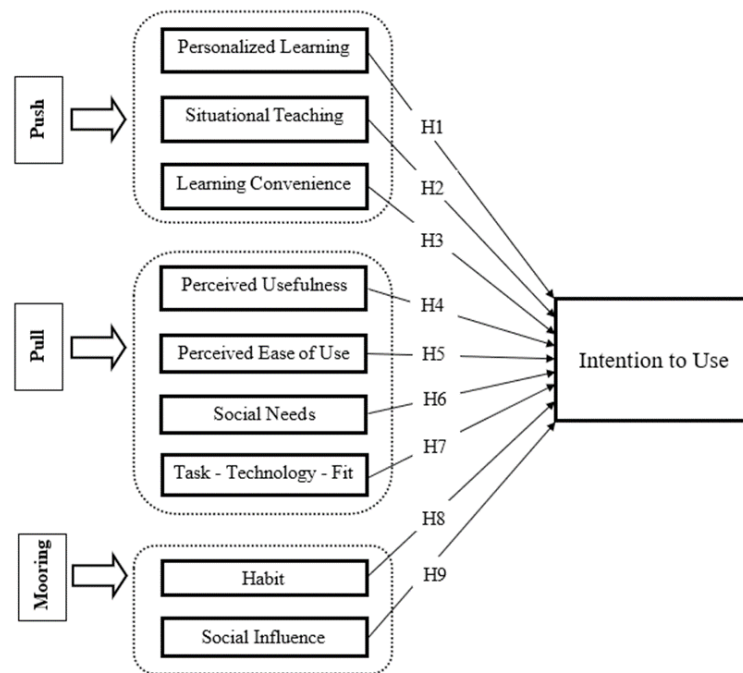

The Technology Acceptance Model (TAM) is based on the theory of rational behavior and was discovered by Davis, Bagozzi & Warshaw (1989). The TAM model consists of two main determinants: perceived usefulness will reflect the extent to which an individual thinks using technology will improve job performance, meanwhile, perceived ease of use will refer to the degree to which a person thinks it is easy to use a technology system (Moon & Kim, 2001). In the field of education, the TAM model has been used to study the factors affecting teachers' acceptance of learning on mobile devices (Mac Callum & Jeffrey, 2014). In addition, Al-Rahmi et al. (2021) built up the factors affecting university students' acceptance of e-learning technology based on the TAM model.

The Theory of Reasoned Action (TRA) is a general theory of behavior that was first introduced in 1967. The TRA theory holds that the conscious performance of a behavior will be influenced by a person's intention and normative beliefs and attitudes towards performing that behavior (Ajzen, 1991). Accordingly, normative

beliefs and motivations to conform will create a subjective norm, or social influence, that does not depend on the individual's point of view. The opinions and behavior of people around will determine the behavior and intention of consumers themselves (Al-Suqri & Al-Kharusi, 2015). On the other hand, the theory of planned behavior (TPB) is an improvement of the theory of reasonable action (TRA), that explains different behaviors and behavioral intentions, which are not under one's intentional control (Ajzen, 2002). In the study, this theory is used to analyze and explain the impact of social influence on usage behavior. Subjective norms are social influences, which will be influenced by normative beliefs - the beliefs of others involved about the performance of a particular behavior; and perceived behavioral control is influenced by controlling beliefs about the presence of factors that can trigger or hinder the performance of consumer behavior.

## 2.2. Research Hypothesis

**Figure 2.1. The theoretical framework for the Intention to Use the Metaverse Education**

### Application Platform

Lee (2022) showed that personal learning is glossed as using a technological tool or related skills to complete a task by an individual to fulfill his or her own learning needs (e.g. searching and reading online materials for writing an essay, looking for information to enhance knowledge). Personalized learning in this study means that users can formulate their own learning plans through the Metaverse Education. Lv, Yang & Zhang (2020) believed that in the era of artificial intelligence, personalized learning is the mainstream of future development, and the platform should provide users with a stronger independent learning environment. Moreover, research by Wang and Shin (2022) also found that personalized learning plays a significant positive role on the intention to use the Metaverse Education Application Platform.

Situational teaching means that under the guidance of the teaching program and teaching materials, teachers create various situations to make students immerse into the abundant, natural or semi-natural customary situation, arousing students' emotional experience, helping the students to understand teaching content rapidly and correctly (Wang & Zhou, 2011). Among the pushing factors, situational teaching has a more significant impact to better reflect the user's use intention of the Metaverse Education Application

Platform (Wang & Shin, 2022). Furthermore, research by Guo and Gao (2022) analyzing empirical data on the three kinds of learning activities shows that Metaverse-powered experiential situational English teaching can promote the improvement of students' sense of interactivity.

Learning convenience is defined as the ability of the students to perform learning activities in unlimited time and space (Jin et al., 2021). In virtual learning platforms, students find convenience of working and learning at their own pace (Raghupathi, 2013). Previous studies proved that convenience has a positive and significant impact on intention to use (Izquierdo-Yusta & Schultz, 2011; Wardana et al., 2022). The results of the study by Lisana (2022) argued that learning convenience is a variable in the push factor of the PPM framework and it had a positive significant direct effect on students' switching intention. Besides, previous studies agreed that learning convenience is one of the important push factors that affect the decision of university students to use learning platforms (Chen & Keng, 2019; Jin et al., 2021).

**H1:** *Personalized Learning has a positive impact on users' intention to use the Metaverse Education Application Platform.*

**H2:** *Situational Teaching has a positive impact on users' intention to use the Metaverse Education Application Platform.*

**H3:** *Learning Convenience has a positive impact on users' intention to use the Metaverse Education Application Platform.*

Davis (1989) defined perceived usefulness as “the degree to which a person believes that using a particular system would enhance his or her job performance”. Perceived usefulness in this study refers to the user's expectation of obtaining benefits from using the Metaverse education application platform. Besides, Davis (1989) also defined perceived ease of use as “the degree to which a person believes that using a particular system would be free of effort”. In this study, perceived ease of use relates to how simple it is for users to learn how to utilize the Metaverse Education Application Platform. Research by Toraman (2022) found a significant positive correlation between perceived usefulness, perceived ease of use and the Metaverse usage intention. Perceived usefulness, perceived ease of use is one of the factors that have a strong impact on users' intention to use Metaverse (Akour et al., 2022). Moreover, many other studies also showed that perceived usefulness, perceived ease of use have a positive impact on intention to use the Metaverse Education Application Platform (Wang & Shin, 2022; Alawadhi et al., 2022; Almarzouqi, Aburayya & Salloum, 2022).

Lu & Yang (2014) defined social needs as “the requirements of connecting, interacting with people, creating and maintaining social connections through social networks”. Besides, social need is the learners' drive to utilize the resources that let them interact with and collaborate with others during the learning process (Mondi, Woods & Rafi, 2008). Xie, Zhao & Ma (2019) verified that in a virtual community, social needs are the core factor affecting the interaction of members of the community. When users perceive a social networking site is fit for their social needs, they will have the intention to use it (Lu & Yang, 2014). Wang and Shin (2022) also showed that social needs have a significant positive effect on the intention to use the Metaverse platform.

Task - Technology - Fit (TTF) is the ability to concretize practical aspects when using technology in life, including users' perception of technology as well as the fit between characteristics and tasks of technology (Afshan & Sharif, 2016). In the past, Rogers has supported the assumption that technology is compatible when it aligns with user preferences (Rogers, 2017). Additionally, TTF is considered an important factor when deciding to apply a particular technology in a learning management system to improve student learning performance (McGill & Klobas, 2009).

*H4: Perceived Usefulness has a positive impact on users' intention to use the Metaverse Education Application Platform.*

*H5: Perceived Ease Of Use has a positive impact on users' intention to use the Metaverse Education Application Platform.*

*H6: Social Needs have a positive impact on users' intention to use the Metaverse Education Application Platform.*

*H7: Task - Technology - Fit has a positive impact on users' intention to use the metaverse education application platform.*

Habit is defined as a human instinct that has the effect of reducing human cognitive load in the decision-making process (Sun et al., 2017). In the past, due to the impact of the pandemic, students had to switch to online learning, some places have applied the Metaverse Education Application Platform in the past. Students are used to online learning, and this habit has an effect on students' motivation to continue using the Metaverse Education Application Platform (Li, 2018). A study on internet service applications also shows that users are not willing to use new services even if they have relative advantages, i.e. previous usage habits have a positive impact on with the intention of using the educational application platform Metaverse (Cheng, Lee & Choi, 2019).

Social Influence is described as the fact that users are influenced by friends, classmates, public opinion, news or other factors when they make decisions to use (Zhou, Lin & Deng, 2021). Lee's research considers social influence as a factor that makes users perceive that others approve and encourage them to participate in using the Metaverse Education Application Platform (Lee, Hsieh & Hsu, 2011).

*H8: Habit has a positive impact on users' intention to use the metaverse education application platform.*

*H9: Social Influence has a positive impact on users' intention to use the metaverse education application platform.*

### **3. RESEARCH METHOD**

#### **3.1. Research sample and data collection**

Primary data source was collected online with Google Form support. The respondents are students of a number of high schools/colleges/universities/ postgraduate or above students in Ho Chi Minh City who are interested in innovative technology applications or recognize the Metaverse Education Application Platform.

The initial target sample size was 200. However, during the survey period from January to February 2023, the research questionnaire reached 217 respondents. After checking and filtering the data, there are 201 valid samples remaining for the analysis.

#### **3.2. Research design**

This study uses the online questionnaire interview method which is referenced from previous research papers. These studies have been conducted in a number of other countries and some of them published in international journals. With reliable sources, the current study has adapted some questions to suit the research background in Vietnam.

The questionnaire is divided into two parts so that the respondents' portraits become more specific and diverse. The first part is the questions about the respondents' basic characteristics (gender, education level and ways to recognize the Metaverse Education Application Platform). The second part is the questions related to the main content of the study aimed at data mining for analysis. The questions revolved around the respondents'

perceptions of the characteristics of the Metaverse Education Application Platform (convenience, usefulness, ease of use,...), habits, social needs and their intention to use this platform in the future.

The factors in the study were measured on a 5-point Likert scale (1-Strongly disagree, 2-Disagree, 3-Normal, 4-Agree, 5-Strongly agree). The questionnaire includes a total of 37 items, the respondents will receive the Vietnamese version of the questionnaire for their convenience. Quantitative methods will help research to measure and determine the factors affecting the intention to use the Metaverse Education Application Platform and the level of influence of each factor. The obtained research results will be an important basis for recommending appropriate solutions.

### **3.3. Data Analyzing**

After collecting survey results, the data was filtered and cleaned for analysis using SPSS software. The research methods used include:

- Filtering, checking and entering data.
- Cronbach's Alpha test to evaluate the reliability of the scale. The value of more or less contribution is reflected through the correlation coefficient of the total Corrected Item - Total Correlation variable. Thereby, allowing to eliminate inappropriate variables in the research model.
- Exploratory Factor Analysis (EFA) to determine the number of factors affecting a set of measurable variables and the strength of the relationship between each factor and each measurement variable.
- Pearson's correlation test to measure the level of impact between independent variables and dependent variables.
- Multiple Linear Regression (MLR) analysis and Mean value to estimate the relationships between dependent and independent variables in the model.

## **4. RESULTS AND DISCUSSION**

### **4.1. Results**

#### **4.1.1. Sample description**

The primary data was collected online using Google Forms, resulting in 201 valid samples for analysis. Among the participants, 39.3% were male, and 60.7% were female. Regarding education level, 7.5% were high school students, 8.5% were college students, 72.6% were university students, and 11.4% were postgraduate or above students. In terms of awareness of the Metaverse Education Application Platform, 43.9% discovered it through social networks, 22.6% through advertisements, and 33.4% through family and friends. The grammar is correct in this version.

#### **4.1.2. Cronbach's Alpha test**

Cronbach's Alpha test is used to assess the reliability of observed variables within a factor. It measures the correlation between these variables. Generally, a good scale should have a Cronbach's Alpha reliability of 0.7 or higher (Nunnally, 1978). However, for preliminary exploratory studies, a threshold of 0.6 is acceptable (Sekaran & Bougie, 2016).

In this study, variables with a Cronbach's alpha value  $\geq 0.6$  are considered satisfactory. The results in **Table 4.1** indicate that all variables have Cronbach's alpha values exceeding 0.6, suggesting a very good scale. Therefore, these nine independent variables and one dependent variable will be used for EFA analysis.

**Table 4.1. Result of Cronbach's Alpha test**

Construct	Item	Number of Items		Cronbach's Alpha	Results
		Before the test	After the test		
Personalized Learning	PL	3	3	0.668	< 0.7 (low internal consistency)
Situational Teaching	ST	5	5	0.798	> 0.7 (high internal consistency)
Learning Convenience	LC	4	4	0.696	< 0.7 (low internal consistency)
Perceived Usefulness	PU	4	4	0.773	> 0.7 (high internal consistency)
Perceived ease of use	PE	3	3	0.629	< 0.7 (low internal consistency)
Social Needs	SN	3	3	0.659	< 0.7 (low internal consistency)
Task - Technology - Fit	TT	3	3	0.627	< 0.7 (low internal consistency)
Habit	HB	4	4	0.784	> 0.7 (high internal consistency)
Social Influence	SI	4	4	0.726	> 0.7 (high internal consistency)
Intention to Use	IU	4	4	0.772	> 0.7 (high internal consistency)

#### 4.1.3. Exploratory Factor Analysis (EFA)

EFA is a quantitative method that reduces a set of interdependent measures into a smaller, more meaningful set of variables while retaining most of the information from the original variables (Hooper, 2012). In this study, the team employed the principal component extraction model with Varimax rotation. They conducted three separate EFA tests on 33 items, grouped into three categories: Push, Pull, and Mooring. Only variables with a factor loading greater than 0.5 were retained.

After removing the variables with bad values from the model, the final analysis results are shown in Table 4.4 as follow: Push group include 3 factors (ST, LC, PL) with 10 items; Pull group include 4 factors (PE, PU, SN, TT, PE) with 13 items; Mooring group include 2 factors (HB, SI) with 8 items and dependent variable include 1 factor (IU) with 4 items.

#### 4.1.4. Multiple Linear Regression Analysis

The magnitude of the independent factors' influence on the dependent variable can be determined using the linear regression equation. The multiple linear regression model is a multivariable regression model with nine independent variables. After the EFA stage, the model was constructed using these nine constructs, and it was constructed as follows:

$$IU = \beta_0 + \beta_1 PL + \beta_2 ST + \beta_3 LC + \beta_4 PU + \beta_5 PE + \beta_6 SN + \beta_7 TT + \beta_8 HB + \beta_9 SI$$

The results of the regression analysis presented in Table 4.2 show that the independent variables in the regression account for 57.4% of the changes in the dependent variable. Additionally, the Durbin-Watson value obtained is 1.854, indicating the absence of multicollinearity among these variables.

**Table 4.2. Model summary of multiple linear regression analysis**

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	.758 <sup>a</sup>	0.574	0.554	0.66782243	1.854

Six out of the nine independent variables (Situational Teaching, Learning Convenience, Personalized Learning, Task-Technology Fit, Habit, and Social Influence) positively impact the dependent variable, Intention to Use (IU) (Table 4.3). These findings confirm six hypotheses from the research framework, which are presented in Table 4.4 and will be discussed further.

The standardized linear regression equation is as follows:

$$IU = 1.132E-16 + 0.315 HB + 0.227 ST + 0.216 SI + 0.160 LC$$

**Table 4.3. Model summary of regression coefficients**

Model		Unstandardized Coefficients		Standardized Coefficients		
		B	Std. Error	Beta	t	Sig.
1	(Constant)	1.132E-16	0.047		0.000	1.000
	ST	0.227	0.057	0.227	3.985	0.000
	LC	0.160	0.057	0.160	2.824	0.005
	PL	0.157	0.053	0.157	2.963	0.003
	PU	0.065	0.053	0.065	1.219	0.224
	SN	0.006	0.050	0.006	0.115	0.909
	TT	0.157	0.062	0.157	2.554	0.011
	PE	0.083	0.050	0.083	1.656	0.099
	HB	0.315	0.054	0.315	5.806	0.000
	SI	0.216	0.061	0.216	3.567	0.000

a. Dependent Variable: IU

**Table 4.4. Summary of hypotheses testing results**

Hypotheses	Decision
H1: Personalized Learning has a positive impact on users' intention to use the Metaverse Education Application Platform.	Sig. = 0.003 < 0.05 and $\beta = 0.157$ Supported
H2: Situational Teaching has a positive impact on users' intention to use the Metaverse Education Application Platform.	Sig. = 0.000 < 0.05 and $\beta = 0.227$ Supported
H3: Learning Convenience has a positive impact on users' intention to use the Metaverse Education Application Platform.	Sig. = 0.005 < 0.05 and $\beta = 0.160$ Supported
H7: Task - Technology - Fit has a positive impact on users' intention to use the Metaverse Education Application Platform.	Sig. = 0.011 < 0.05 and $\beta = 0.157$ Supported
H8: Habit has a positive impact on users' intention to use the Metaverse Education Application Platform.	Sig. = 0.000 < 0.05 and $\beta = 0.315$ Supported
H9: Social Influence has a positive impact on users' intention to use the Metaverse Education Application Platform.	Sig. = 0.000 < 0.05 and $\beta = 0.216$ Supported

#### 4.1.5. The results of Mean value

To identify the most significant predictor among the observed variables in the research model and propose specific business implications for the Conclusion section, this test utilizes mean values and compares them.

**Table 4.5. The results of Mean value of the remaining valid variables**

Variable	Mean	Variable	Mean	Variable	Mean	Variable	Mean
PL1	3.60	ST1	3.59	LC1	3.58	TT1	3.66
PL2	3.67	ST2	3.74	LC2	3.66	TT2	3.72
PL3	3.78	ST3	3.78			TT3	3.69
		ST4	3.82				
		ST5	3.83				

Variable	Mean	Variable	Mean	Variable	Mean		
HB1	3.55	SI1	3.68	IU1	3.63		
HB2	3.55	SI2	3.71	IU2	3.80		
HB3	3.55	SI3	3.75	IU3	3.75		
HB4	3.42	SI4	3.74	IU4	3.62		

#### 4.2. Discussion

The study successfully applied Push-Pull Theory (PPM), Theory of Rational Action (TRA), Theory of Planned Behavior (TPB) to understand user intention and behavior in adopting the Metaverse Education Application Platform. The team discovered three new variables - Learning Convenience (Push), Task-Technology-Fit (Pull), and Habit - which enhance the PPM model and contribute to users' intention to use the platform. Notably, this study excludes variables from the Technology Acceptance Model (TAM), such as Perceived Ease of Use and Perceived Usefulness. TAM has been extensively researched and applied in various fields, but it doesn't explain the adoption of the Metaverse technology in Vietnam's education sector due to its limited popularity and usage.

The TRA and TPB theories effectively explain the impact of Social Influence on the Intention to Use variable in the context of the Metaverse Education Application Platform. Previous studies have applied these theories to analyze consumer purchase behavior in virtual worlds. By integrating these well-established theories, the research model provides comprehensive coverage for the learner community compared to other models. The study also developed a specific research framework and hierarchical integration model by incorporating the PPM model. This approach allowed for the exploration of significant factors influencing the intention to use the Metaverse Education platform.

This study identifies six key factors that positively predict students' intention to use the Metaverse Education Application Platform. These factors, ranked in descending order of impact, are Habit (HB), Situational Teaching (ST), Social Influence (SI), Learning Convenience (LC), Personalized Learning (PL), and Task-Technology-Fit (TT).

## 5. CONCLUSION

### 5.1. Implication

Firstly, Habit (HB) is the most important factor in the research model, positively predicting Intention to Use (IU) the Metaverse Education Application Platform. The mean values of three observed variables HB1, HB2, HB3 of Habit factor (HB) are all equal. This implies that, learners intending to form a habit of learning through Metaverse Education, they need to use the Metaverse Platform for regular learning. Teachers should create learning habits through the Metaverse Education Application Platform for students, Metaverse should be installed on the student's learning medium. So buying a Metaverse license is important for students to really own to discover things fresh and interesting.

Secondly, Situational Teaching (ST) is the next important factor positively predicting Intention to Use (IU). With the observed variable ST5 having the largest mean value = 3.83 implies that the case-based teaching simulated on the Metaverse platform is interesting, furthermore, it is easier for teachers to guide students with this virtual reality experience method. Therefore, this feature should be utilized for lecturers to incorporate in their lectures to enhance students' concentration, enjoyment and learning performance.

Thirdly, Social Influence (SI) is the third important factor positively predicting Intention to Use (IU). With the observed variable SI3 having the largest mean = 3.75 implies that people who have opinions valued highly by learners will influence Intention to Use (IU). Therefore, educational institutions can take advantage of this to understand the needs of learners for learning applications to enhance interaction and stimulate interest. In addition, companies providing Metaverse services should combine with influential Key Opinion Leaders (KOLs) in the technology world to act as media ambassadors for the educational and educational Metaverse brand to promote this platform to learners more widely.

Fourthly, Learning Convenience (LC) is the next important factor positively predicting Intention to Use (IU). With observed variable LC2 having the largest mean value = 3.66 implies that Metaverse Education is convenient for learners to learn from anywhere. Educational institutions, in addition to providing knowledge to learners through classroom lectures, should design situations or lectures available on the Metaverse platform so that learners can learn anywhere, as long as they feel convenient and flexible for their learning. If learners are absent from class, they can still learn on Metaverse Platform, ensuring knowledge is not interrupted. Besides, business organizations can review and poll employees to apply this technology to remote working management.

Finally, although two factors Personalized Learning (PL) and Task - Technology - Fit (TT) have the least positive impact on Intention to Use but equally important. Personalized Learning (PL) with the largest mean of PL3 = 3.78 and Task - Technology - Fit (TT) with the largest mean of TT2 = 3.72. This implies that learners can find their own way of learning through the Metaverse Education Application Platform. Furthermore, the useful functions of Metaverse Education are enough to assist them in completing their learning tasks. Educational institutions should guide learners to choose learning methods suitable to their goals, so that learners can be oriented and easily access the features that support them to successfully complete their studies.

In short, the Metaverse Application born in this context plays an even more important role in transforming the form of learning and working into a virtual reality environment in the future. The virtual reality environment saves the costs of renting premises, management, and security staff compared to real-life offices. To meet these needs, technology companies like Metaverse should increase their awareness and wide use in the market through marketing on media channels. In order to personalize learning and work, technology companies

should create many useful features so that everyone has the opportunity to familiarize themselves with this new Metaverse Application. The study has accomplished research's objectives with the help of the research findings, and the conclusion has solved all of the research questions that were offered.

## 5.2. Limitation and further research direction

Firstly, this study has provided a fresh perspective on the Metaverse Education Application Platform, but also because of its newness, this application is still unfamiliar to many people, so the number of samples collected is limited. Secondly, this study uses primary data and the questionnaire contains many concepts that have not been properly interpreted, so respondents may not have a clear understanding of the author's intentions, affecting the quality of information and analysis results. Thirdly, the geographical scope is limited and it is not big enough. Fourthly, research methods are limited in diversity, especially data collection methods should control the reliability to assess accurate data. Therefore, future studies should expand the research to other subjects than students and expand the survey scale outside Ho Chi Minh City. Although the three elements of Perceived Usefulness (PU), Perceived Ease Of Use (PE) and Social Needs (SN) are excluded from the research model, they also imply that the Metaverse Education Application Platform should be widely used to have more studies proving the presence of these factors to improve the user experience and their acceptance under the TAM model.

## FACTORS AFFECTING THE DECISION TO USE THE DATING APPS OF UNIVERSITY STUDENTS IN HO CHI MINH CITY

**Authors:** Tran Le Yen Nhu<sup>1</sup>, Vo Kim Hien<sup>2</sup>, Duong Nguyen Thu Hien<sup>2</sup>,  
Pham Thi Minh Phuong<sup>2</sup>, Pham Phung Thanh Thao<sup>2</sup>  
**Mentor:** Ho Minh Thang<sup>3</sup>

**ABSTRACT:** *This research paper investigates the factors influencing the use of dating apps among university students in Ho Chi Minh City by examining the types of dating apps being used, the motivations behind their use, and their impact on students' interpersonal relationships, the study explores the various factors that contribute to the decision to use dating apps among students in Ho Chi Minh City. In Vietnam alone, there are nearly 100 online dating applications, most of which are developed by foreign companies and offer free basic features. To ensure safety while using dating apps, the study examines several key elements that individuals should consider when interacting with others online. The research employs quantitative research methods, utilizing survey questionnaires to collect data from 357 students currently enrolled in universities in HCMC. The collected data is analyzed using TRA (Technology Readiness Assessment), TAM (Technology Acceptance Model), and TPB (Theory of Planned Behavior) models to test the relationship between various observed variables, such as Attitude, Word-of-mouth, Perceived Privacy and Security, Perceived Enjoyment, Perceived Playfulness, Perceived ease of use, and the decision to use a dating app. The findings of the study indicate that variables such as Attitude, Word-of-mouth, Perceived enjoyment, and Perceived playfulness significantly influence the decision to use dating apps. These results contribute to students' understanding of dating app usage and needs while also offering recommendations and solutions for adopting a safe approach when engaging with dating apps and establishing social relationships.*

**Keywords:** *online dating apps, online dating, hookup culture*

### 1. INTRODUCTION

Using a dating app seems to be a popular activity all around the world. Nonetheless, there are still certain stereotypes among students regarding the use of those dating applications. This study was conducted in order to determine what influences students' decisions to choose a dating app. It is the fact that using dating apps is often associated with sexualization, such as in cases involving FWB, ONS, or cheating. In order to determine the true demands, this research investigates the factors that influence student usage of dating apps in Ho Chi Minh City. A series of studies on the decision to use dating apps have been and are being conducted around the world. Accordingly, studies have shown that factors affecting the decision to use dating apps include Attitude, Word-of-mouth, Perceived enjoyment, and Perceived playfulness. On the basis of further development of the past theory in the context of research on the decision to use dating apps, authors such as Kimmel & Kitchen (2014), Hennig-Thurau, Gwinner, Walsh, & Gremler (2004), Chu, Choi (2011), Chu & Kim (2011), Alam, S. S., and Norjaya added the WOM variable in their research, H. Jeff Smith, Tamara Diev and Heng Xu, Huang (2016), Liu et al. (2016) added the variable perceived privacy and security. In addition, if Carol & Thomas (1988), Malone (1981), and Webster (1989) find that Perceived enjoyment has a significant influence on user decisions, then Cha (2011), Cho et al. (2015), Chen et al. (2007) stated that Perceived ease of use also has an impact on the decision of the users to use an application.

Today, couples meet as a consequence of dating applications, as opposed to the past, when people met and fell in love as a result of fate or just catching each other's looks. Dating apps also change how people interact. However, there are many unfavorable effects of dating apps in addition to the positive ones, especially for today's youth. Dating apps started to appear one by one, steadily upending the norms of traditional dating and making them popular tools. In addition, not many applications are developed with the same intentions due to the model's complexity. While some are evident in that their goal is to find a long-term love partner, others are meant to facilitate short-term friendships and interactions rather than romance. However, people may use applications in ways that are inconsistent with their intended function and may continue for a long time. Finding the variables influencing students' decisions to use dating apps in HCMC is crucial and urgent due to the importance of responding to young people's use of dating apps nowadays.

