## WELCOME NOTES

*Dear Friends and Colleagues,*

On behalf of the ten leading economic universities in Vietnam: *Academy of Finance (AOF)*, *University of Economics - The University of Danang (DUE)*, *National Economics University (NEU)*, *Thuongmai University (TMU)*, *Banking Academy of Vietnam (BAV)*, *University of Economics & Business – Vietnam National University (VNU-UEB)*, *Foreign Trade University (FTU)*, *Hue College of Economics – Hue University (HCE)*, *University of Economics Ho Chi Minh City (UEH)*, and *University of Economics and Law Ho Chi Minh City (UEL)*, we are delighted to extend our warmest greetings to all participants, students, and researchers attending this prestigious event. It is with immense pleasure that we come together to explore, discuss, and enrich our understanding of the dynamic fields of economics and business.

The International Conference for Young Researchers in Economics and Business 2023 (SR-ICYREB2023) is organized by the ten leading economic universities in Vietnam, and with the participation of students from these universities with the goal to create and develop an academic exchange environment with new ideas and research outcomes of students from economic and business universities. It also promotes experience exchange and enhances local and international coordination between students in scientific research to adapt to the new context.

The next few days are packed with engaging sessions, keynote speeches from renowned experts (Minh Tuan Bui - Tax Partner, Deloitte Vietnam and Aaron Saw, Head of Corporate Reporting Insights, ACCA), interactive workshops, and opportunities to connect with fellow enthusiasts. We encourage you to actively participate, share your thoughts, challenge assumptions, and contribute to the collective growth of knowledge in these vital disciplines.

We extend our heartfelt gratitude to all the organizers, sponsors, and speakers who have dedicated their time and efforts to this conference. Your contributions are invaluable to the success of this event.

Let's embark on this intellectual journey with open minds, ready to absorb new ideas and forge lasting connections. May this conference be a catalyst for inspiration, innovation, and collaboration that resonates far beyond its closing remarks.

Once again, a warm welcome to the International Conference for Young Researchers in Economics and Business 2023 (SR-ICYREB2023).

Best regards,

**On behalf of the Organizing Committee**

**Assoc. Prof. Dr. Co Trong Nguyen**

**People's teacher, President**

**Academy of Finance**

**ASSOCIATE PROFESSOR NGUYEN TRONG CO  
PEOPLE’S TEACHER, PRESIDENT OF THE ACADEMY OF FINANCE**

Assoc. Prof. Nguyen Trong Co is the President of the Academy of Finance. He has been working for the Academy of Finance since he was young and held different positions such as lecturer, Head of Financial Analysis Department, Deputy Head of Human Resources Department, and Vice President before being nominated the President of Academy of Finance in 2014.

He is the Editor of the Journal of Finance and Accounting Research and serves the Scientific Board of Finance Research Sector as Vice President and a member of *Scientific Board of Banking Research Sector*.

He was also nominated as honour member of FCPA Australia.

Assoc. Prof. Nguyen Trong Co is the author/coauthor of more than 21 valuable text books and supplementary materials such as “Financial Analysis”, Finance Publishing House, 2017, “Auditing management and usage of mineral resources for sustainable development in Viet Nam”, Finance Publishing House, 2016 and etc.

He has researched actively with more than 20 research projects spread on different fields: corporate finance and public finance, and technological markets. In the Academy of Finance, he has published more than 70 articles in both local and international journals.

## KEYNOTE SPEAKERS:

### **Keynote 1:**

**Minh Tuan Bui - Tax Partner, Deloitte Vietnam**

**Keynote topic: “BEPS 2.0 – Global Minimum Tax (Pillar 2) and Investment Attraction in Vietnam”**

Minh is Deloitte Private Leader with nearly 20 years of professional experience serving in tax and business advisory services. He holds Tax & Legal Leader position of Deloitte South East Asia in Industrial Products & Construction sector. In Vietnam, he is Leader of Korean Service Group, Tax Leader of Deloitte Private market segment; Global Investment and Innovation Incentives (GI3) Lead Partner. Minh brings a wealth of accumulated knowledge and expertise in various areas of global taxation and in Vietnam to provide his clients with prominence in strategic tax advisory, particularly in strategic tax advice to Vietnamese and international corporations operating in Vietnam; tax due diligence; corporate tax system health check; and tax controversy. With broad experience, Minh has a proven track record of successfully helping corporate clients access the financial reporting of complex tax positions as well as assisting them in negotiating with all levels of tax, customs authorities to obtain currency and certainty.

Minh has contributed significantly to the development of Vietnamese taxation system through his public speeches, quality articles, and interviews, and providing comments on draft tax laws and regulations.

Minh has been recognized as Vietnam’s Tax Controversy Leader by the International Tax Review for four consecutive years (2016-2019).

**Keynote 2:**

**Arron Saw, Head of Corporate Reporting Insights**

**Keynote topic: “Reporting of R&D: Disclosure without recognitions?”**

Aaron drives corporate reporting-related research activities and policies within the Policy and Insights team at ACCA to deliver high quality, professional and innovative inputs on key issues in the global corporate reporting agenda. Aaron believes in sharing knowledge widely. He focuses on making practical and relevant propositions to professional accountants and their organisations on improving the quality of financial and sustainability reporting.

His areas of interest include financial and sustainability reporting, business resilience, digital technology, and improving audit quality. He has designed the framework for a community that supports the professional development of SMPs – the SMP100.

Prior to this role, Aaron was the head of policy and technical for ACCA Maritime Southeast Asia (comprising Malaysia, Brunei, Indonesia, and the Philippines). He also had a decade of experience in a Big Four accounting firm in Malaysia where he was involved in providing audit and assurance services to multinationals and small and medium-sized enterprises operating in a wide range of industries, as well as technical consultancy, developing training programmes and conducting trainings.

Aaron has a Bachelor of Commerce (Honours) Accounting. He is a fellow of ACCA and a member of the Malaysian Institute of Accountants.

## MEMBERS OF COMMITTEES OF THE INTERNATIONAL CONFERENCE FOR YOUNG RESEARCHERS IN ECONOMICS AND BUSINESS 2023 (SR-ICYREB 2023)

### I. ORGANIZING COMMITTEE

No.	Name	Title, organization	Responsibility

# CONTENTS

STUDENT RESEARCH - INTERNATIONAL CONFERENCE FOR YOUNG RESEARCHERS IN ECONOMIC AND BUSINESS 2023  
(SR-ICYREB2023).....1

## Part 1 FINANCE AND BANKING

1. THE IMPACT OF AIR POLLUTION ON CASH HOLDINGS OF LISTED COMPANIES IN VIETNAM: THE MODERATING EFFECT OF FINANCIAL LEVERAGE  
**Trinh Ngoc Tien, Nguyen Viet Huong Ly, Le Minh Tu, Nguyen Hoang Khanh Huyen, Pham Thi Hong Van** .....4
2. FINANCIAL LEVERAGE AND INVESTMENT DECISIONS IN VIETNAMESE LISTED COMPANIES  
**Ta Thi Thuy Duong, Nguyen Phan Ly Ha, Le Binh, Nguyen Thi Ngoc Thu** .....16
3. EVALUATING THE EFFECTIVENESS OF ETFS IN VIETNAM BY THE MISPRICING AND VALUE AT RISK  
**Nguyen Bao Thy, Nguyen Thi Hai Yen, Le Tran My Hanh, Le Tuong Vy, Tran Thi Kim Anh**.....30
4. REDUCING CREDIT DEFAULT RISK IN COMMERCIAL BANKS BASED ON CREDIT SCORING USING MACHINE LEARNING  
**Nguyen Yen Nhi, Duong Do Thao Nhu, Truong Diem Phuc, Vu Hong Ngan, Pham Thi Yen Huong** .....46
5. PREDICTING LOAN APPROVAL USING MACHINE LEARNING  
**Tran Hoai Thuong, Dinh Minh Tue Ha, Tran Gia Han, Duong Tran Ngoc Thuy Tien, Tran Thi Anh Thu** .....58
6. TESTING AND MEASUREMENT OF ASYMMETRIC INFORMATION: EMPIRICAL EVIDENCE FROM COMPANIES LISTED ON THE HO CHI MINH CITY STOCK EXCHANGE  
**Vu Duc Ngoc Thien** .....73
7. PREDICTING THE FINANCIAL HEALTH OF SMES IN VIETNAM: A COMPARISON AND EVALUATION OF RESULTS BETWEEN CLASSICAL MODELS AND MACHINE LEARNING MODELS  
**Huynh Thanh Hai, Vu Thi Hanh Dung, Phan Thi Thuy Duyen, Le Tuong Vy, Le Quang Bao** .....87
8. LEGAL ISSUES ARISING WHEN APPLYING BLOCKCHAIN TECHNOLOGY IN THE FIELD OF REAL ESTATE BUSINESS: EXPERIENCES OF SOME COUNTRIES AND RECOMMENDATIONS FOR VIETNAM  
**Nguyen Thi Huyen Trang, To Thi Hai Yen, Nguyen Manh Tuong**.....100
9. FACTORS AFFECTING GREEN BANKING IMPLEMENTATION IN VIETNAM: EMPIRICAL STUDY AT THE LISTED COMMERCIAL BANKS ON HO CHI MINH CITY STOCK EXCHANGE  
**Nguyen Thi Thu Huyen; Le Duong; Nguyen Ngoc**.....119
10. FACTORS AFFECTING THE ONLINE LIFE INSURANCE PURCHASING INTENTION OF PEOPLE IN HANOI  
**Tran Thi Hong Duyen, Nguyen Thi Thu** .....130
11. IMPACT OF FINANCIAL LEVERAGE ON THE FINANCIAL PERFORMANCE OF VIETNAMESE MANUFACTURING LISTED FIRMS DURING THE COVID PERIOD  
**Tran Thi Tra My, Phung Hoang Dao, Chu Thanh Dat, Tran Duc Kien, Le Thanh Hien** .....146
12. DEFINING AND MEASURING FINANCIAL LITERACY OF YOUNG ADULTS: A CASE OF VIETNAM  
**Bui Nhat Quang, Do Huy Phuc, Ma Ngoc Huong Giang, Pham Thanh Hung** .....160
13. A RESEARCH ON THE IMPACT OF FINANCIAL INDICATORS ON EARNINGS MANAGEMENT – EMPIRICAL EVIDENCE IN LISTED FIRMS ON THE STOCK MARKET IN VIETNAM  
**Le Thanh Ngan, Dinh Thanh Bao, Phung Thi Hong Nhung, Tran Thi Thuy Vy, Nguyen Thi Kim Long** .....171

14.	THE FINANCIAL CONTAGION EFFECTS OF THE GLOBAL COVID-19 PANDEMIC: EVIDENCE FROM FINTECH AND TRADITIONAL FINANCIAL MARKETS <b>Luong Bao Thanh Khoa, Vu Thang Thinh, Vu Xuan Loc</b> .....	186
15.	ANALYSIS OF FACTORS INFLUENCING INVESTMENT DECISIONS IN THE VIETNAMESE STOCK MARKET OF STUDENTS IN HO CHI MINH CITY <b>Nguyen Mai Lien, Nguyen Thi Kim Ngan, Tran Phan Thuy Tien, Luong Tuong Vy</b> .....	199
16.	ECONOMIC POLICY UNCERTAINTY AND INVESTMENT DECISIONS: DO BUSINESS CHARACTERISTICS MATTER? <b>Vo Dinh Que Chau, Tran Thi Kim Ngan, Nguyen Thi My An, Nguyen Thi My Hiep, Nguyen Van Hung</b> .....	215
17.	DEVELOPING A Z-SCORE MODEL TO PREDICT THE LIKELIHOOD OF BANKRUPTCY FOR REAL ESTATE COMPANIES IN VIETNAM'S STOCK MARKET <b>Nguyen Van Cong Thanh, Vo Thi Kieu Oanh, Pham Thi Quynh Oanh</b> .....	230
18.	TESTING OF FAMA-FRENCH THREE-FACTOR MODEL FOR REAL ESTATE STOCKS IN VIETNAM <b>Pham Thi Kim Duyen</b> .....	239
19.	EVALUATING THE EFFICIENCY OF COMMERCIAL BANKS IN VIETNAM: AN APPLICATION USING DATA ENVELOPMENT ANALYSIS (DEA) <b>Do Thi Quynh Nhu</b> .....	246
20.	A STUDY ABOUT THE EFFECT OF INTEREST RATE AND ASSET STRUCTURE ON STOCK PRICE RETURN OF COMMERCIAL BANKS IN VIETNAM <b>Tran Minh Quan</b> .....	258
21.	SUPPLY CHAIN DISRUPTIONS AND FIRM OUTCOMES: EVIDENCE FROM SOUTHEAST ASIAN COUNTRIES <b>Bui Quynh Trang, Nguyen Thi Giang, Dinh Thi Hong Duyen, Dang Thu Ha, Hoang Anh</b> .....	271
22.	HOW DOES THE ACCESS TO FINANCE IMPACT BANK'S PROFITABILITY: THE CASE OF VIETNAM <b>Ngo Quang Tuan, Do My Ha Trang, Nguyen Duc Thang, Le Phuong Anh</b> .....	285
23.	FINANCIAL LITERACY, DIGITAL LITERACY AND CUSTOMER CHOICES TOWARD DIGITAL BANKING SERVICES: AN EMPIRICAL STUDY IN VIETNAM <b>Hoang Nguyen Khanh Phuong, Tran Hoang Hai, Le Thi Ngoc Thao, Hoang Thanh Thuy, Duong Thu Tra</b> .....	299
24.	ASSESSING THE PRICE AND OUTPUT EFFECTS OF MONETARY POLICY IN VIETNAM: EVIDENCE FROM A VAR ANALYSIS FROM 2018-2022 <b>Nguyen Viet Anh, Nguyen Thi Tam Anh, Trieu Minh Dang, Nguyen Thu Hoai, Truong Duc Huy</b> .....	314
25.	DEMOGRAPHIC FACTORS AND FINANCIAL LITERACY OF WOMEN IN NEW RURAL AREAS IN HANOI: AN EMPIRICAL RESEARCH <b>Phan Thanh Dieu Linh, Bui Hai An, Do Huyen Vy, Nguyen Duc Tam</b> .....	332
26.	THE IMPACT OF DEBT OVERHANG ON THE INVESTMENT EFFICIENCY AT THE FIRM-LEVEL IN VIETNAM <b>Do Nguyen Hanh Dung, Ly Khanh Linh, Nguyen Thi Thu Nhi, Su Van Hoai Linh</b> .....	349
27.	THE IMPACT OF CORPORATE SOCIAL RESPONSIBILITY ON CORPORATE FINANCIAL PERFORMANCE: EVIDENCE FROM LISTED FIRMS ON VIETNAM STOCK MARKET <b>Tuong Bao Ngoc, Hoang Thien Trang, Nguyen Phuong Quynh Anh, Nguyen Thao Nguyen, Duong Khanh Van</b> .....	364

## **STUDENT RESEARCH - INTERNATIONAL CONFERENCE FOR YOUNG RESEARCHERS IN ECONOMIC AND BUSINESS 2023 (SR-ICYREB2023)**

The Fourth Industrial Revolution (Industry 4.0) is the era of everything being connected to the Internet, marked by disruptive technologies in digitalization, virtual reality, artificial intelligence, and more. As soon as this revolution formed, it had a significant impact on the social lives of humans, gradually permeating every corner of existence. It replaces all manual labor in factories, workshops, and production lines. Any repetitive tasks, no matter how skilled, can be replaced by machines. Therefore, a high-quality workforce is an essential factor for the development of a nation, enabling the exploitation of other resources, leveraging strengths, and enhancing competitiveness in the global market.

At the same time, the Industry 4.0 demands that universities transition from traditional teaching and scientific research models to enterprise-oriented university models to fulfill three main tasks: education, scientific research, and community service. Vietnam is immersing into the regional and global economies as well as the trend of globalization, Vietnamese students and economic students in particular, are facing competitive pressures in both domestic and international labor markets.

Currently, the revised Higher Education Law provides an important legal basis to promote the implementation of autonomous universities, efficient utilization of resources, improvement of higher education quality, ensuring international integration, and better meeting the demand for human resources training in the socialist market-oriented economy and contributing to the socio-economic development of the country.

Hence, in order to reach beyond the boundaries of a nation or region and find one's place, Vietnamese students need to become global citizens, capable of meeting all recruitment needs and adapting to life and work anywhere in the world. Scientific research plays a role in equipping students with knowledge, skills, and scientific methods for learning and research. Engaging in scientific research helps students accumulate experience in report writing, information collection, and other skills needed to meet social demands.

Within the framework of the comprehensive cooperation agreement among universities in the economics and business sector, the Academy of Finance has collaborated with various universities including the University of Economics - The University of Da Nang, University of Economics Ho Chi Minh City, University of Economics and Law Ho Chi Minh City, Thuongmai University, Banking Academy of Vietnam, National Economics University, Hue College of Economics – Hue University, University of Economics - Vietnam National University Hanoi, and Foreign Trade University to jointly organize the international conference “Student Research International Conference for Young Researchers in Economics and Business (SR-ICYREB2023)”. The goal of the SR-ICYREB2023 is to establish and develop an environment for academic exchange, new ideas, and scientific research results of students from various universities in the economics and business. Sharing experiences and enhancing collaboration in management and scientific research activities among students are intended to promote the scientific research endeavors of students from these universities in the new context.

The articles and presentations at the SR-ICYREB2023 hold value not only from a theoretical perspective but also from a practical standpoint. In this conference, the Organizing Committee received more than 300 submissions from student authors and selected 235 papers for publication in the proceedings. The content of these published articles focuses on key issues such as economics, finance, accounting, business administration, socio-economic development, etc... he conference will serve as a platform for students from various economic and business universities to exchange ideas, provide academic opinions, share research experiences, analyze current situations, forecast contemporary issues, and discuss opportunities and challenges for the upcoming phase of socio-economic development.

## THE IMPACT OF AIR POLLUTION ON CASH HOLDINGS OF LISTED COMPANIES IN VIETNAM: THE MODERATING EFFECT OF FINANCIAL LEVERAGE

Author: Trinh Ngoc Tien<sup>1</sup>, Nguyen Viet Huong Ly<sup>2</sup>,  
Le Minh Tu<sup>2</sup>, Nguyen Hoang Khanh Huyen<sup>2</sup>, Pham Thi Hong Van<sup>2</sup>  
Mentor: Nguyen Thanh Liem<sup>3</sup>

**ABSTRACT:** *This study explores the relationship between air pollution and cash holdings in Vietnam, a bank-dominated economy. We examine a sample of 385 non-financial listed firms between 2016 and 2021. We document a non-significant association between air pollution and cash holdings. This might imply that a lack of strict regulations and inadequate enforcement, coupled with a general disregard for environmental concerns among the Vietnamese population, could lead to an insignificant link between cash holdings and air pollution. Additionally, we investigate the impact of the Covid-19 outbreak on the link between air pollution and cash holdings. Despite the pandemic's substantial global impact on various business aspects, our results suggest that it does not significantly affect the relationship between air pollution and cash holdings. Finally, we extend the literature by showing that debt can moderate the relationship between cash holdings and air pollution. Our results suggest that highly indebted firms may be less inclined to invest in environmental protection activities, resulting in a negative correlation between air pollution and cash holdings. These findings provide evidence supporting the idea that debt may emerge as a factor that reduces the need for firms to engage in environmental protection efforts.*

**Keywords:** *Air pollution, cash holdings, financial leverage.*

### 1. INTRODUCTION

The issue of air pollution has been significant for the entire world. Firstly, substantial air pollution has a negative impact on the mental and physical health of dwellers. Exposure to small particles endangers health conditions and increases the risk of contracting a variety of ailments (M. Franklin, Zeka, Schwartz, & epidemiology, 2007). Interestingly, Dong et al. (2021) claim that air pollution has a significant effect on analysts' moods and is conducive to bad decisions of managers. Secondly, air pollution limits corporate growth by decreasing market value, debt capacity, stock returns, and other resources (Levy & Yagil, 2011; B. Li, He, Gao, & Zeng, 2021).

In response to air pollution, a number of environmental protection measures, including rules to restrict businesses' ability to operate, have been released. Firms are also subject to societal disapproval if they fail to address environmental concerns. Therefore, businesses are more likely to facilitate investments enabling firms to act in line with stricter environmental requirements (Farrell et al., 2016; Zhao & Sun, 2016). In general, the issue of air pollution in developing nations should be more severe as developed countries tend to be more effective in addressing environmental issues.

In order to fund activities to battle environmental concerns, cash could be important. Generally, these environmental investments are quite expensive, and there is no guarantee for associated financial returns. According to the pecking order theory, cash is the least expensive because of asymmetric information. Information asymmetry is a major problem, particularly in developing economies, making it difficult for

<sup>3</sup> University of Economics and Law, Vietnam National University Ho Chi Minh City, Email: liemnt@uel.edu.vn

firms to get external financing at a reasonable cost. Therefore, if firms in highly polluted areas need to tackle environmental issues, a natural tendency would be to rely on the internally generated cash flows or cash holdings, or a positive association between air pollution and cash holdings in a developing country could be expected. On the other hand, it is also likely that less stringent pollution-mitigating measures in less developed nations refrain firms from saving cash to invest in activities required to address environmental pollution, leading to an insignificant relationship between air pollution and cash holdings in such countries.

Various studies have identified determinants of corporate cash holdings. The macro-level factors include governmental effectiveness (D. Chen, Li, Xiao, & Zou, 2014; R. R. Chen, El Ghouli, Guedhami, & Nash, 2018; Thakur & Kannadhasan, 2019), culture (Y. Chen et al., 2015), legal efficiency (Shah & Shah, 2016), public trust (Dudley & Zhang, 2016), political ambiguity (Phan, Nguyen, Nguyen, & Hegde, 2019; Xu, Chen, Xu, & Chan, 2016), tax ambiguity (Hanlon, Maydew, & Saavedra, 2017), banking sector stability (Cui, Cuong, & Shimizu, 2020). However, there is little research on how air pollution, a macro-level determinant, affects cash holdings. Until recently, only B. Li et al. (2021) and Tan, Tan, and Chan (2021) have examined this link in China pointing to a positive relationship between the two factors but the time of the study is short (2013 – 2017), and the outcome could have been affected.

Debt could affect firms' tendency to invest in environmental R&D since highly indebted firms tend to be more financially constrained, at least compared to trade credit-financed firms (Guo, Su, Song, Hu, & Finance, 2022). Therefore, even when firms are located in highly polluted areas, managers are not likely to save cash for environmental investments if they have piles of debt to pay back. Once again, environmental projects do not provide a financial return, while eating up firms' resources. Vietnamese listed firms rely on debt financing due to the ubiquitous presence of banks. At the same time, Vietnam's environmental restrictions are quite lax, incentivizing firms to prioritize debt payback. Given this setting, the research seeks to confirm the impact of the interaction between leverage and air pollution on corporate cash holdings.

The current study makes a variety of literary contributions. Firstly, it examines the link between air pollution and cash holdings in a highly relevant context - Vietnam, a developing country. This context is relevant due to several rationales. First, to the best of our knowledge, no research has been conducted in this country. Second, Vietnam has a fledgling financial market and a high level of information asymmetry, so cash is a highly important source of financing (X. V. J. I. R. o. F. Vo, 2018). Therefore, firms should have fewer incentives to invest in activities to solve pollution issues when the requirements are still lax and the outcome of the investment is not certain. Therefore, the impact of air pollution on cash holdings could be different in Vietnam compared to the findings of previous studies. Third, we believe that firms should have incentives to refrain from cash hoarding for environmental concerns if there is more debt. Vietnam's banking system is considered an important source of financing and debt accounts for a large proportion of firms' liabilities. If debt tends to deter firms from saving cash to address environmental issues, this should be of important implications to stakeholders who care for the environment. We offer a range of robustness checks, after which the main results remain unchanged, which lends credence to our findings.

## **2. THEORETICAL BACKGROUND AND HYPOTHESIS DEVELOPMENT**

### **2.1. Theories**

#### **2.1.1. Trade-off theory**

The trade-off theory posits that firms' cash holdings are determined by weighing the marginal utility of holding cash against the marginal costs associated with it (Myers, 1984). The marginal benefits of retaining cash include reducing the risk of financial distress, facilitating the implementation of focused corporate

environmental responsibility strategies, and avoiding the costs associated with external financing or asset sales based on the precautionary motive proposed by (Keynes, 1936). In an unfavorable market, external funding may be difficult or expensive to obtain, necessitating an increase in internal funds such as cash reserves to address the costs of air pollution and mitigate associated risks. Consequently, air pollution can have a positive impact on a firm's cash holdings.

### **2.1.2. Neoclassical theory**

According to the neoclassical economic theory, corporate environmental responsibility practices are expected to increase costs and reduce shareholder wealth (Ruf, Muralidhar, Brown, Janney, & Paul, 2001). Harper and Sun (2019) contend that environmentally irresponsible businesses often prioritize cash utilization to maximize shareholder value and avoid conflicts between management and shareholders. In developing countries, where air pollution regulations may be insufficient and weak, companies may adopt a more cautious financial allocation strategy by holding more cash reserves to invest in projects with predictable future profits rather than investing in research on environmental pollution (Chang, Graff Zivin, Gross, & Neidell, 2019). Consequently, a negative correlation between a company's cash holdings and air pollution may exist.

### **2.1.3. Pecking order theory**

According to the pecking order theory, firms have a preference for utilizing internal financing primarily, such as cash, due to the absence of external transaction costs. In cases where internal financing is insufficient, firms resort to debt issuance, followed by equity as a last option. The theory emphasizes the expensive nature of external finance (Myers, 1984), and moreover, the pressure that arises from using debt, which motivates companies to invest efficiently to generate profits that can be used to pay off the debt. Therefore, among investment sectors, companies that are indebted typically prioritize the use of cash holdings to fund exceptionally profitable investment initiatives rather than infrequently profitable investments in pollution control (Anderson et al., 2017). Consequently, it is expected that debt plays a moderating role in the relationship between air pollution and cash holdings.

## **2.2. Hypothesis development**

The literature suggests a number of harmful impacts of air pollution on dwellers and degrade living quality (Plaisier et al., 2010; Stafford, 2015). Air pollution impairs cardiac and respiratory function, increasing the fatality rate. B. A. Franklin, Brook, and Pope III (2015) attribute the number of sick days to air pollution. Not only does air pollution degrade physical healthy, but it also exerts a depressing effect (Q. Zhang et al., 2017), causing nervousness and irritation (Evans, Colome, & Shearer, 1988) as well as suicide (Bakian et al., 2015).

As far as firms are concerned, air pollution could lead to poor decision-making. Ackert, Church, and Deaves (2003) argue that air pollution diminishes people's capacity for information processing. Firms might also have to hoard cash to offer welfare benefits to keep employees or to pay healthcare expenditures (Akpalu & Normanyo, 2017). Failing to adhere to environmental regulations causes enterprises to experience a sharp decline in stock values (Ramiah, Martin, Moosa, & Finance, 2013). Tan, Zhang, Zhang, and Chan (2021) suggest that air pollution can enable pessimism and lower management cognitive capability, as a result, firms tend to raise cash holdings to prevent risk. To sum up, firms have multiple reasons to address environmental issues, as far as performance-related rationales are concerned.

According to D. Zhang, Du, Zhuge, Tong, and Freeman (2019), they conduct research on China's manufacturing firms and discover that because of its high liquidity and low financial cost, cash reserves can greatly aid in financing pollution investment, avoiding having to raise funds repeatedly and frequently. They

discover that financially-constrained firms are more likely to use internal funds like cash to finance pollution investments. In addition, G. Zhang, C. Fang, W. Zhang, Q. Wang, D. J. E. M. F. Hu, et al. (2019) show that in industries that are more labor and pollution-intensive, the impact of cash on pollution investment is especially significant.

Finally, to battle air pollution, governments have been introducing a number of environmental policies (H. Zhang et al., 2016). Environmental taxes and administrative fines have increased environmental costs for businesses such as purchasing and installing environmentally friendly and efficient equipment, forcing investments in anti-pollution measures (Hu, Xue, Liu, & Finance, 2022). In addition, businesses find it expensive and challenging to attract outside financing because of the asymmetric information and substantial uncertainty surrounding the execution of environmental rules (Duchin, 2010; Xu et al., 2016), managers are forced to rely only on internal finance, causing an increasing desire for cash (B. Li, Guo, & Zeng, 2019). As a result, large cash holdings are required by businesses for cautious motives (Keynes, 1936).

Accordingly, cash holdings are assumed to correlate positively with air pollution.

H1: Air pollution is positively associated with cash holdings.

Air pollution lowers risk-taking incentives for firms. Air pollution tends to reduce firm investment in risky projects (B. Li et al., 2021). In addition, air pollution can enhance pessimism and lower management cognitive ability (Tan, Zhang, et al., 2021). As there is lower risk related to investment, firms might have less need to hold cash for precautionary reasons.

When studying large public enterprises in the US, Harper and Sun (2019) found that businesses preferred to put money into initiatives that would likely have fewer agency conflicts and would maximize shareholder value over environmental efforts. Thus, it is anticipated that cash holdings will negatively correlate with environmental contamination.

Interestingly, Tan, Tan, et al. (2021) find that firms with more cash holdings tend to have lower performance in highly polluted cities in China, compared to less polluted ones. Therefore, this evidence could imply that firms should not hold much cash in highly polluted environments. First, if air pollution mentally makes executives more risk averse, firms tend to conduct less investment, especially risky investment, thus making cash holdings costly and prone to agency cost and opportunity cost. Second, the regulations in Vietnam might not be as strict as in other jurisdictions, so the need for cash holdings to address environmental issues should be lower.

Vietnam has actually experienced the fastest-growing per-capita greenhouse gas emitter annually in 20 years (Tran, Drogui, Doan, Le, & Nguyen, 2017). Furthermore, the unsustainable exploitation of natural resources has been alarming and adversely affected long-term growth. It seems that coupled with the strong increase in urbanization and economic growth, air pollution is the cost that Vietnam is paying. Even though stricter laws have been introduced with some enforcement of dust management measures, and enhanced monitoring of industrial emissions, the enforcement is still not adequate (International Trade Administration, 2021). According to Provincial Governance and Public Administration Performance Index Surveys, the percentage of respondents choosing the environment as their biggest concern has dropped from 12.53 percent to 8.85 percent from 2016 to 2019. Finally, studying Vietnamese Environmental Protection Law, Thi Nguyen (2020) associates it with backward legislation and the enactment capacity is still low.

As a result, air pollution should be negatively related to cash holdings.

H2: Air pollution is negatively related to cash holdings.

If firms need to invest in pollution-abatement activities, cash might help due to its low cost, at least

compared to trade credit (G. Zhang, C. Fang, W. Zhang, Q. Wang, D. J. E. M. F. Hu, et al., 2019). Cash enables firms to continue to fund their current projects in the event of any shocks to the credit market (Campbell, Hilscher, & Szilagyi, 2008; Kaplan & Zingales, 1995). Because pollution control investment is expensive and does not provide financial returns, compared to investments in production, firms are more inclined to utilize cash than debt when investing in pollution protection. Debt puts firms under pressure to pay it back, which encourages them to invest effectively. This negative effect might be stronger when cash plays a more significant role as a source of financing. In a developing country like Vietnam, information asymmetry is high and the cost of external financing is high, accordingly. Furthermore, the regulatory strictness is low, compared to other countries, to allow more foreign direct investment and economic growth. These institutional traits make it more likely for firms to use cash for activities that generate profits to pay for loans, rather than investments in pollution control.

From the above arguments, debt may weaken (strengthen) the positive (negative) effect of cash holdings on investments in pollution control, in line with the argument that debt reduces the capacity for environmental research (G. Zhang, C. Fang, W. Zhang, Q. Wang, D. J. E. M. F. Hu, et al., 2019). Therefore, it is expected that leverage reduces the correlation between air pollution and cash holdings.

H3: Leverage has a moderating effect on the relationship between air pollution and cash holdings.

### 3. RESEARCH METHODOLOGY

The research sample in this study is non-financial firms listed on the Vietnam Stock Exchange in the six years from 2016 to 2021. We removed observations that have extreme values, such as negative equity or total debt larger than total assets. Firms in the financial sector including banks and financial institutions and insurance companies are excluded from the sample because their financial statements differ significantly from the rest (Al-Najjar & Hussainey, 2011; Pandey, 2001). The final dataset consists of 2128 observations, covering 385 firms. We have gathered information on air pollution using the particulate matter measurement index (PM2.5) over the years 2016 to 2021 from the contribution of the General Consulate of the US in Vietnam.

To test the individual effect of air pollution on cash holdings (Hypotheses H1 and H2), the baseline model in this research is as follows (B. Li et al., 2021):

$$\text{Cash}_{i,t} = \beta_0 + \beta_1 \text{PM2.5}_{i,t} + \beta_2 \text{Size}_{i,t} + \beta_3 \text{Levi}_{i,t} + \beta_4 \text{CFO}_{i,t} + \beta_5 \text{PTBi}_{i,t} + \beta_6 \text{NWC}_{i,t} + \beta_7 \text{ROAi}_{i,t} + \text{Industry dummies} + \mu_{i,t} \quad (1)$$

To test the moderating effect of leverage on the link between air pollution and cash holdings (Hypothesis H3), the interaction term is added as follows:

$$\text{Cash}_{i,t} = \alpha_0 + \alpha_1 \text{PM2.5}_{i,t} + \alpha_2 \text{Levi}_{i,t} + \alpha_3 \text{PM2.5} * \text{Levi}_{i,t} + \alpha_4 \text{Size}_{i,t} + \alpha_5 \text{CFO}_{i,t} + \alpha_6 \text{PTBi}_{i,t} + \alpha_7 \text{NWC}_{i,t} + \alpha_8 \text{ROAi}_{i,t} + \text{Industry dummies} + \epsilon_{i,t} \quad (2)$$

Where:  $i,t$  represent firm  $i$  in year  $t$ . Cash is measured by cash and cash equivalents divided by total assets (Guizani, 2017; Habib, Hasan, & Al-Hadi, 2017). Cash and cash equivalents are reported in cash flow statements, which refer to cash on hand, bank deposits that are readily available for payment and their equivalents.

PM2.5 is the proxy for air pollution, referring to particulate matter with an aerodynamic equivalent diameter of less than or equal to 2.5 microns in the atmosphere, which can go directly to the alveoli. PM2.5 is a very popular measure of air pollution, see, for example (X. Li, Jin, & Kan, 2019; Tan, Tan, et al., 2021). Unfortunately, other measures of air pollution in Vietnam are quite limited, resulting in a considerable loss in observations. Therefore, we decide only use PM2.5 as our sole proxy for air pollution.

Firm size (Size) is measured as the logarithm of total assets at the end of year t. Leverage (Lev) is computed as the ratio of total debt to total assets (X. Li et al., 2019; Tan, Tan, et al., 2021). Cash flow (CFOA) is also accounted for, because firms that have higher operating cash flows, calculated as the ratio of operating cash flow to total assets, may hold more cash (Opler, Pinkowitz, Stulz, & Williamson, 1999). Growth opportunities (PTB) are measured as the ratio of the market value to the book value of equity. Net working capital (NWC) is measured by the difference between current assets and current liabilities and divided total assets. Return on assets (ROA) is defined as net income divided by total assets. Finally, firms of different industries may have different levels of cash due to their intrinsic operating styles. Therefore, industry dummies, following Thomson Reuters classification, are added to control for this potential.  $\mu$ ,  $\epsilon$  are the residuals in the models.

The current research employs estimation strategies including OLS, fixed effects model, and random effects model. Other defects including heteroskedasticity and autocorrelation could also be handled using random effect model cluster standard error. Furthermore, to determine whether multicollinearity between variables exists, this study performed the Variance Inflation Factor (VIF) test to check for panel data. The results of the VIF test show that all coefficients are less than 10, which means that multicollinearity does not occur in the studied number (Kennedy & Kennedy, 1992).

#### 4. RESULTS AND DISCUSSION

##### 4.1. Descriptive statistics

Table 1 provides the descriptive statistics for the variables in the empirical models. The average value of cash holdings in Vietnam is 15.7%, roughly the same as in the study of (Tan, Tan, et al., 2021) for Chinese companies for the period from 2013 to 2018. The average value of PM2.5 air pollution concentration is 88.3, ranging from 35.59 to 117.78, suggesting that the overall air quality in Vietnam is poor, a very tiny percentage of persons who are extremely sensitive to air pollution may have a mild health risk for some contaminants. According to a 2022 annual survey by IQAir, Vietnam was ranked 30th in the globe and third most polluted country in Southeast Asia after Indonesia and Laos. The mean of leverage is about 19.6%, indicating that about one-fifth of total assets are financed by debt.

**Table 1. Descriptive statistics.**

Variable	Obs	Mean	Std.Dev	Min	Max
Cash	2282	0.157	0.165	0.00062	0.961
Size	2282	27.635	1.703	23.288	33.694
NWC	2281	0.083	0.211	-0.745	0.918
ROA	2245	0.057	0.077	-0.491	0.828
PTB	2136	1.355	1.702	0.022	42.269
Lev	2281	0.196	0.172	0	0.782
CFOA	2282	0.04	0.145	-1.083	1.115
PM2.5	2310	88.313	20.760	35.591	117.782

Source: author’s calculation from research data

##### 4.2. Correlation matrix

Table 2 presents the pairwise correlation coefficients between variables in the research model. In general, most of the correlation coefficients between variables are quite low. Air pollution has a negative association with cash holdings, offering some first evidence to support the negative effect hypothesis, which implies that businesses’ operations and production can be impacted by air pollution. Pollution can lower

labor productivity, raise production costs, and harm an organization’s overall business operations. As a result, the company’s income and earnings may decline, which would lower its cash holdings. Nevertheless, the coefficients in the correlation matrix do not necessarily constitute a valid base for causal inferences, therefore, regression analysis is conducted to give a more robust basis.

**Table 2. Correlation matrix.**

Variables	Cash	Size	NWC	ROA	PTB	Lev	CFOA
Cash	1.0000						
Size	-0.1672	1.0000					
NWC	-0.2427	-0.2155	1.0000				
ROA	0.3318	-0.0109	0.0409	1.0000			
PTB	0.1236	0.2585	-0.1293	0.2727	1.0000		
Lev	-0.3428	0.3655	-0.2925	-0.2414	0.0070	1.0000	
CFOA	0.1776	0.0008	-0.1872	0.3324	0.0751	-0.1384	1.0000
PM2.5	-0.0519	0.0512	0.0449	-0.0338	0.0083	-0.0251	-0.0703

Source: author’s calculation from research data

### 4.3. Regression analysis

Table 3 provides regression results to analyze the relationship between cash holdings and air pollution levels of listed firms in Vietnam. OLS result suggests that PM2.5 does not have a significant association with cash at 10 percent, which is not in line with hypothesis H1, H2, and two theories: trade-off theory and neoclassical theory. This result also holds for the panel data regression technique that controls for individual effects which are prevalent due to panel data structure (Column 2).

The research result differs from those of previous studies to some extent. Tan, Tan, et al. (2021) when conducting on companies with A-shares listed on the Shanghai and Shenzhen Stock Exchanges between 2013 and 2018, report a positive relationship between the two factors, but claim that this is due to some cognitive bias: air pollution causes managers to be pessimistic in terms of earnings forecasts as well as suffer cognitive bias toward risk aversion. Tan, Tan, et al. (2021) also claim that the positive relationship between the two factors is due to the strict regulation of the Chinese government. Meanwhile, B. Li et al. (2021) based on information from Shanghai and Shenzhen A-share listed firms from 2013 to 2017 and air quality monitoring information made available by the China National Environmental Monitoring Center, argue that air pollution increases the level of cash holdings to fund investments in environmental activities. Nonetheless, B. Li et al. (2021) acknowledge that businesses that generate a significant amount of pollution are frequently the backbone of the community’s economy in China. If excessive measures are used against enterprises that produce a lot of pollution, negative impacts on local economic and social development could progress. As a result, the government might compromise and keep these polluting businesses operating normally, leading to these large enterprises feeling less pressure to keep cash for pollution-abatement measures. Therefore, even though a positive relationship between air pollution and cash holdings is recorded, it is still possible that if regulations are not so strict or the attitude of government/citizens is not demanding, this relationship could become insignificant.

The insignificant effect is recorded in the present study, which is the new finding of the research. First, the attitude of people towards protecting the environment is not serious and laws need to have stronger enactment in reality. This could be due to the fact that Vietnamese citizens have been accustomed to adapting to poor air quality over a long period of time, as a result of some sacrifice to attract foreign investment to facilitate economic growth. Second, there are a considerable number of vehicles commuting, contributing significantly

to air pollution by emitting combustion-related pollutants that have reached alarming levels. This is not related to firms' behavior, partly justifying the insignificant effect of air pollution on cash holdings.

We improve the robustness of the findings by adding important control variables. First, in Column (3), we control for the level of annual industrial production in each province. The impact of air pollution (if any) on cash holdings could be, indeed, due to the impact of high levels of industrial production, investment, and firm operations are obviously linked to decisions related to cash management. Second, in Column (4) we control for the level of corporate support policy in each province. If firms receive high support from local governments, it might imply that firms could be partly exempted from strict pursuance of environmental standards. Therefore, the inclusion of these extra variables could change the previous result. Nonetheless, PM2.5 is still insignificant and the size of the coefficient does not change markedly.

Furthermore, we examine the factor of the Covid-19 outbreak. The virus outbreak already has a significant impact on firms worldwide in all aspects. Studies have shown that due to lockdown policies to prevent the spread of Covid-19, air pollution reduces. Additionally, the outbreak effectively affects investment opportunities and introduces uncertainty to firms' operations, obviously affecting cash holdings. Given that this factor affects both air pollution and cash holdings at the same time, we divide the sample into two periods: before 2020 (when there is no obvious impact of the Covid-19 outbreak) and from 2020 onwards.

Table 4 shows the estimation results for both periods, with (columns 1, 2) and without further control variables (columns 3, 4). PM2.5 remains insignificant throughout the four specifications, ensuring the robustness of the previous findings.

In Vietnam, banks play a significant role in the financial market as the primary source of funding for businesses (Nguyen, Ta, & Nguyen, 2018; X. V. Vo, 2018). Saddour (2006) suggests that leverage can substitute cash for environmental investments, allowing companies to finance such projects through debt and reducing the need for large cash holdings. This allows companies to invest in machinery, equipment, and technology to innovate production methods and reduce air pollution, thereby decreasing their reliance on cash while mitigating the effects of pollution.

In other words, G. Zhang, Fang, Zhang, Wang, and Hu (2019) suggest that debt may have a negative effect on pollution protection investment due to its high financial cost, implying that businesses are more inclined to finance potentially profitable investment initiatives provided by external financing (Anderson et al., 2017), as a result, debt basically reduces the capacity for environmental research. Since investments in environmental R&D do not generate profits, firms taking out loans must put their attention on paying off debt rather than utilizing that cash to fund such projects. This effect should strengthen in a country with weak environmental laws/weak enforcement of environmental standards. As a result, it is anticipated that debt can moderate the relationship between cash holdings and air pollution. We ascertain this by examining the effect of the interaction between leverage and air pollution on cash holdings.

In Table 5, the variable  $PM2.5*Lev$  has a negative and significant association with cash, in line with hypothesis H3 that the leverage factor has a moderating significance of lessening the impact of air pollution on cash holdings of listed non-financial firms in Vietnam. This outcome provides empirical support for the pecking order theory. It is clear that in the case of Vietnam, due to more lax environmental regulation and enforcement and the attitude of citizens toward environmental issues, debt might emerge as a factor that reduces the need to invest in environmental protection activities. This effect is present for the whole period, as well as before and during the outbreak of Covid-19.

**Table 5. The moderating effect of leverage on the relationship between PM2.5 and Cash.**

Cash	Whole sample	During Covid-19	Before Covid-19

## 5. CONCLUSION

Holding the right amount of cash is important to capitalize on investment opportunities, to facilitate precautionary purposes yet effectively address opportunity cost/agency cost. Many studies have provided insights into understanding the changes in cash holdings; nonetheless, air pollution receives little attention, especially in the setting of developing countries. Using a sample of listed firms in Vietnam from 2016 to 2021, we document a non-significant association between air pollution and cash holdings, not confirming hypothesis H1, H2, and two theories: trade-off and neoclassical theory. Even though this is somehow inconsistent with the positive linkage found in studies in China, we offer some plausible explanations to harmonize the results. First, the environmental protection measures might force firms to increase cash to fulfill the requirements, lax regulations and enforcement together with the not so serious environmental concerns of people in Vietnam could lead to an insignificant link between cash holdings and air pollution. Second, air pollution could also have a negative impact on cash holdings if managers are made more risk-averse. This is because they might invest in less risky projects or just fewer projects overall, so less cash is required.

In addition, we find that leverage facilitates a negative association between air pollution and cash holdings, in line with hypothesis H3 and pecking order theory. Since activities in environmental protection do not generate returns, firms taking out loans must prioritize debt payment. This effect should strengthen in a country with weak environmental laws/weak enforcement of environmental standards, such as Vietnam. This implies that for a firm to be more environmentally responsible, its debt levels should be lower to allow it to have more flexibility to care for investments in environmental protection.

### 5.1. Implications

This study has important implications for decision-makers, investors, managers, and other involved parties. First, the research findings indicate a non-significant association between air pollution and cash

holdings in a developing country like Vietnam. Therefore, decision-makers and policymakers should shift their attention to other critical effects of air pollution, such as public health, environmental sustainability, and social well-being, when formulating policies and making decisions. Second, managers should acknowledge that air pollution may not have a significant direct impact on cash holdings and should instead focus on implementing effective financial management strategies to maintain liquidity and cash flow stability. Additionally, recognizing the leverage facilitates a negative association between air pollution and cash holdings, managers should assess leverage levels, employ risk management measures, and adopt sustainable business practices to mitigate environmental risks.

## 5.2. Limitations and prospects

Our study has certain limitations that provide new possible avenues for future research. First, the data on air pollution has been only collected from a few significant cities, which may not be representative of the entire population so there is a call for research on gathering more random and representative data on air pollution in other Vietnamese provinces in the future. Second, the study period was relatively short, with the analysis data only examined for the years 2016 through 2021. For thorough research, later studies can incorporate data from a larger range of years. Third, the research has been limited to Vietnam's listed firms, its generalizability may be constrained. Therefore, future research should continue with more developing countries and examine whether the findings hold.

## FINANCIAL LEVERAGE AND INVESTMENT DECISIONS IN VIETNAMESE LISTED COMPANIES

**Author: Ta Thi Thuy Duong<sup>1</sup>, Nguyen Phan Ly Ha, Le Binh, Nguyen Thi Ngoc Thu**  
**Mentor: PhD. Nguyen Hai Yen<sup>2</sup>**

University of Economics and Law, Vietnam National University Ho Chi Minh City

**ABSTRACT:** *This research examines the impact of financial leverage on investment decisions by using unbalanced panel data of Vietnamese listed companies for 13 years from 2008 to 2021. The fixed effect model is applied to investigate this relationship. The results show that financial leverage has a positive impact on investment decisions in Vietnamese listed companies during the studied period. Also, there is an existence of long-term effects of leverage on investment decisions. Unlike previous studies, we investigate the effect of CEOs' characteristics, namely CEO's ownership, duality, age, gender and education level on the relationship between leverage and investment. The results highlight that the positive impact of leverage on investment is reduced when the age and education level of the CEO are higher, however, this relationship becomes stronger in case of the existence of CEO's ownership. We do not find the effect of CEO's gender and duality on the link between financial leverage and investment. These findings will be useful to shareholders in making decisions on selecting the right manager for the firm.*

**Keywords:** *financial leverage, investment decisions, CEOs' characteristics*

### 1. INTRODUCTION

A wise investment decision will help increase the value of the companies, consequently enhancing the owner's asset worth (Nga, Dien, Linh, & Tuoi, 2019). For this goal, the first step is to choose whether a form of capital (short-term capital, long-term capital, equity, or debt) will be utilized to invest in assets. Over the past decades, many studies have been conducted on debt and investment decisions, but controversial with inconsistent conclusions. The majority of global studies reveal a negative association between financial debt and investment decisions (Aivazian, Ge, & Qiu, 2005; Jensen & Meckling, 1976; Lang, Ofek, & Stulz, 1996; Odit & Chittoo, 2008; Sajid, Mahmood, & Sabir, 2016; Stulz, 1990), while other authors show a positive correlation between financial leverage and investment decisions (Franklin & Muthusamy, 2011; Thi Bich Ngoc, Ichihashi, & Kakinaka, 2022; Trang & Quyen, 2013).

Previous studies have primarily focused on the contextual influences that determine the link between financial leverage and investment decisions, such as growth rate, state ownership and crisis. However, CEO characteristics are also factors of concern. According to agency cost theory suggested by Jensen and Meckling (1976), this association might be impacted by differences in maximizing utility between managers and executives. In addition, the upper echelons theory (UET) suggests that each chief executive officer (CEO) approaches investment decisions differently. In particular, some researchers have published their findings, but there have been no obvious conclusions about the impact of CEO's on the link between financial leverage and companies' investment decisions (Bathala, Moon, & Rao, 1994; Fosberg, 2004; Friend & Lang, 1988; Hasbrouck & Schwartz, 1988; Kaur & Singh, 2021; Stulz, 1990).

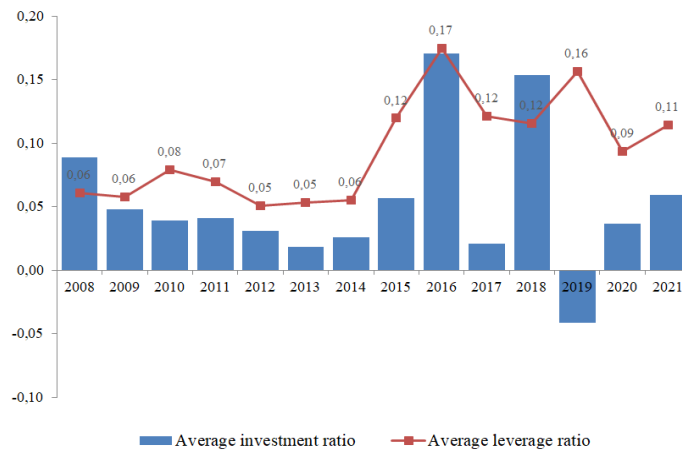

Furthermore, the majority of previous studies on the relationship between financial leverage and investment decisions have been conducted in advanced countries and not much studies in developing

<sup>2</sup> Mentor: Nguyen Hai Yen; Tel: +84 987176269; Email: yennh@uel.edu.vn

countries. As a developing country, Vietnam has approximately 98% of enterprises classified as small and medium sized (Ministry of Planning and Investment, 2021). These enterprises face many difficulties due to lack of internal capital, experienced labor and financial resources. Therefore, to get more investment capital, firms only choose to borrow capital from commercial banks.

During the research period, there were unanticipated changes in the average investment ratio and average leverage ratio of Vietnamese listed companies based on the reviewed sample data. Due to variation of these two factors over time (figure 1), investigating this relationship in Vietnam has become necessary.

**Figure 1. Average investment and leverage ratio of Vietnamese enterprises from 2008 to 2021**

(Source: Authors' Calculation on self-collected data.)

In summary, the topic of leverage-investment has been investigated in financial literature, but it is inconclusive. Specifically, the role of CEO characteristics in the relationship between financial leverage and investment has not yet been investigated. Moreover, most studies have focused on samples from developed countries such as the U.S, China, Canada, the case of developing transition countries like Vietnam have a few empiricals. Although Vietnam and China have some culture, society and politics in common, Vietnam also has many differences, such as the size of its economy and companies, its history of transformation, its level of openness to the global economy, and its emerging financial market. Studying in a Vietnamese context is believed to be valuable for corporate financial empirical. Therefore, we have chosen to study the topic “Financial leverage and investment decisions in Vietnamese listed companies”.

## 2. THEORETICAL FRAMEWORK

### 2.1. LEVERAGE AND INVESTMENT THEORIES

Modigliani-Miller (1958) concluded that under the assumption of perfect capital markets, the value of companies does not rely on which financial source is utilized to invest, and a firm's financial leverage ratio has no effect on the firm's value and hence a firm's financing and investment decisions are independent. In the case of taxes, however, M&M (1963) argued that companies will choose capital with lower interest rates to avoid paying more taxes; a firm's financial leverage ratio influences capital costs, affecting the firm's value and investment decisions. Despite significant advances in the research process, M&M ignores the cost component owing to the danger of utilizing debt and the asymmetric information, even though the information asymmetry is the primary reason which causes agency concerns with agency costs.

According to Jensen and Meckling (1976), agency costs arise due to conflicts of interest between shareholders and management. As a result of these conflicts, corporate managers tend to select a capital structure that maximizes their own benefits rather than the benefits of the company's shareholders. While financial leverage may provide tax advantages (Modigliani & Miller, 1958), Jensen (1986) argues that the temptation to use cash flow for interest and loan payments can constrain managers' rewards (in terms of salary, reputation, etc). Consequently, managers may adopt strategies to limit or reduce the use of financial leverage in investment decisions in order to protect their current position and income.

## 2.2. Related Literature and Hypothesis development

Using a range of methodologies and reasons, studies on the influence of financial leverage on investment have found inconclusive outcomes.

Myers (1977) discovered a negative association between financial leverage and investment in his study on the influence of financial leverage in corporate governance. He contends that when debt usage is high, the odds of completing projects with positive net present value are reduced, hence creditors will also receive a portion of the return on investment, utilizing more debt would harm shareholders' interests. In other words, a high debt ratio may cause management to pass up investments with positive net present values. Hence, the agency problem develops when debt drives underinvestment; the more debt, the less investment. Jensen (1986) and Stulz (1990) suggest that the conflict between management and shareholders is the primary source of the detrimental impact of financial leverage on investment decisions. Managers seek to grow the company's size even if it involves unsuccessful initiatives and lower shareholder returns, resulting in overinvestment. As a result, management's exploitation of the company's free cash flow is reduced, and minimizing investment. Although conducted at different periods and locations, McConnell and Servaes (1995), Lang et al (1996), Aivazian et al (2005), Firth et al (2008) all show that leverage prevents investment decisions. On the other hand, Hite et al (1977) show a positive link between financial leverage and investment decisions. Financial leverage allows organizations to pay fewer taxes while increasing earnings. Besides, financial leverage encourages higher investment while lowering financial risk hence the cost of bond financing. He also demonstrates that when businesses compensate for all choice factors, the effect of financial leverage is significantly different when production, investment, and financing decisions are examined concurrently.

According to our research, there has been some published empirical evidence in Vietnam connected to the relationship between financial leverage and corporate investment decisions. However, the findings of these investigations are conflicting. Trang and Quyen (2013) discovered that financial leverage is positively correlated with the investment activities of companies in general and companies with high growth opportunities, but it is negatively correlated with investment for firms with few growth opportunities. Thao (2014), Nguyen and Loc (2018) found that financial leverage is negatively correlated with investment activities for both companies with high growth potential and companies with low growth potential. However, Thi Bich Ngoc, Ichihashi and Kakinaka (2019) found that financial leverage has a positive impact on investment decisions after examining the link between financial leverage and investment decisions in Vietnamese SMEs.

Based on a theoretical assessment and empirical data, it is evident that the majority of research demonstrates a negative influence of financial leverage on investment decisions. This is because a high debt ratio raises the chance of a company going bankrupt, puts pressure on interest expenditures, and encourages enterprises to decrease investments to avoid liquidity concerns. As a result, the authors propose the first hypothesis as follows:

*H<sub>1</sub>: There will be a positive relationship between financial leverage and investment decisions.*

### **2.3. Theoretical basis of CEO's impact on the relationship between financial leverage and investment**

Over the past two decades, research in behavioral finance has increasingly played an important role in explaining financial decisions that traditional finance theories have not explained clearly. The upper echelons theory (UET) supposes that executives' different traits have an impact on structure and strategy and therefore it will directly have an impact on a firm's strategic courses of action and organizational performance (Nielsen & Huse, 2010). There is growing empirical evidence that manager-specific characteristics have a significant effect on financial decisions such as capital (Bertrand & Schoar, 2003; Graham & Harvey, 2001; Kaur & Singh, 2021). Among which, Kaur and Singh (2018) believed that the qualities of managers have a considerable effect on financial leverage's usage. However, empirical evidence on the presence of CEO's impact on the relationship between a business's financial leverage and investment decisions have been still absent. Meanwhile, since Vietnam transitioned to a market management mechanism, businesses have been self-accounting and allocating capital sources. As a result, the CEO has played an important role in the financial decision-making of companies. Therefore, the authors widened the understanding of the important function played by CEOs in order to explore the influence of CEO characteristics on the relationship between financial leverage and investment decisions. We consider CEO education level, gender, age, ownership and duality as CEO characteristics:

#### **CEO's Education**

According to Finkelstein and Hambrick (1996), highly educated CEOs are more likely to take chances and risk seeking. Similarly, Bertrand and Schoar (2003) discovered that managers with master's degrees are more likely to utilize debt for investments. They supposed that these managers are more open and proactive in using debt when growth prospects appear. In contrast to the preceding findings, Kaur and Singh (2018) found no association between education level and the decision to use financial leverage. As such we offer the following hypothesis:

*H2: The education level has a positive impact on the association between financial leverage and investment decisions.*

#### **CEO's Gender**

Difference in manager's gender will lead to diversity in the style of leadership and decision-making. Faccio et al (2016) discovered that firms led by female CEOs have more consistent earnings, a lower debt ratio in their capital structure, and these are less likely to go bankrupt than companies led by male CEOs. According to behavioral finance theory, women have a smaller degree of overconfidence bias than males, which along with differences in family duties and societal norms, results in a higher level of apprehension women face more risks and precautions (Bernasek & Shwiff, 2001; Hudgens & Fatkin, 1985). Males are more likely to occupy CEO roles in enterprises in Vietnam. However, in recent years, Vietnam has been a bright spot in Southeast Asia for gender diversity, with recent studies indicating that Vietnam has a substantial number of women holding high positions such as CEOs and corporate executives. Hence, we consider the CEO's gender in this study. The following hypothesis is proposed:

*H3: Female CEOs have a negative influence on the link between financial leverage and investment decisions.*

#### **CEO Age**

According to UET, older CEOs are more risk averse and indecisive than younger generations (Hambrick & Mason, 1984). As a result, they will prioritize internal capital sources compared to loans.

Moreover, managers may be in a period of economic stability, the objective of safety and minimal risk in the profession will be prioritized. Thus, any threats to their stability are ruled out (Carlsson & Karlsson, 1970). Other research indicates that elderly CEOs have less cash and wield less leverage (Bertrand & Schoar, 2003; Serfling, 2014). Based on the theoretical considerations presented above, the authors offer the following hypothesis:

*H4: CEO age has a negative influence on the link between financial leverage and investment decisions.*

### **CEO Ownership**

According to research on the relationship between CEO equity ownership and firm capital structure, increasing management ownership can help businesses reduce the use of leverage to minimize bankruptcy risk, supporting the view that there is a negative relationship between ownership ratio and leverage (Bathala et al., 1994; Friend & Lang, 1988; Hasbrouck & Schwartz, 1988). Bathala et al (1994) explained firms accept a trade-off between equity and debt in order to control agency costs. When the CEO invests a major portion of his assets in the firm as a shareholder owning shares, CEO's benefits are connected to the value of the companies. Thus, CEOs will strive to minimize or limit the use of financial leverage in the company's investment activities due to using cash flow to pay interest and debt would lower managers' rewards (Fosberg, 2004; Jensen, 1986; Kaur & Singh, 2021; Stulz, 1990). From that, we proposed the following hypotheses:

*H5: CEO share ownership ratio has a negative influence on the link between financial leverage and investment decisions.*

### **CEO Duality**

When the Chairman of the Board (COB) and CEO are held by one person, this is referred to as duality. In terms of the decisions to use debt, Wellalage and Locke (2012) discovered that duality reduces communication conflicts with the management team and creates a clear sense of unity in decisions. On the other hand, Fosberg (2004) argued that organizations with a two-tier leadership structure are more likely to use the appropriate amount of debt in their capital structure than organizations where the CEO is dual. He discovered that organizations with a two-tiered leadership structure had greater debt/equity ratios, however, it is not statistically significant. We suggest the following hypothesis:

*H6: CEO duality has a negative influence on the link between financial leverage and investment decisions.*

## **3. RESEARCH METHOD**

### **3.1. Research models**

The author conducts statistical description analysis, correlation analysis to eliminate multi-collinear phenomena between independent variables. We use regression estimation of effects via ordinary least square (OLS), fixed effects model (FEM), and random effects model (REM) regression approaches. After selecting the appropriate method to run the model, the author tests the statistical assumptions regarding the impact coefficient, multicollinearity, and heteroscedasticity. Then, overcome the model's defect by robust or cluster standard error.

We use the basic model mentioned by Aivazian et al (2005). We also include growth opportunities, firm age and liquidity factor and return on assets ratio. These control variables have been incorporated to provide possible influences on investment decisions (Cevik & Miryugin, 2022; Doan & Nguyen, 2018; Firth, Lin, & Wong, 2008; Nguyễn & Lộc). Specifically, the model is expressed as follows:

$$INV_{i,t} = \alpha + \beta_1 LEV_{i,t} + \beta_2 CF_{i,t} + \beta_3 TBQ_{i,t} + \beta_4 ROA_{i,t} + \beta_5 LIQ_{i,t} + \beta_6 SIZE_{i,t} + \beta_7 AGE_{i,t} + \varepsilon_{i,t} \quad (1)$$

INV represents the net investment of companies, determined by the net investment to total assets of the current year (INV1). LEV is the financial leverage, which is measured using two proxies. The first one is calculated by dividing the total long-term debt by the total assets (LEV1). The ratio indicates the dominant role of long-term debt (Aivazian et al., 2005) and we used this proxy in this study. The second proxy is the ratio of total debt to total assets (LEV2), which would be used as a robustness test, and the remaining variables will be introduced in Table 1.

In addition, we consider the CEO’s characteristics such as age, educational level, gender, share ownership rate, and duality. We determine the impact of CEO’s characteristics on the relationship between financial leverage and investment decisions basing on the following model with interactive variable:

$$INV_{i,t} = \alpha + \beta_1 LEV_{i,t} + \beta_2 CF_{i,t} + \beta_3 TBQ_{i,t} + \beta_4 ROA_{i,t} + \beta_5 LIQ_{i,t} + \beta_6 SIZE_{i,t} + \beta_7 AGE_{i,t} + \beta_8 CEOage_{i,t} + \beta_9 CEOownership_{i,t} + \beta_{10} CEOedu_{i,t} + \beta_{11} CEOdual_{i,t} + \beta_{12} CEOgender_{i,t} + \beta_{13} CEOage*LEV_{i,t} + \beta_{14} CEOownership*LEV_{i,t} + \beta_{15} CEOedu*LEV_{i,t} + \beta_{16} CEOdual*LEV_{i,t} + \beta_{17} CEOgender*LEV_{i,t} + \varepsilon_{i,t} \quad (2)$$

Moreover, we also consider the one-period lagged (t-1) impact of financial leverage on corporate investment based on the regression model:

$$INV_{i,t} = \alpha + \beta_1 LEV_{i,t-1} + \beta_2 CF_{i,t-1} + \beta_3 TBQ_{i,t-1} + \beta_4 ROA_{i,t-1} + \beta_5 LIQ_{i,t-1} + \beta_6 SIZE_{i,t-1} + \beta_7 AGE_{i,t-1} + \varepsilon_{i,t-1} \quad (3)$$

### 3.2. Variable measurement

The variables used in the above research model are measured in detail in the table measuring the representative variables used in the model.

**Table 1. Variable definitions**

Variable	Code	Measures	Previous studies
<b>Dependent variable</b>			
Investment 1	INV1	Net capital expenditure (capital expenditure minus depreciation)/ total assets for the current year	Firth et al (2008); Danso, A., Lartey, T., Fosu, S., Owusu-Agyei, S. and Uddin, M. (2019); Nga et al(2019).
Investment 2	INV2	Net investment/ lagged net fixed assets= (Capital expenditure- depreciation)/ lagged net fixed assets	Lang et al. (1996), Aivazian & Qiu, J. (2005), Odit và Thu Chittoo (2008), Mehmet Umutlu (2009); Segara, R., & Yang, J. Y. (2020).
<b>Independent variables</b>			
Leverage 1	LEV1	Long-term debt /Total assets	Aivazian et al (2005); Franklin & Muthusamy (2011).
Leverage 2	LEV2	Total debt / total assets	Chen (2004), Chava and Roberts (2008); Chen et al (2010); Pamela et al (1983); Mehmat (2009), Ahn et al(2005).
Cash flow	CF	Operating cash flow/ net fixed asset	Odit and Chittoo (2008); Khurshed, Syed & Habib, A (2013); Firth et al (2008); Franklin & Muthusamy (2011).
Tobin’s Q	TBQ	(Market value of common equity + Total assets – Common equity – Deferred taxes) / Total assets	Segara, Reuben, and Jin Young Yang (2020); Franklin & Muthusamy (2011).
ROA	ROA	Ratio of earnings before interest, taxes, depreciation and amortization (EBITDA) to total assets	Franklin & Muthusamy (2011) Luciano, R. (2003); Fosu (2013)
Size	Size	Log of total assets	Franklin & Muthusamy (2011). Odit và Chittoo (2008); Khurshed, Syed et al (2013); Serhan Cevik and Fedor Miryugin (2020).
Age	Age	The logarithm of years since the firm was organized	Firth et al (2008), Serhan Cevik and Fedor Miryugin (2020), (Diaz et al., 2016; Doan and Nguyen, 2018).
Liquidity	LIQ	Current assets/Current liabilities	Dejong et al (2018); Franklin & Muthusamy (2011).

CEO Age	CEOage	A logarithm numeral variable expressing age of the CEO adjusted by year	Hambrick & Mason (1984), Carlsson & Karlsson (1970), Bertrand & Schoar (2003), Serfling (2014), Kaur, R., & Singh, B. (2021).
CEO Ownership	CEOownership	Ratio of number of shares owned by the CEO to the number of outstanding shares of the firm	Bathala et al (1994), Jensen (1986); Stulz (1990); Fosberg (2004); Kaur and Singh (2018), Kaur, R., & Singh, B. (2021).
CEO Duality	CEOdual	A dummy variable which is assigned the value of one if CEO is the chairperson and zero otherwise	Abor (2007), Mokarami et al (2012), Wellalage et al Locke (2012), Kaur & Singh (2021)
CEO Education	CEOedu	A dummy variable which is assigned the value of one if a CEO is a postgraduate, for instance, carries a master's and/or PhD degree and zero otherwise	Finkelstein and Hambrick (1996); Bertrand and Schoar (2003); Wang et al(2016); Kaur & Singh (2021).
CEO Gender	CEOgender	A dummy variable which is assigned the value of one if the firm is female owned and zero otherwise	Faccio et al (2016); Hudgens & Fatkin (1985); Johnson & Powell (1994), Kaur, R., & Singh, B. (2021).

(Source: Authors' Collection.)

#### 4. RESULTS AND DISCUSSION

Table 2 reports the overall observations, mean, standard deviation, minimum, and maximum values of financial variables included in the model. The mean investment value is 0.03 and 0.092 whereas Lang (1996) reported a value of 0.122, and Kumar et al (2019) reported 0.809. This outcome might be attributed to the fact that the majority of Vietnamese firms are small and medium-sized, that the life cycle of enterprises is not too long, and that comparable features and forms of investment capital are used, resulting in minimal volatility. The average value of LEV1 (long-term debt to total assets ratio) is relatively low at 0.060 and LEV2 is 0.208 (short-term debt to total assets), indicating that Vietnamese firms rely more on short-term debt.

**Table 2. Descriptive statistics of research data**

Variable	Obs	Mean	Std. dev.	Min	Max
INV1	3370	.030	.066	-.324	.372

**Table 3. Descriptive statistics on CEO characteristics**

Variable	Obs	Mean	Std. dev.	Min	Max
CEOage	3370	49.230	7.971	24	78
CEOownership	3370	4.740	9.343	0	71.82
CEOgender	3370	.077	.268	0	1
CEOedu	3370	.289	.454	0	1
CEOdual	3370	.223	.416	0	1

(Source: Authors' Calculation on self-collected data.)

The young age group accounted for 3% while the middle age group accounted for 73% and the elderly group accounted for 24%. This result indicates that CEOs in Vietnam tend to be concentrated in the middle age group. The average CEO ownership ratio is 4.74, with a high ownership ratio of 72%, reflecting the concentration of ownership and share ownership in some organizations. Female CEOs only make up less than 10%, highlighting a significant gender disparity in corporate management. Executives who simultaneously serve as CEO and Chairman is not common. The percentage of CEO with a postgraduate degree is less than that of CEO qualifications with a university degree or less.

**The impact of financial leverage on firm’s investment**

According to the multicollinearity test results, the variance inflation factor (VIF) magnification coefficients are all less than 10, and the maximum VIF coefficient is 1.18, showing that the possibility of the phenomenon of multicollinearity is negligible. Because White’s test reveals that the model has heteroscedasticity, the OLS model is inapplicable. To choose the best model, we applied REM and FEM regression with the Hausman test (chi-square statistic = 70.67, P-value = 0.000), which shows the REM is inconsistent and inefficient, thereby FEM is more suitable at 1% level of significance.

The result of the FEM model (1) in Table 4 shows that financial leverage has a positive impact on investment decisions with a significance of 1%. This result rejects hypothesis  $H_1$  about the negative relationship between financial leverage and investment decisions. Our results show that firms with higher financial leverage are more likely to make new investments to expand their businesses. This is because financial leverage allows firms to increase their return on equity by using debt to finance their investments. By using debt, firms can reduce their tax liability and increase their earnings. Furthermore, financial leverage can also encourage higher investment levels while lowering financial risk, which in turn can lead to lower costs of bond financing (Hite, 1977). This result is consistent with the findings of studies conducted by Franklin & Muthusamy (2011), Trang & Quyen (2013), Ngoc et al (2019), Nguyen & Dong (2016).