This study tries to determine the factors affecting students' decision to use dating apps in HCMC, the goals and needs of using dating apps, and recommendations for safe approaches for college students in using dating apps in general. In order to achieve the research objectives, this study has the following specific goals:

- + To realize the level of awareness of students about the concept of dating apps.
- + To measure student interest in dating apps today.
- + To identify the factors affecting the decision to use a dating application and the level of impact of those factors.
- + To understand students' needs for using dating apps, and at the same time propose recommendations and solutions to find a safe approach for young people in finding social relationships on their own

## **2. RESEARCH METHODOLOGY**

### **2.1. Research subject**

Research subject: The decision to use the dating app of university students in Ho Chi Minh City

Research sample: Students studying at universities in Ho Chi Minh City

### **2.2. Research Methods**

This research relied on practice, consulted on controversial issues in today's society, and practical suggestions will always be considered important by our team throughout this study. After choosing a research topic, the group began to search for relevant documents. In order to have the best preparation, as well as a basis to start the research, the group asked and answered questions around the topic.

Starting by making assumptions from presumptive models and available studies, with suitable hypotheses, the team conducts testing with actual data from the survey questionnaire. Continuing with the establishment of a survey questionnaire, the questions and measurement methods used in this paper are mainly adapted from relevant previous studies and through group observations in the current situation. All items were measured using a five-point Likert scale, with scores ranging from "strongly disagree" to "strongly agree". In addition, we also provide some demographic information and personal habits from which to test the difference between the above factors in the decision to use the dating application. After preparing the questionnaire from the survey results and preliminary research, the research team continued to the qualitative research stage to test the research hypotheses obtained from the theoretical basis and measure the influence of the factors between the relationships through a random survey of students belonging to universities in HCMC using a survey form via Google Form. The survey was conducted from December

2022 to February 2023, with 357 respondents who are students studying at universities in HCMC. The information, data, and research results will be based on survey questionnaires in the form of an online survey and through social networking platforms such as Facebook and Zalo.

The research team collected qualitative results based on variables, including:

- Six independent variables: Attitude, Word-of-mouth, Perceived privacy and security, Perceived enjoyment, Perceived playfulness, Perceived ease of use
- One dependent variable: Decision on using dating apps

### **3. THEORETICAL FRAMEWORK**

#### **3.1. Theoretical basis of the topic**

##### **3.1.1. *The concept of dating apps***

Dating apps are software applications designed to generate connections between people who are interested in romance, casual sex, or friendship (Treena Orchard). Dating apps appeared in 2003 and grew in popularity from 2007 to 2008 (Quinoz, 2013) with the introduction of the Apple iPhone and the first App Store. Numerous dating apps have been created with the aim of relieving stress and helping users find their soulmate, or sometimes just a soulmate.

##### **3.1.2. *The concept of online dating***

Dating was “upgraded” in the 4.0 era by adding a brand-new type: dating through social networks. The idea of online dating applications can be attributed to the growing usage of cellphones, Internet connectivity, and GPS. By providing information about yourself or responding to someone else’s information, you can establish a love relationship online through online dating. However, online dating also has many downsides. If we only look at dating applications as a tool to make friends and lovers, we are purposefully excluding one of the primary motivations for why many people use them: sex or one-night stands. Therefore, finding safe approaches to using dating apps, in general, is essential.

##### **3.1.3. *The concept of Hookup culture***

Uncommitted sexual encounters, also known as hookups, are becoming more common in popular culture as a result of shifting social and sexual norms as well as evolving sexual preferences. A manner of life known as “hookup culture” promotes and entails informal, transient connections between uncommitted individuals. Since mating has traditionally been the major goal of sexual activity in order to allow reproduction and the genetic continuation of genes, long-term relationships have historically been prized. The satisfying of physical and emotional needs is another motive other than just reproduction for having sex (Birnbaum and Gillath 2006). Over the past 60 years, a number of cultures have liberalized their views on sexuality, and the use of birth control (such as condoms and oral contraceptives) has increased (Garcia et al. 2012). The significance of the sexual goals of physical pleasure and emotional fulfillment has increased as a result of these developments.

#### **3.2. Theoretical models of research**

##### **3.2.1. *The Technology Acceptance Model (TAM)***

TAM is a widely accepted theoretical framework that is used to assess the variables influencing the adoption of information systems and to explain user acceptance behavior for various information systems and technologies. TAM takes into account the perceived utility and perceived usability of information systems as two fundamental elements that affect users’ intentions to accept or reject information systems.

Technology user acceptability is dependent on perception, which influences intention and action. The model is based on the supposition that user attitudes influence whether information technology is accepted or rejected; user attitudes are influenced by perceived ease of use and perceived usefulness, and when technology is perceived as being easy to use, users perceive its usefulness. Many scholars utilize and reference this idea while examining and explicating technology usage behavior (Y. Lee, Kozar, & Larsen, 2003). Perceived usefulness and perceived ease of use, in line with TAM, have a direct impact on attitude. Attitude impacts intention to use, which in turn affects the behavior of embracing information technology systems or services (Wu and Wang, 2005).

**Figure 3.1.**

*The technology acceptance model - TAM*

*Note: Adapted from Davis et al. (1989).*

**3.2.2. The theory of reasoned action (TRA)**

The TRA was created by Fishbein and Ajzen (1975). According to this theory, behavioral intentions drive action, and intentions are influenced by both personal attitudes toward the activity and the subjective norms that surround its execution. Behavior-related intentions are influenced by attitudes and subjective norms. In which attitude is the manifestation of particular elements that represent the consumers’ favorable opinions. The subjective normative measure measures how consumers feel about the people who have an impact on their behavioral tendencies, demonstrating the role that social relationships play. Consumers’ consumption tendencies are both substantially and weakly influenced by how much they trust their acquaintances. In this theory, individual consumer beliefs about a product or brand will influence attitudes toward behavior, and attitudes toward behavior will influence buying propensity, which does not directly affect buying behavior. Therefore, attitude will explain the reasons leading to consumers’ buying tendencies, and trends are the best factor to explain consumer behavior trends. The results of these two factors form the intention to perform the behavior. Applying TRA, a number of studies have discovered that the decision to use information technology applications and the actual system is strongly influenced by the predecessors (Alam, Syed Shah, et al. (2018)).

**Figure 3.2.**

*Theory of Reasoned Action - TRA*

*Note: Developed by Ajzen and Fishbein (Ajzen, 2011).*

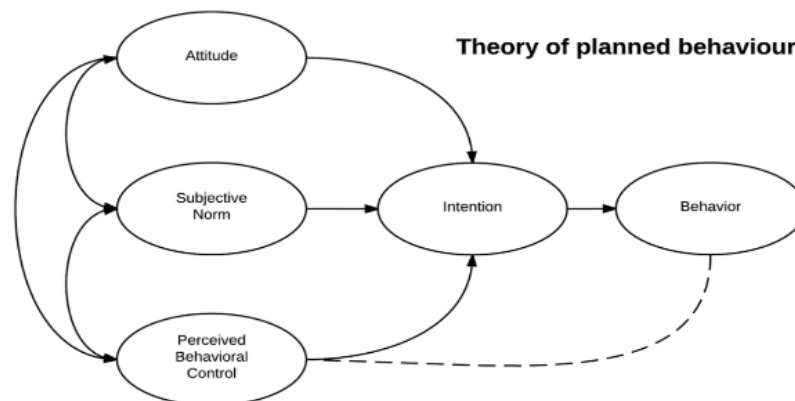

### 3.2.3. Theory of Planned Behavior - TPB

TPB was developed from TRA (Ajzen and Fishbein, 1975), which was created due to the previous theory's limitation on the assumption that human behavior is purely by mind control. According to this theory, individuals are grounded and motivated in their decision-making and make a rational choice between solutions. The best tool for predicting behavior is intention; and behavior is determined by a person's behavioral intention (BI). Ajzen suggested that behavioral control factors directly affect the tendency to perform the behavior and that if the person is accurate in his perception of the degree of control, then behavioral control also predicts the behavior. TPB model is evaluated to be more optimal than TRA model because TPB overcomes the disadvantages of the TRA by adding factors controlling cognitive behavior. In the world, this model has been widely used for a long time and has been practically verified through the scientific work of famous researchers.

Figure 3.3.

*Theory of Planned Behavior - TPB*

*Note: Adapted from Ajzen (2005).*

## 4. RESEARCH MODEL

### 4.1. Hypothesis of research model

#### 4.1.1. Attitude

A statement that a person's actions are determined by his/her behavioral intentions, which are influenced by attitudes toward that behavior. Theory of Reasoned Action (TRA) and the theory of planned behavior (TPB) developed by Ajzen and Fishbein take into account individuals' attitudes and social norms as well as the individual's ability to control perceptions as factors that accurately predict behavioral intention. Empirical studies have supported this theory, according to them, intention is a good predictor of behavior. Attitude towards a behavioral element is a judgment of positive or negative assessment of behavior based on the belief that the individual possesses the necessary opportunities and resources to engage in such behavior. Attitudes towards online dating sites are found to influence the intention to use the websites. In general, the more favorable the attitude towards behavior, the more favorable the intention to adopt it. Hence, it was coined that:

***Hypothesis 1: Attitude has a positive influence on intention to use online dating sites.***

#### 4.1.2. Word-of-mouth (WOM)

Since research participants joined the dialogue, an oral tradition has been the foundation of WOM (Kimmel & Kitchen, 2014). (Arndt, 1967a, p. 190; Engel et al., 1969; Gruen, Osmonbekov, & Czapski, 2006; Katz & Lazarfeld, 1955) Defined as person-to-person verbal communication between

a non-commercial communicator and a recipient regarding a brand, product, or service provided for sale. Electronic WOM, also known as eWOM, is a new type of WOM that was brought about by the development of the Internet. It occurs online and enables interactions between customers, who are frequently strangers. eWOM is defined as any positive or negative statement made by potential, actual or past customers about a product or company, made available to many people and organizations through the internet ( Hennig-Thurau, Gwinner, Walsh, & Gremler, 2004, p.39). This user-experience communication increasingly influences consumer usage decisions and has shifted the power of influence from the marketers to the users, who seek the opinions of other consumers and form their own (Chu & Choi), 2011). Besides, a study by Alam, S. S., and Norjaya, M. Y. demonstrates that WOM is also seen as a potential method of communication in a rising e-commerce economy, and also becomes highly essential and significantly affects customer trust.

***Hypothesis 2: Word-of-mouth positively influences students' decision to use dating apps***

#### **4.1.3. Perceived privacy and security**

Mukherjee and Nath (2007) identified that the privacy and security features of the website are the key antecedents of trust, which in turn positively influences the behavioral intentions of customers. Self-disclosure is an important element in both real life and online dating; it can be characterized as the voluntary sharing of personal information, such as sentiments and experiences (Huang 2016). However, Liu et al. (2016) found that self-disclosure on Facebook differs from other micro-blogging social media like Twitter and Tumblr in terms of usage trends. Liu et al. (2016) underline that elements that affect one's self-disclosure on social media with follower-based include similarity or interest in a field in their research. Online users increasingly find themselves at risk in their online activities. A large number of individuals using the Internet have serious privacy concerns, and gaining public trust is a major barrier to the continued growth of dating apps. According to a report by the Norwegian Consumer Council 2020, popular dating apps including Tinder, Grindr, OkCupid, etc. have transferred users' personal data to advertising and marketing companies – a violation of the European Union's General Data Privacy Regulation (GDPR), Union (EU). The results show that consumers value security features significantly more than the other three trust metrics.

***Hypothesis 3: Perceived privacy and security are essential to the confidence level of consumers willing to provide personal information to dating apps.***

#### **4.1.4. Perceived enjoyment**

Perceived enjoyment is defined as the degree to which the activity of computer use is perceived as pleasurable in its own right, beyond any predictable performance consequences (Carol & Thomas, 1988; Deci, 1971; Malone, 1981). A person will be more interested in doing or repeating an activity they find enjoyable than doing an uninteresting activity. This is supported by the work of Triandis (1971, 1980 as cited in Teo, 1999), who argues that feelings of joy, euphoria, delight or discouragement, disgust, dissatisfaction and an individual's hatred of a particular action has influenced many researchers who have studied the importance of enjoyment in the workplace (e.g. Webster, 1989; Webster & Martocchio, 1992; Malone 1981) considered interesting. Interest reflects the part of the enjoyment of any technology that is perceived by consumers when they tend to use that technology. Either way, it increases the chances of being satisfied and can lead to a habit of using that technology especially in the case of hedonistic applications.

***Hypothesis 4: Perceived enjoyment is positively related to behavioral intention in using dating apps.***

#### 4.1.5. Perceived playfulness

The hedonic and behavioral intention components are related. Hedonic factors consist of two elements: joy and playfulness. In TAM, the concept of subjective satisfaction was included to clearly construct the role of intrinsic motivation. This idea clarifies the extent to which utilizing a certain commodity or service is considered enjoyable by customers. Perceived pleasure was found to have a favorable impact on Internet users in a Singapore study. In the latter research, it was shown that hedonic elements, such as consumers' judgments of fun or playfulness, significantly influenced how they felt about utilizing a system.

**Hypothesis 5: Perceived playfulness has a positive influence on intention to use online dating sites.**

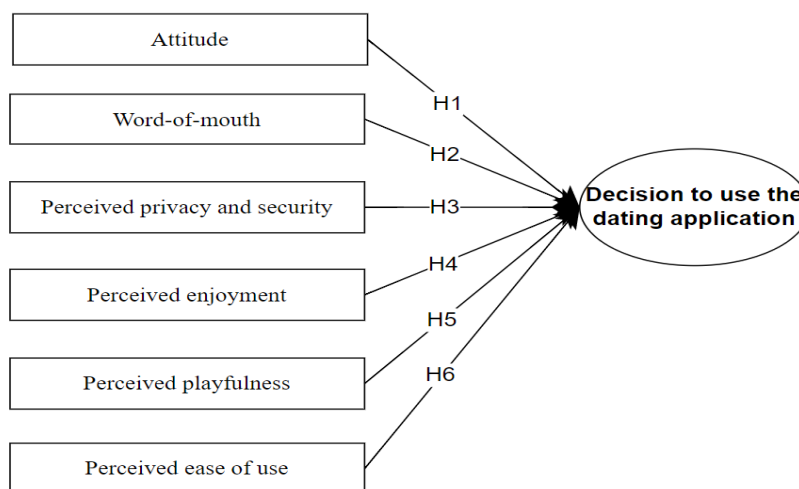

#### 4.1.6. Perceived ease of use

Some individuals see online dating as shopping. They peruse photos in quest of the perfect mate. According to Cha (2011), a person's decision to make an online purchase depends on a variety of factors, including gender, social norms, flow, rewards, perceived ease of use, enjoyment, and security. Customers are more inclined to purchase online when online businesses are simple to use and the checkout process is rapid, according to a study by Cho et al. (2015). Perceived simplicity of use has a big impact on customers' propensity to purchase online (Chen et al., 2007). But, an app's usability is just as important as its layout, website aesthetics, and reputation. The number of users increases as a result of trust being positively impacted by simplicity or ease of use.

**Hypothesis 6: Perceived ease of use has a positive and significant impact on usage behavior**

**Figure 4.1.**

*The proposed research model*

Interpretation of the proposed research model:

H1: Attitude has a positive influence on the intention to use online dating sites.

H2: Word-of-mouth positively influences students' decision to use dating apps

H3: Perceived privacy and security are essential to the confidence level of consumers willing to provide personal information to dating apps.

H4: Perceived enjoyment is positively related to behavioral intention in using dating apps.

H5: Perceived playfulness has a positive influence on the intention to use online dating sites.

H6: Perceived ease of use has a positive and significant impact on usage behavior.

**4.2. Proposed research scale and questionnaire**

The Likert scale is a useful instrument for measuring and assessing each person’s view and opinion on a range of issues based on the degree of agreement. The study team utilized a 5-point Likert scale with the following 5 answer choices:

Level 1 = Totally disagree; Level 2 = Disagree; Level 3 = Normal; Level 4 = Agree; Level 5 = Totally agree

The scales were developed based on earlier research studies, after which part of the material was modified to fit the study report. They are presented in Table 5.2

**5. RESEARCH RESULTS**

**5.1. Descriptive statistical analysis**

**Table 5.1.**

*Survey respondents' personal information.*

General Information		Frequency	Valid Percent
Gender	Male	145	40.6
	Female	212	59.4
Academic year	Freshman	107	30.0
	Sophomore	75	21.0
	Junior	142	39.8
	Senior	33	9.2
Have you ever heard about dating apps?	Yes	289	81.0
	No	68	19.0
Have you ever used dating apps?	Yes	94	26.3
	No	173	48.5
	Used to	90	25.2
How long since the date you used the dating app?	< 3 months	79	47.9
	3 - 7 months	51	30.9
	8 - 12 months	9	5.5
	> 12 months	26	15.8
How much time do you spend on dating apps?	1 - 2 hours/ day	151	91.5
	1- 4 hours/ day	13	7.9
	> 6 hours/ day	1	0.6

All of the 357 responses to the survey’s data had reliable results, according to the data. The bulk of them (81%), who are mostly female (59.4%), have heard of dating apps. To be more precise, the study included 25.2% of respondents who had used dating apps, 26.3% of those who were currently using them, and 48.5% of those who had never used them. Additionally, the majority of them (30.8%) and (39.8%) are Freshmen. 9.2% of respondents are Seniors, and the remaining 21% are Sophomores. The majority of them (47.9%) have only used dating apps for three months or less; just over 31% of respondents have used them for three to seven months; roughly 15.8% have used them for more than twelve months; and the remaining 5.5% of respondents have used them for eight to twelve months. More than 90% of respondents reported using dating apps for one to two hours per day, 7.9% for one to 6 hours per day, and 0.6% for more than 6 hours per day.

**5.2. Checking the reliability of the scale by Cronbach’s Alpha coefficient**

All scales pass the test used to establish the reliability of the scale since their Cronbach's Alpha coefficients are significant at the required level of 0.6. Because the correlation coefficient for the total variable is greater than 0.3, the observed variables of the factors ATT, PP, PEU, and DTU are all acceptable.

The test results indicate that the significant variables are not only those with reliability coefficients of Cronbach's Alpha scales of WOM5 (.640), PPS1 (.732), and PE1 (.821). The variable total correlation for this observation (Corrected Item - Total Correlation) is less than 0.3. As a result, the scale will not include the observed variables WOM5, PPS1, and PE1 because they only partially account for the DTU component. The second Cronbach's Alpha analysis was performed and the criteria were satisfied. Thus, the scale is reliable, and all observed variables have good explanations for the DTU factor.

**Table 5.2.**

*The results of the scale reliability assessment (Cronbach's Alpha)*

DTU	<b>Decision to use</b>	.799		
DTU1	Creating a dating relationship on dating app is a good idea		.341	.859
DTU2	I feel comfortable using dating apps		.688	.731
DTU3	If there is a need, I would consider using a dating app		.558	.770
DTU4	I will definitely try out the dating app in the future		.738	.712
DTU5	I will continue to use the dating app in the future.		.699	.725
Scales		Cronbach's Alpha	Total Correlation	if Item Deleted
ATT	<b>Attitude towards using dating apps</b>	.726		
ATT1	I find that the dating app helps me find a date		.658	.608
ATT2	I find that the dating app will help me find true love		.537	.658
ATT3	The majority of people who join the dating app are not aiming for a serious relationship		.460	.689
ATT4	I use dating apps to expand my relationship		.408	.712
ATT5	Dating app connections lead to toxic relationships		.381	.717
WOM	<b>Word of mouth of dating apps</b>	.640		
WOM1	I was known about the apps through friends and relatives		.506	.529
WOM2	Some of my friends recommend me to use dating apps		.510	.532
WOM3	I trust what my friends and relatives say about dating apps		.450	.563
WOM4	Someone who has had a bad experience with a dating app		.399	.585
WOM5	Other people look for relationships like FWB,ONS		.171	.710
PPS	<b>Perceived privacy and security</b>	.732		
PPS1	I feel comfortable sharing personal information on the app		.218	.775
PPS2	I control the information I want to share		.598	.643
PPS3	User identity is verified		.497	.685
PPS4	I am provided with complete privacy policy of the app		.629	.629
PPS5	Dating apps always do what they promise		.533	.670
PE	<b>Perceived enjoyment</b>	.821		
PE1	I find using dating apps very interesting		.275	.863
PE2	I spend a lot of time on this app		.574	.799
PE3	Dating apps can help me relax by sharing with others		.738	.746
PE4	I enjoy my time using the app		.757	.744
PE5	I find using dating apps to be entertaining		.740	.746
PP	<b>Perceived playfulness</b>	.849		
PP1	I don't realize how much time has passed		.626	.827
PP2	I often forget what I need to do		.304	.897
PP3	Interacting with dating apps is really excited		.803	.779
PP4	Interacting with dating apps is fun		.831	.770
PP5	Interacting with the dating app makes me want to explore		.757	.791

### 5.3. Exploratory factor analysis (EFA)

#### 5.3.1. Exploratory factor analysis (EFA) for the independent variable

The factor extraction method used is Principal Components with Varimax rotation. The analysis's results are as follows:

**Table 5.3.1.1.**

*KMO coefficient and Bartlett Test of independent variables in the first time*

KMO and Bartlett's Test			
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.	Bartlett's Test of Sphericity		
.910	Approx. Chi-Square	df	Sig.
	4064.061	315	.000

*Source: SPSS Analysis*

The results of testing the independent variables of KMO and Bartlett are shown in the table above:

- The results of the SPSS analysis show that the factor analysis is consistent with the research data when the KMO value is 0.911, greater than 0.5 and less than 1.
- Barlett's test has significance level sig = 0.000 < 0.05, proving that the data used for factor analysis are appropriate and that the variables are correlated with each other, from which we can reject the hypothesis H0: observed variables not correlated with each other.

Perform factor analysis according to Principal components with Varimax rotation. The results show that the observed variables are initially grouped into 6 groups:

**Table 5.3.1.2.**

*Total Variance Explained of independent variables in the first time*

Factors	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total
1	9.812	36.340	36.340	9.812	36.340	36.340	4.784
2	2.265	8.390	44.730	2.265	8.390	44.730	4.637
3	1.793	6.639	51.369	1.793	6.639	51.369	2.585
4	1.369	5.070	56.439	1.369	5.070	56.439	2.195
5	1.179	4.365	60.804	1.179	4.365	60.804	1.944
6	<b>1.073</b>	3.975	64.779	1.073	3.975	<b>64.779</b>	1.345
7	.937	3.470	68.249				
8	.832	3.083	71.331				
9	.800	2.963	74.295				
...	...	...	...				

*Source: SPSS Analysis*

The analysis results show that the original 27 observed variables are divided into 6 groups. Eigenvalues of all factors are greater than 1, factor 6 has the lowest Eigenvalues of 1,073. The total extracted variance value is 64.779% > 50%, showing that the EFA model is suitable. This value explains 64.779% of the variability of the data.

**Table 5.3.1.3.***Result of factor analysis for independent variables for the first time*

	Rotated Component Matrix Component					
	1	2	3	4	5	6
PE3	.772					
PE2	.768

WOM1				.672		
WOM3				.648		
ATT4					.578	
<b>PEU4</b>					.577	
<b>WOM4</b>					.571	
ATT2						
ATT3						.657
ATT1						-.643
ATT5						.593

*Source: SPSS Analysis*

The results of the first EFA show that the independent variables are divided into 6 factor groups after rotating 27 observed variables. Realizing that there are 3 confused variables that need to be considered and fixed.

#### **Factor convergence correction**

The research team found that the observed variable and the factors converged among other factors, notably PP3, PEU4, WOM4. This phenomenon can occur for one of the following reasons:

Cause 1: The questionnaire is not constructed clearly, the questions are relatively similar, leading to misunderstandings for survey takers, thereby making this variable separate, not showing the same common property with the remaining observed variables in the original group.

Cause 2: Survey takers do not focus on the question, leading to incorrect answers

After comparison and consideration, the new factor labeling method was used before moving on to the next study. Specifically, the research team will remove unsuitable factors and name the observed variables that converge depending on their attributes. Specifically, the variable PP3 was mixed between PEU and

PPS based on survey questions and study findings; nevertheless, the PP3 factor’s significance for these two observed variables was not comparable. As a result, the group chose the PP3 variable type.

In a similar vein, the names and definitions of the mixed variables PEU4 and WOM4 in the ATT factor group, ATT7 and ATT6, are comparable. And to keep monitoring, the remaining variables are constantly adjusted. The results of the EFA factor analysis stopped at the second implementation after removing the observed variable PP3 because of confusion and convergence in other factors. In general, due to changes in the remaining components, there are also some changes in variable names as mentioned above. Thus, after preliminary assessment, the total decision to use dating app scale includes 6 independent variables, respectively: ATT, WOM, PPS, PE, PP, PEU with 26 observed variables. All observed variables of this scale meet the requirements due to the factor loading coefficient (Factor loading) > 0.4 and are included in conducting CFA analysis.

**5.3.2. Exploratory factor analysis (EFA) for the dependent variable**

**Table 5.3.2.1.**

*KMO coefficient and Bartlett Test of independent variables for the first time*

KMO and Bartlett's Test			
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.	Bartlett's Test of Szphericity		
.910	Approx. Chi-Square	df	Sig.
	4064.061	315	.000

The results of the SPSS analysis show that the factor analysis is consistent with the research data when  $KMO = 0.796 > 0.5$ . With a significance level of  $Sig = 0.000 < 0.5$ , the results of Bartlett’s test show that the observed variables in the group are correlated with each other.

**Table 5.3.2.2.**

*Total Variance Explained for independent variables*

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	<b>2.982</b>	59.649	59.649	2.982	59.649	<b>59.649</b>
2	.836	16.719	76.368			
3	.611	12.210	88.578			
4	.359	7.188	95.766			
5	.212	4.234	100.000			

Source: SPSS Analysis

**Table 5.3.2.3.***Component matrix for independent variables*

	Component
	1
DTU4	.882
DTU5	.856
DTU2	.845
DTU3	.727
DTU1	.479

*Source: SPSS Analysis*

The analysis results show that there is a factor extracted at eigenvalue equal to  $2.982 > 1$ . It proves that this factor explains 59,649% of the data variation of 5 observed variables participating in EFA.

From the analysis results, the first variables meet the requirements of EFA analysis with factor loading coefficients all greater than 0.4. As a result, no variables are dropped, and the model stays the same.

## 5.4 Regression analysis

### 5.4.1. Testing the linear regression between variables

**Table 5.4.1.***Matrix of linear correlation between variables*

		Correlation						
		DTU	PE	PP	PEU	PSS	WOM	ATT
DTU	Pearson Correlation	1	.512**	.522**	.443**	.462**	.477**	.464**
	Sig. (2-tailed)		.000	.000	.000	.000	.000	.000
PE		.512**	1	.805**	.501**	.428**	.452**	.400**
		.000		.000	.000	.000	.000	.000
PP		.522**	.805**	1	.624**	.512**	.415**	.464**
		.000	.000		.000	.000	.000	.000
PEU		.443**	.501**	.624**	1	.642**	.551**	.410**
		.000	.000	.000		.000	.000	.000
PPS		.462**	.428**	.512**	.642**	1	.515**	.523**
		.000	.000	.000	.000		.000	.000
WOM		.477**	.452**	.415**	.551**	.515**	1	.400**
		.000	.000	.000	.000	.000		.000
ATT		.464**	.400**	.464**	.410**	.523**	.400**	1
		.000	.000	.000	.000	.000	.000	

*Source: SPSS Analysis*

The research team discovered that factors Attitude (ATT), Word-of-mouth factor (WOM), Perceived enjoyment factor (PE) and Perceived playfulness factor (PP), Perceived ease of use (PEU) with factor Perceived of privacy and security (PPS), have a good correlation with factor Decision to use the dating application (DTU), in which the Pearson correlation relationship between variable Attitude and variable Decision t was found to exist, in which, the Pearson correlation relationship between variable Attitude and variable Decision to use factors is  $r = 0.464$ , the Pearson correlation relationship between variable Word-of-mouth and variable Decision to use factors is  $r = 0.477$ , the Pearson correlation relationship between variable Decision to use and variable Perceived of privacy and security factors is  $r = 0.462$ , and

the Pearson correlation relationship between variable Decision to use and variable Perceived ease of use factors, Perceived playfulness factors and Perceived enjoyment factors is respectively 0.443, 0.522, 0.512. In particular, all the Sig coefficients are less than 0.05, which ensures a significant correlation between the variables for the research team to run the linear regression model.