Aside from the effect of financial leverage on investment, additional control variables in the model also have a certain influence on the dependent variable. The firm size and the growth opportunities have a positive impact, while the firm age has the negative effect, the factors of cash flow, liquidity, and return on assets have not yet had a significant impact on investment decisions. Specifically, the growth opportunities as measured by Tobin's Q is positively associated with investment decisions at the 5% significance level. This result is also consistent with the results of Gomes (2001), Aivazian et al (2005) and Li et al (2010). Firm size has a positive impact on investment decisions in the FEM regression, but not statistically significant. This implies that the size of the firm has no important role in the firm's investment decisions. This result is consistent with the findings of Kumar (2010), and Ruiz-Porras and Lopez-Mateo (2011). The firm age has a negative impact on the investment decisions. The younger companies create more investment opportunities (Adelino, Ma, & Robinson, 2017; Kaur & Singh, 2021). It can be explained that since long-established companies in the sector are in a period of stability and saturation in the market, their objective is to focus on preserving. Moreover, companies with a long history of operation often already have loyal customers and a varied product portfolio, so instead of focusing on product or service expansion, the firm may focus on protecting profits by optimizing operations and decreasing expenses. ROA and investment decisions have a negative association, which is not statistically significant. Our results are consistent with Nga et al (2018). This result contradicts prior research by Odit and Chittoo (2008), Trang and Quyen (2013). Liquidity has a negative impact on firms investment at the 1% significant level. This implies that when the LIQ increases, the firms' investment decisions decrease. This result is similar to the study of Kale and Noe (1990) on US firms and Zou and Xiao's (2006) which showed that high liquidity can lead to wasted cash and reduce investment productivity.

### **The impact of financial leverage on firm's investment: the moderation role of manager's characteristics (CEO)**

The results of the model (2) in Table 4 examined the impact of CEO's characteristics on the link between leverage and firm's investment, particularly share ownership, age, and education level of CEO have an impact on the positive relationship between leverage and investment. In specific, the positive effect of leverage on investment will be enhanced for firms whose CEO controls a large percentage of share ownership. Meanwhile, CEO's age and education level reduce the positive impact of financial leverage and investment. The characteristics of CEO's duality and CEO's gender have not found an impact on this relationship.

The result displays that the interaction variable between leverage and CEO shares ownership (LEVxCEOownership) is positive and statistically significant at 5%. This conclusion is contrary to hypothesis  $H_5$  that the CEO share ownership has a negative impact on the link between financial leverage and investment decisions. The positive effect of leverage on investment is stronger for companies where the CEO has a high percentage of share ownership. It implies that increasing ownership will enhance the impact of financial leverage on investment. This can be explained by the fact that when CEOs own a large portion of a company's stock, they can have greater motivation and influence over the company's investment decisions. Specifically, they have a financial interest in investing and seeking profits. Therefore, they tend to focus more on investment projects that are likely to yield higher returns. The result is consistent with the findings of Jensen and Meckling (1976), Berger et al (1977).

The interaction variable between leverage and CEO's age (LEVxCEOage) has a negative association at the 1% significant level. This result supports hypothesis  $H_4$  that CEO's age has a negative impact on the link between financial leverage and investment decisions. Because younger CEO will decide to use leverage to invest more. This can be explained by younger CEO's ambition to succeed in their career, which drives them to make stronger and more risky decisions than older CEO. As a result, young CEO are more motivated to innovate and invest than to maintain medium, stable, and long-term growth. This is consistent with the findings of Hambrick and Mason (1984), Margarethe and Bantel (1992), and Li et al (2014).

The interaction variable between leverage and CEO's education (LEVxCEOedu) has a negative association with a significance of 5%. This result negates hypothesis  $H_2$  that the education level of the CEO has a positive impact on the link between financial leverage and investment decisions. To explain this, CEO with a high degree of education will have a cautious and measured perspective of the market and will not make bold decisions, thereby reducing the ability to use leverage in investments. Our finding is contrary to the results of many prior studies such as Finkelstein and Hambrick (1996), Bertrand, who proposed that the education level of CEOs is related to the ability to finance more debt due to the risk-taking attitude of higher-educated CEOs.

The interactive variable between leverage and CEO's duality (LEVxCEOdual) is negative, but not statistically significant. This finding is consistent with Sheikh and Wang (2012), Kaur and Singh (2021).

The interactive variable between leverage and CEO's gender (LEVxCEOgender) has a negative coefficient, but not statistically significant. Our result is consistent with the result of Kaur and Singh (2021).

### **The impact of financial leverage on firm's investment: the effect of lagged leverage**

The regression results of the lagged variable model (3) and (4) in Table 5 show that financial leverage in the previous period has a positive impact on the current period investment, at a significance level of 1%.

Our result is similar to Navissi and Sajad (2016). When debt of the previous period increases, the enterprise can use this money to invest in the next period that helps to increase the ability to invest and generate profits. Moreover, with stable interest rates of long-term debt, businesses can make specific plans for investment decisions in the coming periods. This result supports our suggestion proposed in the research model section, the selection of the lagged variable model confirms the existence of the lagged impact of leverage on investment decisions.

**Table 5. The effect of one lagged period leverage**

(Source: Authors' Calculation on self-collected data.)

**Robustness tests**

To test the robustness of the research model, we use another measure of financial leverage and another measure of investment decisions. Table 6 shows that the correlation between financial leverage and investment decisions are still positive when using the investment variable with a different measure (INV2) but still using long-term debt to quantify leverage (LEV1), this result is consistent with the results obtained when using the model (1), thus ensuring the robustness of the research model.

INV2 is a new investment decisions measurement variable included to test the robustness.

(Source: Authors' calculation on self-collected data.)

Besides, when we measure financial leverage by total debt to total assets (LEV2), we find that financial leverage has a negative impact on investment decisions for both measures of investment decisions (INV1, INV2) at 1% significance level. This result is also consistent with previous studies by Jensen and Meckling (1976), Aivazian et al (2005a), Firth et al (2008), Nguyet et al (2014), Ngoc et al (2019), Cevik et al (2020). As mentioned in the research review, these studies support the theory of the investment constraining effect of debt due to agency problems. Debt creates pressure on using cash flow to pay interest and loan capital will reduce the benefits of managers (in terms of salary, reputation,...). Therefore, to protect their current position and income, managers will find ways to avoid or minimize the use of financial leverage in the company's investment activities. In addition, stemming from the fact that the short-term debt of Vietnamese enterprises accounts for a relatively large proportion (64% of the total number of observations have the ratio of short-term debt greater than long-term debt). Although short-term debt has a low-interest rate, there is uncertainty about the supply of subsequent loans. As a result, using too much short-term debt in total debt will cause certain difficulties in long-term investment decisions.

## 5. CONCLUSION

This paper extended earlier empirical studies on the relationship between financial leverage and investment decisions in Vietnamese listed companies. With a dataset of 564 firms from 2008 to 2021, we found that financial leverage is positively related to investment decisions. The robustness of this result is verified by an alternative definition of firm investment. Also, the regression model with lagged independent variables highlighted there is an existence of long-term effects of leverage on investment decisions.

Unlike previous studies, we investigated the impact of CEO's characteristics on the relationship between financial leverage and investment decisions. We found that the positive impact of financial leverage on investment decisions is reduced when the age and the education level of the CEO are higher. Meanwhile, the positive effect of leverage on investment will be stronger for businesses with CEOs who own a high percentage of the stock. The attributes of CEO's duality and CEO's gender have no effect on this relationship.

Our results inferred some implications. The managers can consider using a suitable level of financial leverage to expand their enterprise. However, they need to consider the maturity of the debt and compare the level of suitability with the loan purpose as well as the firm's cash flow to pay the debt obligation, avoiding the situation of short-term loans to implement long-term financing projects. Furthermore, these findings will be useful for shareholders to make decisions on selecting the suitable manager for the firm. If being risks seeking to take more opportunities, shareholders should choose CEOs who are young and have a college degree or less, they will take on more risk in investing. Besides, shareholders also consider CEO's share ownership rate, a high CEO ownership rate indicates that CEO's benefits are tied to the firm, so the CEO will consider the company's investment choices.

To conclude, this study provides new insights into the leverage–investment relationship and the role of CEO's characteristics. Due to insufficient data on internal information of the companies, many observations were excluded which may affects the reliability of the results. It will be useful to extend this research to test how this relationship matters across industrial lines and using more estimated methods for robustness check. This is something new that could be looked at in future research.

## EVALUATING THE EFFECTIVENESS OF ETFS IN VIETNAM BY THE MISPRICING AND VALUE AT RISK

**Author: Nguyen Bao Thy<sup>1</sup>, Nguyen Thi Hai Yen<sup>2</sup>, Le Tran My Hanh<sup>2</sup>,**

**Le Tuong Vy<sup>2</sup>, Tran Thi Kim Anh<sup>2</sup>**

**Mentor: MS Vo Thi Le Uyen<sup>3</sup>**

**ABSTRACT:** *The research article aimed to evaluate the efficiency of 10 ETF funds in Vietnam from January 2018 to early November 2022. Firstly, based on Beta, Alpha, Sharpe and Treynor ratio, the study evaluates the efficiency of the ETFs and finds two outstanding funds: FUEVFN30 and FUESSVFL. Then, conducting the ARX-GARCH model showed the impacts affecting the mispricing of ETFs. The E1VFN30, FUESSV50, and FUEMAV30 funds are overpriced. In addition, the GARCH-t and GJR-GARCHt models are used to estimate the VaR, indicating that the mispriced funds (E1VFN30, FUESSV50, and FUEMAV30) have a minimal loss rate when the market experiences bad events which are higher than other ETFs. After that, the researchers used the Backtesting method to test and choose the GJR-GARCHt model to estimate VaR more accurately and reasonably. Finally, through the evaluations and VaR, the study proposed an investment portfolio, including FUEVFN30 and FUESSVFL funds with the proportion being 13.74% and 86.26%, respectively.*

**Keywords:** *ETF, VaR, ARX-GARCH, GARCH-t, GJR - GARCHt, Backtesting.*

### INTRODUCTION

Since the 1990s up until now, ETFs have become one of the most popular passive investment platforms among professional investors. In Vietnam's market, (Anh & Huong, 2021) used the Sharpe ratio to evaluate the effectiveness of investment portfolios of investment funds. The research team believes that ETFs are a new and urgent research area for the nascent investment environment that the world is paying attention to.

Value at Risk is the maximum loss amount in a certain period of time, if the worst cases are excluded. This index was born after the Sharpe, Treynor, and Jensen indices, so its popularity is still not really high compared to its predecessors. VaR is applied to different financial instruments such as stocks, bonds, foreign currencies, and derivatives, as a statistical measure of portfolio risk based on the latest positions, taking into account portfolio diversification and leverage (Jorion, 2009). (Dowd, 1999) và (Tehrani, Mohammadi, S. M, & Nejadolhosseini, N. S, 2014) have both proposed investment decisions based on VaR. To estimate VaR, (Fuess, Kaiser, D. G., & Adams, Z., 2007) combined VaR with the GARCH model, and the result was that GARCH-type VaR performed better than other VaRs on most fund barrier indices. The authors have shown that GARCH-type VaR is a superior risk measure, especially for trading strategies that exhibit negative skewness, excess kurtosis, and provide daily prices. The VaR method will be an effective tool for measuring the potential risk of investment funds in the future. Therefore, in this study, the group will use the VaR measure to estimate market risk.

ETFs are a relatively new investment tool in the Vietnamese market, so data as well as scientific research are still limited. Therefore, the group believes that this is a new and urgent topic, so they have carried out the

study: **“EVALUATING THE EFFECTIVENESS OF ETFs IN VIETNAM BY THE MISPRICING AND VALUE AT RISK”** The study uses data from 8 domestic funds and 2 foreign funds in the Vietnamese market between January 2018 and early November 2022 to evaluate the performance of the funds. The study will use 4 indices: (1) Sharpe ratio, (2) Beta, (3) Alpha, (4) Treynor ratio to preliminarily evaluate the performance of the funds. The focus of the study is the application of the ARX(p,q) - GARCH(r,s) model to evaluate the impacts affecting the mispricing of ETF (PD) with 5 endogenous variables including the VN-Index, Gold price, Oil price, trading volume and volatility. The general objective of this research is to evaluate the effectiveness of ETF funds in the Vietnamese market using the Value at Risk method. Based on the research findings, we propose an investment portfolio consisting of two ETF funds, FUEVFNVD and FUESSVFL, which have been considered to be the most optimal.

## 2. LITERATURE REVIEW

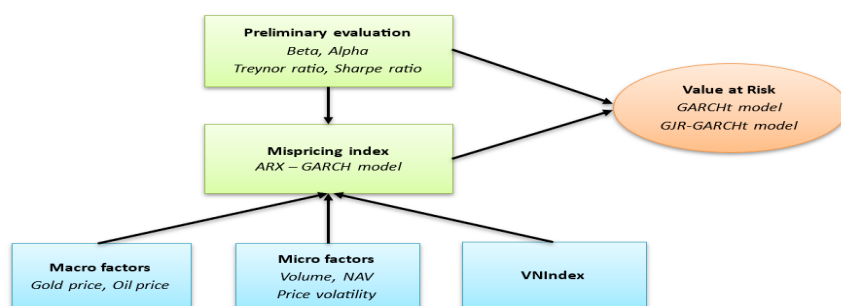

Exchange Traded Fund (ETF) is an investment fund that simulates the fluctuations of stock or bond indices, which are traded on stock exchanges. ETFs have become one of the most popular passive investment vehicles among retail and professional investors due to their low trading costs and high liquidity. Globally, the total asset scale of ETFs managed worldwide has increased significantly from 2009 to 2019, with an increase of nearly 400% to USD 11.4 trillion on November 19 in 2019, (MBS, 2020). Therefore, ETFs are becoming a trend worldwide and in Vietnam.

To evaluate the performance of investment funds, most previous studies have used tools such as the Sharpe ratio, Treynor ratio, Jensen’s Alpha. (Jayadev, 1996) used the Sharpe ratio, Treynor ratio, and Jensen’s Alpha to evaluate two growth-oriented mutual funds but the results of these ratios did not work well. According to the research of (Liang, 1999), using the Sharpe ratio, Treynor ratio, and Jensen’s index to evaluate the performance of South African stock investment funds, the results of Jensen’s index and Treynor ratio are used to make decisions and determine market timing for fund managers. (Povilas, 2014) attempts to introduce and compare the risk and performance ratios of Lithuanian mutual funds using the Alpha, Beta, Sharpe, and Treynor ratios. The research paper by (Stefanus & Robiyanto, R, 2020) examines ETF funds from 2018-2019 using indicators such as the Treynor. (Vardhini RN & Naupal Reddy, 2020) demonstrates that the Sharpe performance measure, Treynor Ratio, and Jensen measure help investors make effective decisions, but the research is limited by the relatively small number of observed variables due to the newness of the ETF market in various countries. Another study by (Sumit, 2019) uses indicators including Return, Risk, Sharpe Ratio, Beta, Jensen’s Alpha to analyze the annual profit. It shows that ETF funds generate the highest profits over a 5-year period, even during market downturns, and perform better than index funds.

Value at Risk is the maximum amount of potential loss at certain intervals, after excluding the worst-case scenarios. VaR is a relatively new risk measurement tool, and its popularity is not yet widespread. Combining VaR with other risk measures can help evaluate investment portfolios or simply describe the potential loss that could occur within an investment portfolio (Linsmeier & Pearson, N. D., 2000). (Alexander & Baptista, A. M., 2002) has indicated that portfolio managers can use mean-VaR to select investment portfolios instead of the traditional average variance. The research by (Tehrani, Mohammadi, S. M., & Nejadolhosseini, N. S., 2014) used VaR value estimation through the GARCH (1,1) model and the Monte Carlo estimation method, while conducting a model test using the Kupiec test method to increase confidence in the model. The study also used the adjusted Sharpe ratio to evaluate the efficiency of ETFs in Iran. The conclusion of the research shows that both VaR calculation methods using GARCH and Monte

Carlo are reliable - a good alternative for calculating VaR and making investment decisions. (Ali, M. Raza, & N. Zaman, 2021) examined the impact of macroeconomic indicators such as interest rates, inflation, and GDP on the VaR of US equity ETFs using MPT and EMH. The Modern Portfolio Theory is a theory aimed at maximizing investment portfolios to maximize expected returns with a certain level of risk, and risk is a necessary trade-off to achieve higher profits. It was developed by Harry Markowitz in the early 1952s and has been widely used by investors and fund managers (Thào, 2019). The efficient market hypothesis states that stocks are always traded at fair values in the stock market. Fama (1970) stated, “A market in which prices always fully reflect available information is called an efficient market.” Malkiel (1992) argued that a capital market is considered efficient if it fully and accurately reflects all relevant information in determining stock prices (Lan, 2019). The authors found that economic indicators significantly impact the VaR of ETFs, and their findings have implications for risk management strategies. Another study by [ (Bouzouita, A. Karoui, & M. B. Ghorbel, 2021) investigates the relationship between market volatility and ETF profitability in emerging markets using MPT and EMH. The authors found that market volatility has a significant impact on ETF profitability, and they suggest investors consider this factor when making investment decisions.

Most research studies focus only on the performance of funds without considering their risk levels. Therefore, we use not only commonly used ratios such as Beta, Alpha, Treynor, and Sharpe to assess the historical performance of funds but also GARCH-t and GJR-GARCHt models to estimate Value at Risk to effectively measure risk. Additionally, we use Backtesting to select the best VaR measurement model.

**Figure 1. Research framework**

### 3. METHODOLOGY

#### 3.1 Preliminary evaluation method

Investors utilize various methods to evaluate the performance of a portfolio. Monitoring the year-to-year returns of the portfolio is a common practice. However, when attracting potential investors, simply presenting trend analysis is insufficient. Investors typically seek a comparative assessment of portfolio performance against other portfolios, different asset classes, or the overall market. According to the studies of (Samuel Anbu Selvan S.C.B & Ram Raj G, 2021) and (Sathish Kumar and Ram Raj, 2019) the research team will use the following indices for this study. These ratios provide investors with a sense of confidence regarding how the portfolio performed in relation to the market or other assets.

##### 3.1.1 Beta

Beta is a measure of systematic risk of a security or an investment portfolio relative to the overall market:

$\beta = \frac{Cov(R_i, R_m)}{Var(R_m)}$  ; If an investor wants to invest with a higher Beta, they must accept higher risk.

### 3.1.2. Alpha

The Alpha is an indicator used to evaluate the effectiveness of an investment fund relative to the market index:

$$\alpha = R_p - [R_f + (R_m - R_f) * \beta]$$

If the Alpha is positive, it indicates that the fund has achieved higher returns than the expected return based on the level of risk and vice versa.

### 3.1.3 Treynor ratio

The Treynor ratio is a measure of the return earned by an investment compared to the systematic risk taken. The higher the Treynor ratio, the better the investment performance.

$$\text{Treynor} = \frac{R_p - R_f}{\beta}$$

### 3.1.4 Sharpe ratio

The Sharpe ratio is a measure of how much return an investment generates per unit of risk taken when investing in an asset or following a trading strategy. The higher the Sharpe ratio, the more likely the investment is considered to generate higher returns for the risk taken.

$$\text{Sharpe} = \frac{R_p - R_f}{\sigma_p}$$

The aforementioned coefficients are all important indicators in evaluating the efficiency of an investment portfolio, but they can also be influenced by various factors. Therefore, it is necessary to exercise caution and combine them with other indicators to comprehensively assess the effectiveness of the investment portfolio.

## 3.2 Evaluating using model

### 3.2.1 ARX – GARCH model

The Autoregressive model with exogenous variables and Generalized autoregressive conditional heteroskedasticity model is represented by the ARX(p, q<sub>1</sub>, q<sub>2</sub>,...q<sub>k</sub>) - GARCH(r,s) model:

$$Y_t = \sum_{i=1}^p \phi_i y_{t-i} + \sum_{i=1}^k \sum_{j=1}^{q_i} \psi_{ij} x_{it-j} + a_t,$$

$$|a_t = e_t \sqrt{h_t} ; h_t = \alpha_0 + \sum_{i=1}^s \alpha_i a_{t-i}^2 + \sum_{j=1}^r \beta_j h_{t-j}$$

where: x<sub>1t</sub>, x<sub>2t</sub>,...,x<sub>kt</sub> : are the exogenous variables included in the model; e<sub>t</sub> : is a sequence of random variables following a normal distribution N(0,1).

To ensure that the right-hand side of the variance equation for is always positive and satisfies the conditions on the covariance in the study of (Mike K. P. So, Cathy W. S. Chen and Feng-Chi Liu, 2022), we need to have the following conditions:

$$\alpha_0 > 0, \alpha_i, \beta_i \geq 0 \text{ and } \sum_{i=1}^s \alpha_i + \sum_{j=1}^r \beta_j < 1$$

According to the study of (Mike K. P. So, Cathy W. S. Chen and Feng-Chi Liu, 2022), the ARX-GARCH model is very useful for analyzing the time series profit of the market. This result is consistent with the study of (Baillie, R. T., Bollerslev, T. and Mikkelsen, H. O., 1996) for the S&P 500 index. The profit of the SE300 index has an AR(3) form in the study of (Karolyi, 1995), based on the Akaike information criterion (AIC), which also shows that the ARX-GARCH model is optimal for forecasting profit with the impact of exogenous variables.

### 3.2.2 Value at Risk - VaR using the GARCH-t model:

The GARCH model has the advantage of capturing the time-varying volatility of financial time series, which can be updated regularly to reflect changes in market conditions and is a common method for estimating VaR. (PHUỐC, TOÀN, N. V., & THÀNH, V. B., 2017) in their research that the GARCH(1,1) model can be used to forecast VaR through testing the impact of structural breaks. Building on previous authors, a study by (Füss, Dieter G Kaiser, & Zeno Adams, 2007) asserted computed and measured VaR using three methods, including Historical Simulation, Conditional Autoregressive Value at Risk, and GARCH. The GARCH model was used to estimate income rate volatility based on probability distributions. Other studies by (Bollerslev, 1986); Huang and Lin, 2004; So and Yu, 2006, and others) have used heavy-tailed distributions.

GARCH (p,q) model has the following form:

$$\sigma_t^2 = \omega + \sum_{i=1}^p \alpha_i \varepsilon_{t-i}^2 + \sum_{j=1}^q \beta_j \sigma_{t-j}^2$$

Value at Risk according to GARCHt:

$$\widehat{VaR}_{t+1}^q = -\widehat{\sigma}_{PF,t+1} t_v^{-1}(q) \sqrt{\frac{v}{v-2}}$$

### 3.2.3 Value at Risk – VaR using the GJR-GARCHt model

The study by (Mostafa, Pritam Saha, Mohammad Rafiqul Islam, & Nguyet Nguyen, 2021); (Duan & Jung-Chu Lin) proposed that for non-normally distributed data, the GJR-GARCH model with a t-student distribution can be applied as a risk measurement tool to counter the market uncertainty of unstable ETFs. The studies by (Mostafa, Pritam Saha, Mohammad Rafiqul Islam, & Nguyet Nguyen, 2021); (Duan & Jung-Chu Lin) all concluded that the GJR-GARCH model provides better and superior estimates for the volatility of returns compared to the GARCH model.

The GJR-GARCH (Glosten, Jagannathan, and Runkle - GARCH) is an extension of the GARCH model that adds asymmetry to address the leverage effect in predicting asset price volatility, developed by (Robert F. Engle, Emil N. Siriwardane, 2018). This model provides risk forecasts for financial assets, thereby supporting risk management for investors and investment funds. The GJR-GARCH (p, q) model has the form:

$$\sigma_t^2 = \omega + \sum_{i=1}^p \alpha_i \varepsilon_{t-i}^2 + \sum_{j=1}^q \beta_j \sigma_{t-j}^2 + \sum_{k=1}^p \gamma_k I_{t-k}^2 \varepsilon_{t-k}^2;$$

With  $I_{t-i} = 1$  if  $\varepsilon_{t-i} < 0$  and  $I_{t-i} = 0$  if  $\varepsilon_{t-i} \geq 0$

Value at Risk according to GJR – GARCHt:  $\widehat{VaR}_{t+1}^q = -\widehat{\sigma}_{PF,t+1} t_v^{-1}(q) \sqrt{\frac{v}{v-2}}$

The research of (Hò Thủy Tiên, 2017) applies the GJR-GARCH model to test the impact of structural breaks, showing that incorporating structural breaks into the GJR-GARCH model can be used for VaR forecasting.

### 3.3 VaR – Backtesting test

Backtesting Value at Risk is crucial because it helps validate the accuracy and reliability of VaR models in estimating and managing portfolio risk. By Backtesting VaR, historical data can be used to assess how well the VaR model predicted actual portfolio losses during past market conditions. This allows for the evaluation of the model’s performance and provides insights into its strengths and weaknesses. It helps identify any deficiencies or biases in the model’s assumptions and calculations. It is a critical step in the risk management process and aids in making informed investment decisions.

There are various methods of measuring VaR and each method has its own limitations, so it is important to have proper evaluation methods to assess the quality of the calculated risk values. The idea behind this test is to examine each VaR value compared to the Profitability rate, defined as follows:

$I_t(\tau) = \{1 \text{ if } r_t < -VaR(\tau) \text{ 0 if } r_t \geq -VaR(\tau) \}$  ; where:  $I_t(\tau)$ : Contains a value of 0 or 1;  $r_t$ : return rate.

#### 3.3.1 Unconditional coverage test - POF test

VaR-Backtesting is a commonly used method to test the accuracy of the VaR model, a financial risk measurement method that includes checking whether actual losses are consistent with expected losses. The most widely known experiment is based on the failure rate proposed by Kupiec (1995). Kupiec’s experiment, or POF-test (proportion of failures), measures whether the number of outliers is suitable for the level of confidence. This testing method has the advantage of being suitable for the distribution model of gaps in reality, without necessarily assuming that gaps follow a normal or similar distribution.

$$\text{Hypothesis: } \begin{cases} H_0: p = \hat{p} = \frac{x}{T} \\ H_1: p \neq \hat{p} \end{cases}$$

where: T is the number of observations; x is the number of expectations.  $\hat{p}$  is the exceedance probability. The idea is to find out whether the observed failure rate  $\hat{p}$  is significantly different from p, the failure rate suggested by the confidence level.

According to Kupeic (1995), the POF-test is best performed as a likelihood-ratio test. The test statistic takes the form:  $LR_{POF} = -2\ln\left(\frac{(1-p)^{T-x} p^x}{[1-\hat{p}]^{T-x} \hat{p}^x}\right)$

$LR_{POF}$  follows a Chi-square ( $\chi^2$ ) distribution with 1 degree of freedom. If the test statistic  $LR_{POF} >$  the critical value of the  $\chi^2$  distribution, then  $H_0$  is rejected- the model is inaccurate and vice versa.

#### 3.3.2 Conditional coverage test - Mixed Kupiec test

(Haas, 2001) introduced a new improved testing method by combining the ideas of Christoffersen and Kupiec, called the Mixed Kupiec test. In (Nieppola, 2009) study, multiple methods were used simultaneously to perform VaR tests, and the results indicated that the Mixed Kupiec test was the best solution as it is able to capture more general forms of dependence.

According to (Haas, 2001), Kupiec's TUFF test, time until first failure test, can be used to evaluate the time between two threshold crossings. The statistical test for each threshold crossing is as follows:  $LR_i = -2\ln\left(\frac{p(1-p)^{v_i-1}}{\left(\frac{1}{v_i}\right)\left(1-\frac{1}{v_i}\right)^{v_i-1}}\right)$ ; where:  $v_i$  the time between two threshold crossings  $i$  và  $i-1$

After computing the LR test statistics for each threshold crossing, a test of independence is obtained where the null hypothesis is that there is no dependence between the threshold crossings and the fitted model. With  $n$  as the number of threshold crossings, the statistical test for independence is given by:

$$LR_{ind} = \sum_{i=2}^n \left[ -2\ln\left(\frac{p(1-p)^{v_i-1}}{\left(\frac{1}{v_i}\right)\left(1-\frac{1}{v_i}\right)^{v_i-1}}\right) \right] - 2\ln\left(\frac{p(1-p)^{v_i-1}}{\left(\frac{1}{v_i}\right)\left(1-\frac{1}{v_i}\right)^{v_i-1}}\right)$$

Mixed Kupiec test:  $LR_{mix} = LR_{POF} + LR_{ind}$

$LR_{mix}$  follows  $\chi^2$  distribution with  $n + 1$  degrees of freedom. If the test statistic  $LR_{mix} >$  the critical value of the  $\chi^2$  distribution, then  $H_0$  is rejected - the model is inaccurate and vice versa.

#### 4. DATA AND PRELIMINARY EVALUATION RESULTS

##### 4.1 Data

- Data: 10 ETF in Vietnam, including 2 foreign funds and 8 domestic funds
- Dependent variable: The mispricing of 6 domestic ETF funds, including E1VFN30, FUESSV30, FUESSVFL, FUESSV50, FUEMAV30, and FUEVFN30.
- Independent variables: Daily closing the VNIndex, gold price, oil price, trading volume, NAV and daily price volatility of ETFs.
- Independent variables: According to research by (Nguyen, Nguyen, T. T. N., & Nguyen, T. T. M., 2021) has found that macro factors such as crude oil price, gold price have a positive influence on the evaluation of ETFs. Another study by (Rahmanto & Wibowo, B., 2021) and (Lucy F. Ackert & Yisong S. Tian, 2008) found that trading volume has a negative effect on the mispricing of ETFs based on NAV value. By contrast, the study of (Gunduz Caginalp & Mark DeSantis, 2017) also shows that the price movement of ETFs positively affects the evaluation of ETFs. In addition, ETFs in Vietnam are stock index ETFs modeled after baskets of securities on the Vietnamese stock exchange, so the Vietnam Stock Market Index (VNINDEX) will have an impact on ETF evaluation. Besides, the study of (Ching-Chung Lin, Shih-Ju Chan & Hsinan Hsu, 2006) shows NAV (Net Asset Value) positive effect on the mispricing of ETF. Independent variables used in studies are collected from Investing, concluding:

1. Daily closing VNIndex
2. gold price
3. oil price
4. trading volume
5. NAV of ETFs
6. daily price volatility of ETFs

- Timeframe: From January 2018 to early November 2022.

4.2 Preliminary assessment

Table 1. Preliminary assessment result

	Beta	Rank Beta	Alpha	Rank Alpha	Treynor	Rank Treynor	Sharpe	Rank Sharpe	Average rank
E1VFN30	0.93248	1	0.0000254	7	0.046689	8	0.055912	7	5

FTSE	0.19842	9	0.0000604	6	0.079847	5	-0.076439	8	4

Source: Authors' Calculation

When the Beta is close to 1, it is better because the fund's volatility is equal to that of the market. A positive Alpha is preferable as it indicates that the fund achieves higher profits than expected based on its risk level. Similarly, higher values for the Treynor and Sharpe ratios are better. As a result, FUEVFNVD and FUESSVFL are the two funds with the best evaluation results. Investors may consider investing in them, but they should also take into account other factors that may affect efficiency, such as the fund's cash flow, the companies in the index basket, and the management capabilities of fund managers.

4.3 The ARX (p,q)- GARCH (r,s) model results

$$PD_{f,t} = \left| \frac{P_{f,t} - NAV_{f,t}}{NAV_{f,t}} \right|$$

where:  $PD_{f,t}$ : The value of ETF f mispricing at the time t;  $P_{f,t}$ : The closing price of ETF f at the time;

$NAV_{f,t}$ : The Net Asset Value of ETF f at the time t

ARX Model:

$$PD_{f,t} = \alpha_f + \beta_{f1} * PD_{f,t-1} + \beta_{f2} * PD_{f,t-2} + \beta_{f3} * D(NAV_{f,t}) + \beta_{f4} * D(Goldprice_t) + \beta_{f5} * D(Oilprice_t) + \beta_{f6} * D(VNINDEX_t) + \beta_{f7} * Vlttycc_{f,t} + \beta_{f8} * Volume_{f,t} + \beta_{f9} * Volume_{f,t-1} + \beta_{fi} * X_{f,t} + \beta_{fi} * Y_{f,t} + a_t$$

where:  $Goldprice_t$ : Logarit of Gold price at time t;  $Oilprice_t$ : Logarit of Oil price at time t;  $VNINDEX_t$ : Logarit of VINDEX at time t;  $Vlttycc_{f,t}$ : Volatility of trading price of at ETF f at time t;  $Volume_{f,t}$ : Logarit of the transaction volume of ETF f at time t;  $X_{f,t}$ : Separate variables of ETF f at time t;  $Y_{f,t}$ : Breakpoints of ETF f at time t.

**Condition:**  $a_t = e_t \sqrt{h_t}$  and  $h_t = \alpha_0 + \sum_{i=1}^s \alpha_i a_{t-i}^2 + \sum_{j=1}^r \beta_j h_{t-j}$  ( $\alpha_0 > 0, \alpha_i, \beta_i \geq 0$ )

Source: Authors' Calculation

The result's five of six funds show significant positive correlation between dependent variable and the one-lag mispricing. This indicates that investors mispriced the value of the funds in the past, they can make wrong decisions in the future. The mispricing of most ETFs has negative correlation with the first difference

in their NAV, including FUESSV30, FUESSVFL, FUESSV50, and FUEVFN30. This result shows that if these ETF are operating well in the market, investors can evaluate ETFs potential and minimize mispricing based on NAV. By contrast, E1VFN30 and FUEMAV30 have opposite correlation, indicating that when the NAV increases, the mispricing of these ETFs also increases, meaning that investors have too high expectations, but the funds are not performing well.

The relation between the first difference in gold price and the dependent variable of E1VFN30 and FUESSV50 funds are significant positive. According to the study of [37], the gold price has a positive impact on the profit from ETFs. When the gold price rises, the expectation of the fund's profit can increase which may cause mistakes in valuing the fund. On the other hand, the first difference in oil price has a negative correlation with the dependent variable of most ETF funds but is not significant.

The mispricing of E1VFN30, FUESSV30, and FUEMAV30 funds has a negative correlation with the D(VNINDEX) variable, while the FUESSVFL, FUESSV50, and FUEVFN30 have the opposite relationship. E1VFN30, FUESSV30, and FUEMAV30 funds based on the VN30 index- representing the index of the 30 most capitalized and liquid stocks on HOSE, accounting for over 80% of the capitalization of VNINDEX. Therefore, based on the VNINDEX, investors can predict the fluctuations of E1VFN30, FUESSV30, and FUEMAV30 funds. Other ETF funds including FUESSVFL and FUEVFN30 have reference of VNFINLEAD and VN Diamond index - consist of stocks that have potential and good returns in the stock market. Therefore, investors will have high expectations for the value of these funds, leading to some mispricing about the real value of the ETF.

The trading volume and price volatility of most ETF funds are significantly positively correlated with dependent variables. This shows that when trading volume and price volatility increase, the mispricing of the fund will increase because investors may be influenced by market psychology and make wrong decisions. In addition, the trading volume of six ETF funds is quite limited, according to the study by (Gunduz Caginalp & Mark DeSantis, 2017) showing that when trading volume is small, market inefficiency will exist. Therefore, because ETFs in the Vietnamese market are still relatively new, the market is not yet efficient.

#### 4.4 The Value at Risk using the GARCH-t and GJR-GARCHt models

\* GARCH-t (1,1) model:

$$\sigma_t^2 = \omega + \alpha \varepsilon_{t-1}^2 + \beta \sigma_{t-1}^2$$

\* GJR-GARCHt (1,1) model:

$$\sigma_t^2 = \omega + \alpha \varepsilon_{t-1}^2 + \beta \sigma_{t-1}^2 + \gamma I_{t-1} \varepsilon_{t-1}^2$$

With  $I_{t-1} = 1$  if  $\varepsilon_{t-1} < 0$  and  $I_{t-1} = 0$  if  $\varepsilon_{t-1} \geq 0$

\* VaR using the t-student distribution:

$$\widehat{VaR}_{t+1}^q = -\widehat{\sigma}_{PF,t+1} t_v^{-1}(q) \sqrt{\frac{v}{v-2}}$$

**Table 4. The loss ratio**

*Source: Authors' Calculation*

After conducting preliminary evaluations and ARX-GARCH models, the researchers calculate the VaR to determine the ETFs are appreciated by financial indexes and the funds need to be cautious in the model result, which are truly accurate when the market experiences bad events with different levels of confidence. The results show that FUEVFNVD has the lowest loss ratio when the market experiences fluctuations on November 2, 2022, and this fund is also appreciated in Table 1. Meanwhile, the FUEIP100, FM and FTSE funds are underestimated, specifically the Alpha, Sharpe and Treynor Ratio are negative, and the Loss Ratio of these three funds is also higher than that of the other funds. In addition, the results of the ARX-GARCH model show that the E1VFN30, FUESSV50 and FUEMAV30 funds are expected but are not yet performing effectively, their Loss ratios are also slightly higher than the benchmark. As a result, having the relation between the preliminary evaluations, the mispricing and VaR shows that the funds appreciated have lower the minimum loss ratios when the market experiences adverse fluctuations. Furthermore, if mispricing of the fund, these funds will have higher risks than the other.

#### **4.5 Value at Risk-Backtesting**

According to Table 6 and 7, VaR is calculated at different confidence levels by GARCH-t and GJR-GARCHt models. After Backtesting using the POF-test and Mixed Kupiec test, it is found that the GJR-GARCHt model is more accurate and suitable when the number of violations failure rate of almost all ETF funds is in the number of expected exceptions. While the GARCH-t method in some cases have the observed number of exceptions exceeds expected exceptions but still cannot reject H0 by using both the POF-test and Mixed Kupiec test such such the FUEVFNVD fund case at 90% and 95% confidence levels in GARCH-t model and the FM fund at 90% confidence level in both the GARCH-t and GJR-GARCHt models. In addition, for some funds, the number of violation failure rates are too small compared to the expected exceptions, so the hypothesis is rejected, and the model was incorrect, which include E1VFN30 fund at 95% confidence level, FUEIP100 fund at 90% confidence level, and FM fund in 90%,95% and 99% confidence level. Moreover, two funds have the observed number of exceptions exceeding expected exceptions of the GARCHt model but can't reject H0 by using POF-test because of not enough distance, consisting of FUEMAV30 and FM funds, with the respective confidence levels of 99% and 95%.

Source: Authors' Calculation

According to Table 8 and 9, the GJR-GARCHt model is accurate and suitable for most ETF funds except for the FUEIP100 and FM funds, while the GARCHt model is not suitable for the E1VFN30, FUEMAV30, FUEIP100, FUEVFNVD, FM, and FTSE funds. As a result, this study should use the GJR-GARCH method instead of the GARCH-t method to calculate the more incorrect VaR.

The FUEVFNVD and FUESSVFL funds have achieved higher-than-expected profits compared to other funds. However, their volatility and risks are also higher. In addition, FUEVFNVD has a Sharpe ratio that exceeds all other funds and FUESSVFL is in second place. Besides, these two funds have also shown better historical investment efficiency. According to the ARX model, investors should be cautious in valuing E1VFN30, FUESSV50, and FUEMAV30 funds, as they are currently overvalued compared to their real values. Moreover, given the complex fluctuations of the market, it is not guaranteed that ETF funds will perform as expected. Therefore, investors need to build an optimal investment portfolio to prevent risks while ensuring profits. As a result, the researchers propose a recommended investment portfolio based on previous evaluations and the VaR-GJR-GARCH model’s loss ratio (selected by backtesting).

**Graph 1. Efficient Frontier**

Source: Authors’ Calculation

**Table 7. Proposed Investment Portfolio**

	<b>FUESSVFL</b>	<b>FUEVFNVD</b>
Weight	13.74%	86.26%

Source: Authors’ Calculation

When an investor has some capital to invest, the allocation for FUEVFNVD is 86.26% and FUESSVFL is 13.74%, and this portfolio provides the lowest risk.

**Table 8. Loss Ratio and Standard Deviation of Proposed Investment Portfolio**

Confidence level	90%	95%	99%
Portfolio loss rate	-5.53%	-6.88%	-10.85%
Portfolio standard deviation	0.017221602		

Source: Authors’ Calculation

From the proposed investment portfolio, it can be seen that the minimum loss rate for investors in the market fluctuations with varying probabilities is lower than that of individual investments. At the same time, according to the efficient frontier graph, the portfolio proposed by the research team is optimal. This helps investors to prevent risks.

**5. CONCLUSION AND RECOMMENDATION**

**5.1 Conclusion**

The authors have observed that funds with good preliminary evaluations are less likely to be mispriced, resulting in lower levels of risk. Conversely, funds with poor preliminary evaluations are more prone to

mispricing and higher levels of risk. Besides, the mispricing is less influenced by macroeconomic factors and is primarily affected by internal factors and the VNIndex. This research will provide investors with a more comprehensive understanding of the relationship between preliminary evaluations, mispricing index, and value at risk. However, there are still some limitations to this study, including the following: Regarding preliminary evaluations, additional indices such as Sortino ratio, Fama method, etc., can be implemented to provide a more comprehensive assessment of fund performance; ETFs are relatively new investment tools in Vietnam, and the limited trading volume restricts the effectiveness of ETFs in the stock market; Some funds lack sufficient data for the ARX-GARCH model, and the data collected for certain funds may not cover a sufficiently long period. Therefore, the evaluation and comparison of ETF models may not be entirely accurate. Some suggestions for future research: It is necessary to regularly calculate indices, models, and Value at Risk (VaR) because past data alone cannot guarantee the effectiveness of future evaluations. Therefore, investors should evaluate the performance of ETF funds periodically; The research team suggests constructing an investment portfolio based on the investor's lowest risk tolerance. However, it is possible to create multiple investment portfolios to align with the risk appetite of each investor group.

## 5.2 Discussions

(Trang, 2023) ETF funds recorded a net capital inflow of 12,636 billion VND in Q4/2022. Among them, VNDiamond ETF fund ranked second with 2,890 billion VND, accounting for 22.36% of the total, just behind the foreign fund Fubon ETF. In fact, since its launch in May 2020, the FUEVFNVD fund certificate of DCVFM Diamond ETF has consistently been among the best-performing funds in the market and of course, significantly outperforms important indices such as VN-Index or VN30 over the same period. It is not an exaggeration to say that Diamond ETF can both be an attack weapon in an uptrend and a safe haven in a downtrend (according to Cafef newspaper). Based on a preliminary evaluation, DCVFM VNDiamond ETF is one of the good domestic funds that deserves consideration and investment. This ETF also has its own attraction thanks to its quality reference portfolio. The fund's index portfolio currently includes 18 stocks that meet the condition of foreign investor ownership of at least 95%, of which MWG, FPT, REE, PNJ... are the names with the highest proportion (according to Cafef newspaper). Therefore, the author group proposes to prioritize investment in the FUEVFNVD fund, followed by the FUESSVFL fund, which has a negative correlation with many other funds, including FUEVFNVD, and may also consider adding the FUESSV30 or E1VFN30 fund (according to the research results of the author group). Depending on investors' risk appetite, capital source, and market situation, they should make rational investment decisions for themselves to achieve the best possible profit level. In addition, investors should consider factors that affect the mispricing of funds and the loss rate to make appropriate investment decisions. Investors should also build a suitable portfolio to prevent risks in the complex market fluctuations.

In our study, there are some limitations that need to be addressed. Firstly, in terms of preliminary evaluation, additional indices such as the Sortino ratio and the Fama method can be applied to comprehensively evaluate the performance of the funds. Secondly, ETFs are a relatively new investment tool in Vietnam, and the trading volume of the funds is still limited, resulting in their performance in the stock market being less effective. Additionally, the duration of data collection to conduct the ARX-GARCH model is not sufficiently long. Lastly, the Value at Risk test has only been back tested using the POF-test and Mixed Kupiec test.

As guidelines for further research, we suggest that investors regularly calculate indices, models, and VaR values in order to evaluate the performance of ETF funds. This is important because past data may not

fully reflect future evaluations. By regularly assessing their investments, investors can ensure that they are making informed decisions and adjusting their strategies as needed. Additionally, it is important to consider a variety of criteria when evaluating ETF fund performance, such as the fund's historical returns, expense ratios, and management fees.

Mentor: Ho Trung Thanh<sup>1</sup>**

**ABSTRACT:** Credit risk management is a top concern of commercial banks because it directly affects the financial stability and profitability of these banks. Accurately assessing and predicting credit default risk is critical to minimizing potential losses. This study focuses on minimizing credit default risk in commercial banks using supervised machine learning techniques, namely credit scoring. The proposed method uses historical credit data to develop a credit scoring model based on supervised machine learning algorithms. By leveraging a data set containing past credit transactions and related outcomes, the model explores patterns and relationships between different credit attributes and defaults. This allows the model to generate a credit score to quantify the creditworthiness of a potential borrower.

**Keywords:** Credit score classification, Machine learning, Stacked Generalization Classification

### INTRODUCTION

The importance of credit scoring in lending decisions for financial institutions and the economy at large cannot be denied. Reliable and effective credit scoring enables lenders to manage their risk exposure through selective credit allocation based on a statistical analysis of previous customer data. Back in 2007 and 2008, there was a severe financial crisis in the US leading to a large-scale collapse of the US institutions. About 10,000 billion US dollars disappeared, 30 million were employed, and a series of bankrupt banks (Duignan, 2023). This is the most severe economic downturn in the US since the Great Depression in 1929. The reason comes from US financial institutions starting to offer risky mortgage loans to rescue real estate buyers. The form of mortgage is aimed at low-income home buyers, with less knowledge, less information, and very high lending risks. At that time, these banks did not consider borrowers and their ability to pay the loan. When the bubble of real estate popped out, not only the US banking system collapsed but the whole world suffered a global economic crisis. It is clear that credit scoring is an essential activity, not only to ensure recoverable loans but also as a foundation for developing a thriving financial system. With the background of nowadays government's consumption stimulation, consumer demand tends to increase, which indirectly leads to an increase in demand for consumer loans. Banks cannot simply employ human resources for analysis when confronted with that issue and a vast and complicated volume of credit information. As a result, several quantitative ways to evaluate credit risk have been proposed in recent years. Data mining is a technique that has gained greater traction than other techniques because it can take genuine knowledge from databases and transform it into valuable information. However, unstructured data, such as text, emails, or telephone calls, cannot be used directly in the standard techniques for credit default prediction without first undergoing processing. That is why more studies using machine learning have been used to exploit this information for credit risk predictions (Kriebel & Stitz, 2022).

<sup>1</sup> University of Economics and Law, Viet Nam National University Ho Chi Minh City, Vietnam.

The use of Machine Learning in the banking industry can be the way to reduce the risk of default by “eliminating” customers with high repayment risks, thereby minimizing risks in credit transactions. In addition, this study evaluates the extent to which a supervised machine learning model accurately predicts the classification results of customers with large data sets to limit the risk because machine learning techniques frequently lack the capacity to comprehend data and persuade clients to follow (Dumitrescu, Hué, Hurlin, & Tokpavi, 2022). The study’s main goal is to divide credit applicants into three categories: “good credit”, which is accountable for repaying debts; Credit will not be granted to those with “poor credit” because of the high likelihood of default and the “standard credit”. This classification serves as a foundation for banks to analyze customer solvency and make loan-granting decisions, lowering the risk of credit failure. Simultaneously, when assessing and evaluating, Machine Learning approaches help save time and money in credit scoring and loan decision-making, boost business efficiency, and reach new potential consumers considering some critical customer qualities. Limiting credit default risk leads to multiple benefits for commercial banks. Banks can avoid significant financial losses by minimizing the default risk. It also results in increased profitability as banks can invest more in profitable ventures instead of provisioning for non-performing loans. Additionally, implementing credit scoring models leads to better decision-making, increased operational efficiency, and higher customer satisfaction as banks can offer tailor-made loan products that match the customer’s creditworthiness and needs (Kithinji, 2010).

Numerous studies have been conducted on the application of machine learning in evaluating credit. (Munkhdalai, Munkhdalai, Namsrai, Lee, & Ryu, 2019) carried out a study to compare the FICO credit score with machine learning credit scoring. The techniques employed in this study include Multilayer Perceptron (MLP) neural network, XGBoost algorithm, and Random Forest Regression. (Busmann, Giudici, Marinelli, & Papenbrock, 2021) takes a strategy that combines network analysis with Shapley values to post-process the analysis findings when used with the XGBoost machine learning model. Each of these strategies offers benefits that point to ways to improve financial sector operations. However, they concentrate on analyzing the outcomes of each unique algorithm separately. In this work, we also use the Machine Learning method to predict and classify data, to classify and evaluate credit scores. The current study seeks to make the following contributions to the existing literature. First, the study will compare the performance of ensemble approaches, which combine the judgments of various classification models that have resulted in superior classification performance than those of individual models. Second, this study classified clients into three groups: “poor credit”, standard credit”, and “good credit”, noting that earlier studies tended to focus on binary categories like “likely to default” and “unlikely to default”.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Credit default**

The majority of banking profits are generated through lending activities and the issuance of credit/loans. Lending out credit is an important component of what banks operate since it may result in significant profits. However, there is also a large risk associated with making decisions in this area, and financial institutions can face significant losses as a result of mistakes (Dang Huong Giang, 2020). This failure of operation can be considered a credit default, in which financial institutions’ customers do not fully repay or fail to repay a loan by the set time, leading to difficulties in the bank’s business and financial operations. The occurrence of credit default risk can be caused by many reasons such as customers’ financial inability, unfavorable business situation, or customers’ lack of goodwill in debt repayment (Gizaw, Kebede, & Selvaraj, 2015). Credit default risks negatively affect the bank’s business activities such as affecting customer deposits,

causing reduced profits or financial losses, and adversely affecting the reputation of the bank. Therefore, managing and minimizing the risk of credit default is very important to ensure the sustainability of the bank's business and financial operations and to use credit scores as a tool to limit the credit default risk.

### **2.1.1. Credit score**

Credit score is a number that reflects a person's credit history (*Surviving Debt: Expert Advice for Getting Out of Financial Trouble*, 2023), and is a decision support system that helps managers in the financial decision-making process. This is an important decision of commercial banks in considering "accepted" or "rejected" a person's credit application. The "accepted" or "rejected" depends on the credit score based on the expectation that the person will be able to repay or not to his or her financial obligations. Thus, when evaluating and approving a loan from people with low credit scores, banks will tend to increase interest rates, require collateral or refuse to give loans. Therefore, in order to limit credit default risks, banks will need to assess the financial capacity and ability of customers to pay debts. Credit scores are used to assess a customer's ability to pay off debt in the future. If the customer has a high credit score, the bank will assess the customer's default risk lower, assign the customer a lower interest rate, and grant the customer a loan with a higher limit (Lee, Park, & Heo, 2019).

Commercial banks use a method known as credit scoring. Credit scoring method is a method of assessing a borrower's credit score, based on the use of algorithms and credit models, it is used to provide a credit score for each borrower. The credit scoring method has many advantages, including the ability to quickly and accurately assess a person's finances, help make an objective loan decision, and reduce risk for lenders.

### **2.1.2. Credit scoring risk**

Credit scoring algorithms and models are based solely on indicators from the collected data sets, regardless of the subjective abilities of individual credit borrowers. It can be said that a person encounters a house fire or traffic accident that makes them unable to repay their credit, which can cause bad debt that cannot be disbursed by the bank. In fact, information about individual circumstances or local economic conditions is not included in the performance of the credit score classification judgment model (Avery, Calem, & Canner, 2004). In addition, the reliability of the data also affects the analysis of the credit score results, the level of confidence in the data based on the profile provided by the borrower and through the bank's validation process. Choosing the wrong model to classify credit scores makes the results after implementation have many errors in assessing whether to "accept" a person's loan application, which will affect the creditworthiness of bank credit and security information leakage can also occur when applying models and algorithms based on customer historical data sets.

### **2.1.3. Machine Learning**

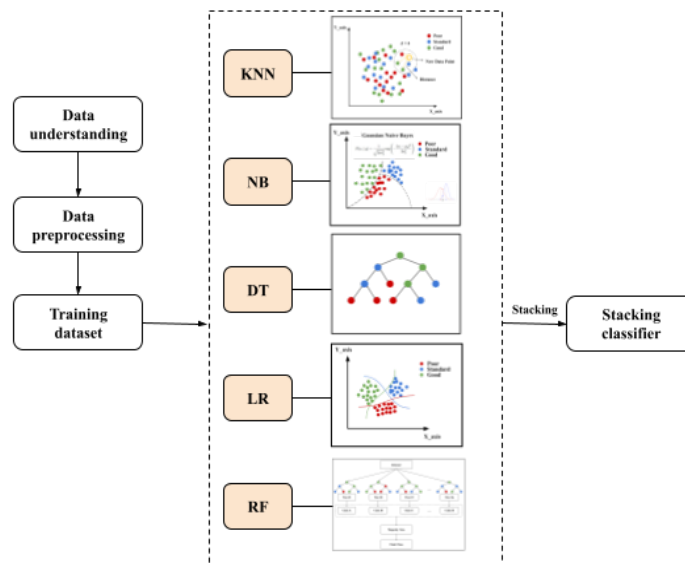

Machine Learning, a branch of artificial intelligence, is a technique for improving system performance by learning from experience through computational methods. The purpose of Machine Learning is to learn from data. Sometimes after viewing the data, one cannot interpret the pattern or extract information from the data. In that case, we will apply Machine Learning. When designing and building Machine Learning systems, it is necessary to consider factors such as problem identification, data collection, and creation, data evaluation, predictive modeling, etc. The use of different datasets leads to different types of Machine Learning. There are two main types of Machine Learning: Supervised Machine Learning and Unsupervised Machine Learning. Among them, Supervised Machine Learning is commonly used, and we also use this form of Machine Learning in credit score classification.

**2.1.4. Supervised Machine Learning**

Supervised Machine Learning is a method where algorithms learn features from a training data set, and then apply it to a test set for classification or prediction purposes. The training set and the test set are divided from an input data set, where the training set includes the input values needed for prediction or classification. Supervised Machine Learning is commonly used in credit scoring models to find the relationship between customer features and credit default risk and then predicts default classification usually in binary format. Across many literature sources, the implementation of Supervised Machine Learning algorithms in credit scoring models has shown good prediction accuracy.

**3. RESEARCH METHOD**

This study uses the Staking classification method. After data was preprocessed, they will be used to run individual models, these are K-nearest Neighbor, Naïve Bayes, Decision Tree, Random Forest, and Logistic Regression. The final classifier will be conducted by mapping all models based on the Stacking classifier. This model is used to classify 3 classes of borrowers: Bad Credit, Standard, and Good Credit. Figure 1 shows the approach method of this study.

**Figure SEQ Figure \\* ARABIC 1. Recommended credit scoring model**

Phase 1: Data understanding with credit scoring dataset.

Phase 2: Training dataset is data that has been processed to put the data set into the scoring model.

Phase 3: Use five individual models including to predict outcomes and show comparisons of results.

Phase 4: After considering the return results of the lowest model, it will continue to use that model according to the Stacking method in combination with the remaining models to calculate the results of the accuracy of the combined models.

Phase 5: Synthesize and analyze the final results to assess the appropriate capabilities of future models and choose the most necessary model for the business.

**Logistic Regression**

Logistic Regression (LR) is a popular statistical regression model used for binary classification tasks. It is a supervised learning algorithm that predicts the probability of a binary outcome based on one or more

independent variables. Unlike linear regression, which is used for predicting continuous values, logistic regression is designed for predicting a categorical variable with two possible outcomes, often referred to as the positive class and the negative class. The dependent variable in logistic regression is typically binary (0 or 1), representing the two classes.

### ***K-Nearest Neighbor***

K-Nearest Neighbor (KNN) is a popular algorithm used in Machine Learning for both classification and regression tasks. It is a non-parametric and instance-based learning algorithm, meaning it doesn't make assumptions about the underlying data distribution. The choice of the parameter  $k$  is crucial and can significantly impact the performance of the algorithm. A small value of  $k$  may result in a noisy decision boundary, while a large value of  $k$  may smooth out the decision boundary too much. KNN is a simple and intuitive algorithm, but it can be computationally expensive, especially when dealing with large datasets. Additionally, it requires the definition of a suitable distance metric to measure the similarity or dissimilarity between data points, such as Euclidean distance or Manhattan distance.

### ***Naive Bayes***

Naive Bayes (NB) is a classification algorithm based on Bayes' theorem, which is a fundamental concept in probability theory. It is a simple yet powerful algorithm commonly used in Machine Learning and natural language processing tasks. Bayes' theorem states that the posterior probability of a class label given the observed features is proportional to the prior probability of the class label multiplied by the likelihood of the observed features given the class label. The Naive Bayes algorithm assumes that the features (or attributes) are conditionally independent given the class label. This is called the "naive" assumption, as it assumes that there is no correlation between the features. Naive Bayes is particularly useful when dealing with high-dimensional data, such as text classification, spam filtering, or sentiment analysis. It can handle a large number of features efficiently, as the computational complexity is linear with the number of features.

### ***Decision Tree***

Decision Tree (DT) is one of the most popular methods used in various fields, such as Machine Learning, and image processing. This method is shaped like a tree, consisting of nodes and branches. Each node represents features in a category to be classified and each subset defines a value that can be taken by the node. Because of their simple analysis and accuracy on many types of data, DT has found many implementation fields.

### ***Random forest***

Random Forest (RF), which aggregates multiple trees by combining different DTs, is a Supervised Learning Classification model for building a forest from a set of trees. The paired trees are trained for random feature selection using an internal bootstrap mechanism that does not allow interaction between DTs. It detects outliers and anomalies in the dataset. It can be said that RF is one of the most accurate Machine Learning methods, generating accurate and highly categorical classifiers for many datasets.

### ***Stacked generalization***

Stacked generalization (SG) is one of the methods that combine many Machine Learning methods to improve predictability. It is based on training a learning algorithm to combine the predictions of related learning algorithms instead of choosing a single learning algorithm (Tugay & Oguducu, 2020). In this study, the implementation consisted of two phases. The first is to use the 5 algorithms mentioned above to train on the available data set. After making the final prediction of 5 algorithms, choose the algorithm with the lowest predictability and combine it with the remaining 4 algorithms to give the best predictability for this problem.

**Performance metric**

To assess the credit classification ability of the models listed above, this study uses confusion matrix, and performance metrics such as accuracy, precision, recall, F1-score, sensitivity, and specificity.

**Table 1. Example of confusion matrix**

<b>Predicted Actual</b>	<b>Positive</b>	<b>Negative</b>
<b>Positive</b>	True Positive	False Negative
<b>Negative</b>	False Positive	True Negative

In addition, to measure the performance of models at various threshold settings, it is necessary to use Receiver Operating Characteristics (ROC) - a probability curve and Area Under Curve (AUC) - representing the classification level of the model. It indicates the more accurate the prediction of the classes of a model the closer the AUC is to 1. With the vertical axis being True Positive Rate (TPR) and the horizontal axis being False Positive Rate (FPR) (Narkhede, 2018).

**4. RESULTS AND DISCUSSION**

The data used for the credit scoring model is the copyright CC0 credit-related information dataset, which consists of 28 columns and 100,000 rows. It can be divided into three different types: numerical columns, categorical columns, and unrelated columns for business problems. For this study, there are 12 independent variables that are considered: Credit\_History\_Age, Num\_Credit\_Cards, Credit\_Mix, Annual\_Income, Delay\_from\_due\_date, Payment Behaviour, Age, Occupation, Total\_EMI\_per\_month, Outstanding\_Debt, Num\_of\_Delayed\_Payment, and Monthly\_Balance.

After performing data preprocessing, table 2 shows the results of the distribution of credit\_score values, where the Standard class accounts for more than 50% of the dataset. The dataset is divided into two parts: 80% for training and 20% for testing. Therefore, the test set also has a difference in frequency between values, concentrated in the Standard class.

**Table 2. Distribution of credit\_score values**

	<b>Bad</b>	<b>Standard</b>	<b>Good</b>	<b>Total</b>
<b>Frequency</b>	18,419	34,744	11,765	64,928
<b>Percentage</b>	28.4%	53.5%	18.1%	100%

Table 3 shows the suitable hyperparameters for each individual model. After selecting the hyperparameter, each model will be trained with the training set using a cross-validation method with k = 5. This study focuses on multiclass classification. Therefore, the tables below show the classified ability of the five models in the direction of A and NOT A: classify class zero versus NOT zero (class one or class two); classify class one versus NOT one (class zero or class two); classify class two versus NOT two (class zero or class one).

**Table 3. Hyperparameter**

<b>Model</b>	<b>Hyperparameter</b>	<b>Value</b>
<b>Random forest</b>	N-estimators	9
	criterion	gini
	max_depth	9

<b>Decision tree</b>	criteria	log_loss
	max_features	sqrt
	min_samples_split	3
<b>K-Nearest Neighbor</b>	n_neighbors	5
	metric	manhattan
	weights	distance
<b>Naive Bayes</b>	var_smoothing	0.53366

#### 4.1. Five individual models

**Table 4. Confusion matrix and AUC of five individual models**

		TP	FP	TN	FN	AUC
<b>Logistic Regression</b>	0 vs rest	1,060	969	8,377	2,580	0.74
	1 vs rest	5,965	4,877	1,150	994	0.52
	2 vs rest	41	74	10525	2,346	0.70
<b>K-Nearest Neighbor</b>	0 vs rest	2,134	1,335	8,011	1,506	0.93
	1 vs rest	4,974	2,422	3,605	1,985	0.85
	2 vs rest	1,138	983	9,616	1,249	0.93
<b>Naive Bayes</b>	0 vs rest	2,020	1,454	7,892	1,620	0.76
	1 vs rest	3,101	1,607	4,420	3,858	0.62
	2 vs rest	1,758	3,046	7,553	629	0.78
<b>Decision Tree</b>	0 vs rest	2,164	1,676	7,670	1,476	0.78
	1 vs rest	4,720	2,244	3,783	2,239	0.72
	2 vs rest	1,132	1,050	9,549	1,255	0.75
<b>Random Forest</b>	0 vs rest	2,291	1,116	8,230	1,349	0.86
	1 vs rest	5,151	2,032	3,995	1,808	0.80
	2 vs rest	1,389	1,007	9,592	998	0.88

With the *Logistic Regression model*, from table 4, there are some discussions. Class zero has quite an average number of false predictions, with FP = 2,580 and FN = 969. This shows that the model has the ability to falsely predict both Positive and Negative. Class one has a high number of false predictions, with FP = 994 and FN = 4,877. This shows that the model tends to predict wrongly when up to 4,877 samples are not class one but are misunderstood as belonging to class one. Class two has a low number of false predictions, with FP = 2,346 and FN = 74. Therefore, the model has the ability to predict at least 3 wrong models. Also from table 4, it can be seen that LR has better classification ability than random with AUC = 74 and AUC2 = 70. Class one has AUC = 0.52, whose value is at the average level. Therefore, this model has a relatively better classification ability than random, but the performance is not high.

From table 4, there are some discussions about the *K-Nearest Neighbor model's* performance. With class zero versus rest, it can be seen that the index of accurately predicting NOT zero points is high (TN = 8,011) and correctly predicting class zero correct points is also quite high (TP = 2,134). With class one versus rest, the number of correctly predicting points other than class one is quite low (TN = 3,605) and the number of correctly predicting class one correctly is quite high (TP = 4,974). With class two versus rest, the number of correctly predicting points other than class two is very high (TN = 9,616) and the score correctly

predicting class two is very low (TP = 1,138). The AUC value shows that the recognition of three classes is all good (AUC > 0.8) and very good (AUC > 0.9).

With *Naive Bayes model*, from table 4, there are some discussions. With class zero versus rest, the number of correctly predicted non-zero points (TP = 7,892) is quite high, and the number of predicting zero points (TP = 2,020) is also relatively large. With class one versus rest, a relative number of correctly predicted non-zero points (TP = 4,420). However, the number of falsely predicted zeros (TP = 3,858) is almost equal to the correct score. This is the point to note about this model. With class two versus rest, the number of correctly predicted non-zero points (TP = 7,553) is quite high. However, the number of falsely predicted non-zero points (TP = 3046) is the second highest in the model. This affects the accuracy of the prediction and needs more attention. About the area under the curve of the Naïve Bayes model, class two has the largest AUC (0.78), the second is class zero (0.76) and the lowest is class one (0.62). Thus, the Naive Bayes model is most effective for class two. However, the difference between classes is relatively large as well as the efficiency of the model for class one is quite low, leading to the prediction ability having many mistakes.

With the *Decision Tree* model, there are some discussions about its performance. About class zero versus rest, the prediction of zero points (TP = 2,164) and NOT 0 points (TN = 7,670) is relatively accurate. The biased predictions are also relatively low. With class one versus rest, the prediction of class one (TP = 4,720) and points other than class one (TN = 3,783) is relatively accurate. This is the most biased prediction in all 3 classes. About class two versus rest, the prediction of class-two points (TP = 1,132) and not-two points (TN = 9,549) has high accuracy. This has the lowest false predictions in all three classes. Also, the AUC of the classes has the relatively same area. In general, the Decision Tree model makes predictions for each class without much difference.

From table 4, there are some discussions about the *Random Forest model's* performance. With class zero versus rest, it can be seen that the number of correctly predicted non-zero points is very high (TN = 8,230), the number of correctly predicted class zero is also relatively (TP = 2,291), and the false predictions are also relatively high. For class one versus rest, there is a high number of correct predictions for class one (TP = 5,151) and a relatively high number of other classes one (TN = 3,955), but the model also predicts a lot of other classes one mistakenly for class one (FP = 2,072), which leads to quite high confusion rate between class one and other classes. Finally, two versus rest, similar to layer zero, has a high number of correct predictions other than class two (TN = 9,630), in addition, the number between FP and FN of this matrix is not too different, maybe The model also predicts quite well the classes of class two, but there are still some samples of class two that are misclassified and are considered as a non-class two sample. Also, class two with the highest AUC (0.88), the AUC value of class one (0.79) is lower than that of class zero (0.86), and class two (0.88) may affect the results, as the model class one classifier is not as efficient as class one. This will lead to misclassification more to other classes.

**Table 5. Performance matrix of five individual models**

	Class	LR	KNN	NB	DT	RF
Accuracy	0	0.729	0.781	0.763	0.757	0.810
	1	0.548	0.661	0.579	0.655	0.704
	2	0.814	0.828	0.717	0.822	0.846

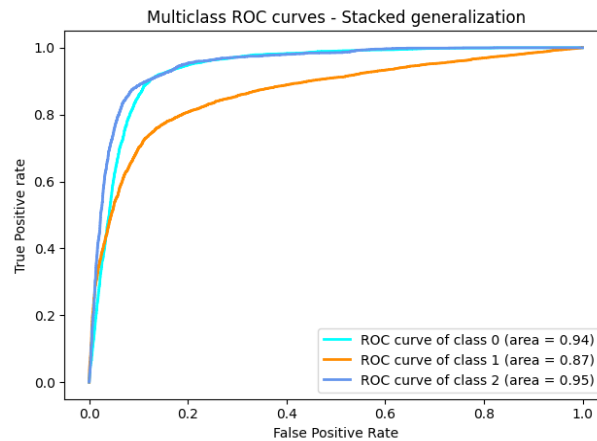

<b>Precision</b>	0	0.522	0.615	0.581	0.563	0.672
	1	0.550	0.673	0.659	0.678	0.717
	2	0.357	0.537	0.366	0.519	0.580
<b>Recall</b>	0	0.291	0.586	0.555	0.595	0.629
	1	0.857	0.715	0.446	0.678	0.740
	2	0.017	0.477	0.736	0.474	0.582
<b>F1 Score</b>	0	0.374	0.600	0.568	0.579	0.650
	1	0.670	0.693	0.532	0.678	0.728
	2	0.033	0.505	0.489	0.500	0.580
<b>Sensitivity</b>	0	0.291	0.586	0.555	0.595	0.629
	1	0.857	0.715	0.657	0.678	0.720
	2	0.017	0.477	0.520	0.474	0.582
<b>Specificity</b>	0	0.896	0.857	0.844	0.821	0.881
	1	0.191	0.598	0.733	0.628	0.663
	2	0.993	0.907	0.713	0.900	0.905

Table 5 shows the performance of five individual models. There are some findings about the results. First, most of the models give an accuracy of about 50%, in which, Logistic Regression gives the lowest results in class zero and class one, and Naive Bayes gives low results in class two. Meanwhile, Random Forest gives the best results in all three classes. Secondly, the indicators of precision, recall, and F1-score are similar, most of them are above 50%. Overall, Logistic Regression gave the lowest results and Random Forest gave the highest results. The Sensitivity index represents the ability to detect A (positive) and the Specificity indicates the ability to detect NOT A (negative). Models are most sensitive to class one when the sensitivity of class one is higher than that of the other classes. This happens because the dataset is unbalanced. Finally, Random Forest model gives the best results when five per six criteria are higher compared to the others. Meanwhile, Logistic Regression has 4 per 6 criteria lower than the remaining models. Thus, it can be concluded that using ensemble models can give better predictions than weak/individual models.

#### Stacked generalization model

**Table 6. Performance matrix of stacked generalization model**

<b>Class</b>	<b>0</b>	<b>1</b>	<b>2</b>
<b>Accuracy</b>	0.832	0.722	0.872
<b>Precision</b>	0.719	0.718	0.682
<b>Recall</b>	0.657	0.792	0.568
<b>F1 Score</b>	0.687	0.753	0.619
<b>Sensitivity</b>	0.657	0.792	0.568
<b>FPR</b>	0.343	0.208	0.432
<b>Specificity</b>	0.9	0.641	0.94
<b>FNR</b>	0.1	0.359	0.06

**Figure SEQ Figure \\* ARABIC 2. Multiclass ROC curve of stacked generalization model**

Table 6 shows the performance of the Stacked generalization model. The final results after running a stacked generalization model with five individual models for accuracy improved results in all three classes show that the best model result performance gives good results for the learning process to analyze the results type of credit score for the dataset.

With figure 2 of the ROC curve for the three classes, it is clear that the AUC index for each class is 0.94, 0.87, and 0.95, respectively. These values are proof that the stacked generalization model performs well in terms of classifications. That is, it is certain that the Stacked generalization model produces predictions that are the most accurate. Additionally, it works very well with class zero and class two when the AUC index is greater than 90%, which is a very good threshold for determining the categorization level.

#### 4.3. Discussion

From the unbalanced dataset, it can be seen that the results tend to be biased toward the Standard class. For ground truths that are Standard, the value is correctly classified quite a lot; for ground truths other than Standard, the values that are misclassified as Standard are also very many. This can be considered as a limitation of the data set for this study. However, from table 5 and table 6, it can be seen that the use of the association model, namely stacking, has overcome some limitations of the data, resulting in more effective credit classification results than individual use of models.