5.4.2. Linear regression analysis

A linear regression function was used with a single input method to test the concordance between the decision variable using a dating app and the observed variables.

**Table 5.4.2.1.**

*Result of regression model*

Model Summary					
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	.634	.403	.390	.51767	1.829
a. Predictors: (Constant), ATT, PE, WOM, PEU, PSS, PP					
b. Dependent Variable: DTU					

*Source: SPSS Analysis*

The research team found that the variables Attitude (ATT), Word-of-mouth (WOM), Perceived Enjoyment (PE), Perceived Playfulness (PP), Perceived Ease of Use (PEU), and Perceived of Privacy and Security (PPS) have a good correlation with the variable Decision to Use the Dating Application (DTU), in which the Pearson correlation relationship between variable Attitude and variable Decision t was found to exist. It can be determined by looking at the findings of R squared (R Square) and R squared (Adjusted R Square) in the Model Summary table. According to the adjusted R-squared value of 0.390, the independent variables used in the regression analysis account for 39.0% of the variation in the dependent variable, while random errors and out-of-model variables account for the remaining 61.0%. The results of this table also give Durbin–Watson values to evaluate the phenomenon of first-order series autocorrelation. The value DW = 1.829, is in the range of 1.5 to 2.5, so the results do not violate the assumption of first-order series autocorrelation.

**Table 5.4.2.2.**

*Variance analysis*

ANOVA					
Model	Sum of Squares	df	Mean Square	F	Sig.
Regression	51.465	6	8.578	32.008	.000
Residual	76.375	285	.268		
Total	127.840	291			

*Source: SPSS Analysis*

*Source: SPSS Analysis*

The table ANOVA provides information about the regression model fit, the table gives us the results of the F test to evaluate the fit hypothesis of the regression model. The F-test sig value is 0.000 < 0.05, so the regression model is suitable.

**Table 5.4.2.3.**

*Regression coefficient results*

Coefficients					
Model		t	Sig.	Collinearity Statistics	
				Tolerance	VIF
1	(Constant)	2.428	.016		
	PE	2.210	.028	.332	3.009
	PP	1.775	.077	.273	3.658
	PEU	.062	.950	.429	2.331
	PPS	1.568	.118	.485	2.064
	WOM	3.423	.001	.600	1.666
	ATT	3.274	.001	.660	1.514

Source: SPSS Analysis

The significance of each independent variable’s regression coefficient in the model will be assessed using the t (student) test. The regression H0: The regression coefficient for the independent variable Xi is equal to zero. As there are many independent variables, we will test multiple H0 hypotheses. Inspection results The dependent variable is affected by the variable X1 if the regression coefficient of the independent variable, Xi, is statistically different from zero.

- If Sig 0.05: Reject the hypothesis H0.
- If Sig > 0.05:Accept that there is no association between the independent and dependent variables and that the independent variable Xi’s regression coefficient is zero.

The Coefficients table includes the regression coefficients, the VIF index to assess multicollinearity, and the t-test results for testing the significance of the regression coefficient hypothesis. The dependent variable Decision to use DTU is not affected by the independent variables Perceived ease of use (PEU) or Perceived privacy and security (PPS), which have sig test sig values of 0.950 > 0.05 and 0.118 > 0.05, respectively. With t-test sig values below 0.05, the remaining variables—attitude, word-of-mouth, perceived playfulness traits, and felt enjoyment—are all statistically significant and have an impact on the dependent variable DTU. The fact that all of these independent variables have positive regression coefficients demonstrates that they have a positive influence on the dependent variable. The VIP coefficients of the independent variables and all lose chum 10, so the data does not violate the assumption of multicollinearity (Hair et al, 2009).

**Figure 5.1.**

*Histogram Regression Standardized*

Source: SPSS Analysis

The chart provides result Mean = 2.34E-15 = 2.34 \* 10^-15 = 0.00000... which is close to 0, standard

deviation is 0.990 which is close to 1. Thus, it can be said that the residual distribution is approximately normal, assuming a normal distribution of residuals is not violated.

**Figure 5.2.**

*Normal P-P Plot Residual plot*

*Source: SPSS Analysis*

The chart gives information about the residual data points, which are concentrated quite close to the diagonal, so the residuals have an approximate normal distribution, assuming the normal distribution of the residuals is not violated.

**5.5. Analyzing the influence of demographic variables on the decision to use dating apps using T-test and ANOVA**

**5.5.1. Testing for differences by gender**

**Table 5.5.1.1.**

*Result of testing difference by Gender*

	GENDER	N	GENDER	N
DTU	Male	111	Female	181

*Source: SPSS Analysis*

**Table 5.5.1.2.**

*Result of Levene test by Gender*

	Levene's Test for Equality of Variances		t-test for Equality of Means		
	F	Sig.	t	df	Sig. (2-tailed)
Equal variances assumed	1.592	.208	-2.180	290	.030
Equal variances not assumed			-2.209	242.870	.028

*Source: SPSS Analysis*

The results show the Sig. Levene's Test = 0.208 > 0.05 and Sig.(2-tailed) = 0.030 < 0.05. So, there is a significant difference in the current student's decision to use a dating app by gender.

**5.5.2. Test for age difference by Academic year**

**Table 5.5.2.1.***Results of Levene test by Academic year*

Test of Homogeneity of Variance			
Levene Statistic	df1	df2	Sig.
.867	3	288	.459

*Source: SPSS Analysis*

The Levene's Test outcome demonstrates that Sig value = 0.459 > 0.05. This means the variables are similar, so it prevents the rejection of hypothesis  $H_0$ . As a result, we do not have enough evidence to determine the difference in decision-making under the influence of the academic year.

**Table 5.5.2.2.***Average Values by Academic year*

Descriptives			
	N		N
1 <sup>st</sup> year	71	3 <sup>rd</sup> year	123
2 <sup>nd</sup> year	65	4 <sup>th</sup> year	33
Total	292		

*Source: SPSS Analysis*

The survey results show that the higher academic year, the higher the Mean value. This also implies that the higher the student's academic year, the higher they need to use dating apps.

### 5.5.3. Testing for differences by reasons to use dating apps

**Table 5.5.3.***Average Values by reasons to use dating apps*

	Responses	
	N	Percent
Find friend	82	32.7%
Find an exclusive	99	39.4%
Hookup	53	21.1%
Other	17	6.8%
Total	251	100.0%

*Source: SPSS Analysis*

Based on the observations, it is found that students tend to use dating apps to meet new people, and the app's assessment of a person's personality and relationship qualities is reasonable. The percentage of people for whom hooking up is just less common than making friends and love matches is 21.1%. Warnings are required for users who have other reasons, or simply those who do not have social experiences, even though the application platform is monitored for safety. These users mostly include those who do not have a lot of toxic interactions. Users that use it for unclear reasons account for the lowest percentage, which is just 6.8%.

### 5.5.4. Testing for differences by status relationship

**Table 5.5.4.1.**

*Results of Levene test by status relationship*

Test of Homogeneity of Variance			
Levene Statistic	df1	df2	Sig.
20.672	3	285	.000

*Source: SPSS Analysis*

The Levene’s Test outcome demonstrates that Sig value = 0 < 0.05. This means the variables are different. Therefore, we look at the Robust Test result presented in the table below.

**Table 5.5.4.2.**

*Results of Robust Test by status relationship*

Robust Tests of Equality of Means				
	Statistica	df1	df2	Sig.
Welch	6.459	3	37.887	.001

*Source: SPSS Analysis*

The table Results of Robust Test by Status Relationship presented that Sig.Welch = 0.001 < 0.05 proved that the decision to use dating applications varies depending on relationship status.

**Table 5.5.4.3.**

*Average Values by status relationship*

Descriptives		
	N	Mean
Single	171	3.25
Dating	82	3.95
Chat up	11	4.45
Complicated	25	3.68
Total	292	3.53

*Source: SPSS Analysis*

According to the aforementioned facts, the vast majority of people who are classified as chat ups use the highest Mean number. Furthermore, it suggests that people involved in inquiry connections have high utilization desires. The number of students in “romantic relationships” is also second only to “chat up” in terms of mean value.

**5.6. Conclusion of the research results**

After empirically confirming Cronbach’s alpha scale with SPSS statistics. According to studies, the two main motivations for students in HCMC to use dating apps are to find real love and make new acquaintances. According to the study, 4 factors affect students’ plans to use the application in HCMC, while 2 out of 6 hypotheses had no bearing on their intentions. Thus, there are a total of six hypotheses in the study, of which the research team accepts four while rejecting the other two. The test results are summarized in the table that follows.

**Table 5.6.**

*Summary of hypothesis testing results*

Hypothesis	Evaluate
H1: Attitude has a positive influence on intention to use online dating sites.	Agree
H2: Word-of-mouth positively influences students' decision to use dating apps at universities	Agree
H3: Perceived privacy and security essential to the confidence level of consumers willing to provide personal information to dating apps.	Disagree
H4: Perceived enjoyment is positively related to behavioral intention in using dating apps.	Agree
H5: Perceived playfulness has a positive influence on intention to use online dating sites.	Agree
H6: Perceived ease of use has a positive and significant impact on usage behavior.	Disagree

**6. CONCLUSION AND RECOMMENDATIONS****6.1. Conclusion**

In order to better understand how young people in Ho Chi Minh City use online dating services, this study has taken a survey-style approach. Six factors, including attitude, word-of-mouth, perception of privacy and security, perception of enjoyment, perception of fun, and simplicity of use, were identified in the article. On the positive side, the use of dating applications has met the practical needs of some users, especially those who are so busy that they have little time for meeting, learning or personal interactions. Online chats can be a better way to start a conversation and get to know each other, as face-to-face matchmaking can often be embarrassing. Besides, the opponent's information is publicly displayed on their profile. However, there are a lot of drawbacks to using dating apps. The information that users provide into the app is not validated, so it could not be accurate. Other dangers include fraud, data leakage threats, and the misuse of dating apps for immoral purposes. Additionally, there are advertisements to purchase program upgrade packages, along with the difficulties of utilizing the application. This causes discomfort during the process.

Using a dating app is still controversial. The way we socialize and meet new people is changing significantly; consequently, it takes a long, sincere, and patient experience from both partners on both sides to become a long-term friend. This is especially true for the purpose of finding the ideal match, whether through an online application or face-to-face. When accepting new friendship offers, particularly through online dating apps, it is crucial for each person to establish a balance between sincerity and increased caution.

**6.2. Recommendations**

Several recommendations can be made based on the research's findings to help students readily make choices regarding the use of dating applications, dispel misconceptions about them, and find a safe approach for college students when using dating apps. Firstly, the government needs to come up with cybersecurity policies. Nowadays, the dangers of the internet grow in direct relation to the advancement of modern technology. Therefore, it is crucial and imperative to ensure information security, network security, and the prevention of cybercrime and legal breaches online. At the same time, it's important to increase knowledge among all citizens, businesses, agencies, and organizations; to improve cooperation between ministries and divisions in avoiding and fighting cyberattacks; and to rigorously enforce laws against breaking the law online. Secondly, the app developers must develop rules that will safeguard users, improve security, and attract new users. Additionally, it's important to stop the issue of junk SIM and refrain from registering for login accounts using false papers, identification cards, or stolen citizen IDs. Thirdly, sex education in schools is crucial for students' future development and understanding, which helps cultivate their own social knowledge and use the

apps appropriately and safely. And also, this can help them be cautious about disclosing too much confidential information to prevent fraud and unwarranted consequences when using dating apps.

### 6.3. Limitations of the research

The present findings must be interpreted in the context of some limitations. Firstly, the fact that the data collection with a sample size of only 357 participants was only conducted in Ho Chi Minh City made the results less objective and less generalizable. Secondly, the data was based mainly online, so the highest accuracy cannot be guaranteed. Specifically, some respondents have a superficial attitude and are not too interested in this survey, so direct data collection, such as interviewing any student, etc., is necessary to ensure the accuracy of the survey. In addition, some respondents are new users and did not know the application thoroughly. With different purposes and needs, there will be different evaluation decisions. As a result, their assessments can be ambiguous and confusing during survey execution. The major problem happened with the research process when the data was gathered and analyzed using specialist software in order to maximize the value of the data's results. Finally, the main researchers are students, who lack the knowledge and abilities necessary to effectively synthesize, process, and analyze the data. As a result, the data's meaning may not be appropriately and effectively exploited.

## ENHANCING LOGISTICS OPERATIONS FOR DELIVERING AND RECEIVING GOODS AT CHAN MAY PORT, THUA THIEN HUE PROVINCE, VIET NAM

Phan Nhieu Thuc Nhi<sup>1</sup>, Nguyen Thanh Duy<sup>1</sup>

Mentor: Le Thi Phuong Thanh<sup>1</sup>

**ABSTRACT:** *Chan May Port in Thua Thien Hue province has become one of the key seaports for logistics operations in terms of cargo delivery and reception in the Central region and the whole country. However, the logistics of delivering and receiving goods through the port still contain several disadvantages in terms of the limited organization of implementing the process, and the insufficient direct manpower in complementing, especially in high season. As such this research aims to analyse the status and propose solutions to enhance logistics operations for the delivery and receipt of goods at Chan May Port, Thua Thien Hue Province. In addition to secondary data, primary data was collected through a survey of 90 respondents from 30 companies (including Chan May Port Joint Stock Company and 29 customer companies). Descriptive statistical analysis, comparative analysis, economic accounting methods, frequency analysis, reference methods were used to analyse the data.*

*For future development, the port not only requires modern equipment, strong financial resources, and an abundant and highly skilled workforce with a deep understanding of international laws but also needs to establish a network for cargo delivery and reception within the domestic and global port systems. Building good relationships with domestic and international shipping companies will yield high efficiency and productivity, affirming the reputation of the company and Chan May Port, leading to sustainable development and positioning Chan May Port as a comprehensive and top-tier port in Vietnam.*

**Keywords:** *Logistics operation, delivering and receiving goods, seaport, Chan May*

### 1. INTRODUCTION

Chan May port, Thua Thien Hue province, is Vietnam's premier comprehensive seaport (Ministry of Industry and Trade, 2022). With its favorable maritime location connecting Singapore, the Philippines, and Hong Kong, Chan May Port is situated in the center of Vietnam, between the two major cities of Hue and Da Nang in the Central region. It serves as the nearest gateway to the East Sea and connects Central Vietnam with Northeastern Laos, Northeastern Thailand and Myanmar. In 2019, Chan May Port generated a revenue of 175 billion VND, marking a 17.88% increase compared to the same period in 2018. In 2022, the port's revenue reached 184.2 billion VND, representing 9.24% increase compared to 2021 (Chan May Port Joint Stock Company, 2022).

However, despite having well-established procedures and regulations, there are still several issues that need to be addressed regarding logistics operations at Chan May Port. The delivery and receipt of goods still face challenges in terms of scientific processes, particularly the lack of digitization in these procedures. Direct personnel involvement is required across multiple departments, and the organization and distribution of machinery and equipment have not been optimal. The team responsible for delivery and receipt, as well as cargo control and management, experiences delay in many cases, impacting contract schedules (Chan May Port Joint Stock Company, 2022).

Therefore, it is necessary to explore solutions to address these issues in compliance with regulations, scientific processes, and efficiency. Consequently, the research topic "Logistics Operations for Delivery and

<sup>1</sup> University of Economics, Hue University.

Receipt of Goods at Chan May Port, Thua Thien Hue Province” holds significant theoretical and practical significance.

The research objective is to systematize theoretical and practical issues related to logistics operations for the delivery and receipt of goods via seaports. The study involves analyzing and evaluating the current state of logistics operations for the delivery and receipt of goods at Chan May Port, Thua Thien Hue Province, during the 2020-2022 period. Additionally, the research aims to propose solutions to enhance logistics operations for the delivery and receipt of goods at Chan May Port, Thua Thien Hue Province in the foreseeable future.

## **2. THEORETICAL BACKGROUND AND METHODS**

The term ‘logistics’ has long been in use worldwide, primarily in the military sector. It encompasses various tasks related to troop movement, force deployment, facility and warehouse design and arrangement, weapons management, and more, all aimed at achieving victory over the enemy. In business operations, logistics refers to minimizing costs, from procuring raw materials to executing production plans and delivery. The goal of logistics in business is to minimize incurred expenses while still achieving the objectives set by the enterprise (Phan Van Hoa, 2014).

According to Article 233 of the 2005 Commercial Law (National Assembly, 2005), logistics services are classified as follows:

Main logistics services: Cargo handling services, including container handling activities; Warehousing and storage services, involving container warehouses and facilities throughout the logistics chain; Agency services for transportation, customs, and cargo handling planning.

Other support services such as handling returned goods, inventory management, expired goods, damaged goods, and redistributing goods; rental and leasing of containers.

The Commercial Law of 2005 defines the concept of goods delivery and receipt logistics as follows: “Goods delivery and receipt are commercial activities in which the service provider receives goods from the sender, organizes transportation, warehousing, storage, paperwork, and other related services to deliver the goods to the recipient as instructed by the shipper, carrier, or other parties involved.”

According to FIATA (International Federation of Freight Forwarders Associations), the concept of freight forwarding services is defined as: “Freight forwarding services encompass any services related to transportation, consolidation, warehousing, handling, packaging, or distributing goods, as well as consulting services related to these services, including customs, finance, insurance, payment, and document collection related to goods” (FIATA, 2019).

Fundamentally, logistics operations for goods delivery and receipt involve a collection of tasks and procedures related to the transportation process, aiming to facilitate the movement of goods from the sender to the recipient.

Based on this, logistics operations for sea freight are carried out through the following seven steps: (1) Vessel chartering; (2) Cargo packaging (for exports); (3) Customs procedures (for exports)/customs declaration (for imports); (4) Cargo inspection; (5) Loading cargo onto the vessel (for exports)/receiving cargo at the port (for imports); (6) Sending documents to relevant parties/delivering goods to customers; (7) Payment and contract settlement.

To achieve the research objectives, secondary data was collected from local agencies, particularly from Chan May Port Joint Stock Company, Lang Co, Thua Thien Hue Province, and published works. Further,

primary data was collected through a survey of 30 companies (including Chan May Port Joint Stock Company and 29 customer companies). In each company we selected three individuals as follows: 01 company leader, 01 head of transportation department, and 01 logistics officer. The total sample size is 90 respondents.

Survey method: For some companies with offices in Hue, the author conducted direct interviews. For other companies, the author conducted interviews via Zalo, Messenger, etc. Evaluation criteria: A Likert scale with five levels of measurement was used, including Level 1 (L1): Strongly Disagree; Level 2 (L2): Disagree; Level 3 (L3): Neutral; Level 4 (L4): Agree; Level 5 (L5): Strongly Agree.

Regarding data analysis, the authors utilize primarily economic research methods such as descriptive statistical analysis, statistical classification analysis, comparative analysis, economic accounting methods, frequency analysis, and reference methods.

### 3. RESULTS AND DISCUSSION

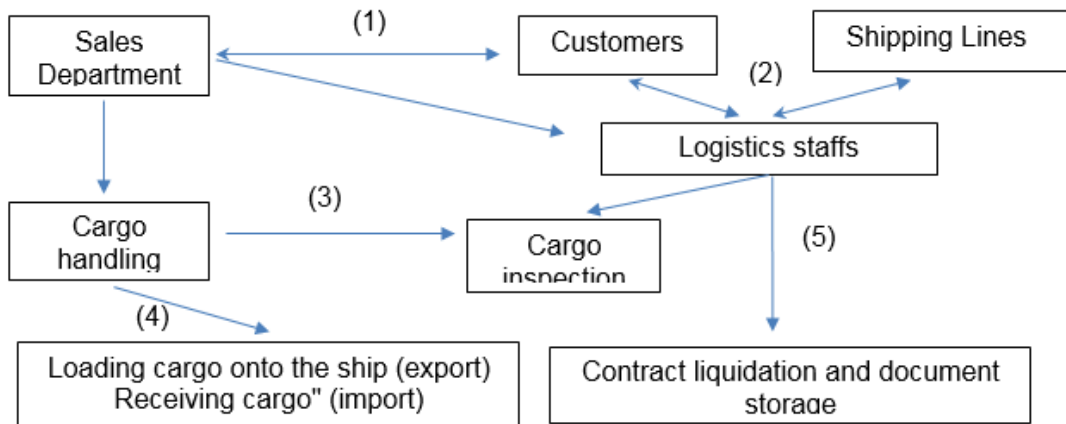

#### 3.1. Process of cargo delivery and receipt for export and import at Chan May Port

The logistics process of cargo delivery and receipt at Chan May Port is carried out as follows:

**Step 1:** Customers send their requests to the company. Customers provide the relevant documents to the delivery and receipt staff regarding the exported or imported goods.

**Step 2:** The delivery and receipt staff communicate with shipping lines, charter vessels, make reservations, coordinate the timing, location, vessel anchoring, and arrangement of cargo handling.

**Step 3:** The delivery and receipt staff proceed to inspect the customs declaration to clear the customs for export or import goods.

**Figure 1: Delivering and receiving goods process for export and import at Chan May Port**

**Step 4:** The stevedoring company carries out tasks such as customs declaration, cargo inspection, loading and unloading goods onto the vessel for exports, and receiving and releasing goods for imports.

**Step 5:** The relevant parties confirm the document files. The Finance and Accounting Department handles payments, contract settlements, and document archiving. The logistics process of cargo delivery and receipt for export and import at Chan May Port concludes.

In general, the cargo delivery and receipt process at Chan May Port is relatively simple, streamlined, and emphasizes the personal responsibility of the executing staff. However, this process has some limitations.

- The shipment of goods to and from the port is usually seasonal, concentrated within specific periods (mainly from January to March and October to December each year), during which there may be insufficient staff to operate or face difficulties in terms of manpower.

- When there is a large number of large vessels arriving at the port, or multiple contracts and a large volume of goods.

- The constantly changing policies and regulations of the government and international community, limited staff capacity, and inadequate conditions and time for updating, particularly in customs procedures, customs clearance, quarantine inspections, and cargo security controls. In the upcoming period, the company needs to adopt reasonable measures to address these issues, ensuring smooth and highly efficient operations.

### 3.2. Current situation of logistics operations in the delivery and receipt goods for export and import at Chan May Port

#### 3.2.1. Implementation status of delivering and receiving goods for export and import through ports

During the period from 2020 to 2022, the global economy experienced a recession due to the negative impact of the Covid-19 pandemic. However, Vietnam has made remarkable achievements and emerged as one of the few economies in Asia that still achieved positive growth. This success can be attributed to the effective implementation of the dual goals of “promoting economic and social development while preventing and controlling Covid-19”.

**Table 1. Implementation status of logistics plans for cargo delivery and receipt, import and export at Chan May Port during the period 2020-2022**

Criteria	Unit	2020		2021		2022		Implementation comparison (%)	
		Implementation	Comparison to the plan (%)	Implementation	Comparison to the plan (%)	Implementation	Comparison to the plan (%)	2021/2020	2022/2021
Cargo throughput	Million tons	2.4	101.0	3.1	106.1	3.5	89.7	129.2	112.9
Total revenue	Billion VND	137.2	104.2	168.6	104.1	184.2	81.8	122.9	109.3
Pre-tax profit	Billion VND	15.9	178.8	2.2	130.9	-9.4	-	13.7	-431.2
Pay taxes	Billion VND	6.6	195.1	0.8	26.7	0.8	153.6	12.1	96.3

Source: Chan May Port Joint Stock Company

At Chan May Port, the company’s leadership has resolutely directed the collective efforts of the workforce to both effectively implement the government and local authorities’ instructions on disease prevention and to ensure efficient production and business operations. Table 1 shows that the company achieved all business targets for the years 2020-2021, exceeding 100% of the plans. However, only in 2022, with the company’s prediction that the Covid-19 pandemic would end and the economy would recover, many planned targets for 2022 were set based on pre-pandemic conditions in 2019.

Nevertheless, the overall economy of our country, particularly the Central region, has not fully recovered. Therefore, the cargo throughput and revenue achieved in 2022 reached 89.7% and 81.8% respectively. However, compared to the performance in 2021, these indicators still showed a significant increase of 12.9% and 9.3% respectively. The pre-tax profit of -9.4 billion Vietnamese đồng in 2022 was due to the company’s expenses for depreciation, principal and interest repayments, particularly when Terminal 2 was put into operation.

### 3.2.2. The situation of logistics operations for delivery, receipt, import, and export of goods at the port

In the period from 2020 to 2022, the volume of goods exported through Chan May Port has seen significant growth over the years. Table 2 shows that the volume of goods exported in 2022 increased by 12.1% compared to 2021, reaching 2.9 million tons.

**Table 2. The situation of Logistics for Delivery, Receipt, Import, and Export of Goods at Chan May Port during the period 2020-2022.**

*Unit: Thousand tons*

Criteria	2020	2021	2022	Comparison (%)

*Source: Chan May Port Joint Stock Company*

Despite the ongoing and complex Covid-19 pandemic, thanks to the efforts of the company's leadership, transportation and shipping activities for export goods have increased and recovered. Among the volume of goods exported during the 2020-2022 period, the majority are export goods. In 2022, the volume of exported goods accounted for 70.3% of the total volume of goods exported through Chan May Port, while domestic goods accounted for only 29.7%. This indicates that the focus of goods exported through Chan May Port is primarily on exports, rather than domestic transportation. It also shows that the domestic transportation market remains a significant potential for Chan May Port in the future.

Timber remains the main exported commodity through Chan May Port, accounting for 50.1% of the total volume of exported goods in 2022, followed by white sand at 8.9% and clinker at 5.9%. The remaining are items such as cassava chips, titanium, and others. As for domestic goods, in 2022, white sand accounted for the largest share at 57.9%, followed by clinker at 34.9%. The handling capacity of various goods and the quality of services have been consistently improved over the years, ensuring the reputation of being a deep-water international seaport. The majority of exported goods at Chan May Port are sourced from the local province of Thua Thien Hue. The port has not yet implemented a strategy to attract export goods from other regions within the country, especially the North Central region and neighboring countries such as Laos and Myanmar.

For imported goods, although there has been an increase over the years, the quantity of goods imported through Chan May Port in the three years from 2020 to 2022 is relatively low compared to the export volume. It reached 548 thousand metric tons in 2022, equal to 77.1% in 2021. Among them, the quantity of imported goods is not significant, reaching only 36.6 thousand tons in 2022. The main imported commodities are asphalt, palm oil, primarily intended for the local province of Thua Thien Hue. This indicates that the company has not yet fully tapped into customers from other provinces, especially the North Central region from Thanh Hoa to Quang Tri and neighboring countries like Laos and Myanmar.

### **3.2.3. Assessment of the investigating parties**

Among the 90 surveyed individuals, 63 were male, accounting for 70%, and 27 were female, accounting for 30%. The average age was 36.3 years. In terms of educational qualifications, the majority had a university degree, with 65 individuals, accounting for 72.2%; 14 individuals had a vocational level of education, accounting for 15.6%. The remaining individuals had a college degree (7.8%) or a postgraduate degree (4.4%). With such a sample structure and criteria, the gathered information can be reasonably and accurately used for analysis.