When the data sets utilized in various research and the goals of those investigations differ, it is impossible to compare the findings of one study with those of another. However, there are also similarities between the studies. Research by (Bussmann, Giudici, Marinelli, & Papenbrock, 2021) has increased the interpretability, speed, and accuracy of XGBoost’s algorithm in credit scoring, but has not yet been able to process the imbalance of the dataset. Current study also has the same problem. With the experimental results, Stacking can improve the model’s performance in this problem. From the research of (Munkhdalai, Munkhdalai, Namsrai, Lee, & Ryu, 2019), it can be seen that, although Random Forest Regression is not the algorithm that gives the best results, it has relatively high results, corresponding to the results. As a result of this study, Random Forest is considered to be the most feasible algorithm among individual models. As a consequence of this research, Random Forest is regarded as the individual models’ most practical method. The experimental findings demonstrate that the shortcomings of any individual model may be corrected by combining the data from numerous independent models: The limitations of Decision Tree are overcome by Random Forest, and the weakest of five poor models - including Random Forest - are overcome by the

stacking strategy utilized in this work. In general, this study's findings have added to those of earlier research in terms of enhancing machine learning performance in several areas of credit scoring and classification.

As mentioned in the introduction, providing loans plays an important role in the operation of each financial intermediary. To minimize the risk from lending, credit scoring is an indispensable step in the approval process. With the Stacked generalization model above, the results are good for the "Poor" class and "Good" class, quite good for the "Standard" class. When applying the model in business, it will assist banks in credit scoring and credit classification automatically, and then, with the results obtained from the model, loan records will be again reviewed by a professional. Instead of having to make a decision manually, by the use of ensemble models, commercial banks can boost the appraisal process, saving time and increasing efficiency as the validation goes through a minimum of two stages.

## 5. CONCLUSION AND FUTURE WORK

Any financial intermediary has to find a solution for the issue of credit categorization. Many credit classification methods, including K-Nearest Neighbor, Logistic Regression, Decision Tree, Random Forest, Naive Bayes, and Stacked Generalization, are introduced in this work. This research also contrasts and examines how well they can classify things. It is demonstrated using the results that Machine Learning approaches may be used to improve applied credit scoring. Using a customer's characteristics and credit data, decision-makers can use certain techniques to forecast whether the consumer will have a good or negative credit history. However, it should be emphasized that there is no such thing as a perfect model and a completely accurate classification. The presence of Machine Learning models only helping to speed up the credit scoring process, is a suggestion for financial intermediaries before approving loans. Financial institutions are using credit scoring algorithms more and more to develop better strategies. Therefore, with developments in information technology and modeling methodologies, credit scoring issues are one of the applications that have attracted significant attention over the past decade. More and more, financial institutions are seeking better strategies through the help of credit scoring models. Therefore, credit scoring problems are one of the applications that have gained serious attention over the past decades with advances in information technology and modeling techniques.

The future of Machine Learning in credit score classification is very promising and will see many improvements and developments in the coming years. One of the improvements that can be made is to use other algorithms to generate interdependent predictive models that provide superior accuracy. Optimizing data features for training can also improve model accuracy. In addition, the use of data analysis methods such as clustering, PCA, or feature selection to explore the relationship between features and credit scores can improve model performance. Ultimately, applying Machine Learning to improve people's credit scores will affect many aspects of their lives, especially financially. Therefore, developing a reliable and accurate Machine Learning model will be very important for credit decision-making.

## PREDICTING LOAN APPROVAL USING MACHINE LEARNING

**Author: Tran Hoai Thuong<sup>1</sup>, Dinh Minh Tue Ha<sup>2</sup>, Tran Gia Han<sup>2</sup>,  
Duong Tran Ngoc Thuy Tien<sup>2</sup>, Tran Thi Anh Thu<sup>2</sup>  
Mentor: Ho Trung Thanh<sup>3</sup>**

**ABSTRACT:** *Personal loans are an important part of the overall credit activities of the bank, bringing great growth potential as well as sustainable profits for the bank. However, lending to individual customers will bring high risks. Therefore, forecasting the ability to pay debts on time is extremely important and necessary, helping banks enhance customer's ability to pay debts on time, contributing to minimizing bad debts and reducing them, and strengthening credit risk management. To predict the possibility of payment of the loan by the customer, the Machine Learning techniques have been used in predicting the outcomes for large amounts of data. In this study, the machine learning algorithms used are: Logistic Regression, Decision Tree, and Random Forest, which are applied to predict the customer's ability to repay in the bank sector.*

*Keywords: loan; approval; repay; machine learning; customer prediction; bank sector.*

### INTRODUCTION

Banks play an important role in the market economy. The success or failure of the organization largely depends on the credit risk assessment of the industry. Before granting credit to a borrower, the bank decides whether the borrower is bad (in default) or good (non-default). Distributing loans is the core business of most banks. The main part of the bank's assets comes directly from the profits obtained from the loans distributed by the banks. The main goal in a banking environment is to invest their assets in a safe place. Nowadays, many banks/financial firms approve loans after a process of verification and regression validation but it is still not certain whether the selected candidate is a worthy candidate among all the candidates or not (Pham & Nguyen, 2020).

In the context of the economy facing many difficulties and challenges, credit risks tend to be high and complicated, affecting the operations of banks. Credit risk of individual customers is not only an individual risk of each commercial bank, but also a concern of the banking system within each country and globally, affecting the development of the banking system of the whole economy. In order to prevent losses, through predictive analytics of collected data, this paper can give insights which will help businesses make better decisions, take advantage of advantageous competition, increase profits, satisfy stakeholder expectations and steadily enhance the bank's strength and reputation in the marketplace. To understand customer behavior and gain insights into the long-term values of the company and the consumer, customer solvency prediction provides the transaction history of the client group. This may create chances for corporate expansion. Knowing the elements that affect a borrower's ability to repay loans and identifying those with high ability to do so will make banks more appealing to customers.

Machine learning is an evolving branch of computational algorithms that are designed to emulate

human intelligence by learning from the surrounding environment. They are considered the working horse in the new era of big data. Techniques based on machine learning have been applied successfully in diverse fields ranging from pattern recognition, computer vision, spacecraft engineering, finance, entertainment, and computational biology to biomedical and medical applications (Murphy et al., 2015). Based on the desired outcome of the algorithm, the machine learning algorithms are organized in the following groups:

**Supervised learning** - the various algorithms generate a function that maps inputs to desired outputs. One standard formulation of the supervised learning task is the classification problem: the learner is required to learn (to approximate the behavior of) a function which maps a vector into one of several classes by looking at several input-output examples of the function.

**Unsupervised learning** - models a set of inputs: labeled examples are not available.

**Semi-supervised learning** - combines both labeled and unlabeled examples to generate an appropriate function or classifier.

**Reinforcement learning** - the algorithm learns a policy of how to act given an observation of the world. Every action has some impact in the environment, and the environment provides feedback that guides the learning algorithm.

**Transduction** - similar to supervised learning, but does not explicitly construct a function: instead, tries to predict new outputs based on training inputs, training outputs, and new inputs.

**Learning to learn** - where the algorithm learns its own inductive bias based on previous experience.

Besides these groups of machine learning algorithms, they are basically divided into two general groups, supervised and unsupervised learning.

Thanks to the ability and power of machine learning, there are many reports and articles in the same field of classification on the repayment ability made. The article “Predicting on-time debt payment behavior of individual customers at commercial banks” by Pham Thi Huyen and Nguyen Van Ton used machine learning to provide assessment results. These authors used single unsupervised machine learning models as decision trees or for evaluation. The study aims to collect and analyze relevant data, build different machine learning models, compare their performance, and use ensemble approaches to enhance the predictive power of the best-performing model. Ultimately, the goal is to provide insights into the factors that influence customer repayment behavior and develop a robust model for predicting future behavior, which can be used to improve decision-making and risk management in the financial industry.

## 2. THEORETICAL FRAMEWORK

### 2.1. Lending activities

The economy now is changing, competition is increasing in the financial world, and lending has become inevitable. There are many people around the world who in some way borrow money from banks or financial institutions for various reasons to help them overcome financial difficulties and achieve some personal goals. Madaan and his partner (2021) posit that lending is the main income source and the biggest financial risk source for commercial banks. Although lending activities bring benefits to both parties, this activity carries huge risks. In the lending industry, investors offer loans to borrowers in exchange for the promise of repayment with interest. Thus, lenders face the problem of predicting the risk of a borrower defaulting on a loan. Therefore, assessing the credit worthiness of customers before allowing loans is very necessary.

## **2.2. Using machine learning in the field of bank**

### **2.2.1. The application of machine learning in banks**

Leo & Maddulety (2019) define machine learning as a rapidly developing technology in recent years, widely applied in many fields, including banking/financial sector. The research shows that by 2027, 23% of the job market in finance will have changed, with AI and machine learning playing a pivotal role in enhancing efficiency and the automation process. Every new piece of information supplied can increase the predictive power of these models, resulting in an increase in predictive power over time. Within a bank's risk organization, machine learning is anticipated to be used in a variety of contexts.

Aluko & Bagheri (2012) mention Anti-Money Laundering (AML) and Fraud Pattern Detection: AML refers to a set of procedures, laws, or regulations designed to stop the practice of generating income through illegal means. Actually, many countries are now embracing the power of AI and machine learning in fraud detection. They are attempting to strengthen their surveillance system by implementing AI and machine learning. Notably, AI is revolutionizing the banking sector by offering clients personalized services like chatbots that offer self-help answers, which lighten the pressure on call centers. AI and machine learning adoption in the banking sector eliminates human error in high-frequency repetitive tasks.

Another application of AI and machine learning which is risk management is the building tenets of AI and machine learning are learning from past data. Therefore, machine learning and AI are sweeping over the banking sector, where bookkeeping and records are their second name. With support from machine learning and AI, banks can detect and predict the potential risks.

### **2.2.2. Using machine learning in loan approval**

The success or failure of an organization now largely depends on the industry's ability to evaluate credit risk. The prediction of borrower status in future will be defaulter or non defaulter is a challenging task for any organization or bank. Aphale et al (2020) said that credit risk assessment is a crucial issue faced by banks nowadays, which helps them to evaluate if a loan applicant can be a defaulter at a later stage so that they can go ahead and grant the loan or not. This helps the banks to minimize the possible losses and can increase the volume of credits.

## **2.3. Machine learning models**

### **2.3.1. Random Forest**

First introduced by Breiman (2000) as a modification to the simple bagging algorithm, it uses bootstrapped samples of data and a randomly selected subset of variables to build a number of decision trees, and then combines their output via the simple voting. The RF algorithm begins with a bootstrap-sampled data set and builds one decision tree from each bootstrap sample. Hence, in RF, the bootstrap sampling technique applies to both a random selection of cases and a random selection of features.

### **2.3.2. Decision tree**

Decision tree is a machine-learning technique that follows a set of if-else conditions to visualize the data and classify it according to the conditions. Decision tree analysis is arguably the most popular classification technique in the data mining arena. Decision tree algorithms, in general, build an initial tree from training data such that each leaf node is pure, and they then prune the tree to increase its generalization, and hence, the prediction accuracy of test data (Sharda et al., 2021).

### **2.3.3. Logistic regression**

Logistic regression is a very popular, statistically sound, probability-based classification algorithm that employs supervised learning. It was developed in the 1940s as a complement to linear regression and linear

discriminant analysis methods. Logistic regression is similar to linear regression in that it also aims to regress to a mathematical function that explains the relationship between the response variable and the explanatory variables using a sample of past observations (training data). Logistic regression differs from linear regression with one major point: its output (response variable) is a class as opposed to a numerical variable (Delen, 2014).

**3. RESEARCH METHOD**

**3.1. Data Preparation**

The dataset collected the customer base’s information. The company wants to automate the loan eligibility process (real-time) based on customer detail provided while filling out the online application form. These details are ID, Gender, Marital Status, Education, Self-employed, Number of Dependents, Applicant and Co-applicant Income, Loan Amount, Loan Amount Term, Credit History, Property Area.

The primary data are Applicant Income, Co-applicant Income. The secondary data are Self-Employed, Loan Amount, Loan Amount Term, Credit History, Property Area, Loan Status.

**Table 1. Data description**

	Self_Employed	ApplicantIncome	CoapplicantIncome	LoanAmount	Loan_Amount_Term	Credit_History	Property_Area	Loan_Status
count	582	614.000.000	614.000.000	592.000.000	60.000.000	564.000.000	614	614
unique	2	NaN	NaN	NaN	NaN	NaN	3	2
top	No	NaN	NaN	NaN	NaN	NaN	Semiurban	Y
freq	500	NaN	NaN	NaN	NaN	NaN	233	422
mean	NaN	5.403.459.283	1.621.245.798	146.412.162	34.200.000	842.199	NaN	NaN
std	NaN	6.109.041.673	2.926.248.369	85.587.325	6.512.041	364.878	NaN	NaN
min	NaN	150.000.000	0	9.000.000	1.200.000	0	NaN	NaN
max	NaN	81.000.000.000	41.667.000.000	700.000.000	48.000.000	1.000.000	NaN	NaN

Table 1 displays the parameters such as mean, standard deviation, min, max and respective percentage of some variable. Exploring all the variables in the data, it is important to fill missing values and deal with outliers because missing data and outliers can adversely affect the performance of the model. Listing out feature-wise count of missing values:

**Table 2. Missing values**

Loan_ID	0
Gender	13
Married	3
Dependents	15
Education	0
Self_Employed	32
ApplicantIncome	0
CoapplicantIncome	0
LoanAmount	22
Loan_Amount_Term	14
Credit_History	50
Property_Area	0
Loan_Status	0

**Table 3. Data after handle with null values**

Loan_ID	0
Gender	0
Married	0
Dependents	0
Education	0
Self_Employed	0
ApplicantIncome	0
CoapplicantIncome	0
LoanAmount	0
Loan_Amount_Term	0
Credit_History	0
Property_Area	0
Loan_Status	0

Some missing values in Gender, Married, Dependents, Self\_Employed, LoanAmount, Loan\_Amount\_Term and Credit\_History features shown in table 2. To handle missing values, for numerical variables: imputation using mean or median, for categorical variables: imputation using mode. Finally will get a dataset with no null value in table 3.

However, due to these outliers, figure 1 shows the bulk of the data in the loan amount is at the left and the right tail is longer. This is called right skewness. One way to remove the skewness is by doing the log transformation and taking its distribution in figure 2. As taking the log transformation, it does not affect the smaller values much, but reduces the larger values. Next, creating a column of LoanAmount\_log.

Figure 1. LoanAmount

Figure 2. LoanAmount\_log

Based on the domain knowledge, this can come up with new features that might affect the target variable. Let's create some new features:

Figure 3. Total Income

Figure 4. Total Income\_log

Total Income in figure 3 - combines the Applicant Income and Coapplicant Income. If the total income is high, chances of loan approval might also be high. However, it is shifted towards left, the distribution is right skewed. So, taking the log transformation to make the distribution normal as LoanAmount\_log seen in figure 4.

Table 4 indicates the EMI - EMI is the monthly amount to be paid by the applicant to repay the loan. Idea behind making this variable is that people who have high EMI's might find it difficult to pay back the loan. EMI can be calculated by taking the ratio of loan amount with respect to loan amount term.

Table 4. EMI

	EMI
0	355.556
1	355.556
2	183.333
3	333.333
4	391.667
5	741.667

Table 5. Balanced Income

	Balance_Income
0	5.493.444.444
1	5.735.444.444
2	2.816.666.667
3	4.607.666.667
4	5.608.333.333
5	8.871.333.333

Table 5 shows Balance Income - this is the income left after the EMI has been paid. Idea behind

creating this variable is that if this value is high, the chances are high that a person will repay the loan and hence increase the chances of loan approval.

It is necessary to remove the variables which used to create these new features. Because the correlation between those old features and these new features will be very high and logistic regression assumes that the variables are not highly correlated. Removing correlated features will help reduce noise. The removed variables are: ApplicantIncome, CoapplicantIncome, LoanAmount, Loan\_Amount\_Term. Besides, the “Loan\_ID” variable as it does not have any effect on the loan status so it has to be removed.

After all, because of the small dataset, which has oversampling on. Oversampling is a resampling scheme where modifies the distribution of a variable in the dataset by artificially increasing the number of observations that take on a particular value or range of values for that variable. In most cases, this is done by looking at what values are underrepresented in the dataset and artificially increasing the number of observations that take on that value or range of values.

### 3.2. Exploratory Data Analysis (EDA)

#### 3.2.1. Visualize the data

First, look at the target variable - Loan\_Status in figure 5. As it is a categorical variable, let us look at its frequency table, percentage distribution and bar plot. Frequency table of a variable will give us the count of each category in that variable. Among 614 Loan\_Status, there are 422 Yes and 192 No. It means around 69% applicants have been approved.

**Figure 5. Analysis on “Loan\_Status”, “Credit\_History”**

In the train dataset, Credit\_History, around 84% applicants have repaid debts. Credit\_History will have a great influence on each candidate, those who have borrowed and paid back will have higher trust and be hired.

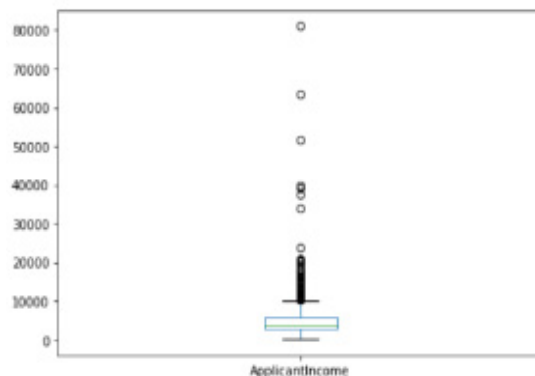

**Figure 6. LoanAmount**

**Figure 7. CoapplicantIncome**

The method of determining the customer's ability to repay debt is based on the customer's characteristics such as customer income and loan. Through analysis of the histogram displayed in figure 6 and 7, knowing the "Co-applicant Income" and "Loan Amount" of all customers.

From figure 8 below, it can be inferred that most of the data in the distribution of applicant income is towards the left which means it is not normally distributed.

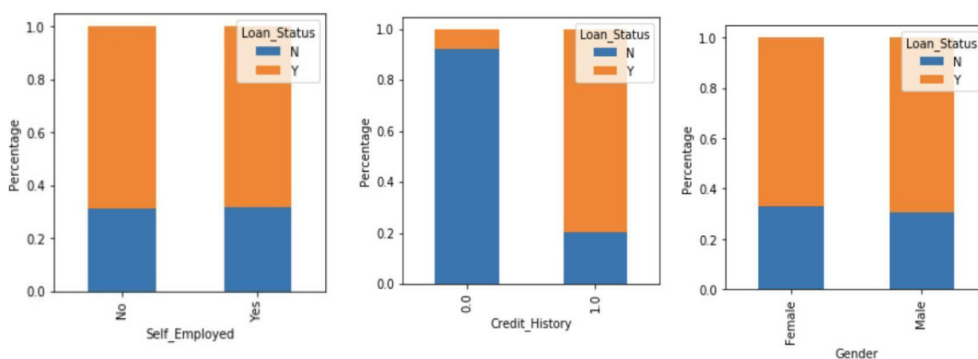

**Figure 8. "ApplicantIncome" distribution**

The boxplot confirms the presence of a lot of outliers/extreme values. This can be attributed to the income disparity in the society. It shows a similar distribution as that of the applicant income. Majority of coapplicant's income ranges from 0 to 5000. There are a lot of outliers in the coapplicant income and it is not normally distributed.

Some of the hypotheses:

- Applicants with high income should have more chances of loan approval.
- Applicants who have repaid their previous debts should have higher chances of loan approval.
- Loan approval should also depend on the loan amount. If the loan amount is less, chances of loan approval should be high.
- Lesser the amount to be paid monthly to repay the loan, higher the chances of loan approval.

Let's try to test the above mentioned hypotheses using bivariate analysis.

**Figure 9. Relation between "Loan\_Status" and "Gender", "Self\_Employed", "Credit\_History"**

In figure 9, the Loan approval and rejection cases are nearly similar for Gender and Self-Employed. So, these features do not have a significant impact on the Loan\_Status. The graphs show that loan approval is virtually gender-neutral, so male and female applicants are equally likely to be approved. The same goes for those who are self-employed or not.

For Credit\_History, the Loan approvals are more in case of Applicants having Credit History. Therefore, this feature has a significant impact on Loan\_Status. The figure 10 below shows a correlation of variables in the dataset.

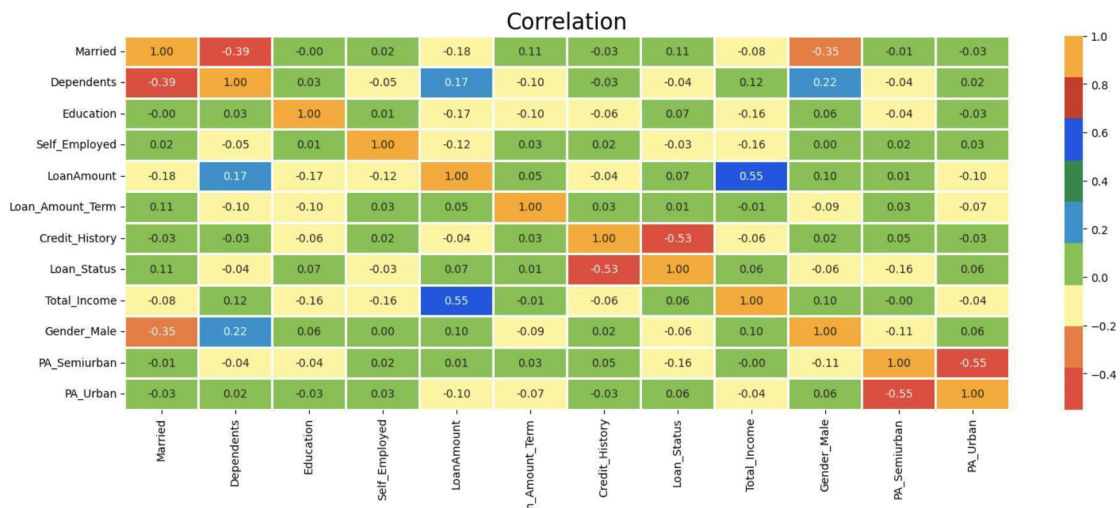

Figure 10. Matrix Correlation

- Chances of loan approval for higher amounts increase with increase in the total income of the applicant.
- Credit History has significant impact on loan approval
- Features Loan\_ID, Gender, Married, Dependents, Education, Self\_Employed and Property Area has little impact on loan approval.
- Majority of the loans were approved where the term is 180 or 360.

### 3.3. Individual model

#### 3.3.1. Decision tree

Decision tree is used to classify, then using the function to calculate values like Confusion Matrix, Accuracy, Precision, Recall, F1 score, Sensitivity, and Specificity to evaluate the results of the used model. Calculate results are displayed below:

Table 6. Metrics of DT

Metric	Value
Accuracy	0.7362
Precision	0,7328
Recall	0.7025
F1-score	0.7173
Sensitivity	0.7025 (error = 0.2975)
Specificity	0.7669 (error = 0.2331)

From table 6, the accuracy of this model shows that the predictive model is quite good with the result of 73.62%. Precision is 73.28% and Recall is 70.25%. The F1 score of 71.73% shows that the precision and recall of this classification model are also quite good. Sensitivity 70.25% and Specificity 76.69%, meaning that accurately identifying individuals with consent and without consent are good.

Figure 11. Confusion matrix of DT

Figure 12. ROC/AUC curve of DT

The Confusion Matrix in figure 11 shows that there are 85 predictions True Positive, 102 True Negative, 36 False Negative and 31 False Positive. As can be seen from figure 12 of the AUC (representing the classification level of the model) of this model is 0.735. This indicates that the data classification model is considered acceptable.

3.3.2 Random forest

RF fits many classification trees to a data set, and then combines the predictions from all the trees. The algorithm begins with the selection of many bootstrap samples from the data (Cutler et al., 2007).

Table 7. Metrics of RF

Metric	Value
Accuracy	0.8228
Precision	0.8275
Recall	0.7933
F1-score	0.81
Sensitivity	0.79 (error = 0.21)
Specificity	0.85 (error = 0.15)

From table 7, the accuracy of this model indicates that the model is correctly predicting the outcome 82.3% of the time. Given a model with precision 82.8% and recall 79%, this means that out of all the samples predicted as positive by the model, 82.8% of them are actually positive, and the model was able to identify 79% of all the positive samples. F1 score of 81% indicates that the precision and recall for a binary classification model are both relatively moderate. A sensitivity of 79% and a specificity of 85%, it is both good at correctly identifying individuals who have the approval and at correctly identifying individuals who do not have the approval.

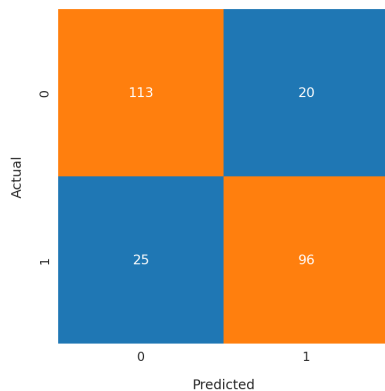

Figure 13. Confusion matrix of RF

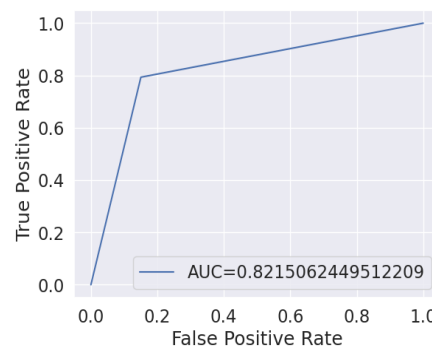

Figure 14. ROC/AUC curve of RF

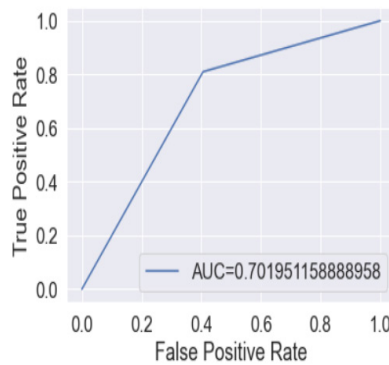

The confusion matrix in figure 13 shows that there are 113 True Negative, 96 True Positive, 20 False Negative and 25 False Negative. In figure 14, the AUC of this model is 0.821. This indicates that the data classification model is good.

**3.3.3. Logistic regression**

**Figure 15. Confusion matrix of LR**

From the Confusion Matrix in figure 15: there are 119 predictions True Positive, 21 True Negative, 5 False Positive and 40 False Negative.

**Figure 16. ROC/AUC curve of LR**

Figure 16 shows that the AUC for this ensemble model turns out to be 0.7. It means that the positive class has a greater prediction probability than the negative class.

**Table 8. Metric of LR**

Metric	Value
Accuracy	0.7
Precision	0.64
Recall	0.81
F1-score	0.71
Sensitivity	0.75 (error = 0.25)
Specificity	0.6 (error = 0.4)

As can be seen from table8, the accuracy of this model indicates that the model is correctly predicting the outcome 70% of the time. Given a model with precision 64% and recall 81%, this means that out of all the samples predicted as positive by the model, 70% of them are actually positive, and the model was

able to identify 64% of all the positive samples. F1 score of 71% indicates that the precision and recall for a binary classification model are both relatively moderate. A sensitivity of 81% and a specificity of 60%, it means that it is good at correctly identifying individuals who have the approval, but not good at correctly identifying individuals who do not have the approval.

### 3.4. Combination model

#### 3.4.1. Random forest and Logistic regression

Stacking is an ensemble method used in machine learning where the predictions of several models are combined to improve the final prediction. In stacking, multiple base models are trained on the same training set, and then a meta-model is trained to predict the final outcome using the outputs of the base models as input.

After analyzing data with the model, the results about all the metrics are shown below.

**Table 9. Metrics of ensemble of RF and LR**

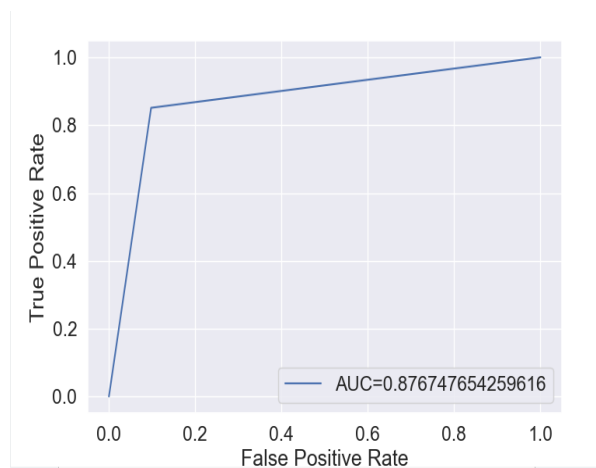

Metric	Value
Accuracy	0.8779
Precision	0.8879
Recall	0.8512
F1-score	0.8692
Sensitivity	0.8512 (error = 0.1488)
Specificity	0.9023 (error = 0.0977)

As can be seen from table 9, the accuracy of this model indicates that the model is correctly predicting the outcome 87.79% of the time. Given a model with precision 88.79% and recall 85.12%. Means the model has a high recall and a moderate precision, meaning that many positive samples were correctly identified, but there were also a relatively significant number of false positives. F1 score of 86.92% indicates that the precision and recall for a binary classification model are both relatively high. A sensitivity of 85.12% and a specificity of 90.23%, it means that it is both good at correctly identifying individuals who have the approval (high sensitivity) and at correctly identifying individuals who do not have the approval (high specificity).

From the Confusion Matrix in figure 17, there are 103 predictions True Positive, 120 True Negative, 18 False Negative and 13 False Positive. Figure 18 indicates the AUC for this ensemble model is 0.88, it is pretty high, nearly 1. This shows that this data classification model is quite good.

**Figure 17. Confusion matrix RF and LR**

**Figure 18. ROC/AUC curve of RF & LR**

**3.4.2. Decision tree and Logistic regression**

After analyzing data with the model, the results about all the metrics are shown below.

**Figure 19. Confusion matrix of DT and LR**

**Figure 20. ROC/AUC curve of DT & LR**

From the Confusion Matrix in figure 19, there are 103 predictions True Positive, 119 True Negative, 18 False Negative and 14 False Positive. From figure 20, AUC for this ensemble model turns out to be 0.86. It is pretty high, this indicates that this data classification model is quite good.

**Table 10. Metrics of ensemble of DT and LR**

Metrix	Value
Accuracy	0.8661
Precision	0.8783
Recall	0.8347
F1-score	0.8559
Sensitivity	0.8347 (error = 0.1653)
Specificity	0.8947 (error = 0.1053)

Table 10 shows that in this case, the model achieved an accuracy of 0.8661, which means that it correctly classified 86.61% of the instances. Precision is 0.8783, which means that of all the instances it classified as positive, 87.83% were actually positive. Recall is 83.47% identified that percent of all the actual positive instances. The F1-score of the model is pretty high. In this case, the model achieved a specificity of 0.8947, which means that it correctly identified only 89.47% of all the actual negative instances.

**4. RESULTS AND DISCUSSION**

**4.1. Results**

**4.1.1. Evaluation**

**Table 11. Prediction for five model types**

Model	Accuracy	Precision	F1-score	Sensitivity	Specificity	AUC
DT	0.7362	0.7328	0.7173	0.7025	0.7669	0.7347
RF	0.8228	0.8275	0.81	0.7933	0.85	0.8215
LR	0.7	0.64	0.71	0.8	0.6	0.7
LR+RF	0.8779	0.8879	0.8692	0.8512	0.9023	0.8767
LR+DT	0.8661	0.8783	0.8559	0.8347	0.8947	0.8647

Table 11 shows the prediction figures for all five model types. It can be seen that the combination of Logistic Regression and Random Forest get higher metrics than the others. Overall, the two combined models used in this paper increased the results more than the models used alone. Among them, the combined model of logistic regression and random forest gave the best results.

#### 4.1.2. Important features

The term “Importance features” relates to methods for scoring each input feature for a certain model; the scores merely indicate the “importance” of each feature. A higher score indicates that the particular characteristic will have more of an impact on the model being used to forecast a particular variable.

**Figure 21. Importance features**

From figure 21, it can be seen that the least influential features group include Property\_Area Urban, Property\_Area\_Rural, Self\_employed, Education, Dependent, Married, Gender. In short, these features do not have an impact on the prediction model and they are not the important feature to evaluate a candidate who wants to make loans in a bank or finance company.

The moderate influential features group include LoanAmount\_log, TotalIncome TotalIncome\_log, EMI, Balance\_Income and the highest influential feature is Credit History. In short, these features have a high impact on the prediction model and they are an important feature to evaluate a candidate who wants to make loans in a bank or finance company.

In summary, from evaluating the influence of features, businesses can analyze customer segmentation and make a suitable plan to promote campaigns for each type of customer. They also early identify customers who do not have ability to repay or not.

#### 4.2. Discussion

This study explores the repayment capacity of customers and identifies the variables that affect the repayment capacity. Applying different machine learning algorithms helps decide which model will be the best to apply to the data set in order to get the results with the highest metrics.

The research consists of five models and when looking at the results in detail, the metrics of each model will all give different results. As can be seen, the results are quite good because the accuracy ranges from 70-88% for all models. However, when dealing with unbalanced data for the response variable, accuracy alone is not enough to draw conclusions. Instead, it has to compare to other performance metrics such as

sensitivity, DT (70%) showed the worst performance, followed by RF with 79%, then LR (80%), followed by LR+DT (83%), and finally LR+RF with 85%, which shows the best results.

Next is the comparison of AUC, LR is ranked last with AUC of 0.7 and DT has AUC of 0.73, followed by RF of 0.82, both LR+DT and LR+RF combined models continue to give high results, respectively 0.86 and 0.88. To compare sensitivity and specificity, LR+RF gives the most promising results, with a sensitivity of 0.85 and specificity of 0.9, these show that this ensemble model is good at correctly identifying individuals who have the approval (high sensitivity) and at correctly identifying individuals who do not have the approval (high specificity). Research results show that there is a strong correlation between customers' delayed payback rate and their income, number of loans and current debt levels.

In particular, it is essential to combine data from a variety of sources as most debt repayment studies use only a single survey sample for data collection. In the future, it will be required to combine information from other sources, including management, professional organizations and credit unions, to get a complete picture of a customer's ability to repay

## **5. CONCLUSION AND FUTURE WORK**

In recent years, the loan industry is growing in popularity, and many individuals are applying for loans for a variety of reasons. However, there are instances where people fail to pay back the majority of their loans to the bank, which causes them to suffer a significant financial loss. Consequently, it would considerably reduce the financial loss if there was a mechanism to effectively categorize the loaners beforehand.

This study showed how to forecast loan repayment ability using machine learning techniques on a very financial history dataset. Prior to performing the exploratory data analysis and feature engineering, the dataset was cleansed. It was discussed how to cope with both missing values and unbalanced data sets. The study used various different techniques. Through studies, it has been discovered that the model combines random forest and logistic regression accurately suit the situation the best. Using Machine Learning in predicting customer solvency offers a number of benefits over traditional methods.

- Processing Complex Data: Machine Learning can process and analyze large amounts of data from a variety of sources, including financial information, credit records, customer behavior, and social data. This helps to create more accurate predictive models and provides more detailed information about the customer's ability to pay.

- Machine learning is not as biased by human emotions or subjective opinions. One of the biggest disadvantages of traditional methods of forecasting is that they are biased by human emotions and subjective opinions. This can lead to inaccurate predictions, as humans are often swayed by their personal biases and emotions.

- Automation and optimization: Machine Learning enables the automation of the solvency prediction process, from data collection and preprocessing to model building and evaluation. It can also optimize the model parameters to achieve the best performance.