#### **\* Evaluation by investigative subjects on delivery services, contracts, and customs procedures**

The survey results show that there are four observations regarding delivery services, contracts, and logistics processes for goods through the port. The average value of these four observations ranges from 3.66 to 3.96 points, with no observation having an average value above 4.0 points. The highest evaluation is regarding “Chan May Port Joint Stock Company having many channels for promoting and advertising logistics services for goods delivery,” with an average value of 3.96 points and a standard deviation of 0.87. It received 36.7% of opinions at level 4, which is “Agree,” and 31.1% of opinions at level 5, which is “Completely agree.” The lowest evaluation is regarding “The contract for logistics services for goods delivery at the company is well-drafted and reasonable,” with an average value of 3.66 points and a standard deviation of 0.69. It received 53.3% of opinions at the “Agree” level and 7.8% of opinions at the “Completely agree” level.

As for customs procedures for import and export of goods, all four observations have low average values below 3.72 points. The highest observation is “The customs procedures for importing goods are clearly structured, well-connected, and smooth,” with an average value of 3.72 points and a standard deviation of 0.70. It received 13.3% of evaluations at level 5, which is “Completely agree.” Based on practical research, the customs procedures for import and export of goods are carried out by the Customs Department of Chan May Port according to Article 21 of the Customs Law 2018 and Decree No. 08/2015/NĐ-CP dated 21/01/2015 of the Government, which provides detailed regulations and measures for the implementation of customs procedures, inspection, supervision, and control. Implementing these procedures correctly and strictly affects the operation time of many enterprises and the company as a whole. Therefore, many companies evaluate this observation as average and agree, meaning at level 3 and level 4. In the coming period, the company needs better measures to coordinate with the Customs Department of Chan May Port to expedite and timely customs clearance, save time, and reduce costs for businesses, contributing to the development of the local economy.

#### **\* Evaluation by investigative subjects on trust in logistics for goods delivery.**

Regarding the criterion of trust in logistics for goods delivery through Chan May Port, there are six observations with average values ranging from 3.74 to 4.07 points. The highest evaluations are for “The company’s reputation in the market” and “Security measures at the port are ensured,” with average evaluation

values of 4.07 points (standard deviation of 0.85) and 4.02 points (standard deviation of 0.79) respectively. This initially indicates that customer companies have a high level of trust and rate the trustworthiness of the company's logistics for goods delivery through the port highly.

***\* Evaluation by investigative subjects on the ability to respond in logistics for goods delivery***

Regarding the criterion of the ability to respond in logistics for goods delivery through Chan May Port, there are five observations with average evaluation values ranging from 3.73 to 4.03 points. The highest evaluations are for "The company's leadership and employees always listen to customer opinions and make adjustments to serve customers well" and "Employees are always ready to assist customers," with average evaluation values of 4.03 points (standard deviation of 0.84) and 3.87 points (standard deviation of 0.82) respectively. Therefore, we can see that the port's staff is always ready to meet and assist with the requests made by customers.

***\* Evaluation by investigative subjects on the service capacity in logistics for goods delivery***

Regarding the criterion of service capacity in logistics for goods delivery at Chan May Port, there are seven observations with average evaluation values ranging from 3.68 to 3.80 points. The highest evaluations are for "Quick document procedures for delivery and receipt" and "Effective application of information technology systems in goods delivery," with both observations having an average evaluation value of 3.80 points and corresponding standard deviations of 0.84 and 0.81 respectively. Therefore, we can see that the staff at Chan May Port is always striving to equip modern information technology systems to carry out delivery and receipt procedures as quickly as possible in order to provide the best service to customers.

***\* Evaluation by investigative subjects on empathy and tangible facilities***

Regarding the criterion of empathy from the staff at Chan May Port towards customers, there are five observations, and the average evaluation values by the investigative subjects range from 3.73 to 3.90 points. Among them, the observation "The company promptly coordinates with parties for adjustments" received the highest evaluation with an average score of 3.9 points and a standard deviation of 0.78. This indicates that the staff at Chan May Port always strives to understand and empathize with customers.

For the criterion of tangible facilities at Chan May Port, there are five observations, and the average evaluation values by the investigative subjects range from 3.59 to 3.69 points. Among them, the observations "The port's vehicles, machinery, and equipment are good and modern" and "The warehouse and transportation infrastructure meet customers' needs well" received the highest evaluations with an average score of 3.69 points. The standard deviation for both of these observations is 0.70. This shows that Chan May Port has made efforts to provide the best and most modern vehicles, machinery, and infrastructure so that customers can experience the best service possible.

***\* Overall evaluation of logistics operations for cargo handling at Chan May Port***

Finally, there is a general evaluation criterion for logistics operations regarding the delivery and reception of goods at Chan May Port, with four observations. The average evaluation values by the investigative subjects range from 3.76 to 3.87 points. Among them, the observation "Customers will recommend Chan May Port Joint Stock Company to many other clients and partners" received the highest evaluation with an average score of 3.87 points and a standard deviation of 0.60. This shows that through the port's operations, the customers feel satisfied and they want to recommend the port to others.

**Table 3. Overall evaluation of logistics operations for cargo handling at Chan May Port**

Target	Rating levels (%)					Mean value	Standard deviation
	L1	L2	L3	L4	L5		
Logistics operations for goods delivery and reception at Chan May Port meet the needs of customers well.	1.1	0.0	35.6	48.9	14.4	3.76	0.74
Customers are quite satisfied with the logistics services for goods delivery and reception provided by Chan May Port Joint Stock Company.	1.1	1.1	25.6	60.0	12.2	3.81	0.70
Customers always maintain their reputation and sustainable loyalty to Chan May Port Joint Stock Company.	1.1	0.0	27.8	63.3	7.8	3.77	0.64
Customers will recommend Chan May Port Joint Stock Company to many other customers and partners.	1.1	0.0	18.9	71.1	8.9	3.87	0.60

*Source: Survey data from 2022*

Regarding the observation “Logistics operations for cargo delivery and reception at Chan May Port meet customers’ needs,” it has the lowest value in the survey, reaching 3.76 points, with a standard deviation of 0.74. Additionally, 1.1% of the evaluations were at level 1, indicating “Strongly disagree.” This indicates that in recent times, especially during the complex developments of the Covid-19 pandemic, the demand for cargo transportation has increased, but the number of staff available to work directly at the port is limited. As a result, the port’s employees have not been able to perform their tasks well and meet the customers’ needs, especially in terms of timeliness. Therefore, the company needs to implement better measures to address the issue of increasing direct workforce. Additionally, the port’s employees need to make greater efforts to improve the quality of service in the future.

Overall, the logistics operations of cargo delivery and reception through Chan May Port, Thua Thien Hue province, have achieved encouraging results in recent times. The delivery and reception processes have been reasonable, streamlined, and smoothly executed. Despite the significant impact of the Covid-19 pandemic during the period from 2020 to 2022, the company’s leadership has implemented various effective measures, strengthened promotion and business relationships, resulting in a substantial increase in cargo volume through the port over the years. In 2022, there was a 12.9% increase compared to 2021, reaching 3.5 million tons, with a revenue growth of 9.3%, amounting to 184.2 billion VND.

However, there are still some limitations in the logistics operations of cargo delivery and reception at Chan May Port, Thua Thien Hue province. Specifically:

- Lack of specialization for each department: The organizational structure of the company is still simple, and the number of employees is limited.
- The Covid-19 pandemic has created difficulties in implementing the delivery and reception processes. The number of customers has significantly decreased, and transaction costs have increased compared to normal times.
- Insufficient transportation vehicles with low capacity affect the timeliness of cargo delivery and reception.
- The freight charges for cargo delivery and reception are relatively high, resulting in additional costs and the profitability not reaching the optimal results.

#### **4. SOLUTIONS TO IMPROVE LOGISTICS OPERATIONS FOR CARGO DELIVERY AND RECEPTION AT CHAN MAY PORT**

##### **4.1. Market promotion and enhancing competitiveness**

With the goal of developing into a multi-functional port that accommodates bulk cargo ships, container ships, and tourist ships, the company needs to focus on market research and studying competitors to enhance its competitiveness. Combining communication strategies and promotion to attract potential

customers, especially customers from the Central and Central Highlands regions, as well as customers from neighboring countries such as Laos and Myanmar.

Furthermore, it is crucial to strengthen logistics contracts between regions with incoming and outgoing cargo to and from Chan May. The company needs a strategic plan to enhance joint ventures and partnerships to strengthen the logistics system in this area. Promoting forms of investment cooperation or capital contributions from customers based on mutually beneficial cooperation is also important.

Maintaining good relationships with traditional customers is essential. Collaboration and information exchange with relevant agencies and proposing coordination mechanisms to address obstacles are crucial.

Continuing to implement diversification strategies by offering supplementary services and exploring potential services to increase revenue and improve business efficiency for the company.

#### **4.2. Quality solutions for delivery and receipt services**

Enhancing the quality of logistics operations for cargo delivery and reception at the port. Step-by-step improvement of each stage in the process of logistics operations for exporting and importing cargo, ensuring strict, scientific, and highly efficient procedures. The cargo delivery and reception processes at Chan May Port are relatively simple, streamlined, and emphasize the personal responsibility of the staff. However, in some cases, there are limitations to this process, especially when dealing with seasonal shipments, a large number of incoming vessels, multiple contracted companies, or a significant volume of cargo. The changing policies of the government and international regulations, especially customs procedures, clearance, inspections, and cargo security controls, contribute to the decrease in the quality of the company's delivery and reception services. Therefore, in the coming period, the company needs to implement reasonable measures to address these issues, ensuring smooth operations and improving the quality of delivery and reception services. Create favorable conditions for businesses to deliver and receive goods. Take customer requirements as guidance for the company's operations.

Timely resolution of difficulties and challenges faced by business customers, seeking solutions to ensure the implementation of logistics operations for cargo delivery and reception in the shortest possible time, while ensuring cost savings and efficiency.

#### **4.3. Human resource, human resource management and production management solutions**

The company needs to develop a team of staff, especially those directly and indirectly involved in logistics operations for cargo delivery and reception, who possess high professional expertise, a professional work attitude, the ability to work independently and in teams, and are ready to adapt to environmental changes. It is necessary to boldly recruit and allocate young personnel with competence, qualifications, and dedication to the company for key positions. Additionally, the company should research and establish a welfare policy to retain talented individuals while ensuring compliance with state regulations. Maximizing external sources of human resources can help minimize management costs and risks for the company.

It is important to explore solutions to create motivation for workers, enhance job productivity and efficiency, and further implement training policies that provide opportunities for personal development. Organizing training and development programs on operating procedures, container handling equipment, service marketing, port operation management, container cargo, and logistics operations ensures a qualified workforce to fulfill tasks and business plans for 2023 and the years ahead.

Ensuring a proper delivery and reception process, cargo counting, and regularly monitoring the warehouse's condition to promptly address issues and perform repairs. Timely meeting customers'

warehouse rental needs and taking proactive measures in equipment repairs and infrastructure to accelerate production progress.

Frequent maintenance and strict adherence to labor safety conditions, loading and unloading equipment, port exploitation procedures, and the deployment of on-duty personnel during cargo loading and unloading operations to ensure safety.

#### **4.4. Pricing, Fees and Financing Solutions**

Price and fees are important tools in the marketing strategies of all businesses. According to the summary and observations from various research works by multiple authors (Phan Van Hoa, 2014), the period before the 1990s was characterized by the era of products and product quality (the first P - Product in marketing, emphasizing high-quality products) with notable goods from Japan, the United States, and Europe. Since the 1990s, we have entered the era of price (the second P - Price in marketing, emphasizing low product prices), with China's goods standing out, along with the four Asian "dragons" of South Korea, Taiwan, Singapore, and Hong Kong, as well as newly industrialized countries (NICs). Currently, we are in the era of "Price and Fees." The future is predicted to be the era of artificial intelligence products, where products will provide maximum convenience and benefit to users (the third P - Place in marketing), whether through extensive distribution channels (such as online shopping) or direct interaction with users (such as self-driving cars or smart home devices that optimize various tasks for humans).

Based on these observations, in the near future, the company needs to implement attractive pricing and fee policies to increase competitiveness and attract customers, including:

- Researching and implementing various forms of service price and fee reductions.
- Applying price and fee discounts based on customer segments: Regular and large customers should receive preferential pricing and distinct advantages compared to other customers.
- Implementing seasonal price and fee discounts: As the market for cargo delivery and reception through ports is seasonal, appropriate pricing policies should be established for each season.
- The company should review and study cost reduction measures for operations and indirect costs to lower the cost of delivery and reception services.
- In addition to focusing on finding new sources of goods and increasing revenue, the company needs to pay attention to maintaining the effective operation of services and high-profit-margin products.
- Enhancing efficiency in financial management, debt management, expediting payment processes, and implementing effective debt recovery measures. Clear responsibilities and specific accountability should be established for debt management within the company.

#### **4.5. Other solutions**

- Implement effective investment plans and ensure balanced coordination of resources, including physical infrastructure, equipment, and personnel, across services to ensure efficient business operations and reduce financial pressure on the company.
- Continue to strengthen project management to ensure proper implementation of projects, meeting technical and aesthetic standards to reduce initial investment costs. The project's effectiveness should be a top priority.

### **5. CONCLUSION AND RECOMMENDATIONS**

Chan May Port in Thua Thien Hue province has become one of the key seaports for logistics operations in terms of cargo delivery and reception in the Central region and the whole country. The logistics process for import and export goods through the port is executed tightly and clearly, showcasing the operational

capabilities of each department and employee within Chan May Port Joint Stock Company. In the upcoming period, the port not only requires modern equipment, strong financial resources, and an abundant and highly skilled workforce with a deep understanding of international laws but also needs to establish a network for cargo delivery and reception within the domestic and global port systems. Building good relationships with domestic and international shipping companies will yield high efficiency and productivity, affirming the reputation of the company and Chan May Port, leading to sustainable development and positioning Chan May Port as a comprehensive and top-tier port in Vietnam.

**\* Recommendations to the State and the Provincial People's Committee:**

- Train human resources in the logistics industry to quickly meet the labor demand and promote training programs for logistics experts with applied skills and the ability to implement logistics management practices and supply chain management in line with developed industrial nations.

- Invest in the construction and development of infrastructure to facilitate the transportation of goods domestically and internationally, including maritime transportation.

- Improve the legal system for cargo delivery and reception in a comprehensive and consistent manner, aligning with the current situation of import and export cargo within the country and globally.

**\* Recommendations to relevant departments and agencies:**

- Customs authorities need to implement measures to prevent negative occurrences when businesses declare customs procedures, which often result in time-consuming procedures for cargo delivery and reception.

- Customs authorities should explore more advanced customs procedures, especially digitalization of customs procedures, to simplify processes while ensuring proper customs management.

- The Ministry of Industry and Trade needs to ensure unity among relevant agencies, departments, and personnel regarding criteria for determining the origin of goods, avoiding confusion for businesses when receiving different feedback from various departments, units, and officials.

## FACTORS AFFECTING STUDENTS' DECISION TO CHOOSE THE BUSINESS ADMINISTRATION MAJOR AT UNIVERSITY OF ECONOMICS, HUE UNIVERSITY

Tran Le Phuoc Ha<sup>1</sup>

Mentor: Le Thi Phuong Thao<sup>1</sup>

**ABSTRACT:** *This study aims to identify the factors affecting the decision to choose the Business Administration (BA) major at the University of Economics, Hue University. The multiple linear regression analysis conducted on a dataset comprising 259 students from the first to fourth year yielded significant findings, identifying a total of seven affecting factors. The results of the study identified seven factors that influence the decision to choose the BA major at University of Economics – Hue University, including: (1) Reference characteristics; (2) University characteristics; (3) Self-characteristics; (4) Major characteristics; (5) Future career opportunities; (6) Opportunities for further education, research, and development at higher levels; and (7) Admission chances. These seven factors explained 79.6% of the variance in students' decision to choose this major. Based on these findings, the study proposes several managerial implications to enhance the recruitment efforts and attract students in the field of Business Administration at University of economics – Hue University.*

**Keywords:** *major selection decision, Business Administration major, students, University of economics – Hue University.*

### 1. INTRODUCTION

The process of selecting a career path to pursue one's passion after completing secondary education is a matter of great concern for both society and individuals themselves. Making an informed career choice not only helps students set educational goals but also enables them to unleash their potential and become valuable contributors to their families and society. When faced with the decision of choosing a profession and a university, most students experience uncertainty and indecisiveness. During this critical phase, various factors significantly influence and impact students' choices. In Vietnam, the Business Administration field is well-established and offers a wide range of opportunities due to its diversity and market demand. Therefore, educational institutions must implement targeted communication programs to raise awareness about this field and guide students in their career selection.

University of Economics, a member institution of Hue University with an enrollment of nearly 8,000 students, plays a pivotal role in providing a skilled workforce to meet the economic development needs of the region. In recent years, the university has taken proactive measures to enhance the quality of education by updating curriculum and teaching methodologies to align with modern trends. Moreover, significant investments have been made in student recruitment efforts. The Business Administration major, one of the most popular programs at the university, has consistently attracted many applicants with high admission scores. However, there has been a concerning downward trend in the enrollment figures for the Business Administration major, as well as other disciplines, which falls short of the intended targets, despite its status as a flagship program. To address this issue and improve the university's overall appeal, particularly in the Business Administration field, it is crucial to conduct research on the decision-making process of prospective students when selecting both their university and major. This research aims to identify the key factors that significantly influence their decisions, enabling the formulation of effective policies that enhance student attraction and enrollment for the university, with a specific focus on the Business Administration major.

<sup>1</sup> University of Economics – Hue University.

## 2. THEORETICAL BACKGROUND

### 2.1 Conceptualizing Students’ Decision to Choose a Major

According to Borchert (2002), the decision to choose a major is a process consisting of five main stages: self-awareness of personal needs, seeking information about schools and majors, evaluating, and selecting solutions, making the final decision on the major, and finally, evaluating the outcome of the chosen major. The selection of a major is a deliberative process in which individuals carefully consider and calculate in order to make the optimal final decision. The chosen major should align with the individual’s personal interests and abilities to achieve their future career goals.

Therefore, students choose a major that they perceive as fitting their own personal style, personality, and future career aspirations (Saemann & Crooker, 1999). Students become aware of the economic and social conditions and their own unique characteristics to plan and envision the achievements associated with selecting a specific field of study (Gul, 1986). The majority of students make their decision to choose a major early on, typically during the final two years of secondary education (Hunjra et al., 2010).

### 2.2 Factors Affecting Students’ Decision to Choose a Major

There are various perspectives on the factors affecting students’ choice of majors. Several factors have been extensively discussed in studies, such as: Self-Characteristics, Reference Characteristics, University Characteristics, Future career opportunities, Major Characteristics, Opportunities for further education, research, and development at higher levels, Admission chances.

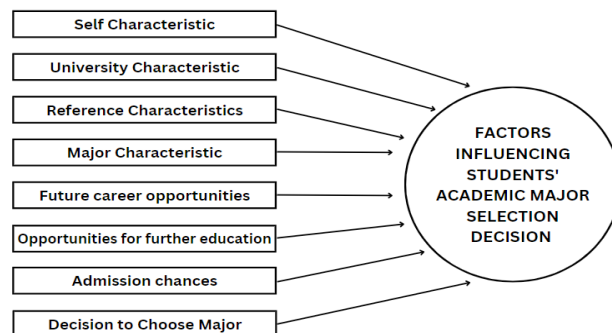

**Table 1. Factors Affecting Students’ Decision to Choose a Major**

<b>Factors Affecting Students’ Decision to Choose a Major</b>	<b>Concept</b>	<b>Author Addressed</b>
<b>Self-Characteristics</b>	Personal characteristics, also referred to as individual traits, encompass the unique personality, qualities, and inner attributes of everyone. They shape an individual’s thoughts, words, and motivations, driving their actions and choices. When selecting a major, individuals may consider factors such as the compatibility with their personal preferences and traits, alignment with their capabilities, and suitability to their economic and social circumstances	DW.Chapman (1981) Borus (1993) Hossler (1984) Gul & Fong (1993) Ruth E.Kallio (1995) Manski & Wise (1983) Le Thyy Van & Cao Hao Thi (2009)
<b>Reference Characteristics</b>	The reference group of characteristics refers to individuals who exert influence on students’ decisions regarding their choice of major. These influential individuals, including parents, siblings, relatives, friends, teachers, and individuals with expertise in the field, hold significant sway over the individual. Before making the crucial decision of selecting a major, individuals often seek opinions and guidance from those they deem relevant and trustworthy, using them as a foundation for their decision-making process.	D.W.Chapman (1981) Hossler và Gallagher (1987) Cabrera & La Nasa (2000) Mario & Helena (2007) Kim et al. (2002) Lowe & Simons (1997) Kniveton (2004) Tran Van Quy & Cao Hao Thi (2007)
<b>University Characteristics</b>	The institutional characteristics of a university refer to its internal attributes and qualities. When choosing a major, students may take into account the specific characteristics of the university, including its geographical location, admission policies, development strategies, reputation and brand, training costs, quality of faculty members, and physical infrastructure. These factors contribute to the decision-making process and influence students in their choice of major	D.W.Chapman (1981) Absher & Crawford (1996) Hossler & Gallagher (1990) Kohn et al. (1976) Ford et al. (1999) Joseph (2000) Vu Thi Hue (2017) Nguyen Minh Ha (2011)

<b>Future career opportunities</b>	Post-graduation expectations encompass the individual desires and aspirations of students upon completing their specialized academic programs at the university, which are influenced by personal characteristics such as family background and living environment. Each individual may have distinct expectations after graduation. However, there are common overarching expectations, including the pursuit of a well-paying job that aligns with their field of expertise, opportunities to work in dynamic environments, prospects for employment in multinational companies, and possibilities for career advancement. These are areas of significant interest for individuals as they transition from their academic journey to the professional world.	S.G.Washburn et al. (2000) Cabera & La Nasa (2000) Sugahara et al. (2008) Tran Van Qui & Cao Hao Thi (2009) Nguyen Minh Ha et al. (2011)
<b>Major Characteristics</b>	The characteristics of an academic discipline pertain to its distinct attributes and offerings. Each field of study presents different courses, study materials, and learning approaches that are tailored to its specific nature. Students opt for a particular major based on the compelling characteristics of the discipline, including its high appeal, availability of extracurricular programs, and a commendable graduation rate.	Malaysia Yusof et al. (2008) Ford et al. (1999) Marvin J.Burns at al. (2006) Gilmour et al. (1981) Carpenter & Fleishman (1987) Uyar et al. (2011) Vu Thi Hue et al. (2017) Nguyen Minh Ha et al. (2011)
<b>Opportunities for further education, research, and development at higher levels</b>	The prospects of further learning, research, and development in higher levels of education (after graduation) have a positive impact on prospective students’ choice of university. Students opt for the Business Administration program due to the opportunities it offers, such as participation in various training programs both domestically and internationally, the potential for higher education continuation, and access to scholarship opportunities.	S.G.Washburn et al. (2000) Cabera & La Nasa (2000) Sugahara et al. (2008) Ha, Xuyen & Tuyet (2011)
<b>Admission chances</b>	The perception of a high likelihood of admission can also influence students’ choice of major. Many students choose a particular field of study because they believe it has low competition rates and a suitable admission cutoff score, thereby increasing their chances of being admitted.	Vu Thi Hue at al. (2017) Nguyen Minh Ha at al. (2011) Ha, Xuyen & Tuyet (2011)

**2.2 Research Model**

Through a comprehensive review of literature and the formulation of hypotheses based on relevant studies, the proposed research presents the following research model. This model draws on several studies, including D.W. Chapman (1981), Cabrera & La Nasa (2000), Kim et al. (2002), and Hà, Xuyên & Tuyết (2011). The proposed research model is as follows:

**Figure 1: Research model of factors influencing students’ decision to choose a major in Business Administration.**

*(Source: Author’s proposal)*

### ***Self-Characteristics***

Chapman's model (1981) suggests that an individual's characteristics play a significant role in their choice of educational institution and major. Gul and Fong's study (1993) found that introverted students are more inclined towards accounting majors due to their preference for independent work environments over group settings. Hossler (1984) argues that when students recognize their aptitude for a specific field of study that aligns with their strengths, they are more likely to select universities offering programs in that field. Manski and Wise (1983) also support the notion that personal factors influence students' decision-making. Additionally, Ruth E. Kallio's research model (1995) highlights the impact of gender on school choice. Building upon these foundations, this study proposes Hypothesis 1.

*Hypothesis 1: "Self-characteristics are positively associated with the decision to choose a Business Administration major among students."*

### ***Reference Characteristics***

During the university selection process, individuals are often strongly influenced by the persuasive arguments and advice provided by their friends and family, as stated by D.W. Chapman (1981). Hossler and Gallagher (1987) further affirm that, apart from parental influence, peers also exert a significant impact on individuals' decisions regarding their choice of university and major. Additionally, Cabrera and La Nasa (2000), Kim and colleagues (2002), Kniveton (2004), and Lowe and Simons (1997) have identified the substantial influence of parental encouragement on individuals' career aspirations. Building upon these findings, this study proposes Hypothesis 2.

*Hypothesis 2: "Reference group characteristics are positively associated with the decision to pursue a Business Administration major among students."*

### ***University Characteristics***

Research conducted by Chapman (1981), Kohn and colleagues (1976), Hossler and Gallagher (1990), and Joseph (2000) suggests that geographical proximity to the university, coupled with affordability, significantly impacts students' decision-making process when choosing their academic environment. Furthermore, Absher and Crawford (1996) emphasize the crucial role played by educational facilities, such as classrooms, laboratories, and libraries, in influencing students' preferences for a particular university. Marvin J. Burns' study (2006) and the work of Hossler and colleagues (1990) indicate that factors such as the university's website development, admissions counseling, strategic advertising through various media channels, and engagement in extracurricular activities or scholarship programs all influence students' decisions when selecting a university and major. Similarly, the research by M.J. Burns and colleagues (2006) highlights the significance of factors such as institutional reputation, prestigious faculty, and renowned teaching staff in influencing undergraduate students' choice of major. Based on these premises, this study proposes Hypothesis 3.

*Hypothesis 3: "University characteristics are positively associated with the decision to pursue a Business Administration major among students."*

### ***Major Characteristics***

Studies conducted by Yusof and colleagues (2008) in Selangor, Malaysia, Gilmour and colleagues (1981), Carpenter and Fleishman (1987), and Uyar and colleagues (2011) have all concluded that the relevance of a major's curriculum to societal needs significantly influences students' decisions when selecting a university and major. Moreover, Ford and colleagues (1999) have observed that factors such as the breadth of the study program, program flexibility, the potential for significant variations, and a wide

range of degree options are crucial considerations for students when choosing a major that aligns with their interests and aspirations. M.J. Burns further adds that the attractiveness of a particular major also plays a role in students' university choices. Based on these findings, this study proposes Hypothesis 4.

*Hypothesis 4: "Major characteristics are positively associated with the decision to pursue a Business Administration major among students."*

#### ***Future career opportunities***

According to Sevier (1998), Cabera and La Nasa (2000), and Sugahara et al. (2008), students are often attracted to the career opportunities available after graduation. Paulsen (1990) notes that students tend to select universities based on the job prospects for college graduates. They are highly concerned about employment opportunities and are influenced by the achievements of alumni in society (Sevier, 1997). Additionally, Cabera and La Nasa (2000) highlight that besides academic aspirations, future career prospects also play a significant role in individual university choices. Building upon these foundations, this study proposes Hypothesis 5.