In the future, further research can focus on other input variables such as information about credit history, income, number of years worked, loan purpose and many other factors to increase the accuracy of the survey, predictive model for debt repayment. In addition, using other techniques such as Neural Networks or Deep Learning to build more complex predictive models, with big data processing and automatic learning capabilities. Another important aspect is dealing with data imbalance problems. In the problem of predicting the repayment capacity, there is often a data imbalance when the number of paying customers is much lower than the number of non-paying customers. This can lead to inaccurate prediction

models due to the lack of information about the group of debtors. One way to solve this problem is to use undersampling or oversampling to rebalance the data. Finally, new technologies such as Blockchain or Big Data can be applied to improve the management and analysis of data related to the customer's ability to repay. Using Blockchain can help increase the transparency and trustworthiness of credit data, while using Big Data can help uncover hidden relationships and trends in the data to develop better solutions. more robust predictive model.

## TESTING AND MEASUREMENT OF ASYMMETRIC INFORMATION: EMPIRICAL EVIDENCE FROM COMPANIES LISTED ON THE HO CHI MINH CITY STOCK EXCHANGE

**Author: Vu Duc Ngoc Thien<sup>1</sup>**  
**Mentor: Nguyen Thi Thu Huong<sup>1</sup>**

**ABSTRACT:** A failed market, or asymmetric information, is a well-known economic concept. This phenomenon can be witnessed in a variety of markets. However, the repercussions of information asymmetry are thought to be more substantial in the stock market. Because, in addition to measurable economic impact, knowledge asymmetry harms trust. The Vietnamese stock market has experienced several successes since its creation, yet it still has many restrictions typical of a young market. The numerous violations of the subjects on the market in recent years reflect those restrictions. Information issues, or more broadly, information asymmetry, are primarily responsible for these errors. The goal of this study was to analyze and assess the degree of information asymmetry in the Vietnamese stock market during a five-year period (2018 – 2022). The author tests the information asymmetry effect using GARCH models for VN-Index data and measures Adverse Selection Component (ASC) using the Glosten & Harris model for the 100 largest capitalization companies on the Ho Chi Minh City Stock Exchange (HOSE). The findings demonstrate information asymmetry, and the ASC value for the entire study period is 89.53%. This empirical finding serves as the foundation for formulating suitable policy recommendations for every market participant, aiding in the growth of a productive, equitable, open, and transparent Vietnamese stock market.

**Keywords:** Stock market, Asymmetric Information, Glosten & Harris model, ARCH/GARCH model.

### 1. INTRODUCTION

The stock market in Vietnam was born late and officially began operations just over 22 years ago on July 28, 2000, not a very short time but also not too lengthy. Vietnam's stock market has made numerous milestones while carrying out its functions. The Vietnamese stock market, on the other hand, nevertheless exhibits many of the inherent limits and flaws of a market that is deemed rudimentary and fledgling. Individual investors bear the largest risks and losses, particularly those resulting from the mistakes of other market participants, although their vast number and significant contribution to trading volume. Individual investors' main risks in Vietnam's stock market in recent years have been primarily tied to information factors. One of the root issues to explore is the problem of information transparency, or the fact that actors have unequal amounts of information, often known as asymmetric information. The study's goal is to examine and measure the extent of asymmetric information in transactions on the Vietnamese stock exchange using adverse selection component. The author then develops suitable policy implications for each target group in order to reduce the impact of asymmetric information.

*Akerlof (1970)* was the first to investigate information asymmetry through an examination of the used automobile market. *Spence (1973)*, extending Akerlof's theory, investigates this problem in the labor market and proposes signaling to lessen information asymmetry in hiring. *Stiglitz (1975)* applies Spence's theory to offer a screening system for successfully grouping and paying workers. Later studies, such as *Glosten & Harris (1988)*, *George et al. (1991)*, *Kim & Ogden (1996)*, *Huang & Stoll (1997)*, sought to evaluate the degree of information asymmetry by using quantitative models. Then, in the study of *Van Ness et al. (2001)*, *Giouvris & Philippatos (2008)*, these models were tested with real stock market data. The concept of

<sup>1</sup> University of Economics and Law, Vietnam National University of Ho Chi Minh City.

information asymmetry is a reasonably frequent research topic in domestic studies. The authors investigate information asymmetry in a variety of industries, including insurance, labor, and agricultural products, although the majority of their studies focus on information asymmetry in the stock market. *Hoang (2004)* was one of the first to propose utilizing a group of models with variable variance (ARCH/GARCH) to find information asymmetry effects. *Khang (2007)* and *Hoai & Khang (2008)* both focus on understanding econometric models used to quantify information asymmetry. *Thuan (2009)*, *Mo (2009)* and *Huyen (2011)* investigate the existing status and potential remedies to reduce information asymmetry in the Vietnamese stock market. *Dinh (2012)*, *Thom (2013)*, *Gam (2013)* and *Tu (2013)* study the determining variables and effects of information asymmetry on entities and the stock market. *Ngai et al. (2016)*, *Anh (2021)* and *Phan (2021)* presented and empirically evaluated a model for the degree of information asymmetry in the Ho Chi Minh City stock market.

In general, theoretical, qualitative, and quantitative research on the impacts of information asymmetry, particularly information asymmetry in the stock market, is fairly established. The authors described the existing situation, the elements that influence it, quantified the extent of information asymmetry, and provided methods to mitigate the impact. However, the majority of quantitative studies on information asymmetry merely perform, or test for, information asymmetry, or just assess information asymmetry using adverse selection component to develop models of influence variables. Furthermore, because stock trading data is updated daily, the scope of prior authors' research is frequently between 6 months and each year, which is sporadic owing to the magnitude of the data. As a result, the author employs stock trading data from 2018 to 2022 in this analysis. To assess the information asymmetry effect, GARCH models were applied to VN-Index data, and Glosten & Harris model were used to measure the adverse selection component for the group of 100 highest capitalization companies on HOSE.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Market Failure and Asymmetric Information**

#### **2.1.1. Market Failure**

Efficient resource allocation is a critical need of every economy. The potential distribution is determined by the economy's technology and resources. Different people will have different opinions on efficiency and fairness; the common denominator is Pareto efficiency. For a given set of consumer preferences, resources, and technology, a Pareto optimal distribution would make some people wealthy if they did not have the capacity to migrate to a different distribution. without anyone becoming broke. When all markets are perfectly competitive, the supply-demand equilibrium will be Pareto efficient (Stiglitz & Rosengard, 2015).

Competitive equilibrium is an efficient state when there is no distortion. *Begg et al. (2014)* define "market failure" as circumstances in which market equilibrium is inefficient. These distortions prohibit the "invisible hand" from allocating resources efficiently. As a result, the causes of market failure include: imperfect competition, public goods, externalities, and information asymmetry. To overcome these flaws in the market system, today's modern economies are a hybrid of the "invisible hand" and the "visible hand". Operating the economy only through market mechanisms or state regulation is like to clapping with one hand (Samuelson, 1915).

#### **2.1.2. Asymmetric in economics**

Akerlof's "The market for lemons: Quality uncertainty and the market mechanism" in 1970 was the first to present the theory of information asymmetry. Asymmetric information occurs when one side in a market transaction has more and better information than the other. Disparities in information put pressure

on businesses to distort transactions. Although the idea of information asymmetry has only been around since the 1970s, it was verified when three economists studying it, George Akerlof, Michael Spence, and Joseph Stiglitz, were awarded the Nobel Prize in Economics in 2015.

The asymmetric information model assumes that at least one party to the transaction has superior information than the other(s), or that one party can influence, respond, or demand terms that affect the initial transaction agreement while the other(s) cannot. According to Akerlof, information asymmetry will result in the establishment of a market with many “bad” items, while excellent ones will be excluded. The cash market manifests itself in a variety of markets, including labor, banking, real estate, insurance, securities, used furniture, and so on.

**Figure 1. Economical effect of Asymmetric Information**

Source: The author draws by Geogebra

The economy is initially in equilibrium at point E<sub>0</sub> in Figure 1, with price P<sub>0</sub> and output Q<sub>0</sub>. If an exchange rate influences the demand side, shifting the curve to the left, the new equilibrium point will be E<sub>1</sub>. At E<sub>1</sub>, the pricing is P<sub>1</sub> < P<sub>0</sub> and the output is Q<sub>1</sub> < Q<sub>0</sub>. As a result of the old equilibrium, the total social residual loses the area of triangle E<sub>0</sub>E<sub>1</sub>A (a waste of time). Similarly, if asymmetric knowledge causes the demand curve to move to the right, the welfare loss would be E<sub>0</sub>E<sub>2</sub>B in a triangle analysis. To summarize, information asymmetry in both of these circumstances leads to society’s poor use of consumption, resulting in a loss of profits to the economy.

Asymmetric information is a market failing those results in the following outcomes:

+ **Adverse Selection:** When participants in a transaction purposefully withhold information, purchasers lack accurate and complete knowledge and give a price willing to pay less than the true value of the items. As a result, vendors lose the incentive to produce high-quality goods and instead supply things of poor quality. As a result, low-quality items – “lemons” – pushed high-quality goods out of the market (Akerlof, 1970).

+ **Moral Hazard:** A situation that emerges after a transaction has concluded in which one party plans to conceal information that is difficult for the other party to control or will cost a lot of money to control. The fact that the party with the advantage of information no longer has the incentive to try or act as rationally as before the transaction occurs makes the less informed party fearful of their own risk of loss (Thom, 2013).

+ **Principle – Agent:** A client-agent dilemma occurs when one party (the principal) hires another (the representation) to accomplish one or more specific goals. Because the executor makes it impossible for the

principle to enforce, evaluate, or support the work, the executor pursues a different aim than the principal. This is due to the interaction of both unfavorable selection and moral hazard (Nga, 2020).

## 2.2. Models for testing and measurement asymmetric information

### 2.2.1. Models to test information asymmetry effects

There has been a great deal of effort towards developing models with variable variance, beginning with Engle's ARCH (1982). Engle (1982) was the first to establish a theoretical foundation for risk modeling. ARCH (Autoregressive Conditional Heteroscedastic) is a variable variance autoregressive model. The model's central idea is that the variance of the residuals across time is proportional to the square of the residuals at earlier points in time. As a result, we will estimate both a mean equation and an equation of variance at the same time. Consider the following simple model:  $Y = \alpha + \beta X_t + u_t$  with  $[X_t]$  is the explanatory variable vector and  $[\beta]$  is the regression coefficients vector. According to the premise of the least squares approach  $u_t \sim N(0; \sigma^2)$ . However, Engle permits the incorrect approach to vary in real time depending on its precision:  $\sigma_t^2 = \lambda_0 + \lambda_1 u_{t-1}^2$ . Bollerslev (1986) extended the ARCH model by including the conditional variance's lag variable in the variance equation, resulting in the Generalized Autoregressive Conditional Heteroscedastic (GARCH) model. The GARCH model's variance equation (1,1):  $\sigma_t^2 = \lambda_0 + \lambda_1 u_{t-1}^2 + \delta_1 \sigma_{t-1}^2$  (Das, 2019). If the residual delay in the ARCH effect test is too large, it will undermine the reliability of the estimation findings by limiting the number of degrees of freedom in the model. Because this problem is difficult to solve for short time series, GARCH models are more widely utilized in risk forecasting (Hoai et al., 2009).

The ARCH/GARCH risk prediction models have been heavily modified from the original Engle and Bollerslev models. This group includes the exponential GARCH model (EGARCH), the mean GARCH model (GARCH-M), the threshold GARCH model (TGARCH), the power ARCH model (PARCH), and the integrated GARCH model (IGARCH). EGARCH and TGARCH are examples of asymmetric models used to investigate the asymmetric effect of shocks.

To overcome the GARCH model's limitation of being unable to distinguish between the effects of negative and positive shocks, as well as the requirement that the coefficient of the variance equation be non-negative, Nelson (1991) proposes the EGARCH model with the assumption that For random variables with an exponential distribution, the variance equation of EGARCH (1,1) is as follows:

$$\ln(\sigma_t^2) = \omega + \alpha \left( \frac{|u_{t-1}|}{\sqrt{\sigma_{t-1}^2}} - \sqrt{\frac{2}{\pi}} \right) + \beta \ln(\sigma_{t-1}^2) + \gamma \frac{u_{t-1}}{\sqrt{\sigma_{t-1}^2}} \quad (1)$$

The left-hand side of (3) is the natural logarithm of the conditional variance, suggesting that the leverage effect of the shocks is exponential rather than quadratic as in the original GARCH model, and that even if the parameters are negative,  $\sigma_t^2$  will be positive (Tsay, 2005). If  $\gamma \neq 0$  and  $\gamma < 0$  indicate a negative shock that is stronger than a positive shock, then information asymmetry or information asymmetry exists.

With the assumption that shocks have asymmetric effects in mind, the TGARCH model includes a dummy variable into the variance equation that defines negative and positive shocks. TGARCH (1,1) has the following variance equation:

$$\sigma_t^2 = \omega + \alpha u_{t-1}^2 + \beta \sigma_{t-1}^2 + \gamma u_{t-1}^2 d_{t-1} \quad (2) \quad \text{with } d_t = \begin{cases} 1 & (u_t < 0) \\ 0 & (u_t > 0) \end{cases}$$

A positive shock (or good news, for  $u_t > 0$ ) and a negative shock (or terrible news, for  $u_t < 0$ ) affect the conditional variance differently in the TGARCH model. The partial effect of the good news will be  $\alpha$ , whereas the partial effect of the negative news will be  $(\alpha + \gamma)$ . If  $\gamma \neq 0$  occurs, then the asymmetry effect exists, and  $\gamma > 0$  demonstrates that negative news has a greater impact than good news (Rabemananjara & Zakoian, 1993; Zakoian, 1994).

### 2.2.2. Models for calculating adverse selection component

One of the effects of asymmetric information is adverse selection. We can quantify the degree of information asymmetry between investors for public companies by measuring the Adverse Selection Component (ASC). *Glosten & Harris (1988), George, Kaul & Nimalendran (1991), Lin, Sanger & Booth (1995), Kim & Ogden (1996), Huang & Stoll (1997)* are examples of popular econometric models for analyzing information asymmetry.

Glosten and Harris (1988) present one of the first trade indicator regression models for spread decomposition. The basic model is:  $\Delta P_t = c_0 \Delta Q_t + c_1 \Delta Q_t V_t + z_0 Q_t + z_1 Q_t V_t + \varepsilon_t$  (3). In there:

+  $\Delta P_t = P_t - P_{t-1}$ : The difference in price between time  $t$  and time  $t-1$ ;

+  $\Delta Q_t = Q_t - Q_{t-1}$ :  $Q_t$  is the stock trading index at time  $t$ , If it's a sale, receive value  $-1$ ; if it's a buy, gain value  $+1$ . However, there will be many continuous transactions in the same time period, making it impossible to determine  $Q_t$ . Thus, *Lee & Ready (1991)* identify:

$$Q_t = \begin{cases} +1 & (P_t > P_{t-1}) \\ -1 & (P_t < P_{t-1}) \\ Q_{t-1} & (P_t = P_{t-1}) \end{cases}$$

+  $V_t$ : Trading volume at time;

+  $c_0, c_1, z_0, z_1$ : Regression coefficients of model (3);

Glosten & Harris argue that the change in transaction price consists of 3 factors: Order cost, storage cost  $C = 2(c_0 + c_1 V_t)$ , and reverse selection cost  $Z = 2(z_0 + z_1 V_t)$ . With  $\bar{V}_t$  being the average trading volume, ASC is calculated as following formula:

$$ASC = \frac{\bar{Z}}{\bar{C} + \bar{Z}} = \frac{z_0 + z_1 \bar{V}_t}{(c_0 + c_1 \bar{V}_t) + (z_0 + z_1 \bar{V}_t)} \quad (4).$$

## 3. METHODOLOGY AND DATA

### 3.1. Research models

#### 3.1.1. GARCH model for testing asymmetric information effect

*Nelson (1991), Glosten et al. (1993), Rabemananjara & Zakoian (1993)* used the EGARCH, GARCH-M, and TARARCH models to show that bad news has a bigger impact on price factors on the US stock market than positive news. *Engle & Ng (1993)* compare and confirm the existence of information asymmetry in the Japanese stock market using a variety of models with variable variance conditions. However, a recent study utilizing the VECH-GJR model on the Taiwan stock market by *Chen & Anh (2020)* found no evidence of information asymmetry.

A few authors in Vietnam investigated and investigated the information asymmetry problem in the stock market. *Hoang (2004)* investigates the GARCH effect on the profitability of the Vietnamese stock market

from 2000 to 2003, demonstrating that negative news has a stronger, faster, and more direct influence than positive news. This outcome is consistent with similar research in developed markets. *Tien et al. (2017)*, *Anh (2021)* use data from the VN-Index to assess the asymmetry of news on the Vietnamese stock market using two models. The study then employs Akaike information criteria (AIC) and Bayesian information criteria (BIC) to select a superior model, concluding that there is an information asymmetry effect.

### 3.1.2. Glosten & Harris model for calculating adverse selection component

*Glosten & Harris (1988)*, *George et al. (1991)*, *Lin et al. (1995)*, *Kim & Ogden (1996)*, *Huang & Stoll (1997)* are all regularly used models with reliable estimation results. However, data on the closing price and the volume of matching transactions per day can only be acquired under certain situations. For the Vietnamese stock market, the types of prices and indexes in the models, and are not responsive and difficult to determine. With the Glosten and Harris model, this might be considered the “original” model as the foundation for the study path, employing the ASC of the price gap to evaluate the extent of information asymmetry in the stock market. This model is widely used, as evidenced by the studies of *Van Ness et al. (2001)*, *Park (2008)*, and others. As a result, the author believes that using Glosten and Harris’ approach to calculate ASC is appropriate with HOSE transactions. The coefficients  $c_0, c_1, z_0, z_1$  of the (3) model is obtained using the standard least squares regression technique.

### 3.2. Dataset

The study tests the existence of the information asymmetry effect on the Vietnamese stock market by using a group of conditional variance models that change through the daily closing price of the market representative index (VN-Index). After testing whether there really exists information asymmetry on the empirical data, the author continues to measure the level of information asymmetry by determining the ASC model for the group of 100 largest capitalization stocks listed on HOSE (VN100). The research process can be summarized by the diagram in Figure 2.

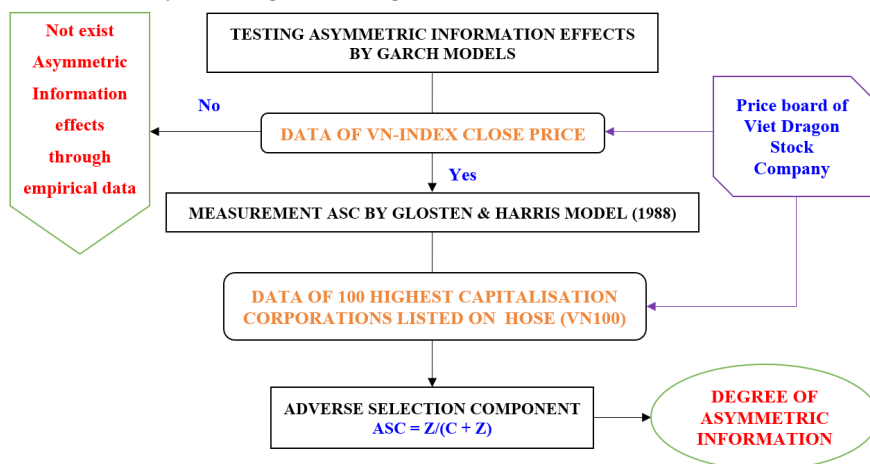

Figure 2. Research process of this paper

Source: The author draws by MS Word

#### 3.2.1. VN-Index for testing by GARCH models

The study employs secondary data, specifically the daily closing price of the VN-Index, to reflect the Vietnamese stock market over a five-year period spanning January 1, 2018 to December 31, 2022. The sample with this data is a time series of days with 1,249 observations. The study calculates the GARCH model group for the profitability of equities traded in the market to assess the information asymmetry effect. The dependent

variable is the percentage change in the VN-Index closing price:  $R_t = \ln\left(\frac{P_t}{P_{t-1}}\right)$ . In there:  $R_t$  is the rate of return of stocks on day  $t$ ,  $P_t$  and  $P_{t-1}$  is respectively, is the closing price of VN-Index on day  $t$  and  $t-1$ .

**3.2.2. VN100 for measurement by Glosten & Harris model**

The author calculates the ASC for stocks in the VN100 basket after checking for the existence of an information asymmetry effect using the VN-Index. However, because of the nature of the business and the structure of capital and assets, the author does not calculate for stocks of banks, securities companies, and insurance companies (Van Ness et al., 2001). The total number of companies analyzed is 78/100 of the highest capitalisation corporations listed on the Ho Chi Minh Stock Exchange. The price used to determine the spread is the daily closing price ( $P_{it}$ ) from January 1, 2018 to December 31, 2022. The total volume of matching transactions for the day ( $V_{it}$ ) is referred to as volume. Because it is impossible to establish whether the trading volume is from a seller or a buyer, the transaction index is legitimate according to Lee and Ready’s (1991) convention.

**4. RESULTS AND DISCUSSION**

**4.1. Descriptive statistics**

**4.1.1. VN-Index data**

**Figure 3. Descriptive statistics of VN-Index series**

Source: The author draws by Python

The graph on the left in Figure 3 depicts the yield series of the VN-Index over a 5-year period, demonstrating that the range of returns is  $(-0.03; 0.02)$ . The special profit fluctuated extremely much in the first quarters of 2020 and 2021, whereas the subsequent periods, despite swings, had fairly constant profit that only fluctuated around an average of 0. Graph of frequency with the density function of returns in the figure to the right depicts a random distribution of returns, however when compared to the balanced bell shape and parameters with the same Jarque-Bera test result, the series of returns does not match the normal distribution.

**4.1.2. VN100 data**

**Table 1. Descriptive statistics of variables in Glosten & Harris model**

Variable	Mean	Medium	Minimum	Maximum	Standard Error
$P_{it}$	36,426.64	24,228.80	2,575.60	289,000	33,879.99
$V_{it}$	2,394,031	856,700	0.0000	$1.65 \times 10^8$	4,649,556
$\Delta P_{it}$	0.0175	0.0000	-104,900	92,500	5,211.5633

$\Delta Q_{it}$	0.0002	0.0000	-2.0000	2.0000	1.3938
$\Delta Q_{it}V_{it}$	-319.5539	1730.0000	$-1.65 \times 10^8$	$1.66 \times 10^8$	7,185,475
$Q_{it}$	-0.0068	0.0000	-1.0000	1.0000	0.9688
$Q_{it}V_{it}$	250,081.5	0.0000	$-1.29 \times 10^8$	$1.65 \times 10^8$	5,159,617

The data on the VN100 companies is designed as a panel data set with 95,038 observations with a cross-section of 78 companies and a time series of days over 5 years. Among the variables observed are:  $P_{it}$ ,  $V_{it}$ ,  $\Delta P_{it}$ ,  $\Delta Q_{it}$ ,  $\Delta Q_{it}V_{it}$ ,  $Q_{it}$ ,  $Q_{it}V_{it}$ . Table 1 contains basic descriptive information regarding the variables. In addition to the dummy variable, all variables used to estimate the regression model by Glosten and Harris include random values ranging from negative to positive, indicating the daily increase and fall in stock prices. The price differential can reach 92,500 points on some days, but it can also fall dramatically from the previous day to 104,900 points.

#### 4.2. Result of testing asymmetric information effect

**Table 2. Unit root test**

Variable	Augmented Dickey-Fuller		Phillips-Perron	
	t-stat	p-value	Adj. t-stat	p-value
$R_t$	-33.1199	0.0000	-33.3158	0.0000

The results in Table 2 show that both the ADF and PP tests produce statistical values with p-value = 0.0000  $\ll$  0.01, indicating that hypothesis  $H_0$  is rejected and the VN-Index yield series is stationary at base-order of lag. The author then estimates a simple linear regression model with only constant variables to get residual series. The ARCH effect is tested using this residual series.

**Table 3. ARCH effect test**

ARCH-LM test			
F-stat	32.5980	p-value	0.0000
Regression with RESID <sup>2</sup>			
	Coef.	t-stat	p-value
C	$1.8 \times 10^{-5}$	6.9996	0.0000
RESID <sup>2</sup> (-1)	0.1433	5.0431	0.0000
RESID <sup>2</sup> (-2)	0.1444	5.0840	0.0000
RESID <sup>2</sup> (-3)	0.1424	5.0114	0.0000
RESID <sup>2</sup> (-4)	0.0349	1.2282	0.2196

If the data cannot reject the hypothesis  $H_0$  that the coefficients in the autoregressive model of variance are all zero, then there is no ARCH effect. When  $H_0$  is refused, there is an ARCH effect. Table 3 shows that the original hypothesis is rejected and that the series of squared residuals has an ARCH effect on the third delay. As a result, the data guarantees two input conditions for the estimate of two models, EGARCH and TGARCH.

**Table 4. Estimation result of EGARCH and TGARCH model**

EGARCH (1,1)		TGARCH (1,1)	
Variable	Coef.	Variable	Coef.
C	$8.9 \times 10^{-6}$	C	$7.8 \times 10^{-6}$
Variance Equation			
$\omega$	-0.8788***	$\omega$	$2.3 \times 10^{-6}$ ***
$\alpha$	0.2202***	$\alpha$	0.0305**
$\beta$	0.9317***	$\beta$	0.8069***
$\gamma$	-0.1091***	$\gamma$	0.1578***

Note: \*p < 0.1. \*\*p < 0.05. \*\*\*p < 0.01.

Based on the  $\gamma$  coefficient, the EGARCH and TGARCH models show that there is an information asymmetry in Vietnam’s stock market using VN-Index data from 2018 to 2022, with a significance of 1%.

**4.3. Result of measurement Adverse Selection Component**

The ASC findings for each ticker from 2018 to 2022 are derived by regressing the OLS for each ticker’s data to determine the coefficients  $c_0, c_1, z_0, z_1$ , then determining the average trading volume and applying the formula (4). The author must compute ASC for each stock separately in order to have a selective foundation when computing ASC for the full sample. Because the calculation results are significant only when  $0 < ASC < 1$  is used, stocks with  $ASC > 1$  or  $ASC < 0$  must be removed before calculating the overall ASC for the sample; otherwise, the overall ASC result can be very high or very tiny (Khang, 2007). Results in Appendix show that five equities, including FPT, PDR, PTB, TMS, and VSH, have an ASC greater than one. If these 5 stocks are excluded, the sample will be 73/78 businesses (more than 93% of the sample); still ensure to estimate the model and calculate the ASC.

For each stock, the process of determining ASC for each year or the entire period of 2018 – 2022 is similar. We additionally compute the corresponding average trade volume for that time period, employing a pooled regression model (Pooled OLS) to get the required coefficients. Brennan & Subrahmanyam (1995), Van Ness et al. (2001), Clarke & Shastri (2001) construct the ASC without taking into account the statistical significance of the regression coefficients, instead focusing on the event 0 ASC 1. As a result, the author did not take into account or examine the statistical significance of these coefficients.

**Table 5. Estimation result of ASC for each year and the period 2018 – 2022**

Year	$\bar{V}_t$	$c_0$	$c_1$	$z_0$	$z_1$	ASC
2018	1.462.565	304.6894	0.0000	2.080.2470	-0.0001	87.18%
2019	997.474	167.7902	0.0000	1.359.4320	-0.0001	89.92%
2020	2.177.432	300.3171	0.0000	1.680.8020	0.0000	86.52%
2021	4.093.325	207.8906	0.0000	2.449.8650	0.0000	93.05%
2022	3.548.838	296.4724	0.0000	3.216.2580	0.0000	88.11%
2018 – 2022	2.477.925	224.8042	0.0000	2.098.6050	0.0000	89.53%

In the case of categorized samples, the year with the highest ASC (93.05%) is 2021 while the year with the lowest ASC (86.52%) is 2020. ASC = 89.53% over the entire 5-year period from 2018 to 2022.

#### 4.4. Discussion

**Table 6. Result of estimation ASC in some papers**

PAPER	MARKET	PERIOD	ASC
Glosten & Harris (1988)	250 companies listed on NYSE	01.12.1981 – 31.12.1983	1.13%
Van Ness et al. (2001)	856 companies listed on NYSE	04.1999 – 06.1999	38.9%
Park (2008)	ETFs on NASDAQ	10.2005 – 12.2005	20%
Hoai & Khang (2008)	104 companies listed on HOSE	02.01.2007 – 28.12.2007	89.66%
Tu (2013)	112 companies listed on HOSE	03.01.2021 – 28.12.2012	72.75%
Ngai et al. (2016)	Companies listed on HOSE	01.12.2012 – 31.05.2013	77%
Phan (2021)	174 companies listed on HOSE	2009	89.2%
		2010	78.5%
		2011	79.1%
		2012	77.9%
		2013	79%
		2014	63.3%
This paper (2023)	78 highest capitalisation companies listed on HOSE	2015	72.2%
		2018	87.18%
		2019	89.92%
		2020	86.52%
		2021	93.05%
		2022	88.11%
		2018 – 2022	89.53%

Table 6 summarizes the research that used the Glosten & Harris model to determine the ASC. ASC was found to be less than 40% in all studies of the US stock market from 1981 to 2005. The ASC for Vietnamese stock market (HOSE) research is nearly always greater than 70%, indicating a large level of information asymmetry. This empirical conclusion accurately represents the challenge of information openness in a young stock market like Vietnam, where mistakes still occur often. The ASC value has increased significantly over the last five years when compared to earlier times, and it's near 90% or even more than 93% in 2021. The results of the author's ASC calculation accurately portray the market condition from 2018 to 2022, including the existing situation and a sequence of infractions. The ASC value of 89.53% for all five years indicates that the potential of reverse selection in a transaction on the Vietnamese stock exchange is quite high, indicating a significant degree of information asymmetry while the study's sample size is small. This is based on the stock code of the Ho Chi Minh Stock Exchange's top 100 companies. This figure highlights the need for Vietnamese investors, listed businesses, policymakers, and related organizations to take more active actions to remove asymmetric information and increase market transparency.

#### 5. CONCLUSION

The paper has been investigated using experimental data, with the results indicating the presence of information asymmetry and a level based on an ASC value of 89.53% over the period 2018 – 2022. To reduce the impact of information asymmetry, synchronized improvements and coordination from all market parties are required. Investors, issuers, securities firms, and state management agencies are key players.

**For investors:** Before the authorities can protect them, investors must first protect themselves. Second, in order to efficiently manage their investment portfolio, investors must constantly increase their expertise and learn from experience. Third, instead of relying on information conduits from other organizations, investors should actively collect and learn information. Finally, when participating in investments, investors must follow the State's standards on transparency and honesty.

**For listed companies:**

- (i) Recognize and fully adhere to information disclosure regulations.
- (ii) Making information available to the public in a timely and accurate manner.
- (iii) Fair competition with an honest accounting and internal audit system.
- (iv) Closely examine and oversee leaders to limit the problem of Principle – Agent.

**For stock companies:**

Firstly, stock companies must rigorously adhere to the terms of the law, which requires a thorough understanding of the principles of securities information.

Secondly, stock companies foster an open and honest company culture.

Thirdly, stock companies assemble a team of skilled and accountable employees.

Fourthly, stock companies broaden their customer information channels.

Fifthly, stock companies is continuing to upgrade current equipment.

**For the State Securities Commission:**

+ The State Securities Commission must conduct regular checks on the ability of enterprises and the audit department, as well as aggressively enforce violations and negative indicators.

+ The State Securities Commission should create a unified legal document on investor protection based on standardizing regulations on stock market management and development in accordance with International Organization of Securities Commissions (IOSCO) recommendations.

+ The State Securities Commission may explore increasing its role and broadening its authority to investigate and manage major violations of stock market matters.

**For Stock Exchanges:**

+ The procedure by which listed firms provide information should be altered. In fact, because the publicized information is concentrated on this agency, information leakage occurs frequently. As a result, corporations can post information on their mass media system, and the Stock Exchange merely needs to confirm that information.

+ Not only the State Securities Commission but also Stock Exchange can use market surveillance technologies. The supervisory process will be more effective when the Stock Exchange becomes the first supervisory body, lowering pressure on the State Securities Commission and enhancing the Stock Exchange's duty.

+ The Stock Exchange should better coordinate with the media spot anomalous material quickly, open up communication lines, and encourage investor feedback. Because there is a lot of information regarding stock market misbehavior that neither the Stock Exchange nor the State Securities Commission can identify, but due to this media power.

Despite tremendous attempts, the paper contains certain flaws due to restricted time and independent research capacity. First, due to data constraints, the topic can only measure the ASC value using each

Glosten & Harris model. Second, the issue not only tests and measures the level of asymmetric information via the ASC value, but also investigates what circumstances influence this change in value. Third, because it does not cover the entire market, the data size is constrained; when compared to the original studies of Glosten & Harris or Van Ness (2001), the number of observations is still tiny. To address the aforementioned inadequacies and restrictions, the author will assess ASC using multiple models the next time when the database of transaction statistics is changed and the information is released more thoroughly. Furthermore, the author will broaden the group of research stocks to include companies listed on the Hanoi Stock Exchange in order to better understand the factors influencing the level of adverse selection as well as asymmetric information of the Vietnamese stock market.

## 6. APPENDIX

### Appendix E. Results of ASC for each company

ID	ASC	MÃ	ASC	ID	ASC	ID	ASC
AAA	84.12%	DXG	86.82%	KOS	91.65%	SAM	96.19%

## PREDICTING THE FINANCIAL HEALTH OF SMES IN VIETNAM: A COMPARISON AND EVALUATION OF RESULTS BETWEEN CLASSICAL MODELS AND MACHINE LEARNING MODELS

**Author: Huynh Thanh Hai<sup>1</sup>, Vu Thi Hanh Dung<sup>2</sup>, Phan Thi Thuy Duyen<sup>2</sup>,  
Le Tuong Vy<sup>2</sup>, Le Quang Bao<sup>2</sup>  
Mentor: Vo Thi Le Uyen<sup>3</sup>**

**ABSTRACT:** Financial health is one of the most important factors to evaluate the effectiveness of the business. Forecasting the financial health of small and medium-sized enterprises (SMEs) helps to make market-appropriate business decisions and increases competitiveness in the international market. However, forecasting financial health for SMEs is faced with many major challenges. Some of them include the shortage of information, especially for start-ups or small businesses. The information on SMEs' financial activities is often not made public, leading to difficulties in data collection and analysis. In addition, existing classic models of financial health forecasting such as Z-score, X-score, and H-score, while commonly used, have some limitations and are not suitable in today's complex business environment. With the rapid development of technology, machine learning models are becoming an important tool in forecasting the financial health of SMEs. The study compared the effectiveness of machine learning models (Logistic, LDA, SVM, Random Forest, XGBoost) and classic models to forecast the financial health of SMEs in Vietnam. The results showed that the best in the machine learning model is XGBoost with a forecast of 94%, and the best classic one is X-Score with a forecast of 85.6%. This suggests that machine learning models can provide better predictive results than traditional classical models. The use of predictive models and machine learning tools such as XGBoost and the SHAP values algorithm is very useful in assessing the financial health of businesses. From the results of the SHAP algorithm, it can be seen that small and medium enterprises should focus on ROA indicators and quick payment ratios to be able to improve or prevent the risk of their business exhaustion.