*Hypothesis 5: "Future career prospects are positively associated with the decision to pursue a Business Administration major among students."*

#### ***Opportunities for further education, research, and development at higher levels***

Opportunities for higher education, research, and development at advanced levels in the future (after completing their chosen major) have a positive impact on prospective students' university choices (Ming, 2010; Trần Văn Quý and Cao Hào Thi, 2009; Vũ Thị Huệ, Lê Đình Hải, and Nguyễn Văn Phú, 2017). According to Paulsen (1990), students often choose universities based on the opportunities for advanced learning, research, and development available to college graduates. Studies by Nguyễn Thị Lan Hương (2012) and Trần Minh Đức (2015) also indicate that opportunities for bridging programs influence students' choice of majors. Based on the aforementioned research findings, the author formulates Hypothesis 6 for this study.

*Hypothesis 6: "Opportunities for higher education, research, and development at advanced levels are positively associated with the decision to pursue a Business Administration major among students."*

#### ***Admission chances***

Saemann and Crooker (1999) conducted a study on factors influencing students' choice of majors, including students' perception of a higher probability of admission to accounting majors in the United States. Worthington and Higgs (2003) and Worthington and Higgs (2004) measured students' perceived admissions probability at the Queensland University of Technology in Australia when selecting majors in finance and economics. In Vietnam, Vũ Thị Huệ and colleagues (2017), Nguyễn Minh Hà and colleagues (2011), and Hà, Xuyên, and Tuyết (2011) have also highlighted admissions probability as a factor impacting students' decisions in choosing majors. Based on these research findings, the author formulates Hypothesis 7 for this study.

*Hypothesis 7: "Admissions probability is positively associated with the decision to pursue a Business Administration major among students."*

### **3. METHODOLOGY**

#### **3.1 Secondary data collection**

The research method used is literature review, which involves collecting and analyzing relevant documents and data such as the curriculum framework, learning outcomes standards of Business Administration majors; the number of students enrolled in Business Administration each year, and the number of students currently being trained in Business Administration at University of economics – Hue University. Additionally, the analysis includes documents such as research topics, projects, articles, and conference papers related to the

motivations for choosing majors that have been conducted recently. Furthermore, a synthesis of research documents is conducted to establish the theoretical foundation of the study.

### **3.2. Primary data collection**

The research utilizes both qualitative and quantitative research methods to serve the research process. Qualitative research: It involves gathering opinions from individuals to construct a measurement scale and assist in qualitative analysis related to the research objectives. Quantitative research: It is carried out based on information collected from survey questionnaires distributed to Business Administration students currently studying at the University. The objective is to address the research goals.

### **3.3. Data Collection Method**

For the exploratory factor analysis (EFA), the expected sample size was determined based on the study by Hair, Anderson, Tatham, and Black (1998) as a reference. According to their research, the minimum sample size should be at least 5 times the total number of observed variables. This sample size is appropriate for studies utilizing factor analysis (Comrey, 1973; Roger, 2006). The formula used is  $n=5*m$ , where  $m$  represents the number of questions in the questionnaire. In this study, there are a total of 36 variables, so the minimum required sample size would be  $36 * 5 = 180$  samples. However, the author chose a sample size of  $n = 270$  to minimize errors and achieve better effectiveness in the data analysis process. The author opted for a non-random sampling method based on quotas. The quota criterion was determined by the proportion of students enrolled in the Business Administration major at the University. In the survey sample structure, a total of 259 students currently studying at the University of Economics, Hue participated. Specifically, there were 45 fourth-year students (17.37% of the total), 83 third-year students (32.05% of the total), 74 second-year students (28.57% of the total), and 57 first-year students (22.01% of the total).

### **3.4. Data analyses:**

The data will be analyzed using the SPSS software, employing several statistical tests and tools for examination, including: Cronbach's Alpha coefficient, Exploratory Factor Analysis (EFA), linear multiple regression model

## **4. STUDY RESULTS**

### **4.1. Profiles of the respondents**

The survey sample consisted of 259 students currently studying at University of Economics – Hue University. Regarding academic cohorts, the distribution was as follows: 45 students from the 53rd cohort (17.37%), 83 students from the 54th cohort (32.05%), 74 students from the 55th cohort (28.57%), and 57 students from the 56th cohort (22.01%). In terms of gender, there were 182 female students (70.2%) and 77 male students (29.73%).

### **4.2. Exploratory Factor Analysis (EFA)**

The reliability of the measurement scale used to assess the factors influencing the decision to choose the Business Administration major among students at the University of Economics - Hue University was examined. With a total of 36 variables, the Cronbach's Alpha coefficient was calculated to assess the scale's reliability. From the results in the evaluation of Cronbach's Alpha results for the scales, we can see that the Cronbach's Alpha values for the scales are as follows:

Self-characteristics: 0.877

Reference characteristics: 0.894

University characteristics: 0.847

Future career opportunities: 0.936

Field of study characteristics: 0.840

Opportunities for higher education, research, and development: 0.898

Admission probability: 0.882

Major selection decision: 0.882

Moreover, the item-total correlations for all observed variables are  $> 0.3$ . Therefore, the scales used in the model are reliable. Hence, all variables will be included for further exploratory factor analysis (EFA) analysis.

Perform an exploratory factor analysis on the constructed variable groups to identify the independent factors.

**Table 2. Results of KMO and Bartlett's test.**

Kaiser-Meyer-Olkin Measure of Sampling Adequacy	0.828
(Sig) Bartlett's Test of Sphericity	0.000

(Source: Data processing 2023)

The KMO coefficient is 0.828 ( $> 0.5$ ), and the sig value is  $0.000 < 0.05$ , indicating that the hypothesis of correlation among observed variables in the overall population is appropriate, and EFA factor analysis is suitable. The factor extraction results using the specified number of factors are 7. These seven factors explain 71.8% of the variance in the data.

**Table 3. Factor rotation matrix of the independent variables**

Observed Variable	Factor Loading Coefficient						
	1	2	3	4	5	6	7
The high likelihood of finding a suitable job in the field after graduation.	0.930						
The opportunity to work in various types of jobs.	0.877						
The opportunity to work for foreign companies and have high career advancement prospects.	0.869						
The potential to secure high-income employment opportunities.	0.868						
The opportunity to work in a dynamic environment.	0.866						
The reputation and brand of the university.		0.824					
The attractive scholarship and policies offered by the university.		0.752					
The modern and well-equipped training facilities.		0.698					
The convenient location of the university.		0.680					
The excellent admissions process at the university.		0.677					
The affordability of tuition fees at the university.		0.659					
The quality of the faculty teachers		0.658					
Wide access to postgraduate scholarships in the field.			0.971				
Diverse scientific research fields.			0.932				
Diverse training programs, both domestic and international.			0.828				
Higher education specialization opportunities.			0.798				
Being compatible with one's personality traits.				0.872			
Being compatible with one's economic and social conditions.				0.826			
Being compatible with one's research and learning abilities.				0.806			
Being compatible with one's personal preferences.				0.784			
The large annual intake of students.					0.891		
The opportunity to choose suitable training programs.					0.878		
The suitable competition rate for admission.					0.877		
The appropriate admission cutoff score.					0.777		
The advice of teachers.						0.812	

The influence of current students studying at the university.						0.790	
The opinions of friends.						0.770	
Family orientation.						0.752	
Major has highly appealing characteristics							0.886
Major has high graduation rate.							0.814
The opportunities it provides for students to engage in various extracurricular activities, internships, and practical experiences that are beneficial.							0.811
The high demand for skilled professionals in the field.							0.702
Eigenvalue	4.050	3.816	3.215	3.155	3.095	2.877	2.782
Percentage of explained variance	12.657	11.925	10.047	9.859	9.672	8.990	8.694
Cumulative percentage of explained variance	12.657	24.581	34.581	44.488	54.160	63.149	71.844

(Source: Data processing 2023)

Ti Furthermore, we will assess the appropriateness of the factor analysis with respect to the variables associated with the dependent factors.

**Table 4. Suitability test of factor analysis with variables pertaining to the dependent factors.**

Kaiser-Meyer-Olkin Measure of Sampling Adequacy	0.703
(Sig) Bartlett's Test of Sphericity	0.000

(Source: Data processing 2023)

The factor analysis yielded a Sig value of 0.000 for the Bartlett's test, indicating that the null hypothesis (H0) is rejected. The KMO value, which assesses the suitability of the factor analysis, is 0.703 (between 0.5 and 1). This indicates that the dataset used for the exploratory factor analysis is highly appropriate.

**Table 5. Results of factor analysis for dependent variables**

Observed Variable	Factor Loading Coefficient
I have carefully thought and researched before making the decision to choose the International Business major.	0.962
I am satisfied with my decision to choose the International Business major.	0.841
I hold a high opinion of the International Business major that I am currently studying.	0.822
The decision to choose the International Business major is considered appropriate.	0.812

(Source: Data processing 2023)

### 4.3. Results of linear multiple regression model

The general research equation for multiple linear regression is constructed as follows:

$$QD = \beta_0 + \beta_1N_1 + \beta_2N_2 + \beta_3N_3 + \beta_4N_4 + \beta_5N_5 + \beta_6N_6 + \beta_7*N_7 + e$$

- Dependent variable: QD (Decision to choose the Business Administration major)
- Independent variables: N1 (Self-characteristics), N2 (Reference characteristics), N3 (University characteristics), N4 (Future career opportunities), N5 (Field of study characteristics), N6 (Opportunities for higher education, research, and development), N7 (Admission probability).
- e represents the standard error.

**Table 6. Statistical measures of model fit**

Rsquare change	Adjusted R Square	F Change	Sig. F Change	Durbin Watson
0.801	0.796	144.565	0.000	1.998

(Source: Data processing 2023)

The Durbin-Watson statistic (d) of 1.630 indicates that the model does not violate the assumption of autocorrelation. The Variance Inflation Factor (VIF) for each predictor variable is less than 2, indicating that the regression model does not violate the assumption of multicollinearity.

Model fit assessment:

To evaluate the overall fit of the model, we consider the F-value. The F-value is 144.565 with a significance level of 0.000, which is less than 0.050. Therefore, the regression model is appropriate and can be used.

The adjusted R-squared value of 0.796 indicates that 79.6% of the variation in the dependent variable is explained by the seven independent variables.

The regression results for factors influencing the decision to choose the International Business major are as follows:

**Table 7. Results of multiple linear regression using the Enter method**

Model	Standardized Coefficients	t	Sig
(Constant)		0.000	1.000
Future career opportunities	0.209	7.428	0.000
University characteristics	0.457	16.246	0.000
Opportunities for further education	0.139	4.922	0.000
Self characteristics	0.315	11.205	0.000
Admission chances	0.121	4.297	0.000
Reference characteristics	0.591	21.016	0.000
Major characteristic	0.256	9.107	0.000

(Source: Data processing 2023)

The results of the significance tests show that all the Sig values are < 0.05, indicating that all the variables are significant in the model.

Interpretation of regression coefficients in the model:

The multiple linear regression equation can be written as follows:

Student's Decision to Choose Administration Major = 0.591 \* Reference Characteristics + 0.457 \* University Characteristics + 0.315 \* Self Characteristics + 0.256 \* Major Characteristics + 0.209 \* Future Career Opportunities + 0.139 \* Opportunities for Higher Education, Research, and Development + 0.121 \* Admission Chances

From this estimated model, we can see that the variables that have an impact on the decision to choose the Administration major for students are ranked in descending order as follows: (1) Reference Characteristics, (2) University Characteristics, (3) Personal Characteristics, (4) Major Characteristics, (5) Future Career Opportunities, (6) Opportunities for Higher Education, Research, and Development, and (7) Admission Chances.

#### 4. RECOMMENDATIONS

The research results demonstrate that the factor "Reference Characteristics" has the strongest influence on the decision to choose the Business Administration major among students at the Hue University of Economics. In other words, social relationships (family, friends, seniors, etc.) have a significant impact on the decision to choose the Business Administration major among students at the Hue University of Economics. Therefore, influencing these stakeholders to create positive perceptions about the university among high school students will have a significant impact and contribute to increasing the number of high school students intending to choose the Business Administration major at the university. The university needs to build its image among current students by establishing and managing a friendly and optimal learning environment. All departments and individuals in the university should consider students as customers and treat them fairly, friendly, and enthusiastically, providing support to the best of their abilities, so that students have a favorable and positive perception of the university and the faculty. Additionally, it is

important to enhance community engagement activities, student initiatives, and support programs that help others and contribute to the community.

The research findings indicate several factors that influence students' decision to choose the Business Administration major. Firstly, the factor with the strongest impact is "Reference Characteristics," suggesting that social relationships (such as family, friends, and previous students) significantly influence students' decisions. Therefore, it is crucial for the university to actively engage with these stakeholders and create positive perceptions of the institution among high school students. Building a friendly and optimal learning environment, where all faculty and staff treat students as customers with fairness, friendliness, and enthusiasm, is essential. Additionally, enhancing community engagement activities and student initiatives that contribute to society can further attract prospective students.

The second influential factor is the "School Characteristics," encompassing elements like infrastructure, faculty quality, tuition costs, scholarship programs, and admission counseling policies. This highlights the importance of the university's reputation and its admission counseling efforts in students' decision-making. The Hue University of Economics should focus on strengthening its admission counseling activities by establishing regular and close connections with high school students. This would facilitate the introduction and promotion of the university's image and the Business Administration program.

The third factor affecting students' decision is "Personal Characteristics." Students choose the Business Administration major based on its compatibility with their interests, personality traits, and learning abilities. This demonstrates that students carefully evaluate their own attributes before making a decision. When promoting the Business Administration major, the university should clearly outline which personal characteristics are suitable for the field on its website. Furthermore, in admission counseling programs, it is important to provide guidance on which personal characteristics align with specific majors. This would enable students to make well-informed decisions and consider their choices more thoughtfully.

Finally, the "Admission Probability," including entrance exam scores, competition rates, and the number of available slots, influences students' choices. The results indicate that the easier it is to gain admission to the Business Administration major, the more students are inclined to choose it. Consequently, the university should establish annual admission cutoff scores to increase the options available to students and to build a strong reputation for the major.

## **5. CONCLUSION**

This study focused on analyzing the factors influencing students' decision to choose the Business Administration major at Hue University of Economics. The results have constructed a predictive model for the impact of these factors on the decision to choose Business Administration, which shows a positive relationship (with a standardized coefficient of 0.769). Therefore, the article suggests that in order to improve the effectiveness of the admission process, Hue University of Economics should focus on building a long-standing and reputable image of the institution and enhance communication efforts through various media channels to attract students. However, this study still has some limitations. It does not clarify the differences in evaluation among students based on demographic characteristics, educational forms (regular, high-quality programs), and academic performance. The sample size of the study was 259, which may be limited compared to the total number of students enrolled in the Business Administration program at the university. These limitations provide suggestions for future researchers to conduct further studies and investigations.

## IMPACT OF TIKTOK SOCIAL MEDIA MARKETING ON DESTINATION DECISION OF TOURISTS

Nguyen Le Ha Vi<sup>1</sup>, Nguyen Thi Hien,  
Mentor: Tran Duc Tri

*ABSTRACT: Short-form video social networks Tiktok has been adopted to promote products and services, especially in tourism industry. This research investigates the impact of social media marketing on the destination decision of tourists to Hue city. Results from surveying 186 tourists to Hue city show that Electronic word of mouth, Entertainment, and Customization have positive impacts on tourists' destination decision. Two factors Interactivity and Trendiness do not have significant influence on destination decision. This research is helpful for tourism businesses and destination marketing organizations to better promote tourism destination images.*

*Keyword: Social media marketing; Tiktok; destination decision; Hue; tourist.*

### 1. INTRODUCTION

In an era where the internet is developing at an explosive speed, the application of communication platforms in tourism promotion has become indispensable. Social media are applications or programs built on the Internet, allowing users to create and share information, ideas, career interests, and more through technological devices and computer networks (Jonathan A. Obar, 2015).

Hue city has been and is about to bring many cultural events but has not been widely promoted to tourists on social networking platforms. (At the same time, this is one of the oldest places to store the quintessence of traditional traditional culture in our country, the historical and cultural value that Hue brings is extremely high and needs to rise to make it a scenic spot worth visiting. According to statistics of the Department of Tourism of Thua Thien Hue province, the total number of tourists to Hue in 2022 is 2.05 million, an increase of 296% compared to 2021. In December 2022, Hue attracted 196.5 thousand tourists, an increase of 957%; in which, international visitors reached 63.5 thousand tourists; staying guests is estimated at 140.5 thousand tourists; revenue in the month is 437 billion Vietnam dong (ThuaThienHueOnline Article, 2022). In addition, continue to implement solutions to promote the development of the tourism industry, especially digital technology solutions, communication strategies to promote tourism. Implement tourism stimulus programs. Connecting major travel agencies to launch new tour programs to the Central region with the main destination of Thua Thien Hue. Invest in developing a system of commercial centers, supermarkets, high-class shopping centers, multi-functional service areas... Thus , it can be seen that the communication and promotion of Hue tourism is one of the prominent factors affecting tourism demand as well as the development of this industry.

Tiktok is a social network that was released in 2017 and widely attracts consumers' attention. It has vertical interface, showing short video and very potential in the field of entertainment. Vietnam ranks 6th in the top 10 countries with the largest number of TikTok users in the world, with about 49.9 million users. According to Data Reportal data, as of February 2023, there were about 77.93 million Internet users in Vietnam. Thus, more than 64% of Internet users in Vietnam are using TikTok. (P.L, 2023).

<sup>1</sup> University of Economics, Hue University.

TikTok has had a profound impact on the world, bringing about significant changes in various aspects of life and culture. It has become one of the most popular social media platforms globally, revolutionizing the way we create and share short videos. With billions of users, TikTok has fostered a diverse online community, connecting people across nations.

One of the notable influences of TikTok is in the realm of music and culture. It has emerged as a crucial platform for discovering new music, associating songs with unique challenges and trends. Many songs have gained immense popularity and climbed the charts through TikTok's viral spread, transforming how we approach and consume music.

Moreover, TikTok has played a pivotal role in shaping Internet culture. It has birthed distinct trends and challenges, influencing the broader landscape of online culture. Dance routines, comedic skits, and performances have become integral components of the digital culture, with TikTok users rapidly ascending to social media stardom in remarkably short periods.

The platform has also brought about a paradigm shift in marketing and advertising. Due to its massive user base, numerous brands and advertisers have leveraged TikTok as a channel to reach potential customers. Short advertising videos on TikTok have proven to be an effective means of promoting products and services.

Furthermore, TikTok has had a transformative impact on various creative industries. It has created new opportunities for artists, musicians, actors, and other creative professionals. Many young talents have risen to stardom through TikTok, garnering attention from traditional entertainment industries.

In summary, TikTok has fundamentally changed how we approach media, music, Internet culture, and marketing. It has fostered global connectivity and opened up new avenues for creativity and communication in the modern world.

Hue tourism is a destination with potential but has not been strongly exploited on the platform TikTok, an increasingly popular social network. With Hue tourism returning from a hiatus, now is a crucial time to promote and capitalize on the platform's potential. This study was conducted with the aim of analyzing the impact of TikTok social media marketing on the destination decision to Hue. This study hopes to provide managerial implications to help Hue tourism businesses and organizations have a better marketing strategy on Tiktok social network, helping to improve their decision to choose Hue tourism destinations.

## **2. LITERATURE REVIEW**

### **2.1. Tiktok Social Media marketing**

Social media are applications or programs built on the Internet to facilitate the creation or sharing of information, ideas, career interests, and other content over the Internet through devices, technology and computer networks. (Jonathan A. Obar, 2011) (Jonathan A. Obar, 2015). Users typically access social media services through desktop and laptop web applications or download services that provide social media functionality for mobile devices. When users participate in these electronic services, they create highly interactive platforms through which individuals, communities and organizations can share, co-create, and discuss.

Tiktok is a Chinese social media and music video platform (LEE, 2017) was launched in 2017 for markets outside of China, including Vietnam. Tiktok use to create short music, lip sync, dance, comedy and talent videos from 3 seconds to 10 minutes (2018) (2019) and short playback videos from 3 seconds to 60 seconds. (Schwedel, 2018) This application has a vast catalog of sound effects, music tracks and filters to enhance videos and make them more attractive.

Social media marketing is a form of marketing on the Internet through the use of social media channels for the purpose of branding and promoting products or services. Social media marketing is part of digital marketing - a combination of marketing activities (2018). With the strong connectivity of social media channels, where different groups of customers come together to exchange, share, interact, exchange, discuss content, images, etc. The implementation of marketing through these channels is gradually becoming a popular and developed form in the current digital era. When using social media marketing, companies can allow customers and viewers to post user-generated content, also known as “earned media,” instead of using newspapers. advertisements prepared by marketing staff. )

Social media marketing can be impacted by elements including entertainment, trends, engagement, customization, and electronic word of mouth (EWOM). (Mileva & Fauzi DH, 2018) (Cheung M. L., 2019).

**Entertainment** is the ability of advertising to satisfy the viewer’s desire for entertainment, aesthetic pleasure, and emotional release (Genadi, 2020). Through entertainment, brands can build and reinforce a consumer’s sense of closeness to convince them to make a purchase. (Dessart, 2015)

**Interactions** mean that users can provide and receive information in both ways. Posting information that aligns with the goals of a target social media user can foster discussion and improve the relationship between consumers and brands. (Cheung P. &., 2020)

**Trending** means that the marketing channel can provide the latest news and hot topics. Consumers will feel motivated to learn about brand trends Encourage them to keep up with the latest brand developments on social media platforms by searching for trends related to ant awake (Gallaughner & Ransbotham, 2010). Trending information can help capture consumer attention, evoke positive consumer emotions, and drive loyalty intent. (Liu, 2021).

**Customization** is a marketing and messaging service that delights consumers, makes the service customizable, and makes it easy to find information, in order to create value for certain consumers. (Cheung P. &., 2020)

**Electronic word of mouth** is intended for communication made by potential users or those already using a brand or product using social media. EWOM evokes positive emotions in consumers and promotes loyalty intention. EWOM will see the extent to which consumers disseminate and upload information on social media platforms. This is done to communicate about the brand by uploading content to their blog and sharing opinions with others (Cheung P. &., 2020).

## 2.2. Destination decision

### 2.2.1. Tourist destinations

(Gartrell, 1994) definition: “Destinations are geographic areas that have the attributes, features, support and services to attract potential consumers.” In the strategic vision, (Buhalis, 2000) Destination is a mixture of products and services that leave experiences for users. (Stephen J. Page, 2006) Definition: “Destination is a mixture of packaged product and service characteristics such as accessibility, safety, convenience, activities and support services”. As such, the destination must have a certain scope of providing necessary facilities and services to visitors .

Tourist destination is one of the most used concepts in the field of tourism. According to (Cooper, 1998) “A tourist destination is a place where the construction of facilities and services is concentrated to meet the needs of tourists”. (Stephen J. Page, 2006) defines “a tourist destination as a mixture of prepackaged product features, services, accessibility, attraction, amenities, activities and support services”. Rubies defines a destination as a geographical area in which a group of tourist resources and attractive factors are located. The infrastructure, equipment, service providers, other support areas and management organizations with which they interact and coordinate activities to provide visitors with the experiences they expect at the

destination which they choose”. The World Tourism Organization has defined a tourist destination as “the geographical space where tourists stay for at least one night, including tourism products, services provided, Tourism resources attract visitors, have administrative boundaries to manage and have an image identity to determine competitiveness in the market. “ (Nguyễn Thị Lê Hương, 2022) ((UNWTO), 2019)

### **2.2.2. Destination decision process**

Destination decision is the process of selecting tourists from search results and perceiving destination attributes provided by optimal stimuli. (Iso-Ahola, 1980). Destination decision is a process by which potential tourists choose a destination from a set of destinations for the purpose of satisfying their trip-related needs. (Hwang GW, 2006), (Lewis, 2010) The process of choosing a tourist destination consists of five steps, including:

- Identify needs;
- Formulating goals and objectives;
- Establish a set of destination alternatives;
- Seek information on the characteristics of proposed alternative destinations;
- Evaluation and selection of destinations;

### **2.2.3. Destination decision**

Destination decision is the decision to choose a tourist destination is the stage of selecting a tourist destination from a set of destinations that meet the needs of tourists (Um S. a., 1990). According to this author, the decision to choose a tourist destination is the second step in the tourist destination selection process (with the first step being the perception of a suitable set of destinations for the tourist’s needs).

According to (Hwang GW, 2006), destination decision is the decision to choose a tourist destination is the stage in which the tourist chooses a destination from the set of available alternative destinations studied in the previous stages, and becomes a real consumer in the future. tourism sector.

## **2.3. Relationship between social media marketing and destination decision**

Woodside and Lysonski (1989) researched and developed a model of the tourist destination selection process based on the research results that are cognitive and psychological behaviors influenced by tourism marketing activities and tourists. . The authors have tested the model and drawn the conclusion that a product or service is considered by customers for a certain period of time before making a final decision, which is the result of the perception process. scores on attractions, references, comparison with other destinations, intention to visit and destination choice decisions on the basis of the impact of favorable or unfavorable conditions and circumstances. This result is influenced by advertising and communication activities. The marketing factor has a strong impact on tourists’ perception when they go through the stage of finding information about the destination when the need and desire to travel arises. This information can positively or negatively affect the perception of the image of a destination that arises in their mind. Based on this model, marketers can assess the competitiveness of a destination and understand why tourists choose that destination over another. a destination comes to their mind. Based on this model, marketers can assess the competitiveness of a destination and understand why tourists choose that destination over another.

Um and Crompton (1991) applied Chapin’s theory (1974) about two groups of factors affecting tourist destination choice by considering the role of attributes as well as stages in the selection process. destination selection, including awareness, knowledge, commitment, and final destination selection. The concepts mentioned in the model are external factors, internal factors and cognitive components. Specifically:

External factors are considered as a combination of social interactions and marketing communication activities for potential visitors. The internal factors arising from the psycho-social factors of tourists include the personality characteristics of each individual, their motivation for tourism or travel motivation, and values. and attitudes of tourists. Based on the research results, (Um S. &, 1991) created a 5-stage destination choice decision-making model in which the marketing element is added and reused again. Specifically as follows: Visitors will form beliefs about the destination or feel about the destination through the information about the destination that they have access to; tourists should also consider psychological and social constraints when choosing a destination; how cognitive processes are affected by destination perceptions; The formation of trust about the destination also takes place through the information that tourists have about the destination; Select a specific destination from visual recall of that destination.

Through the above two studies, it is shown that the social media platform has a significant impact on the formation of demand and perception of the place, thereby serving as a basis for the decision-making of tourists to choose a destination to visit. tourism. Thus, in the era of the internet growing at an explosive rate like today, the application of communication platforms in tourism promotion has become indispensable.

#### 2.4. Proposed research model

From the theoretical basis of social media, destination choice decision and the relationship between social media and tourist’s destination choice decision, in this study, the authors approach geographical research. A tourist destination is a specific geographical area: Hue city, referred to as Hue tourist destination for short, consists of a collection of integrated tourism products and services to provide visitors with comfortable travel experiences. and memorable.

From the model of Tiktok social media factors that affect consumers’ brand interactions (Santi Rimadias, 2020), the authors selectively inherit the elements suitable for Hue tourist destinations, and at the same time show the benefits of social media. as well as the unique features that the destination wants to offer to visitors in order to stimulate their perception. From there, the study proposes the following research models:

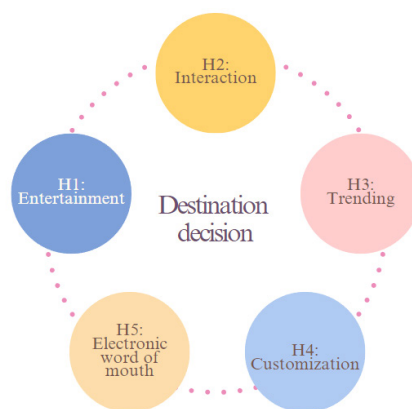

Figure 5 . Proposed research models

### 3. METHOD

#### 3.1. Data collection method

The research focuses mainly on survey respondents belonging to Generation Z (born in 1995 to 2005, ie 18-29 years old). The reason for choosing this age is the age when tourism is booming not only in the world but also in Vietnam. According to the United Nations Population Fund, Vietnam is in the middle of a golden age, with young people (between 15 and 35 years old) accounting for over 30% of the total

population, accounting for the largest proportion (Tran, 2021). Many reports and data from around the world (Dang, 2022) consider young people and young people to be the generation with the highest tourism potential because they love to go out and explore and are willing to spend “a lot of money” on experiences.

Because the survey subjects are tourists coming to Hue, distributed over a large area, the convenient sampling method is suitable for the survey and research process. Research and conduct surveys at popular tourist attractions, such as the Citadel in the period from July 2022 to May 2023. Because time and resources are limited, the questionnaire was collected through a survey of 269 visitors, including both men and women corresponding to different ages from 15-59 years old, with different cultural features between regions of tourists and made in the province of Thua Thien Hue - the destination of tourists.. In which, the survey results obtained have about 186 valid surveys (18 – 29), suitable for the research object proposed by the group for data analysis. Tourists are selected at Hue tourist sites and are accepted to survey if they use Tiktok social network, otherwise will be excluded. The questionnaire was collected from related studies with previous research basis and edited to fit the author’s research.

### 3.2. Data analysing method

This research uses quantitative analysis methods such as Cronbach’s alpha coefficient, factor analysis and regression analysis. Cronbach’s alpha coefficient method is used to evaluate the reliability of the scale. The scale has acceptable reliability when this coefficient is in the range from 0.6 to 0.8. Factor analysis technique is used to evaluate the validity of the scale, thereby adjusting the research model and research hypothesis. According to Hair et al. (2006), the KMO coefficient (Kaiser-Meyer-Olkin) used to consider the suitability of factor analysis must be in the range [0.5-1] and the Bartlett test is statistically significant. millet (Sig. < 0.05). The scales used for factor analysis are Likert scales with 5 levels from 1 strongly disagree to 5 strongly agree used in this study.

### 3.3. Measurement scale

The authors synthesize factors and attributes affecting the choice of tourist destinations from the scale of Santi Rimadias (2020) , and based on the characteristics of communication on Tiktok social network and Hue tourist destination to supplement or remove those attributes deemed appropriate or inappropriate for the study destination. From the combined results, the study collects comments from experts in the field of communication and tourism as a basis for designing the survey questionnaire.

From the proposed research scale, the designed questionnaire consists of three Part: *first* , general information of visitors (gender, age, income , place of residence, number of visits to Hue, time to use Tiktok in 1 day, select and name travel channel) Hue on Tiktok, full names and phone numbers of survey participants) ; *second* , guest reviews of 20 The criterion belongs to 5 factors to measure and evaluate marketing activities about Hue tourism on Tiktok social network.

The 7-level Likert scale is used, which evaluates the factors of social media on Tiktok and decides to choose Hue tourism , showing: *1- completely disagree* to *7 - completely agree* .

## 4. RESEARCH RESULTS

### 4.1. Sample characteristics

Table 1 presents the characteristics of the study sample, showing that the final study sample was collected with 269 tourists, of which 46.5% were male and 53.5% were female. Tourists participating are mainly from 18-29 years old (69.1%), 30-39 years old (13.4%), under 18 years old (7.1%), 40-49 years old age (6.7%) and 50-59 years old (3.7%). Survey subjects are of different ages, so their income levels

are different, income is less than 5 million/month (45.7%), followed by income from 10-15 million/month (19.3% ) income from 5-10 million/month (19.0%), income over 20 million/month (11.2%) and income from 15-20 million/month (4.8%). Regarding provinces and cities, tourists are in Hanoi (9.7%), in Ho Chi Minh City (9.7%), in Da Nang (27.5%) and mainly come from provinces and cities. other (53.2%).

**Table 1: Study sample characteristics**

Characteristic	Quantity	Ratio (%)	Characteristic	Quantity	Ratio
Research sample	269	100	Income		
Sex			Under 5 million/month	123	45.7
Male	125	46.5	from 5-10 million/month	51	19.0
Female	144	53.5	From 10-15 million/month	52	19.3
Age			From 15-20 million/month	13	4.8
Under 18	19	4.8	Over 20 million/month	30	11.2
18-29 years old	186	69.1	City		
30-39 years old	36	13.4	Hanoi	26	9.7
40-49 years old	18	6.7	Ho Chi Minh City	26	9.7
From 50-59 years old	ten	2.7	Danang	74	27.5
Over age 60	0	0	Other	143	53.2

#### 4.2. Scale reliability

Table 2 shows that, the results of Cronbach’s Alpha test are within the appropriate allowable level, no variables are excluded from the model. Therefore, confirmatory factor analysis is performed for the variables in the model.

**Table 2. Cronbach’s Alpha reliability analysis results**

Scale	Symbol	Number of observed variables	Item-Total Correlation	Cronbach’s Alpha
Entertainment	ENT	4	>= 0.596	0.887
Trending	TRUE	3	>= 0.637	0.814
Interact	INT	4	>= 0.786	0.920
Electronic word of mouth	EWOM	3	>= 0.666	0.879
Custom	CUS	4	>= 0.328	0.848
Destination decision to Hue	DS	3	>= 0.574	0.809

All scales have Cronbach’s Alpha coefficient > 0.6 and the total correlation coefficient of the variables in each scale are > 0.3. Therefore, all variables meet the requirements and conduct exploratory factor analysis EFA.

#### 4.3. Exploratory factor analysis

Tables 3 and 4 present the results of the EFA exploratory factor analysis of the evaluation scale of marketing activities about Hue tourism on the social network Tiktok and the scale of deciding to choose Hue tourism. KMO coefficient = 0.768 > 0.5, so factor analysis is appropriate, Sig value. = 0.000 < 0.05, so the variables are correlated with each other in the population.

There are 5 factors extracted based on the Eigenvalue > 1 criterion, so these 5 factors summarize the information of 18 observed variables included in EFA in the best way. The total variance extracted by these 5 factors is 77.753% > 50%, so these 5 factors explain 77.753% of the data variation of 18 observed variables participating in EFA, observed variables have coefficients. loading > 0.5, so the evaluation factors of marketing activities about Hue tourism on the social network Tiktok are appropriate and satisfy the

conditions, specifically, 18 observed variables after performing the analysis are combined into 5 factors: Prize Location, Trending, Interactive, Electronic Word of mouth, Customization.

**Table 3 . The results of exploratory factor analysis EFA**

Variable	KMO	Sig	Eigen value	Extracted Variance (%)	Loading
1. Factors evaluating marketing activities of Hue tourism on Tiktok	0.768	0.000	1.111	0.7775	0.507-0.912
Entertainment					0.703-0.898
Trending					0.705-0.844
Interaction					0.788-0.875
Electronic word of mouth					0.839-0.909
Customization					0.507-0.912
<b>2. Destination decision to Hue</b>	<b>0.681</b>	<b>0.000</b>		0.7363	0.627-0.807

**Table 4 . EFA factor analysis results of the factors**

TT	Factor	Observed variables	Factor				
			F1	F2	F3	F4	F5
1	Interaction	INT1	0.875				
		INT2	0.856				
		INT3	0.845				
		INT4	0.788				
2	Entertainment	ENT3		0.898			
		ENT2		0.878			
		ENT1		0.874			
		ENT4		0.703			
3	Customization	CUS2			0.912		
		CUS3			0.892		
		CUS1			0.879		
		CUS4			0.507		
4	Electronic word of mouth	EWOM3				0.909	
		EWOM1				0.900	
		EWOM2				0.839	
5	Trendiness	TRE3					0.844
		TRE1					0.777
		TRE2					0.705

**4.4. Regression analysis and model testing**

The analysis results show that the research model is consistent with the Sig significance level. <5%. The coefficient  $R^2=0.572$  and the correction coefficient  $R^2$  is 0.314, showing that 31.4% of the variability is explained

by the five components that evaluate the marketing activities of Hue tourism on Tiktok to the decision to choose Hue tourism. The results of ANOVA analysis and F test (Table 5) show that the statistical value is calculated from  $R^2$  the Sig value. = 0.000 (<0.05). This proves that the linear regression model fits the research data.

**Table 5 . The results of the regression analysis of the research model**

Variables	Unstandardized coefficients		Standardized coefficient	t	Significance level (Sig.)	Collinearity statistics	
	B	Error				Tolerance	VIF
Constant	1,978	0.421		4.701	0.000		
Entertainment	0.182	0.069	0.155	2,640	0.009	0.738	1.355
Trending	0.069	0.067	0.066	1.033	0.303	0.635	1.574
Interact	0.095	0.067	0.092	1.403	0.162	0.590	1.694
Electronic word of mouth	0.282	0.038	0.394	7.394	0.000	0.901	1.110
Custom	0.120	0.055	0.130	2.194	0.029	0.724	1.381
<b>Test Indicators</b>							
$R^2$					0.572		
$R^2$ correction					0.314		
F-Statistics (Sig.)					22,528 (0.000)		
Durbin – Watson					1,720		

The results of regression analysis (Table 5) show that the factor of Trendiness, Interaction has Sig value. t-test is 0.303 and 0.162 respectively, which are > 0.05, so these two factors do not have a statistically significant impact on the decision to choose Hue tourism. The remaining three factors are Entertainment, Electronic Word of mouth , Custom Valuable Sig. = 0.009; 0.000; 0.029 < 0.05, so these three factors have a positive impact on the dependent variable The decision to choose Hue tourism has statistical significance.

Standardized regression equation:

$$Y = 0.394*EWOM + 0.155*ENT + 0.130*CUS$$

The results show that the electronic word of mouth factor ( $\beta=0.394$ ) has the strongest impact on the decision to choose Hue tourism. On the social media channel Tiktok, there is also an account specializing in reviewing Hue tourism including landscapes, specialties, traditions, ... and achieved very good outreach effect. It shows that the intention to visit Hue and the intention to return of tourists is created depending on the shared content (including images, sounds, ...) from this review channel and from other websites. users have come to Hue tourism. This is similar to Rimadias (2020)'s study showing the important role of Electronic Word of mouth.

The second is the entertainment factor (beta = 0.155), which affects the formation of Hue tourism decisions because this is the basis for creating excitement from visitors, leading to sharing, posting, etc. Electronic word of mouth element included.

The third is the Custom factor (beta = 0.130). This shows that customers want to receive highly customized and personalized marketing messages instead of generic information. This is also a common feature of new media, as well as media requirements for the new generation of young customers.

Factor Interaction (beta = 0.092 ) does not guarantee statistical significance in the research model. This shows that, on Tiktok social media, the chat interaction between tourists is not really popular and this factor does not affect the decision to choose a tourist destination in Hue.

Besides, the Trendiness factor (beta = 0.039) also does not guarantee statistical significance in the research model. In fact, this factor can affect the decision to choose a tourist destination in Hue because this is the basis for creating interest from visitors, leading to sharing, posting, etc. Entertainment and Electronic

Word of Mouth; There are many trends in Tiktok – factors that help your videos reach more viewers and promote stronger promotion. However, it may be due to the specific characteristics or the time when the author surveyed visitors or the questionnaire for this factor can be confusing, leading to the fact that this factor does not affect or has a negligible effect.

The research results made a discovery when it was the first topic to research on Tiktok social media about Hue tourism. This study highlights the electronic word of mouth (EWOM) element in communicating and sharing information to potential users or those who have used products/services by means of Tiktok social media.

Because this is a research model that has not yet appeared in Vietnam and there are no similar results in related studies, it is not appropriate to compare the data results between this study and other previous studies.

## 5. CONCLUSION

The objective of this study is to test the components of evaluating marketing activities of Hue tourism on Tiktok to the decision to choose Hue tourism. With the above research results as a basis, to provide some useful information for administrators to improve, maintain or improve the factors that contribute to the decision to choose tourism. Hue. The research results show that the three factors of Tiktok social media marketing that affect the destination choice decision are Electronic Word of mouth, Entertainment, and Customization. Two factors that do not have a statistically significant impact are Interaction and Trend.

From the research results, businesses and organizations operating in the field of tourism communication can come up with a more effective marketing strategy on social networks. Specifically, it is advisable to create communication messages that are highly contagious, helping tourists to spread the word of information to other visitors. Communication should be presented for entertainment, not simply for information. In addition, focus should be on Customization, which is personalized and tailored to the needs of each traveler. The other two factors, Interaction and Trending, have no statistically significant effect as well as no negative effect. Tourism businesses and media organizations can consider these two factors further when resources permit.

This study has some limitations since it only focuses on TikTok users aged 18 - 29 years. Firstly, the sampling method is convenient at tourist attractions, so it is not representative and may not include some specific types of tourism. Second, the study only focused on domestic tourists to Hue. Further studies should be carried out on many other tourist destinations and international tourist surveys. Further research can focus on a wider range of objects on tourism in various regions in Vietnam such as Da Nang, Ha Noi, Ho Chi Minh City, etc. Then further research can use other applications to be researched such as Youtube, Facebook, Twitter, etc. Similar research can be done using based on the TikTok phenomenon which is quite rapidly developing as one of the social media. In the future, the social media marketing model can be used to assess the effectiveness of travel media in Hue by using TikTok application.

## FACTORS INFLUENCING CUSTOMERS' DECISION TO PURCHASE ENVIRONMENTALLY-FRIENDLY FOOD IN THE HUE CITY OF HUE

Nguyen Nhu Quynh<sup>1</sup>, Nguyen Xuan Dao<sup>1</sup>, Tong Thi Huong Giang<sup>1</sup>,  
Le Ngoc Thanh Danh<sup>1</sup>, Le Thi Thien My<sup>1</sup>  
Mentor: Tran Ha Uyen Thi<sup>1</sup>

**Abstract:** *The growing global demand for environmentally friendly food can be attributed to increasing concerns regarding health and environmental issues. To facilitate the adoption of eco-friendly food purchasing decisions, it is crucial to examine consumer behavior towards such products. This study aims to investigate the various factors that influence customers' decisions to purchase eco-friendly food in Hue city. In order to achieve this objective, a quantitative approach was employed, utilizing a survey conducted among 225 customers. The sample was selected through convenient sampling from individuals who have shopped, are currently shopping, or plan to shop at Dien May Xanh supermarkets in Thua Thien Hue province. Multiple linear regression analysis was utilized to test the hypotheses. The results indicate that environmental attitude, price, consumption attitude, subjective norms, and eco-friendly food knowledge all have positive effects on customers' decisions to purchase eco-friendly food. These research findings offer valuable insights for businesses, policymakers, and marketers, providing effective strategies for promoting customers' decisions to purchase eco-friendly food.*

*Keywords:* eco-friendly food; purchasing decision; influential factors; Hue city

### 1. INTRODUCTION

Organic food, as defined by JI Rodale, a prominent figure in the field of organic farming in the United States, is distinguished by its lack of pesticides and chemical fertilizers. The global demand for organic food has experienced a notable surge, driven by its perceived benefits for both health and the environment. Consequently, this study aims to delve into the decision-making process of customers when it comes to purchasing eco-friendly food in Hue city, Vietnam, with a particular emphasis on the factors that influence their choices. The city's distinct culinary and cultural heritage, alongside increasing urbanization and a growing awareness of health among its residents, presents an intriguing context for investigating consumer behavior in relation to eco-friendly food.

Existing research conducted by Dang and Nguyen (2020) indicates a rising trend in customer awareness and demand for organic food in Vietnam, primarily motivated by concerns about food safety and environmental sustainability. Notably, Hue city, located in central Vietnam, serves as a significant market for organic food products due to its strong agricultural tradition and local culinary culture (Pham, 2018). However, limited research has been conducted specifically on consumer behavior and decision-making pertaining to eco-friendly food in this region.

To address this research gap, a quantitative approach will be employed in this study. Drawing upon the theoretical framework of the Theory of Planned Behavior (TPB) proposed by Ajzen (1991), the research will explore various factors, including environmental attitude, price, convenience availability, consumption attitude, subjective norms, and eco-friendly food knowledge.

By gaining insights into the motivations driving customers' decisions to purchase eco-friendly food,

---

<sup>1</sup> University of Economics, Hue University

this study will contribute to the existing body of knowledge concerning consumer behavior in the eco-friendly food market. The findings will offer valuable implications for businesses, policymakers, and marketers who aim to promote eco-friendly food consumption and develop tailored strategies that align with the specific context of Hue city, Vietnam.

## **2. BACKGROUND AND HYPOTHESES**

### **2.1. Theoretical framework**

In order to comprehensively analyze customers' purchasing decisions regarding organic food, it is crucial to understand the underlying factors that influence these decisions. Samantha Smith and Angela Paladino (2010) have developed a decision model for purchasing organic food that encompasses inputs, intermediaries, and outcomes. Additionally, this study incorporates relevant theories related to purchasing decisions and builds upon previous research on organic food purchasing decisions as a theoretical foundation. The theories of rational action and planned decision-making, proposed by Ajzen and Fishbein (1980) and Ajzen (1991) respectively, have been extensively utilized in foundational research to comprehend and predict customer purchasing decisions.

The Theory of Planned Behavior (TPB), which has been widely employed in organic food research (Magnusson et al., 2001; Tarkiainen and Sundqvist, 2005), is adopted in this study, following the approach of previous studies. The Theory of Reasoned Action (TRA) suggests that decisions are determined by the evaluation of specific intentions to act (Ajzen, 1991). The concept of decision incorporates the exertion of effort and willingness to implement the decision, encompassing motivations (Ajzen, 1991). Intentions are considered as antecedents to decisions and are regarded as the most reliable predictors of actual decisions (Ajzen, 1991; Ajzen, 2002). To account for situations where individuals may lack complete control over their decisions, such as when product availability constraints influence their purchasing choices, the cognitive element of decision control was introduced to the TRA, leading to the development of the TPB (Ajzen, 1991).

### **2.2. Hypothesis development**

Within the background of TPB, this study develops a conceptual framework shown in Figure 1 for investigating factors influencing customers' decisions to purchase organic food in Hue city. The proposed framework hypothesizes that the customers' decisions to purchase organic food are positively impacted by environmental attitude, price, convenience availability, consumption attitude, subjective norms, and organic food knowledge.

#### **Environment attitude**

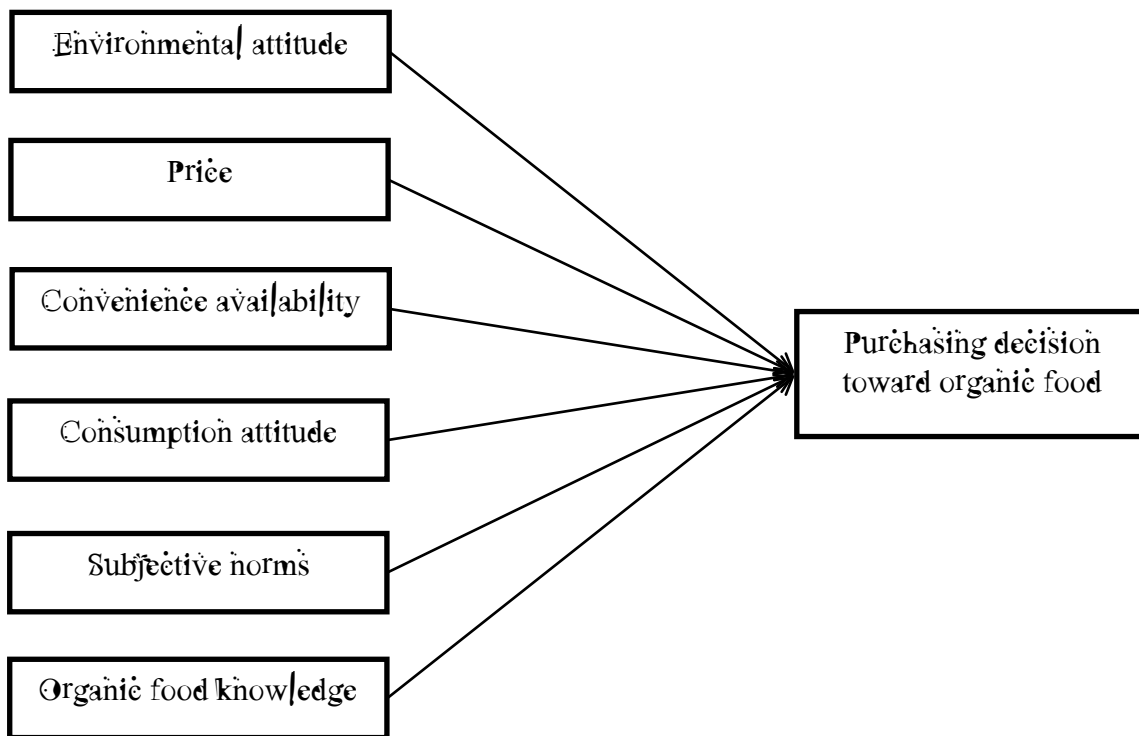

Individual attitudes are conceptualized as the positive or negative sentiments experienced by individuals during the decision-making process (Schiffman et al., Kanuk, 1987). Attitudes play a critical role in shaping individuals' preferences for purchasing, making them a key predictor of decision-making. Previous studies have consistently highlighted the significant influence of attitudes on decisions, with attitude often considered the primary indicator for predicting decisions (Rana & Paul, 2017).

In particular, attitudes towards the environment have been widely recognized as a crucial determinant of decision intentions (Chan & Lau, 2001; Wesley et al., 2012; Law et al., 2017). Consequently, the current study aims to investigate the impact of customers' environmental attitudes on their decisions to engage in environmentally responsible consumption. Based on this, the following research hypothesis is proposed:

Hypothesis: Customers' environmental attitudes positively influence their decisions to engage in environmentally responsible consumption.

By examining the relationship between customers’ environmental attitudes and their decisions to engage in environmentally responsible consumption, this study seeks to contribute to the understanding of consumer behavior in relation to eco-friendly food choices.

*H1: Environmental attitude positively influences the decision to purchase organic food.*

**Figure 1. The conceptual framework**

Source?

**Price**

Customers commonly perceive organic food as being more expensive compared to conventional alternatives (Lea and Worsley, 2005; Magnusson et al., 2001; Raman, 2005). Research by Magnusson et al. (2001) indicates that price is a significant factor influencing consumers’ purchasing decisions, with the expectation that organic food should not carry a higher price tag than conventional products. This implies that customers seek value for their money and require justifiable reasons to justify paying a higher price (Hill and Lynchehaun, 2002; Padel and Foster, 2005). However, providing such justification can be challenging, as customers often lack sufficient information to fully evaluate their purchases (Padel and Foster, 2005). Consequently, customers’ willingness to pay a higher price for organic food is linked to their knowledge of organic food. They seek reasons, such as superior quality or better taste, to justify the premium price associated with organic food.

Price is frequently identified as a significant barrier to purchasing organic food (Lea and Worsley, 2005; Magnusson et al., 2001; Padel and Foster, 2005; Tregear et al., 1994). This barrier is particularly prominent among low-income individuals, for whom high prices can make purchasing organic food difficult or even unfeasible (Tarkiainen and Sundqvist, 2005). However, research suggests that the majority of consumers would increase their consumption of organic food if the price premiums were reduced (Radman, 2005; Lea and Worsley, 2005). While organic food prices generally exceed those of conventional products, prices in certain categories are gradually aligning with conventional goods (Willer and Yussefi, 2006). Therefore,

there is a need to further understand price perceptions in the context of purchasing decisions. It is worth noting that some consumers are willing to pay higher prices for organic food (Lockie et al., 2004; Hutchins and Greenhalgh, 1997; Raman, 2005). Studies have found that customers are willing to spend an additional 10-20% for organic food on average (Lockie et al., 2004; Hutchins and Greenhalgh, 1997; Raman, 2005). This indicates that price premiums may not be a significant barrier to consumer purchases. However, price often conflicts with other motivations, such as environmental concerns (Lockie et al., 2002). In other words, customers may be motivated to purchase organic food due to environmental considerations, but the high prices may limit their ability to do so. Additionally, consumers may face a trade-off between purchasing organic food and allocating money to other luxury items (Tarkiainen and Sundqvist, 2005). This highlights the fact that the organic food market competes not only with conventional food products but also with other commodities.

A willingness to pay a higher price is closely linked to perceptions of quality. Hoang (1996) found that customers are not willing to pay premium prices for organic food if they perceive them to have any defects or image flaws. This suggests that consumers are more inclined to pay higher prices for organic food when they perceive it to be of higher quality compared to cheaper conventional substitutes. Thus, the following hypothesis is proposed:

Hypothesis: Customers' willingness to pay a higher price for organic food is positively influenced by their perceptions of higher quality compared to conventional alternatives.

By examining the relationship between customers' price perceptions, quality perceptions, and willingness to pay for organic food, this study aims to contribute to a better understanding of the role of price in consumers' decision-making processes when it comes to organic food purchases.

*H2: Price positively influences the decision to purchase organic food.*

### **Convenience availability**

Convenience, in the context of purchasing organic food, refers to the ease of availability and the convenience of food preparation at home (Lockie, 2002). Lockie et al. (2004) indicated that a significant barrier to increasing organic food consumption is customer concerns about the convenience associated with purchasing and preparing organic food products. This finding is supported by Mathisson and Scholin (1994), who found that convenience-related factors discourage customers from switching to organic products (as cited in Magnusson et al., 2001). Moreover, Jolly (1991) discovered that the perceived inconvenience of searching for organic products can hinder consumer purchases (as cited in Magnusson et al., 2001)

Hill and Lynchehaun (2002) suggest that customers need to be motivated to switch from their regular brand to an alternative option. Research indicates that transitioning to eco-labeled food products requires consumers to change their habits (Grankvist and Biel, 2001), which requires effort on their part. Furthermore, studies have demonstrated that consumers are unwilling to exert excessive effort to purchase organic food (Padel and Foster, 2005).

Based on the aforementioned arguments, this study proposes the following hypothesis: H3????

### **Consumption attitude**

Attitudes, as defined by Fishbein and Ajzen (1975), encompass individuals' positive or negative evaluations of a specific decision. Similarly, Hoyer et al. (2012) consider attitudes as individuals' positive or negative evaluations of an object, action, problem, or person. MacKenzie et al. (1986) suggest that attitudes should be measured from two perspectives: cognitive and emotional. The cognitive aspect involves evaluation, while the affective aspect involves enjoyment. Sears et al. (1991) propose that attitude

assessment encompasses three aspects: perception, emotion, and decision. Ajzen (2008) introduces two assessment systems, instrumental assessment (whether it is valid or not) and empirical assessment (whether it is interesting or not), which influence attitude bias. In the context of organic food research, the attitudinal variable is often examined in terms of the attitude towards the decision to purchase organic food. Building upon these concepts, the study proposes the following hypothesis:

*H4: Consumption attitude positively influences the decision to purchase organic food.*

#### **Subjective norms**

Subjective norms can be defined as the internalized perception of the desire for the key individuals in the decision maker's life to see them behave in a certain way (Oliver and Bearden, 1985). In simpler terms, subjective norms represent the "perceived social pressure" that individuals feel to make a particular decision (Ajzen, 1991). These norms are influenced by the preferences of reference individuals and their intentions to act in accordance with those preferences (Oliver and Bearden, 1985).