**Keywords:** Financial health, SMEs, classic models, SHAP values.

### 1. INTRODUCTION

In the current market economy, most of the GDP is generated from enterprises. At the same time, enterprises play an important role in promoting the development of the economy, creating jobs for workers to bring a stable source of income. Therefore, the performance of enterprises is the main factor determining the development of GDP in particular and the whole socio-economic economy in general. However, many businesses nowadays face and directly be affected by the global recession of the economy, the post-Covid 19 epidemic, and the Ukraine-Russia war as well as the internal factors of the business itself. Some enterprises with good financial performance will survive and some are on the verge of bankruptcy. Thus, the “financial health” of businesses is an issue that we care about. The financial health of a business or company can be seen as its ability to maintain a balance against changing environmental conditions and in relation to all actors in the business. In assessing financial health and predicting the financial problems of businesses, different indexes are used that can serve as inputs for estimating figures or creating different models. The problem of “financial health” of most businesses is often related to depleted operating capital, high inventory rates, tightening bank lending, and unpaid debts... Evaluate based on financial indicators

<sup>3</sup> University of Economics and Law, Vietnam National University Ho Chi Minh City, Email: [uyenvtl@uel.edu.vn](mailto:uyenvtl@uel.edu.vn)

through financial statements published by businesses. In addition, use non-financial factors to consider the financial impact of enterprises to provide a model to forecast the ability to maintain operations, and the risk of bankruptcy or insolvency of small and medium-sized enterprises (SMEs') in the market... However, there are many studies in the world as well as a few studies in Vietnam interested in the financial health of enterprises, which are almost all done on enterprises with a large capitalization of over VND 100 billion. Currently, there is not much research focused on SMEs', while in Vietnam, SMEs' account for the majority of the market share and are a major contributor to the country's socio-economic development.

On the other hand, SMEs' are currently facing and suffering from many financial risks, difficulties in using capital appropriately, encountering some challenges in the process of "transforming" to meet market demand, especially being heavily affected by the country's economic situation such as epidemics, crises, inflation,...

Edward I. Altman's (I. Altman, 1968) work on the Z-Score model provided the first foundation for predicting the likelihood of bankruptcy in businesses with input data from 22 financial indicators of companies in the US stock market. The Z-score model has given 5 variables to forecast bankruptcy  $X_1$ : Working capital / Total assets;  $X_2$ : Retained profit / Total assets;  $X_3$ : Profit before tax and interest / Total assets;  $X_4$ : Market value of equity / Total Liabilities  $X_5$ : Total liabilities / Total assets. Altman proposed a predictive model with fixed weights based on statistical methods - Multiple Discriminant Analysis (MDA) and the result is a scale of about 3 levels: Safety, risk, and bankruptcy. His research was widely used in the following years, resulting in extremely accurate predictions.

The same method as Altman, in 1984, Fulmer (Fulmer, et al., 1984) introduced the H-Score model forecasting bankruptcy with 9 variables. Also with statistical methods - Multiple Discriminant Analysis. He used his model with businesses with a capital of about \$455,000 as a research platform for small and medium enterprises. Add to the model, Fulmer added fixed-asset elements and the ability to pay interest. The results of Fulmer's H-score model are classified as bankruptcy or safety.

However, in the 1980s, the financial markets changed. Financial data is no longer accurate with Altman's and Fulmer's models of Multiple Discriminant Analysis. The constraints of this approach on assumptions and Multiple Discriminant Analysis do not allow adding dummy variables. This hinders the determination of qualitative factors affecting the ability of the business to go bankrupt. Ohlson (Ohlson & J, 1980) invented his O-Score model in 1980 with a method of using logistic regression to predict the probability of a business's bankruptcy. He outlined nine research variables, which added two dummy variables of earning after tax less than zero over two years and a dummy variable of total debt greater than total assets. The results obtained from this method are more accurate and simpler than the statistical method - Altman and Fulmer's Multiple Discriminant Analysis.

From classical models in foreign studies, access to modern machine learning methods. The study of Huynh Thi Cam Ha (Ha, Uyen, & Mai, 2017) studied the application of the classification tree model in forecasting financial distress in enterprises in Vietnam listed on the Ho Chi Minh Stock Exchange and Hanoi Stock Exchange from 2009 to 2015. The research paper has 6 groups of variables: liquidity group, capital structure group and debt repayment capacity group, profitability index group, operation index group, growth index group, and non-financial index group. The study used two machine learning algorithms, C4.5 and AdaBoost to build a decision tree model. The model removed from 25 input variables the remaining 10 important variables, the results from the study ranked the importance of financial indicators and gave a threshold for the impact of those indicators leading to financial distress. For the C4.5 algorithm, the variable of financial leverage is the most important in affecting distress, whereas AdaBoost algorithm considers the variable representing the growth in equity as important. The results from the decision tree

model are surprisingly accurate with up to 99.5% predictability. However, the disadvantage of the model in the research paper is the need for a large amount of input data, the AdaBoost method needs the number of learning times to be repeated many times because the models learn from each other, leading to difficult model running, requiring large memory.

And most of the previous research papers have shortcomings: First, there is no comparison between methods. The second is aimed at large markets, companies with huge capitalization like the US. Third, there is no explanation of the importance of variables that affect the ability to exhaust. Therefore, this study offered a comparison of the performance of two classical methods and machine learning. Besides, assessing the importance of financial variables affecting the financial health of small and medium enterprises in Vietnam.

In summary, from overviews of studies predicting bankruptcy of domestic and foreign enterprises, most of the research focuses on large markets and businesses with huge capitalization such as the US. The great contribution of Altman, Fulmer, and Ohlson's research has solved the problems of enterprises in quantifying the risk of bankruptcy to help businesses understand the financial situation of their businesses. The models have measured financial indicators collected and aggregated from corporate financial statements over the years but have not yet expanded and agreed on qualitative variables as well as non-financial factors. main: type of enterprise, classification of business lines, number of shares held by shareholders... The influence of non-financial factors also leads to shortcomings in the ability to forecast the financial health of enterprises. This laid the foundation for the development of the research paper which has further practical applications in social life and financial markets.

Recognizing the importance of forecasting "Financial health" and offering solutions to limit the risk of bankruptcy for SMEs' in the post-COVID-19 period is urgent and necessary for the development of the country's economy, the research team decided to implement the project "Forecasting the financial health of small and medium enterprises in Vietnam: Comparing and explaining the results between classic models and machine learning models".

The project is implemented with the desire to contribute to diversifying domestic research as well as contributing to the assessment of the financial potential of SMEs', helping businesses have a better overview of their financial capacity and have an appropriate financial plan for sustainable development. The study will be evaluated by each group of enterprises based on relevant indicators and indicators to bring optimal results and consistency to the study.

The objective of the project is to develop a model for forecasting the financial health of SMEs' in Vietnam. Based on the study of SME theories, on the risk of financial distress and the development of financial health forecasting models.

The research topic uses qualitative and quantitative methods. Document research was conducted by systematizing existing research, finding research gaps, and building model ideas to overcome shortcomings in the connection between research variables and put research hypotheses for the topic. Quantitative research with estimating parameters, testing models, and hypotheses set out to make development recommendations. Refer to the expert method, based on the opinions and models proposed by the expert to increase the practicality of the topic. This article used descriptive statistics and quantitative models from classical to machine learning. The models used are Z - score, X - score, S - Score, H - Score, Logistics Regression, Linear Discriminant Analysis, Random Forest, Support Vector Machine, XGBoost... From there, it is suggested what is the best model to use to assess financial health, or in other words, the risk of financial distress. At the same time, it provides solutions to prevent and limit the risk of financial distress as soon as possible to ensure stable, long-term, and sustainable financial operations.

## 2. THEORETICAL FRAMEWORK

### 2.1. SMEs

Small and medium enterprises (SMEs) is a relative concept used to compare the size of an enterprise compared to large enterprises. The determination of criteria and norms for assessing the size of SMEs differs in each country, depending on the level of economic development, cultural context and the purpose of classifying SMEs. In VietNam, SMEs' definition in Chapter II Decree No. 39/2018/ND-CP date issued 11/03/2018, which has been introduced by the Government on support for small and medium-sized enterprises. Generally, based on the definition of SME Law, a very small-sized enterprise's number of laborers is not more than 10, the total capital is less than 3 billion or total revenue is less than 10 billion. MSMEs are manufacturer and service units that have not more than 200 employees, total capital less than 100 billion and total revenue less than 200 billion. However, most countries define SMEs according to three basic criteria: the average number of employees that enterprises use in the year, the total investment capital of the enterprise, and the total annual revenue of the enterprise. In which the criteria of labor and investment capital are more widely used.

**Table 1. Agriculture, Forestry, Fishery, Industry and Construction**

	<b>Number of laborers</b>	<b>Total capital</b>	<b>Total Revenue</b>
Medium sized enterprises	200	≤ 100	200
Small sized enterprises	100	20	50
Very small sized enterprises	10	3	3

*Source: Author's collection*

**Table 2. Trade and Service**

	<b>Number of laborers</b>	<b>Total capital</b>	<b>Total Revenue</b>
Medium sized enterprises	100	100	≤ 300
Small sized enterprises	50	50	100
Very small sized enterprises	10	3	10

*Source: Author's collection*

### 2.2. Financial distress

Corporate financial health or financial distress has been widely studied in many countries. In 1965, Foster defined financial distress as a “serious liquidity problem which is impossible to be resolved without the large-scale restructuring of the operation or structure of economic entities” (Foster. 1965). Md Zeni and Ameer (2010) defined financial distress as a term used to designate a situation when the obligations in a contract with debt cannot be fulfilled due to financial difficulties faced by the company. Ghazali, et al defined financial distress as temporary in which a company has difficulty paying debt or paying financial obligations (Ghazali et al. 2015). Financial distress is a temporary lack of liquidity, making it difficult to pay financial obligations. This situation increases when there are high fixed costs, illiquid assets, or revenue sensitive to bad fluctuations in the economy. Financial distress can lead to bankruptcy. There are many different views and signs of financial distress, but the general definition is when cash flow is not enough to ensure financial obligations, former shareholders lose ownership and creditors hold the assets of the business. This situation can be solved by restructuring business activities or economic organization structure. Financial distress is only the stage in the process of failure and restructuring of the business.

### ***Signs of financial distress of the business:***

A business runs into financial distress when there is insufficient cash flow to meet its financial obligations, and this can best be reflected by the cash flow of the business. Financially exhausted businesses often have liabilities greater than the total assets or interest payment ratio of less than one. In general, financial distress goes through three main stages: early, middle and later. At an early stage, the business will face many problems such as reduced operating profits, declining sales. The middle stage will make the business in a state of “insolvency”. Finally, in the later stage, when the problems cannot be overcome, the business is forced to end, this is the stage of “insolvency, bankruptcy”.

## **3. RESEARCH METHOD**

### **3.1. Data of research**

In this research, the data includes the financial information of SMEs in Vietnam, which was collected from the FiinPro database. This data comprises financial indicators such as assets, liabilities, revenue, profit, and other indicators. Data collection took place from 2018 to 2021, but some cases were excluded from the dataset to ensure the integrity and accuracy of the research results.

This study utilizes financial indicators to evaluate the financial health of SMEs on the UPCOM, HOSE, and HNX stock exchanges. Only businesses with a capital scale of 100 billion VND or less, established before 2018, and with at least 1-year financial activity were selected for analysis to obtain financial data. Financial distress prediction of SMEs was carried out 1 year prior to the distressing event.

### **3.2. Data preprocessing**

In the process of predicting the financial health of SMEs in Vietnam, processing the financial reports of small and medium-sized enterprises is a complex task that requires caution to ensure the accuracy and reliability of the forecasting results. Data preprocessing helps eliminate incorrect, missing, inaccurate, and irrelevant data before inputting them into the forecasting models.

After completing the data preprocessing process, the data will be cleaned and ready to be applied to the forecasting models and their effectiveness evaluated. The research team divided the dataset into training and testing sets as follows: using the year 2018 for training and testing in 2019, using the year 2019 for training and testing in 2020, and finally using the year 2020 for training and forecasting for 2021 to test.

### **3.3. Expected variables**

#### **3.3.1. Dependent variable**

The research study calculates the dependent variable based on two factors to determine when a company is labeled as distressed:

**Negative free cash flow:** Free cash flow is represented by the three cash flows in variables  $X_2$ ,  $X_3$  and  $X_4$ . When the free cash flow is negative, the company will not have any sources of funds to pay for its short-term debts, which is one of the signs of financial distress when the company cannot generate profits.

**S-Score index  $< 0.862$ :** The S-Score index is currently the most suitable index for evaluating the market in Vietnam, according to research by (Le Hoang Vinh and colleagues, 2022).

Therefore, determining the label for distressed companies is based on meeting at least one of the above conditions.

#### **3.3.2. Independent variables**

When researching the financial health forecasting model of Vietnamese SMEs, financial ratio variables are a crucial part. These variables measure and analyze the financial performance of the enterprise, helping

managers, investors, and other stakeholders to assess the financial health of the enterprise and make appropriate decisions.

In this study, the research team synthesized variables from classic models such as Z-Score, X-Score, H-Score, and added a number of commonly used variables to evaluate an enterprise.

**Table 3. Expected variables in the model**

Variable	Description of variables
$X_1$	(Short_term assets – Short_term debt) / total assets
$X_2$	Dummy operation cash flow (1 if $X_2 > 0$ , 0 if $X_2 \leq 0$ )
$X_3$	Dummy investment cash flow (1 if $X_3 > 0$ , 0 if $X_3 \leq 0$ )
$X_4$	Dummy financial cash flow (1 if $X_4 > 0$ , 0 if $X_4 \leq 0$ )
$X_5$	Earning before interest and tax / total assets
$X_6$	Net revenue / total assets
$X_7$	Earning after tax / total assets
$X_8$	Earning before tax / short-term debts
$X_9$	Earning before interest and tax / equity
$X_{10}$	Net cash flow / total debts
$X_{11}$	Logarithm(Tangible property)
$X_{12}$	Logarithm(Earning before interest and tax / interest expenses)
$X_{13}$	(Short_term assets - inventory) / short_term debts
$X_{14}$	Money / short_term debts
$X_{15}$	Cost of goods sold / inventory
$X_{16}$	Short-term receivables / net revenue
$X_{17}$	Cost of goods sold / payable accounts
$X_{18}$	Net revenue / fixed assets
$X_{19}$	Earning after tax / net revenue
$X_{20}$	Short_term debt / total assets
$X_{21}$	Total debts / total assets
$X_{22}$	Short_term assets / short_term debts
$X_{23}$	Earning after tax / equity

Source: Author's collection

### 3.4. Research models

#### 3.4.1. Random Forest

The Random Forest model is a machine learning algorithm used in classification and prediction problems. This model combines multiple decision trees to create a better classification or prediction model.

Random Forest uses Bootstrapping technique to randomly sample a subset of data from the initial training set to build a decision tree. Then, Random Forest combines these decision trees to create a more general classification or prediction model.

The decision trees are built by finding the most important features to divide the data into groups. The decision trees are built independently, thus, Random Forest minimizes the overfitting phenomenon.

The Random Forest also provides methods to evaluate the accuracy and importance of features. It is

also capable of handling missing and imbalanced data. Another evaluation method of Random Forest is the Out-of-Bag (OOB) error, which is calculated by using data points not used in the tree building process to evaluate the model. The Random Forest model is an effective classification and prediction model, widely used in real-world problems.

### 3.4.2. *eXtreme Gradient Boosting (XGBoost)*

The XGBoost model is a powerful and widely used machine learning algorithm for classification and prediction problems, including financial distress prediction. It is built on the idea of using decision trees to create a high-performance classification or prediction model.

The decision trees in XGBoost are created through a boosting process, in which a sequence of decision trees is generated. Each decision tree learns from the errors of the previous decision tree and is modified to produce a new decision tree with better performance. Each decision tree is trained to predict the value of the dependent variable based on the values of the independent variables.

XGBoost combines a loss function and a regularization function to create an objective function for model optimization. The mathematical formula for the objective function  $F$  in XGBoost is expressed as follows:

$$\text{Objective}(F) = L(y, F) + \Omega(F)$$

where:

Objective(F): the objective function

$L(y, F)$ : the loss function

$\Omega(F)$ : the regularization function

The XGBoost model is a variant of Gradient Boosting, in which some improvements have been made to enhance the speed and performance of the algorithm. An important improvement of XGBoost is the use of a differentiable loss function to optimize the model. Specifically, the loss function used is the log loss, similar to that in logistic regression.

XGBoost also uses decision trees to build the model, but instead of using independent decision trees, XGBoost uses a series of level-wise decision trees, each decision tree is built to optimize the remaining error after the previous decision trees have been built.

### 3.4.3. *Explain machine learning model by using SHapley Additive exPlanations (SHAP)*

Machine learning models are tools used to predict outcomes based on previously trained data. They can be seen as the artificial brain of a system, capable of learning from input data and optimizing parameters to make the most accurate predictions. However, some types of machine learning models, such as black box models, can make it difficult to explain their workings and decision-making processes, leading to difficulties in explaining why a decision was made or how the model arrived at its prediction. To address this issue, Lundberg and Lee introduced the SHAP (SHapley Additive exPlanations) explanation method in 2017. This method is based on Shapley values theory, a concept introduced in 1953 by Shapley and used to allocate value to a group of players based on their contributions to winning a game. SHAP values calculate the contribution of each feature to the model's prediction, helping users understand which features the model is predicting based on and why. The formula for calculating Shapley values for a feature is obtained by taking the average difference between the predicted value of the model with and without that feature.

$$\phi_i(f, x) = \sum_{z' \subseteq x'} \frac{|z'|!(M - |z'| - 1)!}{M!} [f_x(z') - f_x(z' \setminus i)]$$

Where:

$\phi_i(f, x)$  is the SHAP value of the input variable  $i$ th

$x$  is the input vector

$z'$  is the subset of  $X$  without variables  $i$ th

$f_x(z')$  is the prediction of the model on the  $z'$

$f_x(z' \wedge i)$  Is the prediction of the model on the  $z'$  added variable  $i$ th

$M$  is the number of input variables

The formula calculates the Shapley value of a feature by comparing the model's predicted value when that feature is present and when it is absent. Shapley values are computed for all features and summed to obtain the overall Shapley value for that data point.

#### 3.4.4. Model evaluation

The confusion matrix is a tool for evaluating the performance of a classification model. It helps assess the model's predictive ability by comparing the predicted results to the ground truth. The confusion matrix consists of four main parts: True Positive (TP), False Positive (FP), True Negative (TN), and False Negative (FN). Performance evaluation metrics such as Accuracy, Precision, Recall, and F1-score are computed based on the confusion matrix. The Type 1 and Type 2 error rates are important metrics for evaluating the model's classification ability on both Positive and Negative classes. If the error rate is too high, the classification model needs improvement to reduce classification errors.

Accuracy is the ratio of the number of correctly classified cases to the total number of cases and is calculated by the formula:  $\text{Accuracy} = (\text{TP} + \text{TN}) / (\text{TP} + \text{TN} + \text{FP} + \text{FN})$ . Accuracy reflects the model's ability to classify correctly across the entire data set.

Recall is the ratio of the number of correctly classified Positive cases to the total number of actual Positive cases and is calculated by the formula:  $\text{Recall} = \text{TP} / (\text{TP} + \text{FN})$ . Recall reflects the model's ability to classify correctly on the Positive class.

AUC (Area Under the ROC Curve) is the area under the Receiver Operating Characteristic (ROC) curve and measures the model's ability to distinguish between Positive and Negative classes. The closer the AUC is to 1, the better the classification model.

F1-score is the harmonic mean of Precision and Recall and is calculated by the formula:  $\text{F1-score} = 2 * \text{Precision} * \text{Recall} / (\text{Precision} + \text{Recall})$ . F1-score reflects the balance between Precision and Recall.

## 4. RESEARCH RESULTS

### 4.1. Data preprocessing and results

**Table 4. Descriptive statistic of variables**

	Mean	Median	Standard Deviation	Kurtosis	Skewness	Minimum	Maximum
$X_1$	0,222	0,187	0,236	0,282	0,406	-0,947	0,957

Source: Author's calculation

The research team conducted Exploratory Data Analysis on a dataset of 507 companies. The team created a target variable using the S-Score model and free cash flow as the criteria. If a company had either an S-Score < 0.862 or negative free cash flow, it would be unable to pay its short-term debts and would be labeled as 1; otherwise, if the S-Score ≥ 0.862 and free cash flow is positive, it would be labeled as 0. As a result of this labeling, the study identified 97 bankrupt companies and 410 non-bankrupt companies.

After labeling the dependent variable, the research team constructed independent variables from financial statement to fit the list of expected variables entered into the model, including 23 financial indicators. Variables used to calculate the S-Score and those with high correlation were removed to avoid duplication.

Figure 1. Correlation matrix between variables

Source: Author's calculation

Based on the correlation graph, the research team removed variables with high correlation, such as  $X_{21}$ ,  $X_{22}$ , and  $X_{23}$ . In addition, variables used as conditions for the dependent variable calculation, such as  $X_1$ ,  $X_5$ ,  $X_8$ , and  $X_6$ , were also removed to avoid duplication.

Six best variables were selected to be included in the machine learning models for comparison with the classical models that uses fewer variables, to examine the superiority of the machine learning methods over the classical ones. After data calculation, the model selected variables  $X_7$ ,  $X_{13}$ ,  $X_{16}$ ,  $X_{17}$ ,  $X_{18}$ , and  $X_{19}$  for machine learning computation.

The research team performed data splitting into training and testing sets, and tested the predictions based on training and testing over the years. Year 2018 was used for training and predicting for year 2019, year 2019 was used for training and predicting for year 2020, and year 2020 was used for training and predicting for year 2021.

**4.2. Comparison and evaluation of the results between the classical models and the machine learning models**

**Table 4. Comparison of predictive power and error types between the machine learning models and the classical models**

	Accuracy	Type 1 Error	Type II Error
XGBoost	94%*	3,41%***	10,25%***
Random Forest	76%	7,95%	7,69%**
X – Score	85,6%**	12,97%	1,42%*
Z – Score	85,1%***	0,23%*	18,35%
H – Score	81,9%	1,09%**	17%

With \* being the first rank, \*\* being the second rank, and \*\*\* being the third rank

Source: Author’s calculation

In the model evaluation table, XGBoost and X-Score performed the best with accuracies of 94% and 85.6%, respectively. Although XGBoost had a higher accuracy, X-Score misclassified the fewest distressed samples. Random Forest and Z-Score had lower performances, with Random Forest achieving only 76% accuracy and Z-Score achieving 85.1%. However, both error types and accuracy need to be considered when evaluating a model. Therefore, XGBoost and X-Score are noteworthy models, while Random Forest and H-Score need improvement to achieve better performance.

The results show that the XGBoost model is suitable for predicting the financial health of small and medium-sized enterprises. This model provides a more modern approach and prediction in the digitalization process of enterprises. On the other hand, the X-Score model still demonstrates outstanding ability in predicting for businesses despite some limitations. This helps businesses prevent risks and make appropriate adjustments to avoid bankruptcy.

**4.3. Explanation of machine learning model results**

**Figure 2: SHAP evaluation plots of the XGBoost (left) and Random Forest (right)**

Source: Author’s calculation

Based on the calculated SHAP values, it can be seen that both machine learning models evaluate variable  $X_7$  as the most important variable and having a strong impact on the likelihood of a small and medium-sized enterprise falling into financial distress. Additionally, variable  $X_{13}$  also has an impact at a moderate level for the XGBoost model, which evaluates it as high after variable  $X_7$ , while for the Random Forest model, it is evaluated as having the same impact as variable  $X_{18}$ . Therefore, it can be seen that for variable  $X_7$ , which represents ROA, the profitability level based on the assets of an enterprise has a significant impact on whether that enterprise may fall into financial distress or not. Further consideration of  $X_{13}$ , which represents the quick ratio of an enterprise, may also affect the ability to predict financial distress.

To have a clearer evaluation of the impact level of these 2 variables on the predictive ability, the research team visualized the dependency graphs of each variable.

**Figure 3: Dependency plot of variable  $X_7$  (left) and variable  $X_{13}$  (right)**

Source: Author's calculation

It can be seen that these are two opposite variables. For variable  $X_7$ , which represents ROA, the SHAP value analysis of the XGBoost model's predicted value shows that the higher the after-tax profit ratio on total assets, the lower the likelihood of financial distress. A significant decrease in after-tax profit may lead to a decrease in the company's ability to repay debts, as well as a lack of capital for business development. Maintaining a reasonable and stable level of profit will help the company achieve sustainable development and avoid the risk of financial distress.

The analysis of the XGBoost model's SHAP value prediction shows that the higher the quick ratio, the lower the likelihood of financial distress. If a company's quick ratio is too low, the company may not have enough current assets to pay off its short-term debts. This means that the company may have to rely on borrowing or selling long-term assets to meet its short-term obligations. Based on the results from SHAP values, companies should maintain this ratio above 1 to have a stable financial health and minimize the risk of financial distress.

## 5. DISCUSSION

The use of the XGBoost machine learning model to forecast financial health for small and medium-sized businesses is a clear advantage. Compared to classic models such as Z-score, X-score and H-score, XGBoost has better predictability with higher accuracy and better categorization. By using machine learning algorithms and data mining techniques, XGBoost can learn from the historical data of the business and make forecasts about the future financial situation of the business in a more accurate and effective way. One of the important advancements compared to previous studies is the ability to provide comprehensive and consistent explanations of the significant variables that impact the financial health of a business using the SHAP values method. By utilizing this approach, we can easily explain and update the strong influencing factors on the model with changes in the micro and macroeconomic environment.

One of the important progress compared to past research articles is the explanation of important variables that have a full and consistent financial health of the enterprises by the SHAP Values method. Using this method will help us easily explain and update the factors that strongly accelerate the model with changes in the micro and macroeconomic environment to be able to offer response measures in time.

However, to achieve the best results when using XGBoost, it is necessary to have a complete and accurate database to be able to train the model. At the same time, it is necessary to invest in and develop new techniques and technologies to enhance the performance of the model.

In general, the use of the XGBoost machine learning model is an effective solution to improve forecasting and financial management for small and medium enterprises in Vietnam. However, it takes investment and research to be able to apply the model effectively and meet the requirements of the market.

In addition, based on the SHAP algorithm, it can also be seen that the importance of interpreting the machine learning model to be able to understand more about the problem. Because without explaining the internal problems, small and medium enterprises cannot know the directions to overcome their situation when they know the forecast results are exhausted. That's why it's important to explain the machine learning model has given important financial indicators that small and medium enterprises need to pay attention and pay special attention to improve their situation. In addition, other indicators also contribute a lot to the forecast of financial health of businesses, so businesses should not ignore these indicators. In summary, the study has made comparative results between the classical model and the machine learning model. As a result, businesses can see the importance of digital transformation, applying machine learning models and checking their financial health in addition to using classic models that have many shortcomings.

## **6. CONCLUSION**

### **6.1. Using Machine Learning Models to Forecast the Financial Health of Enterprises**

For small and medium-sized enterprises (SMEs) in Vietnam, using machine learning models to forecast the financial health of businesses can bring numerous benefits, not only in making accurate and effective business development decisions.

One of the benefits of using machine learning models is their ability to help businesses forecast economic and market trends in the future. This enables businesses to prepare appropriate plans and strategies to respond to changes in the business environment.

Furthermore, using machine learning models also helps businesses identify potential risks and take preventive measures before they become severe. This enhances the sustainability and stability of the business.

Lastly, using machine learning models can enable businesses to seize new opportunities and develop their operations more effectively. With accurate forecasting capabilities, businesses can make timely and informed decisions to capitalize on market opportunities.

Therefore, employing machine learning models to forecast the financial health of enterprises is an effective solution to improve strategic decision-making and enhance the sustainability of businesses.

### **6.2. Enhancing Investment in Research and Development of Machine Learning Models**

To improve forecasting capabilities and make appropriate strategic decisions in the market, small and medium-sized enterprises in Vietnam need to increase investment in research and development of machine learning models for financial health forecasting.

One way to enhance forecasting capabilities is to analyze historical data of enterprises and utilize machine learning models to identify trends and relationships among different financial variables. The results can be used to make strategic decisions such as investment, product development, and business expansion.

Moreover, increasing investment in research and development of machine learning models can help businesses discover new approaches to enhance forecasting capabilities. Therefore, strengthening investment in research and development of machine learning models brings multiple benefits to small and medium-sized enterprises in Vietnam, enabling them to improve forecasting abilities and make market-appropriate strategic decisions.

### 6.3. Introducing Support Policies and Encouraging Businesses to Adopt Machine Learning Models

To support small and medium-sized enterprises in Vietnam, it is necessary to introduce policies that encourage the use of machine learning models for financial health forecasting. However, applying these models still poses challenges, such as insufficient technical knowledge, lack of resources, and the accuracy of forecasts. Enhancing training, providing financial support, and building better machine learning systems for accurate and cost-effective financial health forecasting can enhance business efficiency in a fiercely competitive market.

### 6.4. Limitations and Difficulties of the Research Topic

During the research and analysis process, the thesis encountered certain limitations and difficulties. One of these challenges was the scarcity of financial health data for small and medium-sized enterprises in Vietnam. This limitation affected the accuracy of the analysis and evaluation results, as well as the construction of financial health forecasting models for businesses.

Additionally, the differences in scale and experience among researchers were also limitations of the research topic. Furthermore, the diversity of external factors affecting the financial health of enterprises complicated the process of drawing conclusions. However, with relentless effort and dedication from researchers, this thesis still provides noteworthy and valuable results for the business community in Vietnam.

## LEGAL ISSUES ARISING WHEN APPLYING BLOCKCHAIN TECHNOLOGY IN THE FIELD OF REAL ESTATE BUSINESS: EXPERIENCES OF SOME COUNTRIES AND RECOMMENDATIONS FOR VIETNAM

**Author: Nguyen Thi Huyen Trang, To Thi Hai Yen, Nguyen Manh Tuong**

**Instructors: Tran Thi Thu Phuong**

**ABSTRACT:** *Blockchain was originally created to enable peer-to-peer digital payment systems (bitcoin). Along with the continuous development of Blockchain technology, applications are becoming more and more popular, including transfer transactions and asset trading. A significant contribution of this technology is the smart contract feature. A traditional real estate transaction across Europe in general and in Vietnam in particular often involves many intermediaries, so these transactions are time-consuming or difficult to operate across borders. When blockchain is combined with smart contracts, there can be an important role to play in these transactions. However, the application of Blockchain technology is still quite new, especially in the field of real estate business and there is no legal regulation such as the rights of the parties may be limited, the ability to modify, and the legal risks that the parties to the transaction may face. Therefore, in addition to illustrating the benefits that Blockchain technology brings to the real estate business, the article also analyzes legal issues arising in countries around the world when applying Blockchain technology, and how Blockchain enhances security for transactions in real estate business. The article also provided a nationwide survey in Vietnam to find out the factors affecting the decision to apply Blockchain technology to keep abreast of the actual situation in Vietnam. From there, provide solutions and recommendations to improve the legal basis for smart contract contributing to strengthening and developing the country's economy.*

**Keywords:** *Real Estate, Blockchain, Smart Contract, Law.*

### 1. INTRODUCTION

Based on the outstanding characteristics, safety and high security, Blockchain works in the following way: Blockchain is a distributed, shared and trusted consensus ledger; therefore it forms a highly reliable digital ledger, which records transactions, especially this ledger is maintained within and between the participants of the network. With blockchain, a single record is shared to each party involved in the transaction. Every transaction that has occurred or is pending will be grouped and stored in a fixed structure called a block. Through the consensus protocol, when each block is validated as true and reliable, the block is linked to the chain and sent to copies of the ledger that is distributed and stored by each member of the network.

When each block is loaded into the ledger, it is linked to the previous block using their respective hashes. This forms a completely traceable and impossible to tamper with record in the blockchain.

Although originally created to limit or eliminate traditional intermediaries in the issuance of currency. Sharing at the seminar “Opportunities and challenges of applying Blockchain in banking and finance activities” organized by the Vietnam Banking Association (VNBA), Dr. Nguyen Quoc Hung - General Secretary of VNBA said that, with its decentralized nature, Blockchain (blockchain) has solved many dilemmas. Many countries around the world, including Vietnam, have recognized the potential of Blockchain technology and sought to apply it in the fields of finance, banking, transportation, logistics, health care, education...especially in the field of real estate business.

Interest in this technology has been reflected in a series of projects to test its feasibility. In Estonia, for example, the government is using blockchain to secure health records, and the UK looked into a blockchain

to pay for and control research grants in 2016. The Catalan government recently announced the “Catalan Blockchain Strategy”, which aims to implement a blockchain ecosystem for regional authorities, including an ID system, sharing of medical data to enhance organ donation, and a self-consumption energy sharing system through blockchain.

Blockchain in the real estate business is the application of blockchain technology at different stages of the real estate transportation and purchase process. Blockchain real estate will use a network of computers and nodes to act as a more advanced and secure escrow company through digitalized forms of smart contracts. However, instead of just trading through documents in exchange for cash like escrow companies, the application of blockchain technology to the real estate business will bring many benefits such as real estate transactions with cryptocurrencies through encrypted legal contracts, etc. In terms of land registries, land registries from Sweden, New South Wales (Australia), GA, and the United Kingdom have explored the use of blockchain to register ownership. In addition, several U.S. private companies are studying the possibility of completing the entire process required to sell assets through a distributed ledger, such as Household, Averspace, Urbit Data, Zillios, or Velow.re. The leasing sector is also deploying the technology through a partnership between the city of Rotterdam (Netherlands) and Deloitte Global (Veuger, 2018) through Rentberry (an app that uses blockchain to lease assets) to help the “Cambridge innovation hub” (UK).

The results of these applied and experimental studies all agree on the potential impact of blockchain technology on the real estate business and the need to stop and change traditional processes, in order to eliminate costly intermediaries. The impact on the sector can be representative because of its importance in the economy: according to the European Commission (2015), “the contribution of the real estate sector to the production of national economies fluctuated in 2012 from 5.7% of total value-added produced in Lithuania to 15.8% in Greece” and the real estate business sector grew more than the entire economy”. However, does this potential disruption, the application of blockchain technology in the real estate business instead of traditional transactions, ensures the rights of buyers/tenants when buying real estate? The disadvantage of buying and selling real estate through the current blockchain system is that there will be no notarized contracts, registration of ownership, or right to use the property separately for each person. Therefore, this sale and transfer is not currently based on the provisions of the current law. It can be seen that, along with the application of high technology, the key of the blockchain model (a subdivision of real estate) is completely legal. Therefore, this paper aims to explore, from a legal perspective, the challenges, limitations and potential opportunities of blockchain applications in the field of real estate business, learning from the experience of countries - how they have solved when they face those challenges, in order to contribute to perfecting Vietnam’s legal system in applying Blockchain to real estate business.

#### Main contributions:

- This article proposes specific solutions and recommendations to improve Vietnam’s legal system when applying Blockchain technology in the field of real estate business.
- In practical terms, the article presents the experience of applying Blockchain technology in the field of real estate business in countries around the world. The results of the analysis help the research team draw experiences to contribute to improving the Vietnamese legal system effectively.
- From the analysis, the paper proposes directions to improve the legal system, seven specific recommendations include: ensuring the security of IDs; clearly defining the nature of real estate business transactions conducted on the blockchain technology platform; perfecting the legal corridor on smart contracts;... There are also solutions on the side of state management agencies and on the side of enterprises, organizations and individuals.