Previous research has demonstrated that subjective norms play a significant role in shaping purchasing decisions (Ajzen, 1991). Bearden et al. (1989) highlight the importance of social influence in determining decisions. Kalafatis et al. (1999) note that engaging in socially commendable actions enhances self-esteem and pride, while failing to do so can lead to feelings of shame. This is particularly relevant to this study as organic consumption has relatively low visibility, implying that subjective norms may have a lesser influence on organic purchasing decisions. While previous studies have differentiated subjective norms based on the effects of different reference groups such as friends, government, and experts on individual decision makers (Parks, 2000), this study does not make such distinctions and considers subjective norms as a unified construct in their influence on the purchasing decision toward organic food. As such, the following hypothesis is proposed:

*H5: Subjective norms positively influence the decision to purchase organic food.*

#### **Organic food knowledge**

Knowledge is widely recognized as a significant influencer in the consumer decision-making process (Laroche et al., 2001). Hill and Lynchehaun (2002) support this notion by identifying knowledge as the primary influencing factor in organic product purchases. Moorman et al. (2004) also found that subjective knowledge influences consumer choices as individuals tend to act in accordance with their knowledge.

Existing research suggests that customers possess a basic understanding of the term "organic" and associate it with being free of chemicals (Hutchins and Greenhalgh, 1997). Lyon et al. (2001) further describe consumers' perception of organic products as natural, raw, and less processed compared to conventional products. However, studies conducted by Hill and Lynchehaun (2002) reveal that while customers grasp the fundamental characteristics of organic products, they lack a deeper understanding of organic farming methods and how they differ from conventional methods. Other research also supports these findings, indicating that customers have limited knowledge of the organic farming certification process (Lockie et al., 2002) and are unfamiliar with the inspection procedures associated with organic production (Padel and Foster, 2005). This indicates that although customers have a basic definition of organic, they lack comprehensive knowledge of its meaning and production processes. Thus, knowledge becomes a crucial influencing factor in the decision to purchase organic food.

Based on the above discussion, the following hypothesis is proposed:

*H6: Organic food knowledge positively influences the decision to purchase organic food.*

### **3. RESEARCH METHOD**

#### **3.1. Data collection**

Quantitative data were collected by using questionnaires to evaluate the relationships as presented in Figure 1. The answers are measured on a 5-point Likert scale: 1 = Strongly disagree, 2 = Disagree, 3 = Neutral (moderate), 4 = Agree, 5 = Strongly agree.

The sample size for this study was determined using the estimation method suggested by Hair et al. (2019), which indicates that a minimum of five samples per estimated parameter is required. Considering the scale used to evaluate customers' decision to purchase organic food, which includes six independent variables and 19 criteria, the minimum sample size was calculated as  $6 \times 19 = 96$ . In order to enhance the representativeness of the sample and ensure a more robust analysis, a total of 234 survey questionnaires were distributed, out of which 225 valid responses were obtained and included in the analysis.

Regarding the demographic composition of the study sample, the proportion of males was 22.2%, while females accounted for 77.8%. The majority of respondents fell within the age group of 20 to 30 years. In terms of occupation, individuals engaged in trading business represented the highest percentage at 32.4%. Furthermore, it was observed that individuals with incomes exceeding 15 million dong constituted the largest proportion at 24.0%. These findings suggest that purchasing organic food may be perceived as an option primarily among individuals with higher income levels.

In summary, the study sample was selected to achieve a higher degree of representativeness within the population under investigation. The collected data will be subjected to further analysis in order to explore the relationships between the identified independent variables and customers' decision-making processes regarding the purchase of organic food.

#### **3.2. Statistical analysis**

In this study, Cronbach's Alpha coefficient was initially employed to assess the internal consistency of the variables and identify any inappropriate variables. Furthermore, exploratory factor analysis was conducted to reduce the large set of variables into a smaller, more manageable set. During this process, variables with factor loading coefficients that differed by less than 0.3 were eliminated (Sandro, 2000). To determine the influence of the independent variables on the dependent variable, multiple linear regression analysis was performed using the method. This analysis helps identify the significance and strength of the relationships between the independent and dependent variables. Additionally, the one-sample t-test method was utilized to assess the suitability of the optimal model. This method compares the means of a sample to a known population mean and determines if there is a statistically significant difference. Furthermore, one-way ANOVA analysis was employed to examine the suitability of the optimal model. This analysis allows for the comparison of means across different groups to determine if there are any significant differences. By employing these statistical methods, the study aims to establish a robust and reliable model that explains the relationship between the independent variables and the dependent variable.

### **4. RESULTS AND DISCUSSION**

#### **4.1. Results**

##### **4.1.1. Scale reliability test results**

To assess the reliability of the observed variables, a scale test is conducted using Cronbach's Alpha coefficient. This coefficient measures the degree of correlation among the variables in the questionnaire, capturing the consistency and internal reliability of the scale (Hays, 1983). Researchers commonly use Cronbach's Alpha to evaluate variables, with the following criteria: Variables with a corrected item-total

correlation greater than 0.3 and a Cronbach's Alpha coefficient greater than 0.6 are considered acceptable and included in subsequent analysis and processing.

The research findings provide the Cronbach's Alpha coefficient for each variable, indicating the reliability of the scale. These results are presented in the accompanying table, allowing for an evaluation of the internal consistency of the variables and their suitability for further analysis and interpretation.

**Table 1. The results of Cronbach's Alpha**

Variable group	Quantity variable	Cronbach's Alpha
Environmental attitude (NTVMT)	4	0.858
Price (GCSP)	4	0.818
Convenience availability (TTSC)	3	0.865
Consumption attitude (TDTD)	3	0.769
Subjective norms (CCQ)	5	0.831
Organic food knowledge (KTVHC)	3	0.758

(Source: The data analysis results, 2023)

#### 4.1.2. Exploratory factor analysis results

After ensuring the reliability of the scale, the study proceeded with exploratory factor analysis (EFA). EFA is a technique used to summarize and reduce data, making it particularly useful in identifying the variables relevant to the research problem and establishing relationships between them. During EFA, the Kaiser-Meyer-Olkin (KMO) measure is used to assess the suitability of factor analysis. The KMO value should fall between 0.5 and 1 for the analysis to be considered appropriate. If the KMO value is below 0.5, it indicates that factor analysis may not be suitable for the dataset (Hair et al., 2019).

Furthermore, the Eigenvalue criterion is utilized in EFA to determine the number of factors to retain. Factors with Eigenvalues greater than 1 are considered meaningful and retained in the model. The Eigenvalue represents the amount of variation explained by each factor, and factors with Eigenvalues less than 1 do not summarize information better than the original variables.

An important output of factor analysis is the component matrix or rotated component matrix. This matrix consists of coefficients that represent the standardized variables in relation to the factors. The factor loading coefficients indicate the correlation between variables and factors, reflecting the strength of the relationship between them.

Additionally, the KMO coefficient and Bartlett's test are performed as part of the analysis. The purpose of these tests is to reject the hypothesis that variables are not correlated with each other in the population. If this hypothesis is not rejected, it suggests that factor analysis may not be appropriate for the dataset.

By examining the results of the factor analysis, the study aims to determine the underlying factors and their relationships, allowing for a more concise and interpretable representation of the data. Table 2 and 3 indicate results of EFA analyses of independent variables and dependent variables, respectively.

**Table 2. Results of EFA analysis of independent variables**

KMO and Bartlett's Test		
KMO coefficient		0.713
Bartlett's test	When Squared (Chi-Square)	2590.701
	DF	300
	Sig.	0.000

(Source: The data analysis results, 2023)

**Table 3. Results of EFA analysis of dependent variables**

<b>KMO and Bartlett's Test</b>		
<b>KMO coefficient</b>		<b>0.648</b>
Bartlett's test	When Squared (Chi-Square)	101,759
	Standard Deviation (df)	3
	Significance level (Sig.)	0.000

(Source: The data analysis results, 2023)

As Tables 2 and 3 show, the analysis includes the KMO (Kaiser-Meyer-Olkin) test and the Bartlett test. The KMO coefficient, which measures the sampling adequacy for factor analysis, has a value of 0.648. Since the KMO coefficient falls within the acceptable range of 0.5 to 1, it indicates that the observed variables are correlated with each other within the factor. Additionally, the statistical significance (Sig) value of 0.000 (less than 0.05) obtained from the Bartlett test confirms that the exploratory factor analysis is appropriate for the data. These results suggest that the variables are suitable for further analysis and interpretation using factor analysis.

**Table 4. The dependent variable factor rotation matrix**

<b>Component Matrix <sup>a</sup></b>	
	<b>Factor loading</b>
QD1	0.670
QD2	0.577
QD3	0.561
Eigenvalues	1.884
Cumulative Variance (%)	62.784

(Source: The data analysis results, 2023)

The load coefficient values >0.5 satisfy the condition, so the observed variables are kept. The observed variables of the dependent variable only single out one factor, proving that the scale ensures unidirectionality, the observed variables of the dependent variable converge quite well. The analysis results show that there is a factor extracted at Eigenvalue equal to 1.884 > 1. This factor explains 62.784 % of data variation of 3 observed variables participating in EFA.

**4.1.3. Correlation regression analysis**

From the results of running EFA analysis, there are 6 independent variables when included in the regression. After the correlation test, the remaining factors are 5 factors affecting the decision to purchase organic food in Hue: environmental attitude (NTVMT), price (GCSP), consumption attitude (TDTD), subjective norms (CCQ), and organic food knowledge (KTVHC ).

The study carried out tests on the relevance of the correlation model (adjusted R<sup>2</sup> value is 0.988 (>0.5) and Sig. of the F test is 0.000 (<0.05)), as well as test determine the defects of the model (Durbin-watson value = 1.396 < 2.6 and VIF values are all less than 10). This proves that the theoretical model also meets the requirements to ensure meaningfulness.

Test the accepted statistical hypotheses (NTVMT, GCSP, TDTD, CCQ, KTVHC) with the corresponding standardized regression coefficients of 0.435; 0.292; 0.412; 0.369; 0.459. The corresponding t-statistic values are, respectively. The general regression equation of the model is rewritten as follows:

$$QD = 0.004 + 0.435 \times NTVMT + 0.292 \times GCSP + 0.412 \times TDTD + 0.369 \times CCQ + 0.459 \times KTVHC$$

Through the coefficient  $\beta$  in the regression model, we know the importance of the factors participating in the equation. The coefficients  $\beta$  all have positive values, showing that the independent variables all

have the same effect on the dependent variable. Any change in the above factors can influence customers' decision to purchase organic food in Hue city. The results show that Organic food knowledge has the highest standardized Beta coefficient ( $=0.459$ ), reflecting the strongest impact on customers' decision to purchase organic food in Hue city. This is followed by the Environmental attitudes ( $=0.435$ ), Consumption attitude ( $=0.412$ ), Subjective norms ( $=0.369$ ), and finally Price with the same standardized beta of 0.292.

#### 4.1.4. One-sample t-test for the factor

One-sample t-test is a hypothesis test about the population mean, used to compare the mean of a population with a specified value (Test value).

**Table 5. Results of one sample t-test of independent variables**

Factor groups	Mean	Test value	Level of significance
NTVMT	3.46	3	0.000
GCSP	3.86	3	0.000
TDTD	3.82	3	0.000
CCQ	3.51	3	0.000
KTVHC	3.31	3	0.000

(Source: The data analysis results, 2023)

The results of one sample t-test analysis by each factor in the decision to purchase organic food in Hue city are shown in Table 5. This analysis aims to test the difference between the mean value of the factors and the test value used (value = 4).

The results show that all factors have a fairly high average value. For example, the mean value of the factor "Environmental attitude" (NTVMT) is 3.46, "Price" (GCSP) is 3.86, "Consumer attitude" (TDTD) is 3.82, The "subjective norm" (CCQ) is 3.51, and "Organic food knowledge" (KTVHC) is 3.31.

However, when conducting one sample t-test, these mean values are not significantly different from the test value used of 3. All factors have the same significance level (Sig) of 0.000, indicating that the difference is very small and insignificant.

This result shows that the factors in the decision to purchase organic food in Hue have no significant difference with a test value of 3. This may indicate that customers in Hue tend to accept, recognize, and appreciate factors related to organic food, including environmental attitudes, prices, consumption attitudes, subjective norms, and food knowledge.

#### 4.2. Discussion

The theoretical framework of this research is rooted in the model developed by Samantha Smith and Angela Paladino (2010), which explores the factors influencing the decision to purchase organic products. Additionally, the theories of rational action and planned behavior, specifically the Theory of Reasoned Action (TRA) and the Theory of Planned Behavior (TPB), serve as fundamental frameworks to understand and predict consumer purchasing decisions.

The TRA, initially proposed by Ajzen and Fishbein (1980) and further developed by Ajzen (1991), suggests that decisions are made based on the evaluation of desirability and expectations associated with a particular behavior. In the context of this study, the decision refers to the effort an individual is willing to invest in implementing the decision, including their motivations. The TRA considers decisions as crucial antecedents to behavior and views them as strong predictors of actual behavior.

Building upon the TRA, Ajzen (1991) introduced the TPB, which incorporates the concept of cognitive decision control. This addition addresses situations where individuals may have restricted decision-

making control,, for instance when product availability limits their choices. The TPB extends the TRA by considering external factors and perceived behavioral control in the decision-making process. It recognizes that individuals' decisions and behaviors are influenced not only by their attitudes and subjective norms but also by their perceived control over the decision.

These theoretical frameworks, including the TPB and TRA, have been widely applied in previous research on consumer behavior, including studies focused on organic products (e.g., Magnusson et al., 2001; Tarkiainen and Sundqvist, 2005). Consistent with these prior studies, the current research incorporates the TPB to understand and predict customers' decisions to purchase organic products.

By utilizing these established theories and frameworks, this study aims to provide valuable insights into the decision-making process of customers when purchasing eco-friendly food in Hue city, Vietnam. It seeks to identify the factors that influence their choices and contribute to the existing body of knowledge on consumer behavior in the eco-friendly food market.

## 5. CONCLUSION

This study identifies five factors that influence the decision to purchase organic food: (1) Environmental attitude, (2) Price, and (3) Consumption attitude, (4) Subjective norms, and (5) Organic food knowledge. These factors are derived from the theoretical framework of organic food purchase decisions, consumer behavior theories, and previous research on the topic. Among these five factors, "Organic food knowledge" has the strongest impact on the purchasing decision of customers in Hue city, followed by "Environmental attitudes", "Consumption attitudes", "Subjective norms", and finally "Price," which has the weakest influence.

The study reveals that most respondents in Hue city have a relatively positive assessment of their decision to purchase organic food (towards agreement). This indicates a growing demand for organic food in the city, as well as the recognition of environmental concerns. Consequently, businesses face challenges in developing strategies to attract customers in this context. Therefore, it is crucial for businesses to promptly plan and adapt their strategies for the increasing trend of the decision to purchase organic food.

It is important to note that this study was conducted over a one-year period in Hue city, which may limit the generalizability of the findings. Because the sample size is limited, the results of the study may be subjective. In addition, several solutions are proposed based on the assessment and analysis of how factors affect the "Consumption decision of customers in Hue City". Overall, this research highlights the factors influencing the decision to purchase organic food in Hue city, emphasizing the significance of food knowledge and the need for businesses to adapt their strategies accordingly. However, it is important to consider the limitations of the study and further research is required to validate and expand upon these findings.

## VISITORS' ASSESSMENT OF THE TOURISM DESTINATION IMAGE AT HUE CITY

Nguyen Thi Kieu Oanh<sup>1</sup>, Ho Nguyen Dieu Anh<sup>1</sup>, Nguyen Ngoc Mai<sup>1</sup>,  
Hoang Hanh Nguyen<sup>1</sup>, Tran Thi Thu Que<sup>1</sup>  
Mentor: Tran Doan Thanh Thanh<sup>1</sup>

**ABSTRACT:** *The perception of a tourist destination plays a crucial role in determining the success of its tourism industry. This study focuses on Hue City and utilizes survey data from 100 randomly selected domestic tourists to assess their perception of the destination's image. The findings indicate that the majority of tourists hold positive views and express a willingness to revisit Hue; however, negative opinions about certain aspects of the destination also exist. Based on these results, the study proposes several strategies to enhance tourists' positive experiences, including promoting the destination through television series, encouraging infrastructure development, and diversifying tourism products.*

**Key word:** *Destination image, Tourism, Hue*

### 1. INTRODUCTION

Hue, renowned for its possession of five world cultural heritages and abundant diverse human and natural tourism resources, holds a prominent status as a national tourist destination. The tourism sector has been recognized as a pivotal driver of the province's economy. In conjunction with the establishment of the Hue Festival brand, the province of Thua Thien Hue, specifically Hue city, is diligently striving to cultivate a distinctive tourist destination image that leaves an enduring imprint in the consciousness of every visitor (Nguyen Thi Le Huong & Truong Tan Quan, 2019).

According to statistics of Thua Thien Hue Department of Tourism, the number of tourists visiting in 2018 reached 4.3 million visitors, of which international visitors reached nearly 2.2 million / year, in 2019 reached 4.8 million visitors, of which international visitors reached 2.1 / year. However, by 2020, due to the impact of the Covid pandemic, the total number of visitors to Hue will only reach 1.687 million, a decrease of nearly 65% (of which, international visitors are estimated at 558.841 thousand arrivals, a decrease of nearly 75%). Revenue from tourism reached about 3,839 billion VND, down 66% (Government e-Newspaper, 2020). With the goal of developing tourism into a spearhead economic sector, striving by 2030 to build Thua Thien Hue to become a destination on par with world cultural heritage cities, striving by 2030 to affirm Hue as a destination. As one of the national tourist destinations, tourism services are identified as a key factor in the local development, accounting for over 55% of GDP contribution (TT.Hue Provincial People's Committee, 2013).

Therefore, building a destination image to move towards building a tourism brand in Hue City in particular and Thua Thien Hue province in general is a matter of concern. Striving to 2030 to build Thua Thien Hue to become a destination on par with world cultural heritage cities, striving by 2030 to affirm Hue as one of the national tourist destinations, tourism services are identified and determined to be a

---

<sup>1</sup> University of Economics, Hue University.

key factor in local development, accounting for over 55% of GDP contribution (TT.Hue Provincial People's Committee, 2013). Attributes must represent a specific destination image with its features, so the results of studies on tourist destination images show that there is no fixed set of attributes to measure. However, tourists' rational perceptions at a destination can manifest either positively or negatively, so it will affect tourists' evaluations of that destination in the same way (Nguyen Thi Le Huong, 2019). Therefore, this study was conducted with the aim of assessing visitors' perceptions of Hue's tourism destination image, thereby proposing some solutions to contribute to building an attractive image.

## **2. Theoretical foundations**

### *Tourism*

According to the World Tourism Organization (UNWTO), tourism is the activity of going to a place other than the usual human habitation and staying there for sightseeing, rest, entertainment or other purposes. purposes other than remunerated activities in the destination for a continuous period of less than one year.

According to the Law on Tourism of Vietnam (2017), tourism is activities related to the trip of people (individuals or groups) to places not belonging to their regular residence area for the purpose of sightseeing, entertainment, recreation, vacation for a period not exceeding one consecutive year (excluding work purposes).

### *Tourists*

Tourist is a person who travels or combines tourism, except in the case of studying or working to receive income in the destination. Tourists include domestic tourists, international tourists to Vietnam and tourists going abroad (Vietnam Tourism Law, 2017).

### *Travel destinations*

In Vietnam, the Law on Tourism has no concept of tourist destination, only refers to the concept of tourist destination. A tourist destination is understood as a place with attractive tourist resources, serving the sightseeing needs of tourists.

### *Pictures of tourism destinations*

There are many concepts of destination image pointed out by researchers. Considered the pioneers of tourism image research, in the book "Tourism and Resort Development", Baud-Bovy . & Lawson (1977) indicate that destination image is the expression of all knowledge, impressions, imagination, feelings of an individual or a group of people about a certain place. Phelps (1986) states that "Destination image is the perception or impression of a place". Tapachai & Waryszak (2000) define "Destination image is the perception or impression of a destination by tourists with expected benefits and consumption values" (Truong Thi Hoang Hanh, 2017). Although formed in different contexts and times, the above image concepts of destinations all have in common that they focus on the "impression" or "perception" of visitors. The repetition of these terms shows that tourists are the ones who will determine the tourist image of any destination (Nguyen Thi Le Huong & Truong Tan Quan, 2019).

### *Scale and criteria for evaluating tourism destination image*

The difference in factors of each individual will lead to different evaluations of a tourism contract. There are two main groups of factors affecting the formation of tourism contract, namely personal factors and travel experience. In which, cognitive assessment will be based on the individual's beliefs and understanding of a destination; and sentiment evaluation will be based on the individual's feelings towards that destination. Specifically, individual factors include psychological factors such as tourist values, motivations and personality; and social factors such as age, education, marital status and other characteristics (Nguyen Thi Le Huong, 2019).

Attributes must represent a specific destination image with its features, so the results of studies on tourist destination images show that there is no fixed set of attributes to measure for every destination. However, tourists' rational perceptions at a destination can manifest either positively or negatively, so it will affect tourists' evaluations of that destination in the same way (Nguyen Thi Le Huong, Truong Tan Quan, 2017).

Echner and Ritchie (1991) also compiled and organized a list of 34 destination image attributes from 14 studies using structural methods. In which, the number of studies measuring destination image attributes are used a lot, such as: Attractions of landscape, nature, friendliness and sincerity of people, Cost and price., Tourist attractions and activities, Nightlife and entertainment, Sports activities.

Beerli & Martin (2004) gave 9 attributes: (1) Natural resources/Destination attractiveness; (2) Recreation and entertainment; (3) Natural environment; (4) General infrastructure; (5) Culture, history and art; (6) Social environment; (7) Tourism infrastructure; (8) Political and economic factors and (9) Atmosphere to measure destination image.

For the tourist destination of Hue, Lien Tran Thi Ngoc (2015) clarified the Hue city tourism policy through the cultural and historical characteristics with the highlighted attributes: Temples, pagodas and tombs of the Nguyen Dynasty. Le Thi Ha Quyen (2017), added Spirituality, safety, friendliness and Recreational, festival and sports activities to measure tourism performance in Hue city. Nguyen Thi Le Huong & Truong Tan Quan (2019), in the study to measure the tourism satisfaction of Thua Thien Hue tourism, approached according to the components of cognitive image and emotional image, in which 7 factors that make up the image have been identified. Perceptions include: (1) Natural attractiveness, (2) Cultural and historical attraction, (3) Tourism and recreational activities characteristics, (4) Hue uniqueness, (5) Tourism environment and infrastructure, (6) convenient transportation and (7) Accessibility and price.

On that basis, within the scope of this study, the assessment of domestic tourists to the tourism destination Hue City has been considered on the following attributes: (1) Tourism environment; (2) Cultural Heritage; (3) Natural scenic spots; (4) Cuisine; (5) Tourist services and (6) Local people.

### **3. METHODS OF STUDY**

#### **3.1 Data collection**

Secondary data collection method: Secondary data is collected through the Statistical Yearbook of Thua Thien Hue province, from reports of the authorities... In addition, the study also synthesizes many documents from related studies.

Primary data collection method: Primary data was collected through survey 100 tourists by random sampling method. Due to the context of the Covid-19 epidemic, the method was implemented by the research team by designing votes on the Google form tool, then posting on forums, pages, groups about tourism... based on questionnaires designed and prepared for research purposes.

#### **3.2 Analyzing and processing data**

*Data processing methods:*

Secondary and primary data were synthesized and processed using Excel and SPSS software version 26.0.

*Data analysis methods:*

Descriptive statistical methods, synthesis and data analysis to assess the perception of tourist destination image Hue City.

**4. RESULTS**

**4.1. General information about the survey sample**

1. Destination

Among the 100 surveyed tourists, there are tourists from Hue City including 37 subjects (accounting for 37.0%); From Outer province, there are 63 people (accounting for 63.0%); Most of the survey samples are from out-of-province visitors, so the survey results will be more influenced by out-of-province visitors.

**Table 1. General information about the survey sample**

<b>Targets</b>	<b>Quantity (People)</b>	<b>Ratio (%)</b>
Destination		
Hue city	37	37.0
Out of province	63	63.0
Sex		
Male	39	39.0
Female	61	61.0
Age		
15-25	65	65.0
26 - 35	19	19.0
36 -45	8	8.0
Over 45	8	8.0
Job Status		
Students	54	54.0
Working	37	37.0
Unemployed	9	9.0

*Source: Investigation and data processing in 2022*

2. Sex

Based on the results of the table above, we can see that there is a large difference in the sex ratio of Male and Female. Of the 100 surveyed subjects, 39 are male (accounting for 39.0%) and 61 are female (accounting for 61.0%). Since women make up the majority, their opinions about destinations will be more practical, because men are often less interested in this issue.

3. Age

Among the 100 surveyed tourists, there is a group of tourists from 15 to 25 years old, 65 (accounting for 65.0%) with this age group often they will travel to many places, so they will have a practical view for tourism destinations in Hue compared to other provinces. From 26 to 35 years old, there are 19 people (accounting for 19.0%); From 36 to 45 years old, there are 8 people (8.0%); And From 45 years old and above, there are 8 people (accounting for 8.0%).

4. Job Status

Among the 100 surveyed tourists, there are: 54 people are studying (accounting for 54.0%), this shows that the cost of traveling to Hue is not as expensive as other places, so it is attractive to students. There are 37 people working (accounting for 37.0%); and 9 people are unemployed (accounting for 9.0%).

**4.2. Source forming the image of tourism destination**

It is essential to consider the sources of formation of the destination image containing the “beliefs, impressions, emotions and expectations” of each visitor. The formation of the destination image can come from information sources, images and personal factors of the interviewed tourists as shown in Table 2).

**Table 2. Source of image formation of tourism destination for Hue City**

Criteria	Quantity (People)	Ratio (%)
Information sources		
Social networks, newspapers, advertising channels	31	31.0
Friend	18	18.0
Relatives	17	17.0
Growing up in Hue	26	26.0
Other...	8	8.0
Frequency to Hue		
1-3 times	30	30.0
3-5 times	9	9.0
More than 5 times	61	61.0
Number of places to know in Hue		
1-3	20	20.0
3-5	16	16.0
Over 5	64	64.0

Source: Investigation and data processing in 2022

### 1. Sources of information about Hue

Among the 100 tourists surveyed, 31 tourists know about Hue through social networking sites, newspapers, advertising channels (accounting for 31.0%); From Friends has 18 people (accounting for 18.0%); From Relatives, there are 17 people (accounting for 17.0%); Know because Growing up in Hue, there are 26 people (accounting for 26.0%); And 8 people chose other information sources (accounting for 8.0%).

Most people know about Hue through social networking sites, newspapers, and advertising channels, so this helps us know that we need to develop and promote Hue tourism through social networks so that people approached and wanted to visit Hue.

### 2. Number of visits to Hue

Among the 100 surveyed tourists, 30 tourists have been to Hue from 1 to 3 times (accounting for 30.0%); Having been to Hue from 3 to 5 times, there are 9 people (accounting for 9.0%); And Over 5 times, 61 people (accounting for 61.0%) is a very high number, proving that Hue also has many attractive things that make them come back many times. But this number does not show that they come to Hue for what purpose is to visit, experience, or just visit a place in their travel itinerary to another place.

### 3. Number of places in Hue that tourists know

Among the 100 tourists surveyed, there are tourists who know from 1-3 places in Hue, including 20 people (20.0%); Know from 3 to 5 places with 16 people (accounting for 16.0%); And know over 5 places with 64 people (accounting for 64.0%).

## 4.3. Visitors' opinions on tourism destination image Hue City

### 4.3.1. Visitors' assessment of the tourism environment

**Table 3. Visitors' assessment of the destination environment in Hue**

Environment of tourist destinations	Quantity (People)	Ratio (%)
Clean	65	65.0
Normal	33	33.0
Polluted	1	1.0
Other	1	1.0
Total	100	100.0

Source: Investigation and data processing in 2022

*The environment of Hue tourist destinations*

Among the 100 tourists surveyed, there are: 65 people who feel the environment of Hue tourist destinations is clean and beautiful (accounting for 65.0%); The group of tourists who perceive the environment of Hue tourist destinations is usually 33 people (accounting for 33.0%); The group of tourists perceived the environment of Hue tourist destinations to be polluted with 1 person (accounting for 1.0%); And the other perception is that there is 1 person (accounting for 1.0%). The majority of tourists have a good perception of the environment at the tourist destination, which plays an important part in creating a good impression for tourists about the destination.

**4.3.2. Visitors' assessment of history and cultural and traditional heritages**

Of the 88 visitors who felt Interesting, 32 tourists were attracted by Historic Sites (accounting for 36.4%); Attracted by Hue Cuisine has 32 visitors (accounting for 36.4%): these two factors account for equal proportions because historical sites are always open to sell tickets to visitors and especially on major holidays During the year there are also promotions and ticket discounts; In the center of Hue city, there are many restaurants and eateries that are always open, so any visitor at any time can visit the destinations and enjoy the cuisine here. Attracted by Culture/Festival has 12 people (13.6%) because not every time traveling in Hue has big festivals, if you want to experience a big festival in Hue, you have to see for example: In what month is the festival held, so are the royal festivals, so culture - festivals account for a small percentage is inevitable; Attracted by people with 9 visitors (10.2%); And there are 3 tourists attracted for other reasons (accounting for 3.4%).

**Table 4. Cultural heritage and traditional factors attracting tourists to Hue**

Cultural heritage, tradition	Quantity (People)	Ratio (%)
Historical sites	32	36.4
Culture/Festival	12	13.6
Cuisine	32	36.4
Human	9	10.2
Other...	3	3.4
Total	88	100.0

Source: Investigation and data processing in 2022

The historical sites that make the most impression and appreciation for tourists are shown in the following table:

**Table 5. Historical sites make visitors feel most attractive**

Historical heritage	Quantity (People)	Ratio (%)
Modern interior	51	51.0
Mausoleum	17	17.0
Pagoda	18	18.0
Souvenir houses	6	6.0
Other...	8	8.0
Total	100	100.0

Source: Investigation and data processing in 2022

*Historical sites attract most tourists*

Among the 100 tourists surveyed, 51 tourists were attracted by the Citadel (51.0%) because this is the symbolic image of Hue city, the image that when it comes to tourists, they all know it is the image of Hue city. Hue, this place has ancient features, hidden about feudal stories, an idyllic beauty that is nowhere else, skillful architecture so most tourists are attracted here; Attracted by the Mausoleum has 17 people (accounting for

17.0%); The pagoda has 18 people (accounting for 18.0%); The memorial houses have 6 people (6.0%); And 8 tourists were attracted by Other Monuments (accounting for 8.0%). In short, Hue is known as famous for its ancient architectures, is a city of heritages, temples, mausoleums with ancient breath and traditions of an ancient glory, so you should visit this place. New visitors are impressed by these destinations.

**Table 6. Visitors' perceptions of spiritual attractions**

Spiritual tourism	Quantity (People)	Ratio (%)
Beautiful / ancient	74	74.0
Bad / Simple	1	1.0
sacred	23	23.0
Other...	2	2.0
Total	100	100.0

*Source: Investigation and data processing in 2022*

#### *Visitors' opinions on spiritual tourism*

Among the 100 tourists surveyed, there are 74 tourists who have a perception of the beautiful / ancient Kinh spiritual tourism (accounting for 74.0%); Feeling spiritual tourism Sacred has 23 people (accounting for 23.0%) because this is the land of hundreds of years of temples and shrines and is also the land of the sacred, so most tourists appreciate Hue; Perception of spiritual tourism Bad/ Simple has 1 person (accounting for 1.0%); And There are other impressions There are 2 people (accounting for 2.0%).

#### **4.3.4 Visitors' opinions on natural scenic spots**

**Table 7. Visitors' ratings of scenery in Hue**

Scenery	Quantity (People)	Ratio (%)
Huong river	41	41.0
Truong Tien Bridge	40	40.0
Thien An Hill	7	7.0
Vong Canh Hill	10	10.0
Other scenery	2	2.0
Total	100	100.0

*Source: Investigation and data processing in 2022*

#### The most impressive landscape

Among the 100 tourists surveyed, 41 tourists were impressed by the Perfume River (accounting for 41.0%), and the Truong Tien Bridge had 40 people (accounting for 40.0%) because these two images always go together, coming to Hue. both see these two images so it is very familiar to locals and tourists alike. Thien An Hill has 7 people (accounting for 7.0%), Vong Canh Hill has 10 people (accounting for 10.0%) because these two landscapes were previously very little known, little interested and it is not a special image. Only when the films filmed here appear on the screen, will customers know about the cool and peaceful natural scenery. Since then, many people know about these two landscapes, especially young people. And other scenery with 2 people (accounting for 2.0%).

**4.3.5 Visitors’ opinions on Hue City’s cuisine**

**Table 8. Visitors’ opinions on food**

Cuisine	Quantity (People)	Ratio (%)
Tasty	45	45.0
Diversity, richness	53	53.0
Not my favorite	0	0.0
Other...	2	2.0
Total	100	100.0

Source: Investigation and data processing in 2022

*Visitors’ opinions on Hue cuisine*

Among the 100 tourists surveyed, 45 tourists commented on the delicious Hue cuisine (accounting for 45.0%) because the characteristics of Hue dishes are bold and very spicy; 53 visitors commented that Hue cuisine is diverse and rich (accounting for 53.0%) because it is said that Hue has 1001 dishes; No one commented that Hue cuisine did not suit the taste (accounting for 0.0%); And 2 people have other comments about Hue cuisine (accounting for 2.0%). Most of the tourists have a very good impression of the food in Hue, this is very important in forming a good feeling about Hue, because to any destination, we have to stop. You can enjoy the cuisine in that place to see how it is different from where you live and especially how much it is different from the same dish but processed elsewhere.

**4.3.6. Visitors’ evaluation of tourism services**

**Table 9. Visitors’ opinions on services at the destination**

Service at the destination	Quantity (People)	Ratio (%)
Satisfied	76	76.0
Normal	23	23.0
Unsatisfied	1	1.0
Other...	0	0.0
Total	100	100.0

Source: Investigation and data processing in 2022

*Review of services in Hue*

Among the 100 tourists surveyed, 76 tourists are satisfied with services in Hue (accounting for 76.0%); Thank you Teacher Normally there are 23 people (accounting for 23.0%); Dissatisfied with 1 person (accounting for 1.0%); And No one feels Other (accounting for 0.0%).

*Tourists love to take a cruise and listen to Hue songs on the Perfume River*

Among the 100 surveyed tourists, 76 tourists like to go on a cruise and listen to Hue songs on the Perfume River (accounting for 76.0%), Hue songs usually take place at night and mainly sing Hue folk songs. which is not available in other places, so every tourist coming to Hue wants to once sit on a boat along the Perfume River and listen to Hue songs in the evening, in the summer it is very cool and suitable for this; There are 19 people who don’t like to go on a cruise and listen to Hue songs on the Perfume River (accounting for 19.0%).

**Table 10. Visitors' opinions on cruising and listening to Hue traditional songs**

<b>Boat service and listening to Hue songs</b>	<b>Quantity (People)</b>	<b>Ratio (%)</b>
Used	76	76.0
Not used	19	19.0
Other	5	5.0
Total	100	100.0

#### 4.3.7. Visitors' opinions on local people

**Table 11. Visitors' perceptions of local people**

<b>Visitors' opinions on local people</b>	<b>Quantity (People)</b>	<b>Ratio (%)</b>
Friendly	76	76.0
Unapproachable	1	1.0
Sociable	22	22.0
Other...	1	1.0
Total	100	100.0

Source: Investigation and data processing in 2022

#### *Visitors' opinions on local people*

Among the 100 tourists surveyed, there are: The group of tourists who perceive the people as friendly has 76 people (accounting for 76.0%); Hard to get close to 1 person (accounting for 1.0%); Sociability has 22 people (accounting for 22.0%); And 1 person has a different feeling (accounting for 1.0%). Visitors to Hue have a good feeling about the people here, this is also an important factor in helping visitors have a good feeling about the destination. Tour guides, vendors, and service providers are all residents living here, so they are the ones in direct contact with tourists, so their attitude also greatly affects the decision to visit. their prices. When a resident has a rude attitude or disrespects them, they definitely have a bad view of the destination. And fortunately, people in Hue are not like that, they are always friendly and enthusiastic with everyone, especially people from other places,

#### 4.3.8. Overall rating of tourists about tourism destination of Hue City

*Overall rating of visitors about the worth to visit and experience of Hue's tourist destinations.*

Among the 100 tourists surveyed, 82 tourists rate Hue as a place worth visiting and experiencing (accounting for 82.0%) because Hue is a land of historical relics, but already a historical relic, there are many omens. interesting things that we don't know about, only when we visit and experience can we understand and see those things, but through newspapers and pictures, we can't feel them all; 1 person rated Hue not worth visiting and experiencing (accounting for 1.0%); 17 people hesitated (accounting for 17.0%); And no one has other reviews (accounting for 0.0%).

**Table 12. Visitors' overall opinions about the destination**

<b>Overall rating of visitors</b>	<b>Quantity (People)</b>	<b>Ratio (%)</b>
Satisfied	96	96.0
Wondering	2	2.0
Not satisfied	2	2.0
Other	0	0.0
Total	100	100.0

## 5. CONCLUSION

The study of destination image and its measurement is characterized by diversity and complexity. The attributes utilized to measure destination image vary depending on the study's goals, scope, and focus. In the case of Hue City, several prominent aspects of the destination's image have been evaluated, encompassing tourists' perceptions and rational assessments. These aspects include the scenic beauty of the city, its culinary offerings, the presence of Hue music, the cleanliness of the tourist environment, the safety of the local traffic, and the warm and welcoming demeanor of the local population. While the majority of tourists hold positive evaluations of Hue as a destination and express a willingness to return if certain shortcomings are addressed, it is important to acknowledge the existence of negative opinions that some visitors may hold, as they compare Hue to other destinations they have experienced.

## READING CULTURE OF STUDENTS AT THE UNIVERSITY OF ECONOMICS, HUE UNIVERSITY

Nguyen Thi Thuy Linh<sup>1</sup>, Nguyen Thi Phuong<sup>1</sup>

Mentor: Le Anh Quy<sup>1</sup>

**ABSTRACT:** *This exploratory study examines the current reading status of students at the University of Economics, Hue University and identifies the factors influencing their reading habits. A survey was conducted among 200 students, and exploratory factor analysis was utilized to uncover the underlying factors behind students' reading preferences. The results indicate that two primary groups of factors, namely individual and technological factors, as well as reading environment and school support, significantly impact students' reading status. The findings suggest the need for interventions to encourage reading habits and provide school-based support for reading activities. Implementing these solutions can help cultivate a reading culture among students and enhance their interest in reading.*

**Keywords:** *reading culture; influencing factors; Student; Hue University.*

### 1. INTRODUCTION

Books are regarded as valuable repositories of human knowledge, offering numerous advantages to individuals. Specifically, they serve as an extensive knowledge base for students, enabling them to engage in reading, access resources, acquire knowledge, study, and prepare for examinations. However, the present reality indicates a significant decline in the number of students who devote their leisure time to reading books, or who have read books but have not achieved satisfactory outcomes.

In recent years, the rapid advancement of information technology has resulted in a gradual detachment from the practice of reading books, and students are not exempt from this trend. A growing number of students at the University of Economics, Hue University (HCE) have progressively forsaken books and lost touch with the reading culture. The reduced inclination towards reading among students leads to a dearth of knowledge, a deficiency in qualifications, a failure to cultivate creative thinking abilities, and a lack of essential skills. Consequently, it becomes imperative and meaningful to evaluate the reading situation and identify the factors that influence students' reading habits at the University of Economics in order to foster the formation of a reading culture.

Considering the aforementioned concerns, it becomes necessary to conduct a more comprehensive study on the reading patterns of students at HCE and the university as a whole. Such an investigation would enable us to identify the factors that impact students' reading behavior within the academic institution. Subsequently, viable solutions can be proposed to encourage students to engage in book reading and cultivate an effective reading habit.

### 2. THEORETICAL BASIS AND RESEARCH METHODS

#### 2.1. Study overview

Reading has become a universal concern transcending national boundaries, as it continues to captivate the attention and interest of society. Particularly in the contemporary era characterized by the proliferation of information and advancements in science and technology, the culture of reading has evolved beyond conventional methods to encompass modern formats facilitated by electronic devices such as smartphones

---

<sup>1</sup> University of Economics, Hue University

and computers. The advent of the Internet has provided accessibility to an array of reading materials, catering to the preferences of younger generations. However, the rapid growth of mass media and popular social platforms like Facebook and TikTok has led to the perception that reading books has diminished in significance, with waning public interest. Consequently, the matter of reading books and the necessity of cultivating reading habits remains enduring concern warranting widespread attention.

The study conducted by Luu Thuy Duong (2009) focuses on investigating the reading and purchasing requirements of students in Hanoi. The research aims to comprehensively assess the present scenario, identify underlying causes and development trends, and propose suitable strategies and solutions to enhance the demand for books among students in the capital city of Hanoi. The aforementioned study conducted by Vu Thi Thu Ha (2013) delves into the reading culture in Vietnam within the framework of integration and development. This research provides insights into the prevailing reading patterns among the Vietnamese populace. Notably, the findings reveal a tendency among readers to conform to group psychology, align with market demands, succumb to public relations strategies employed by publishing entities, and exhibit a preference for “forbidden” books as a means of satiating curiosity and seeking entertainment, rather than engaging in reading for the purpose of knowledge cultivation.

Based on the findings presented in the research article titled “Developing Reading Culture for Students of Dong Thap University” by Nguyen Thi Nhu Quyen (2020), it is evident that the cultivation of a reading culture within the educational setting plays a crucial role in the holistic formation and progression of students. This reading culture not only enhances students’ research and self-study abilities, but also facilitates their capacity for critical analysis, constructive evaluation, positive thinking, and overall cognitive development. Consequently, it becomes evident that reading culture significantly contributes to the enhancement of educational quality and training efficacy within academic institutions.

Furthermore, a study conducted by Nguyen Thuy Quynh Loan and Vo Hoang Duy (2013) titled “Factors Affecting Students’ Reading Habits of Specialized Books: A Case Study at Ho Chi Minh City University of Science and Technology” proposes a comprehensive model that elucidates eight key factors influencing students’ reading habits of specialized books. These factors encompass the roles of lecturers, students themselves, the home environment, the classroom environment, the school environment, the social environment, the virtual world, and the characteristics of the reading materials.

Collectively, these findings underscore the significance of shifting societal perceptions towards reading culture, particularly among students. Cultivating a purposeful and structured reading habit emerges as an imperative pathway towards effective learning and the establishment of a solid foundation for future personal development.

## **2.2. Theoretical basis**

### ***What are books and reading books?***

The advent of books is intricately intertwined with the progression of human writing and language. Initially, they manifested as rudimentary inscriptions etched upon wood and stone, eventually evolving into the written texts on paper that are commonly published as books today. The concept of books varies among individuals, prompting inquiries into their true essence. The understanding of books is subjective, and each person may harbor a distinct conceptualization, shaped by their personal needs, interpretations, and the functions fulfilled by books. This subjective lens serves as the pivotal factor in the process of defining books from an individual standpoint. In accordance with Bui Tuan An’s work, “What is a Book? What are the benefits, roles, and meanings of reading habits?” (2022), the following insights can be discerned:• Books are intellectual products of people, accumulated through practical knowledge, cultures and histories of peoples in the world. These literary works serve as profound instruments for showcasing the accomplishments of

humanity during their inception and evolution. • Books are invaluable assets containing all knowledge, life experiences and human emotions. It is a spiritual food, brings relaxation, inspires readers, and is a solid luggage leading to the path of human success. Books are the most important way to provide knowledge to people in all fields such as life, economy, culture, society...

Reading is the way to approach and deepen the knowledge that the author conveys in the book. Must know how to read reasonably and usefully, in accordance with the law of access to knowledge.

Reading makes a great contribution to fostering and cultivating knowledge and skills in life, helping to form and perfect human personality.

### *Meaning of reading*

The act of reading contributes significantly to the acquisition of knowledge among individuals, thereby fostering an augmentation of one's lexicon and overall understanding. Moreover, the pursuit of reading facilitates the assimilation of a vast repertoire of human wisdom, leading to the expansion and broadening of one's intellectual horizons. Additionally, cultivating a habit of reading engenders the development of focused attention and serves as a means of alleviating psychological strain, ultimately mitigating the burden of stress.

### **2.3. Research models**

Based on the research model of Nguyen Thuy Quynh Loan & Vo Hoang Duy (2013) group proposed two main groups of factors that are individual students affecting the reading status of students.

*Source: Proposal of the research team*

### **2.4. Research Methods**

#### *Methods of data collection and processing*

- Secondary data: The secondary data for this study will be sourced from pertinent scientific research topics, articles, and journals that specifically address the subjects of books and reading.

- Primary data: The primary data will be gathered through a convenient sampling technique from a sample of 200 students representing various faculties within the University. The data collection will be conducted via an online survey utilizing questionnaires designed for this purpose. The survey participants will consist exclusively of University students. The collected data will be used to generate conclusions that can be applied to the broader population under investigation.

Subsequently, the acquired questionnaire data will undergo coding, data entry, cleaning, and processing procedures. Excel and SPSS software systems will be employed as analytical tools for the data analysis..

#### *Data Analysis Methods*

Qualitative methods are used to analyze and synthesize the factors affecting the reading status of students of HCE..

The research team used a survey with a 5-point Likert scale: “Strongly disagree - Disagree - Neutral - Agree - Totally agree” to survey the factors affecting the practice. Reading status of students of the University of Economics, University of Science and Technology.

### 3. RESEARCH RESULTS

#### 3.1. Descriptive statistics

After surveying 200 students at HCE, University of Economics, a total of 200 valid results were obtained (Table 1).

*Sex:* Of the 200 surveyed students, 113 students are female (accounting for 56.5%) and 87 students are male (accounting for 43.5%).

*Course:* There are 28 students in Course 52 (accounting for 14%), 45 students in Course 53 (accounting for 22.5%), 75 students in Course 54 (accounting for 37.5%) and 52 students in Class 55 (accounting for 26%).

*Department:* After surveying 200 students from 5 faculties of the university, the Faculty of Economics & Development has 44 students (accounting for 22%), the Faculty of Business Administration has 52 students (accounting for 26%), the Faculty of Accounting and Finance has 48 students (accounting for 24%), the Faculty of Political Economy has 32 students (16%) and the Faculty of Economic Information Systems has 24 students (accounting for 12%).

#### *Reading level by gender:*

Among the cohort of 87 male students who were surveyed, the predominant frequency of reading among them was determined to be 3 days per week, which constituted the highest proportion of male students at 43.68% (n=38). Additionally, 34.48% (n=30) of male students reported reading on a daily basis, while a mere 9.2% (n=8) engaged in daily reading. Furthermore, 11.49% (n=10) of male students indicated a reading frequency of once a week, whereas a minimal 1.15% (n=1) claimed to read at other intervals. The aforementioned data substantiates the assertion that the leisure-time reading habits of male students remain considerably inadequate. Among the 113 female students surveyed, female students regularly read books in their free time more often than male students often read books. In which, the level of reading books 5 days/week accounted for the highest rate of 37.17% (42 students); the daily level accounted for 27.43% (31 students); the level of 3 days/week accounted for 26.55% (30 students); reading level 1 day/week accounted for 7.08% (8 students) and other level accounted for only 1.77% (2 students).

*Level of reading in the school library:* Out of 200 students participating in the survey, 74 students (37%) have used and read books at the school's library. The remaining 126 students (63%) still have never accessed and used the university's library.

**3.2. Evaluation of the reliability of the scale by Cronbach's Alpha coefficient**

After analyzing Cronbach's Alpha (Table 2), there are 4 variables CNSV3, CNSV4, MTDS4 and MTDS5 with the total correlation coefficient less than 0.3, so they should be removed. The remaining variables all have a total correlation coefficient greater than 0.3 and after conducting the final re-test, they are kept due to ensuring the reliability of the scale.

**3.3. Exploratory factor analysis EFA for independent variables**

From the test results of Table 3, it shows that the value of KMO coefficient reaches  $0.848 > 0.5$ . This proves that this value is suitable and qualified for factor analysis. Bartlett's test results reached 1239,777 with the Sig significance level.  $= 0.000 < 0.05$  shows that there is a correlation between the variables included in the research model. Therefore, survey data used to conduct exploratory factor analysis EFA is appropriate.

The analysis results show that with 11 analyzed variables, there are 3 factors with Eigenvalues greater than 1, these three factors show the best data characteristics compared to extracting the remaining factors later. . And with the total variance extracted is  $65.995\% > 50\%$ . That is, these three groups of factors explain 65.995% of the variation of 11 observed variables. Thus, the conditions of analysis and factor formation are appropriate and no additional observed variables must be removed.

**Table 4. Statistical table describing the average factor "Individual student" and "Reading environment"**

Factor	N	Smallest value	The greatest value	The average value	Standard deviation
Individual students					
CNSV1	200	first	5	4.07	0.900
CNSV2	200	first	5	4.13	0.800
CNSV3	200	first	5	3.28	1.091
CNSV4	200	first	5	3.11	1.019
CNSV5	200	first	5	4.09	0.714
CNSV6	200	first	5	4.41	0.785
CNSV7	200	first	5	4.00	0.894
CNSV8	200	2	5	4.40	0.763
CNSV9	200	first	5	4.10	0.860
CNSV10	200	first	5	4.34	0.853
Reading environment					
MTDS1	200	2	5	4.43	0.668
MTDS2	200	first	5	4.33	0.687
MTDS3	200	first	5	4.36	0.695
MTDS4	200	first	4	2.32	0.966
MTDS5	200	2	5	3.68	1,049

After running descriptive statistics on the average value for two factors "Individual student" and "Reading environment", based on the calculation of the distance value, the results of Table 4 show that:

For the factor "Individual student" there are 2 variables "CNSV3" and "CNSV4" with mean values approximately equal to 3, showing that students are still neutral with 2 opinions "Students only read suitable books". Relevant to the major they are studying" and "Students only read books, documents, and textbooks when assigned by the lecturer". The remaining 8 variables all have an average value of approximately 4, showing that

students tend to agree with these 8 ideas. In general, this result shows that the school's students tend to agree with the ideas set out in the "Individual student" factor that has a great impact on the student's reading situation.

Besides the external environment, the scholastic reading environment garners considerable interest among students. After running the average descriptive statistics for the factor "Reading environment", we can see that the variable "MTDS4" has an average value of approximately 2, which shows that students disagree. Note that "The school regularly organizes "Reading Day" for students. The remaining 4 variables "MTDS1", "MTDS2", "MTDS3" and "MTDS5" have an average value of approximately 4, indicating that students tend to agree with these ideas. Through this result, it is shown that the factor "Reading environment" also greatly affects the reading status of students with a high degree of student agreement. Additionally, it should be noted that the school's current provision of playgrounds and reading contests for students is limited. Consequently, a significant number of students express discontentment with this inadequacy. Consequently, it is imperative for the school administration to allocate greater consideration towards the literacy engagement of students within the institution. Specifically, the implementation of a diverse range of playgrounds and the organization of captivating and educational reading events are essential for fostering a heightened enthusiasm for reading among students. By establishing an environment conducive to healthy reading practices, students will be encouraged to extensively engage with literary materials.

#### 4. CONCLUSIONS AND RECOMMENDATIONS

Drawing upon theoretical frameworks and empirical inquiries, this research undertakes a comprehensive examination utilizing both quantitative and qualitative methodologies to appraise the multifaceted determinants that shape the reading proclivities of students enrolled at the University of Economics and Business, along with the University of Science and Technology. The principal objective is to assess the present reading landscape among students and proffer strategies to promote augmented engagement with literary materials, thereby augmenting the overall caliber of their reading endeavors. The research findings unveil the presence of two discrete classifications of factors that exert influence upon the reading habits of students at both academic institutions: individual student factors and factors encompassing the reading milieu and institutional support. By analyzing the outcomes derived from surveying a sample of 200 students from the University of Economics and Business, several recommendations have been formulated by the research team to encourage greater book reading, cultivate positive reading habits, and generate a heightened interest in reading among students at the aforementioned universities. These proposed solutions are as follows:

*Group of solutions to encourage students to read books:*

Reading more or less books, or how to read books to get the best effect depends largely on each individual student. In order to make reading highly effective and improve reading habits for students of HCE, University of Technology, some solutions are proposed for each individual student as follows:

*Firsly*, students should start reading books with topics that they find interesting. It is advisable to start reading a little, then gradually increase the time and frequency of reading.

*Secondly*, students can identify the great purpose of reading the book that they aim for. It will be a great motivation to help students improve their reading spirit and accumulate lessons learnt from reading books.

*Thirdly*, students actively seek and build a reading environment suitable for them. Organizing time and plan, reading goals are reasonable, and students must be persistent in reading to create a habit of reading regularly.

*Fourthly*, students should choose a quiet reading environment and space, and they should read books in the "golden" time frame to increase the ability to concentrate and increase the ability to absorb the content contained in the book, from which the reading efficiency is also improved.

*Fifthly, students* should filter, note down the main and important contents, in each book so that they could learn more deeply about the content and increase their ability to remember.

*Sixthly, students* should go to the library regularly to be able to search and read more genres of books, thereby improving their understanding and improving their thinking ability to serve their study as well as apply it in their daily life.

*Seventhly, students may* often exchange and share reading with friends and teachers so that they can learn from each other through debating and answering questions about the issues, contents, and implications of each book. From there, it helps students increase their ability to understand, as well as improve critical thinking of each individual.

*Eighthly* they should reduce their time spent hanging out and surfing social media, using the Internet. They should instead use their free time for reading more books. Because, only when they have knowledge they really succeed, but that knowledge they all learn from books.

*Group of solutions to support students reading:*

In addition to the imperative for students to uphold a daily reading regimen, the cultivation of a reading culture within the school holds significant importance. Several strategies have been proposed to facilitate and foster increased book consumption among students in the HCE. Firstly, regular organization of conferences, seminars, and book fairs would serve to captivate and motivate students to engage in extensive reading. Secondly, the implementation of book contests would afford students the opportunity to showcase their comprehension of literary works and the knowledge acquired through reading. Thirdly, a promotional plan for the school library ought to be devised, aimed at enhancing students' awareness of its presence. Furthermore, student feedback concerning the library should be actively solicited, enabling iterative improvements and the establishment of an optimal reading environment within the school's library. Fourthly, the school should strive to develop and enhance its digital library system, incorporating user-friendly functionalities and an intuitive interface that facilitates expedient document retrieval and borrowing via mobile devices or computers. Additionally, the digital library system of HCE could be integrated with the digital library systems of universities within Hue University or the community library. Such integration would broaden the available resources and more effectively cater to the academic pursuits and research endeavors of students.