## 2. THEORETICAL FRAMEWORK

The theoretical framework of this study is based on the theory of Blockchain technology. Blockchain technology by transparently sharing information within a business network. The database stores data in blocks that are linked together to form a blockchain. Then there are blockchain-powered smart contracts, smart contracts are one of the innovations that support blockchain technology that is highly progressive and important (Arup 2017). In 1994, Nick Szabo defined a smart contract as a computerized transaction protocol that implements the terms of a contract. Blockchain technology supports businesses to apply it to transform technological processes, and perform transactions in real estate purchases. Through smart contracts, blockchain technology refers to an automated transaction protocol that aims to meet the terms of the contract agreement, reduce subjective and objective errors, and reduce the number of middlemen in the execution of contracts. In other words, a smart contract is digital computer code (or a programmable contract) that eliminates trusted third parties and self-executes its terms when preset conditions are met; the code is linked to digital currencies (e.g. ether, bitcoin) as a representation or payment of the asset (s) (Arup 2017; Yang et al. 2020). Szabo (1994) discussed some of the economic benefits of automated contracts including reduced contract arbitration (through automation), low fraud losses, and reduced costs of contract enforcement and transactions. However, smart contracts are not suitable for the existing traditional legal framework of many countries applying them. Therefore, their intended use in general transactions and in real estate business transactions to ensure legal obligations raises some difficult legal questions. Wendy Callaghan and Rajika Bhasin (2018) focus on the difficulties of smart contracts in: The encryption of contracts; issues of authority, the identity of the parties involved,... Moreover, Mitch Jackson (2023) has also brought up the 10 biggest legal issues of smart contracts.

From the above basis, the research team decided to analyze and collect information from previous studies in order to better understand the legal issues surrounding the application of Blockchain technology in the field of real estate business of countries ahead in the world, learn the factors affecting the decision to apply Blockchain technology in Vietnam, and give direction for improving the legal system of the country.

### 2.1. General concepts

There are several other definitions of Blockchain as follows:

Blockchain is essentially a distributed database of records or public ledgers of all digital transactions or events that have been made and shared among participants. Each transaction in the public ledger is verified by the consensus of a majority of participants in the system. In addition, once entered information can never be deleted (Crosby et al., 2015).

Blockchain technology uses public key encryption and hash functions to ensure data transparency, integrity, and privacy; using each node in the network as a client and also a server to store application copies, and applying the principles to the nodes participating in the system are subject to the rules of consensus play (Savjee, 2017), (IBM Think Academy, 2016).

Blockchain can be defined as follows: “Blockchain is a digital ledger of cryptographically signed transactions. Each block that is cryptographically linked to the block before it after being saved goes through a consensus decision to validate the data. When a new block is added, the older block becomes difficult to edit. The ledger is then copied to the entire network and any conflicts are resolved automatically through established rules.”

Blockchain in the field of real estate business is: the application of blockchain technology to the real estate business. To put it simply, Blockchain real estate will use a network of computers and nodes to act

as a more advanced and secure escrow company through digitalized forms of smart contracts. Distributed ledgers are algorithms that are considered powerful, disruptive innovations that can transform the delivery of public and private services. (Mark Walport, 2016).

Real estate tokenization is the process that involves converting physical assets, such as real estate, into digital equivalents, called tokens, using blockchain technology. These tokens represent ownership of assets and can be traded on a Blockchain or ledger platform. In addition to replacing private data such as credit card information, the goal of the token is to protect valuable information against theft or cyberattacks. (Verma Shreshtha, 2023).

## **2.2. The role of the application of Blockchain technology in the field of real estate business.**

The application of blockchain to the real estate business is important and necessary. The involvement of blockchain limits and eliminates human involvement in the storage process, verifying liquidity and thereby improving the accuracy and credibility of transactions. In addition, the maximum cost savings and increased transparency help transactions take place safely, efficiently and create trust for real estate investors. From there, it creates a more transparent, clear and developed real estate business environment when blockchain is applied.

### *Advantages of applying blockchain technology in the field of real estate business:*

+ With the results of the research project “Influence of Blockchain in the Real Estate Sector“ by Jan Veuger (2019), one of the main benefits of Blockchain is secure database sharing. Profiles of leasing, buying and selling transactions became common knowledge. Many listing services, collating asset-level information from brokers’ and agents’ own databases is a prime example of why this new technology is so important.

Many independent parties can also use a blockchain-enabled database, but only legitimate parties have access to that database. Therefore, only contractors involved in the management of real estate, such as owners, tenants, lenders, investors, operators and other service providers, always have stable and quick access as well as the ability to modify or add the necessary information.

+ In the research topic of Anniina Saari, Jussi Vimpari, Seppo Junnila (2022) on “Blockchain in real estate: Recent developments and empirical applications.” has given the research results that with blockchain, all subjects acquire a digital identity that cannot be confused or appropriated. It leads to more transparent record keeping with property ownership, mortgage rights, or financing. Now, this technology allows companies to operate without intermediation through the blockchain.

+ A transaction can be made more efficiently through the blockchain. Specifically, the combination of smart contracts and blockchain makes transactions more transparent, clear and efficient. (Amazon’s “What is Blockchain Technology?”).

For example, a sale may depend on a claim or loan approval. With blockchain, real estate entities can check whether such transactions have been made and whether conditions have been met.

+ When Dntech implemented “Learn about Blockchain”, based on the cryptography principle of Blockchain, it almost overcame another problem with real estate that it needs to be more secure and protected from malware through data encryption. For example, it allows encryption of all data transactions in the database to prevent any data breaches, like the cryptocurrency exchange project Extobit.

The application of Blockchain technology helps solve many of the problems that traditional real estate business faces.

The advantages of applying Blockchain technology to real estate business as presented above come from the characteristics of applying Blockchain technology in real estate business. Specifically as follows: Tokenization of real estate; smart contracts; security and transaction control; asset management automation; transparent data tracking and analysis; common ownership and Investment; access to secondary market opportunities; global asset distribution.

### 3. RESEARCH METHODOLOGY

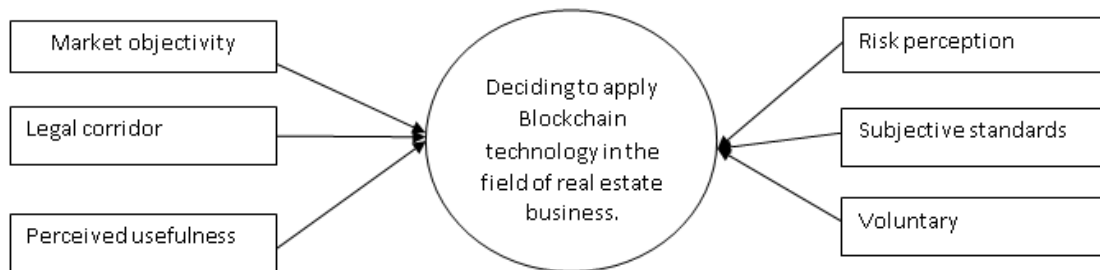

#### 3.1. Proposal of research models and hypotheses

The study of the authors uses the TAM2 technology acceptance theory of Venkatesh and Davis (2000) as the basis of research theory to explain the decision behavior of applying Blockchain technology in the field of real estate business.

On the basis of research, the research team has proposed a model to study factors affecting the application of Blockchain technology in the field of real estate business in Vietnam.

The research model is established based on an overview of domestic and foreign studies on factors affecting the application of Blockchain technology in the real estate business.

In this study, in addition to three factors: feeling usefulness; subjective standards; voluntariness of the TAM2 theoretical model of Venkatesh and Davis (2000), 3 additional factors are market objectivity, legal corridors and risk perception to study their influence on the application of Blockchain technology in the field of real estate business.

**Fig 1. Initial research model**

The research model includes 6 hypotheses affecting the decision to apply Blockchain technology in the field of real estate business: market objectivity (TKQ), legal corridor (HLPL), perceived usefulness (CNTHI), subjective standards (TCCQ), voluntary (TN), perceived risk (CNRR).

#### 3.2. Research method

##### 3.2.1. Qualitative research methods

This study is based on the qualitative research method as the main method. The authors have read, collected, analyzed and studied the available data in documents, articles, studies, etc. related to blockchain technology, the application of blockchain technology in the fields and especially in the field of real estate business. The sources of documents include domestic and foreign documents. The use of this method helps the team capture information related to the topic, thereby uncovering legal challenges, as well as opportunities when bringing blockchain into the real estate business.

In addition, the search and analysis of foreign documents related to blockchain technology and the application of blockchain in the fields of life, especially in the field of real estate business, thereby giving references to Vietnam.

**3.2.2. Quantitative research methods**

The authors combined research using quantitative research methods with the purpose of serving the main research method as a qualitative method, in order to measure and test the relationship between variables in the form of measurements and statistics, and survey the actual situation.

The survey is conducted through Google Forms, then sent to those who are knowledgeable about real estate business and Blockchain technology such as through real estate business groups, conferences on challenges and benefits that Blockchain technology brings,... to target groups who have understanding of Blockchain technology in the field of real estate business throughout the territory of Vietnam.

In the survey, the authors give 5 levels in each observation variable from strongly disagree, disagree, neutral, agree to strongly agree for survey participants to choose and assign values from 1 to 5 to conduct numerical data analysis on SPSS software.

Based on the results of the collected data, the team conducts descriptive statistics, scale tests, and EFA analysis to statistically and analyse the factors influencing the decision to adopt Blockchain technology in the real estate business sector.

Results:

**Table 1. Results of EFA and Cronbach alpha scales.**

Variables	Average	Total variable correlation coefficient	EFA Weight
TKQ: Market objectivity $\alpha = 0.885$			
TKQ1: The development of the domestic real estate market.	3.58	.825	.764
TKQ2: The development of foreign real estate markets.	3.51	.746	.692
TKQ3: The evolution of technology	3.82	.761	.790
HLPL: Legal Corridor $\alpha = 0.840$			
HLPL1: The provisions of the law are unclear and there are no specific regulations.	3.59	.623	.597
HLPL2: The current provisions of the law make it difficult to verify the information of the parties involved.	3.51	.716	.704
HLPL3: The regulation of the law negatively impacts the modification of the Blockchain.	3.37	.654	.718
HLPL4: The law regulating specifically on Blockchain will create many advantages for application in the field of real estate business.	3.68	.717	
TCCQ: Subjective standards $\alpha = 0.856$			
TCCQ1: The information on the mass media.	3.63	.703	.670
TCCQ2: Thanks to the impact of people who have an impact.	3.55	.786	.750
TCCQ3: I am attracted to projects applying blockchain technology in the field of real estate through scientific and technological conferences.	3.57	.699	.771
TN: Voluntary $\alpha = 0.871$			
TN1: I find the application of technology very helpful in all areas of life.	3.81	.756	.799
TN2: I realize that the application of Blockchain technology is essential to catch up with the 4.0 technology revolution.	3.75	.741	.754
TN3: I hope the legal corridor on the application of Blockchain technology in the field of real estate in Vietnam will be more complete in the future.	3.94	.760	.753
CNRR: Risk Perception $\alpha = 0.837$			
CNRR1: The application of blockchain technology in the field of real estate does not have a specific legal corridor, so I do not invest.	3.45	.654	.825
CNRR2: I see the recovery of capital when investing in real estate through the application of Blockchain technology is heavily dependent on co-owners.	3.49	.796	.788
CNRR3: I am afraid of fraudulent activities through Blockchain technology to benefit myself.	3.59	.591	
CNTHI: Perceived usefulness $\alpha = 0.822$			

CNTH1: The application of Blockchain technology contributes to promoting the development in the real estate market.	3.64	.743	.684
CNTH2: The application of Blockchain technology helps to make real estate transactions fast and save (cost, time, ...).	3.69	.821	.808
CNTH3: Systems using Blockchain technology will bring outstanding benefits in terms of security to users.	3.57	.699	
QDUD: Application Decision $\alpha = 0.859$			
QDUD1: I feel satisfied with what the application of Blockchain technology in the field of real estate brings.	3.59	.690	.929
QDUD2: I will continue to apply Blockchain technology in the field of real estate.	3.37	.821	.862
QDUD3: I would like to introduce to everyone about the application of Blockchain in the field of real estate.	3.21	.693	.860

The results in Table 1 show that all scales have a Cronbach Alpha > 0.6 and a Corrected Item (Total Correlation) coefficient > 0.3. Cronbach alpha results for the scale meet the reliability requirements. Specifically, Cronbach Alpha results show that the objective factor of the market is 0.885, the legal corridor factor is 0.840, the propaganda factor is 0.856, the cognitive factor is 0.871, the risk perception factor is 0.837, the effective expectation factor is 0.822, the application decision factor is 0.859.

+ EFA scale results

The results of the study used the KMO and Bartlett scales.

**Table 2. Study results using KMO and Bartlett scales.**

KMO and Bartlett's Test		
Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.685
Bartlett's Test of Sphericity	Approx. Chi-Square	220.846
	Df	3
	Sig.	.000

Table 2 illustrates Bartlett test results between variables in the population Sig = 0.000 (all less than 0.05) and shows that the observed variables are correlated with each other. The KMO coefficients are all greater than 0.5 ( $0.5 < KMO = 0.685 < 1$ ) so the analysis of the above EFA coefficients is appropriate. After performing the Cronbach Alpha and KMO tests, the authors conducted an EFA exploratory factor analysis to ensure the reliability of the scale. The results in Table 2 indicate that the EFA weighting values for each variable have a meaning greater than 0.5 for the concept they measure. Therefore, the initial criteria are significantly related to the extraction factor. On that basis, the results of this study suggest that the scales measured different research concepts. In addition, it can be concluded that the scales and variables in the study all reached convergent values and discriminant values, demonstrating reliability and suitability for multiple linear regression analysis.

In addition, it can be concluded that the scales and variables in the study all reached convergent values and discriminant values, demonstrating reliability and suitability for multiple linear regression analysis.

**Fig 2. Formal research model after adjustment.**

+ After EFA analysis, the research team conducts regression analysis to determine the degree of impact of independent variables on the dependent variable

Model Summary					
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	.717a	.514	.507	.413	2.310
a. Predictors: (Constant), DL2, DL1					
b. Dependent Variable: PT					

**Table 3. Check the fit of the model.**

ANOVA						
	Model	Sum of Squares	Df	Mean Square	F	Sig.
1	Regression	26.498	2	13.249	77.679	.000b
	Residual	25.073	147	.171		
	Total	51.571	149			
a. Dependent Variable: PT						
b. Predictors: (Constant), DL2, DL1						

With R<sup>2</sup> corrected at table 3 by 0. 507. This value explains that with 2 independent variables included in the analysis affects 50.7% of the change of the dependent variable. The F (sig) of the dependent variable in table 4 is less than 0.05 – which means that the research model makes sense to infer overall.

**Table 4. Pearson Correlation Analysis**

Coefficients								
Model	B	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		Std. Error	Beta				VIF	
1	(Constant)	1.241	.177		7.000	.000		
	DL1: Understanding about the application of blockchain technology in the real estate business	.384	.062	.504	6.207	.000	.501	1.994
	DL2: Legal corridors and surrounding risks	.213	.065	.266	3.271	.001	.501	1.994
a. Dependent Variable: PT: application decision								
Table 5. The regression results using the Enter Coefficientsa method.								

Sig. the values of the variables in table 5 are all less than 0.05, meaning that the variables are statistically significant in the model. The Variance Inflation Factor (VIF) magnification factor in Table 5 of each factor has a small value of 1,994, showing that the regression model does not violate multi-linearity, meaning that the independent variables are closely correlated. The independent factors all affect the dependent factors.

The construction regression equation takes the form:  $PT = 0.504*DL1 + 0.266*DL2$

The Beta result of the Normalization Coefficient indicates the importance of each variable independent of the dependent variable. The greater the absolute value of the normalized regression coefficient, the greater the impact. Of the two factors, the understanding factor surrounding the application of blockchain technology to real estate affects the application decision more strongly than the legal corridor factor and the surrounding risks. People will easily make the decision to apply Blockchain technology in the field of real estate business if they have a certain understanding of it along with a clear and specific legal corridor.

After conducting the survey, the research team found that the application of blockchain technology to the real estate business is necessary. Because in the 4.0 era when the world is moving towards digital technology to serve the needs of people in all fields, and improve the quality of life. Blockchain is an application that is doing very well in this, especially in the real estate business. Not only that, Blockchain also brings practical benefits to society.

This application is an irreversible trend, it brings practical benefits to society. For business entities that are businesses that help deploy transactions more effectively, minimize intermediary costs, information transparency, minimize fraud, prevent the spread of fake news causing virtual land fever, smart contract applications, etc. For the state to make management easier, ensuring transparency, high traceability, the ability to eliminate intermediaries, etc. This application is an irreversible trend, it brings practical benefits to society, not only for business entities but also for the State, especially in the context of the 4.0 revolution, digital society and digital economy. Therefore, in order to create favorable conditions for the application of blockchain technology to real estate business, it is necessary to complete the legal framework.

#### **4. ANALYZE THE LEGAL ISSUES ARISING WHEN APPLYING BLOCKCHAIN TECHNOLOGY IN THE FIELD OF REAL ESTATE BUSINESS AND THE EXPERIENCE OF SOME COUNTRIES.**

##### **4.1. Analyze the legal issues arising when applying Blockchain technology in the field of real estate business.**

There are a number of challenges that blockchain technology must overcome in order to be considered as reliable, legitimate, and secure as real estate transportation systems.

Currently the European Union has 28 member states so the creation of a blockchain database that gathers all EU real estate transactions of any kind (buy, rent, transfer, etc.) can certainly make verification time-consuming and costly.

For example, the costs associated with smart contracts and the scalability of the network, a problem that exists with bitcoin, Ethereum and other altcoins (Preukschat, 2017) is quite a lot... A number of developers and researchers are working to solve this problem, and one of them believes that they have found a solution (e.g. iota free a cryptocurrency for the internet of things, with the Tangle system, where no miners exist, Popov, 2018); however, for a real estate transmission system, controlling these costs (e.g., with a legally regulated blockchain where there is a central authority that recounts prices or regulates the authority mechanism with the authority who validates transactions) would be desirable, so that this is not an obstacle preventing people from registering their rights.

On the other hand, there are some specific challenges to be faced when implementing a real estate transit system via blockchain: Controlling the IDs of parties; the legality of contracts and the verification and protection of rights in REM; the registration of co-ownership; the modification of the ledger.

Faced with these challenges, countries around the world have:

##### ***Firstly, for the verification of the identity of the parties involved***

If blockchain technology is deployed to make real estate transactions, one of the most important issues that need to be addressed is the need to check the real ID of the parties, which is the issue of public control. It is essential to give the blockchain an official ID to implement a real estate transit system and one that can contribute not only to providing greater security but also to ensuring that digital owners can actually prove their rights to a given asset. To overcome this problem, IDs must be managed by a central authority (preventing the complete distribution of the real estate market) or by the blockchain itself, as long as the identity of the user is recognized by the countries.

Businesses of the European Union have implemented the application of Blockchain technology using an official ID. For example, the company Accenture has signed a formal agreement with the Netherlands to implement a blockchain-based ID that allows travelers to share their biometrics with customization and border control in advance, enabling the coordination of traveler data (World Economic Forum, 2018).

***Second, control the legality and validity of the contract***

Lawyers, notaries, and even land registries in some jurisdictions ensure that a certain real estate transaction is concluded in accordance with minimum legal requirements, and they inform the buyer of previous obstacles and rights to the property.

Therefore, it is important when designing a blockchain to allow the purchase or mortgage of a property, this control is implemented to avoid removing some essential rights of the buyer when implementing it. In Spain, artificial intelligence (AI) is used to compare the terms written in a smart contract with a database of unfair terms (for example, with a registry of general terms and conditions, such as the Spanish Registry de las Condiciones Generales de la Contratación). In lease agreements, there is currently no need to register in the land registry, blockchain along with AI can give tenants more control over the contents of the contract. In the United Arab Emirates (UAE), the UAE government is setting up its own blockchain system to record all real estate contracts and seeks to contact utility companies such as the Dubai Electricity and Water Authority (DEWA). This system allows tenants to make electronic payments, make paperless transactions and save costs.

***Third, co-ownership***

The application of blockchain technology in the real estate business leads to problems related to the determination of the co-ownership rights of the entities involved in the transaction. Because real estate is an asset with certain characteristics from the point of view of each country, each legal system has a different way of regulating and managing. Proper identification of the obligations and rights held by the right owner will be essential to know what obstacles the property has and what rights the owner has.

In Europe, the identification of rights can be done through tokens or colored coins, i.e. attaching a certain right to a token in such a way that when parties transfer tokens over the blockchain, this right is also created or transferred (EU Parliament, 2018). For example, Altestate has created a token that represents the right to housing, which users can use to sell their square meters of property. This is also the case with Homelend, which allows parties to create mortgages through tokens. The problem, however, is that the existence of several blockchains with different rights to the same asset would complicate the determination of the entity's rights as well as the execution of transactions. Therefore, it is essential to have a formal distributed ledger that collects appropriate information about a given asset, in order to protect legal relations between citizens or at least, to include land registry information about the blockchain of encrypted assets

***Fourth, the possibility of modifying the blockchain***

The ability to change the owner of an asset or modify a certain right or property in certain situations is unavoidable. For example, in the case of a minor who acquires property without sufficient capacity or in the case of an act claiming ownership, the ownership of the property may be subject to a lawsuit and the owner may be changed. The same can happen in cases where illegal activities need to be withdrawn when there are operational errors, or even when the actual situation of the asset changes. Accenture is working on a prototype that would allow for the modification of blockchains, whereby some administrators of the blockchain may have the ability to modify it, which could be used by public authorities to change the blockchain if necessary (for example, it could be a solution to allow the heir to have ownership of a certain

property without the explicit consent of the testator or when this type of application is not suitable for the disintermediation that the blockchain wants to strengthen, but it is essential to maintain the current level of protection given to parties in the EU legal system).

***Legal issues may also arise from activities such as:***

+ There are still uncertainties in the implementation of blockchain-based ownership rights. This is one of the issues to consider if you want to participate in trading for business purposes. Coindesk, a leading blockchain news source, describes the difficulties of applying for land ownership on the blockchain (Reese, 2017). Ghana wants to overcome land registration legality restrictions, so in 2018 it adopted a blockchain-based land registration system that has not been effective with other national policies, such as between the Security Commission and the Ghana Transaction Commission on the issue of cryptocurrencies. Therefore, it is necessary to consider strategic and operational factors in order to effectively apply Blockchain technology to the real estate business.

+ The legality of smart contracts and the interpretation of smart contract language (processing language, computer code) into natural language. According to Ullah et al., barriers to digitalization in general in the Australian real estate sector including blockchain adoption barriers are very complex (Ullah et al., 2021). One of those barriers is the legality of smart contracts. However, the recent interpretation of smart contract language (processing language, computer code) into natural language has received more attention. For example, how to understand the content of smart contracts and the rules of individual binding contracts can become an issue unless natural language is used, for example, in the metadata of smart contracts (Garcia-Teruel and Simo´n-Moreno, 2021).

+ Issues related to ownership certificate. Countries such as the United States and Canada use the Torrens system (which is a certificate of ownership of assets issued by government agencies in some states) to allow the transfer of assets without seeking ownership. Therefore, it is necessary to have appropriate legal tools in this regard.

+ Virtual currency is often used to pay transaction fees for a smart contract to be created and executed on a given block, such as fees for a contract to be added to the chain and executed. For example, in the case of the Ethereum blockchain (EVM), smart contracts are executed on the Ethereum Virtual Machine, and this payment is made through the Ether cryptocurrency, known as “gas” (Huang Y. Wang B., Wang Y., 2020). With the legal risks of cryptocurrencies, there are currently only two countries in the world that recognize this currency, the Central African Republic and El Salvador.

#### **4.2. Experience of some countries.**

On the basis of analyzing the legal situation of some countries in the world when applying blockchain technology to the real estate business, applying in the context and trend of applying blockchain technology in the field of real estate in Vietnam, the research team offers a number of international legal experiences that can serve as lessons for Vietnam in perfecting the law to apply blockchain technology in the field of real estate business.

In order to provide a protocol that allows real estate transactions to be completed in a complete manner, ensuring fairness for both the contracting party and the third party as the current procedures in the traditional form of real estate purchase and sale, this technology must meet the following criteria:

**Firstly**, it must be ensured that all such smart contracts are technically justified and legally reviewed so that they comply with the requirements under applicable laws and regulations. There are countries in the world that have been using smart contracts with legal validity and have the same basic requirements as a paper contract, such as the United Arab Emirates, the Democratic Republic of Georgia, etc.

**Second,** Second, ensure the validity of the IDs. This is an important requirement to implement if you want to apply blockchain technology in the field of real estate business. Recognizing this importance, the world's leading countries in this field such as the Netherlands, Estonia, Canada,...

**Third,** the modifiable capabilities of Blockchain. To ensure the inherent features of the Blockchain, this amendment requires the participation of a competent authority, capable of creating a new transaction that benefits the real owner. Apply this amendment in case of necessity. In today's world, Spain and the European Union are leading the way in authorizing this amendment.

**Fourth,** build a smart contract metadata system to help better define the content of the contract expressed through the code of the smart contract. This tool helps to convert smart contract language (processing language, computer code) to natural language or vice versa (Garcia-Teruel and Simo' n-Moreno, 2021). This is an issue that has received the attention of many countries, including Australia.

**Thursday,** Tokenization of real estate. This is an experience that needs to be considered to improve the law so that it is legally responsive and technically appropriate. Since tokenization can significantly stabilize the crypto economy, reducing the volatility of the digital currency market by ensuring such a "tokenization" with real estate will increase the capitalization of the crypto economy.

**Sixth,** establishing ownership rights when conducting transactions on the blockchain technology platform. This is one of the issues to be concerned about if you want to participate in transactions for business purposes. In order to effectively apply Blockchain technology to the real estate business, it is necessary to pay attention to this issue. The United States and Canada are experienced countries that can learn to solve this problem.

## **5. SOME RECOMMENDATIONS TO IMPROVE THE LAW OF VIETNAM TO APPLY BLOCKCHAIN TECHNOLOGY IN THE FIELD OF REAL ESTATE BUSINESS**

### **5.1. Legal issues arising when applying blockchain technology in the field of real estate business in Vietnam.**

Currently, Vietnamese law does not have a specific regulation for smart contracts, personal ID systems, and co-ownership of real estate through transactions made on blockchain platforms. These legal issues can be summarized as follows:

**First,** in terms of smart contracts, transactions can only be executed when all conditions have been satisfied; in theory, there is no chance for a transaction to occur without all conditions in the contract having been fulfilled. But how to ensure that Blockchain smart contracts still meet all the basic requirements of a paper contract? This is why all the terms of the contract must be clear, and all parties must understand all the terms before agreeing and signing the contract.

This contract has a legal basis for adjustment. These are the Law on E-Transactions 2005, Decree 52/2013 on e-commerce and Decree 85/2021 supplementing and amending a number of articles of Decree 52/2013. The Law on Electronic Transactions has recognized the legal value of electronic contracts and set forth the principle of entering into and executing electronic contracts, whereby the signing and execution of electronic contracts must comply with the provisions of the Law on Electronic Transactions and the law on contracts. Similarly, in e-commerce, Decree 52/2013, as amended and supplemented by Decree 85/2021 (hereinafter referred to as the Decree on e-commerce), also acknowledges the use of automatic information systems in entering into contracts (Article 13 of the Decree on e-commerce). In addition, Vietnamese law has also recognized the legal value of e-signatures in general, digital signatures in particular in the Law on E-Transactions and Decree 130/2018 detailing the implementation of the Law on E-Transactions on digital signatures and digital signature certification services. However, smart contracts still have certain peculiarities that require separate regulation of the law.

In essence, smart contracts are legal terms that are translated into a programming language, so understanding these codes is sometimes not easy for the parties. For complex contracts, the parties will need to rely on the assistance of experts to write code for the contract. This work will likely lead to problems related to the determination of the legal obligations and responsibilities of experts when reflecting the will of the parties through the code, for example in the case of faulty code.

Modifying the terms of a smart contract or terminating a smart contract is not the same as a traditional contract or other conventional electronic contract. As analyzed above, once the smart contract is established, it will be difficult for the parties to change the terms of the contract, as these terms are already expressed in codes. These codes will automatically run when the condition of the code is met. At that time, the contract will be automatically executed. Therefore, the general provisions of the law on contracts or electronic contracts are difficult to apply.

Besides, the parties to the smart contract may be located in different countries, so it is difficult to be sure that they can understand, agree and have a general view of the conditions of the contract. The problem with smart contracts with this foreign element is the determination of the governing law and the dispute settlement body. Based on the general principles of international justice, the parties are allowed to choose the governing law and the agency to settle disputes. However, in cases where there is no choice, it is not easy to determine the dispute settlement agency and the governing law. Disputes related to smart contracts will be difficult to determine the residence and headquarters of the parties when the parties use virtual identities, it is difficult to determine the location of the contract object when it is virtual products, or where the contract is entered into and or where the contract is executed when the contract is concluded and implemented on the blockchain system while the provisions of current law are to determine the dispute resolution authority as well as to determine the applicable law mainly based on factors. territorial connection, determined based on the ability to determine the location of the subject, the location of the object of the contract, or where to conduct on the territory of a certain legal system. Therefore, this is also one of the legal issues that need to be paid attention to and perfected.

**Second**, about the personal ID system According to the current law, in order for a real estate transfer to be considered legal, it is necessary to have enough information about the seller, the buyer, have a certificate of use rights and ownership of the property, and at the same time must fully fulfill tax obligations, registration fees and charges. Meanwhile, the execution of transactions through the blockchain can be done through the virtual IDs of the entities. In addition, one of the current issues is the confidentiality of the information of the subjects. Nowadays, there are more and more leaks, stealing user data from social media platforms and large companies. From there, the entities involved in any transaction, including transactions in the field of real estate business when applying blockchain technology, can steal information, or use incorrect information to participate in transactions... resulting in making the transactions illegal and unfavorable for participants in the transaction. As a result, transactions become illegal, detrimental to transaction participants. So the challenge is to have a personal ID system to overcome the above limitations. Currently, Vietnamese law is aiming to build an electronic identification system for individuals as well as organizations with a variety of related documents such as the Law on Citizen Identity, the Law on Information Technology, the Law on Electronic Transactions, especially Decree 59/2022 regulating electronic identification and authentication (hereinafter referred to as Decree 59/2022). However, the question is how these electronic identities can be used safely, without being used in an unauthorized way, affecting the legitimate rights and interests of the subjects. Issues related to information protection in the network environment are also being regulated by a number of laws such as the Law on Cyber Information Security and the Law on Cyber Security.

**Thirdly**, the fact that real estate is divided into thousands of investment opportunities, sold to thousands of people through cryptocurrency technology on the blockchain platform (real estate blockchain) is very risky. These are:

(1) The issue of co-ownership of digital assets of the subjects: The failure to establish ownership rights is named in the certificate of land use rights and house ownership by that group of joint buyers in the form of co-ownership to determine the right to enjoy income rather than rights to property (property rights include rights: possession, use, disposal). The joint purchase of real estate also generates many inadequacies as when the subject wants to sell his share will handle how? Does the transferee of the proof of stake collect the proceeds or does the transferee of the token verify the amount of money invested by the transferee through the token to collect the proceeds? Or will the owner have to comply with the participation until the right to sell? It is true that the questions have no end and there is no law document that makes this legal corridor clear. To solve this problem, it is necessary to determine the nature of real estate business transactions made on the blockchain platform.

(2) Property management problem: The general purchase will lead to the problem of identifying the manager. The manager must be a person authorized by the co-owners. In the case of shared real estate is the house, the authorized party does not manage well, causing the value of the house to decrease, and all buyers suffer. If the shared real estate is purchased in a form formed in the future, the risk of losing money is even greater because of legal problems, slow progress or suspension, withdrawal is very common in the Vietnamese market. Or in case the manager takes the real estate as collateral at the bank, who will control it because all buyers have no ownership rights on the certificate, no right to use and dispose of such property in accordance with current laws.

(3) The issue of real estate disposition: According to the provisions of Vietnamese law on co-ownership of real estate (in the name of the book), the decision to sell real estate to close profits requires the consent of all owners. 999 people want to sell and one person does not want to, the transaction will be blocked, not to mention the issue of divorce or inheritance At this time, the person who wants to withdraw can only sell his ownership to others in the system, the risk of selling cheap is completely possible. Conversely, those who want to collect the entire ownership will have to buy high prices, invisible medium must buy real estate higher than the market price. There is a regulation that only requires 51% of the owner to agree, the sale of real estate will take place. However, if 51% is owned by the token seller, they can completely sell the product to their own people, which means the remaining 49% will suffer.

(4) Real estate valuation problem: Because the selection and valuation of real estate depend on the token issuer, this unit can completely overvalue the product compared to the market price. Buyers, because of the psychology of only spending a few million VND/investment, easily ignore this. On a large scale, the act of high valuation not only damages buyers but also contributes to pushing up real estate prices, adversely affecting the general market.

In addition, the psychology of the majority of Vietnamese people also significantly affects the application of blockchain technology in real estate business. A large part of Vietnamese people have a suspicious mentality, and fear of being scammed, even when approaching new technologies such as blockchain is a big barrier because a number of projects take advantage of the novelty of blockchain to cheat, causing them to lose trust when hearing about mainstream blockchain projects. Giving them the fear of approaching and investing, thereby making the real estate blockchain in the country develop in a more limited way.

## 5.2. Some recommendations to improve the law of Vietnam to apply Blockchain technology in the field of real estate business.

In terms of orientation to improve Vietnamese law to apply blockchain technology in the field of real estate business With the goal of being able to apply blockchain technology in the field of real estate business effectively, promoting the strengths and advantages of blockchain technology while protecting the legitimate rights and interests of entities involved in real estate business transactions, the completion of the law needs to stick to the following directions:

*Firstly*, it is necessary to ensure how to promote and create favorable conditions for the use of blockchain technology, not create barriers when applying this technology. The advantages of applying blockchain technology in the real estate business are undeniable and tend to be irreversible. Therefore, it is necessary to create a legal framework to create favorable conditions for the application of this technology in the field of real estate business.

*Secondly*, the completion of the provisions of the law aims to ensure the consistency of the legal system when applying blockchain technology in the field of real estate business so that the implementation of the law is favorable, and free from contradictions and conflicts. Because this is an issue related to many legal areas such as law on contracts, law on electronic transactions, real estate business law, law on ensuring cyberinformation security, personal data protection, etc.

*Thirdly*, it is necessary to overcome the limitations and risks of using blockchain technology. As analyzed above, participants in blockchain technology can face a variety of risks that are beyond their control, such as information theft, unauthorized use of ID, being hacked into data systems, etc. These issues need to be controlled through the provisions of the law to ensure the safety of real estate business transactions made on blockchain technology.

*Finally*, the application of blockchain technology in the field of real estate business is carried out beyond national and territorial borders. Therefore, in order to create conditions for this application to develop, it is necessary to build a harmonious legal framework between countries and territories.

### ***Specific Recommendations***

Based on the current Vietnamese law on the field of real estate business, and the legal experience drawn from the previous countries, the research team would like to offer some specific solutions as follows:

*First*, clearly define the nature of real estate business transactions conducted on the blockchain technology platform.

This is an important issue to overcome the shortcomings in determining the ownership of the entity involved in real estate transactions on the blockchain platform, as well as solving the problem of real estate valuation. The subdivision of real estate in parts and traded on the blockchain technology platform has both the characteristics of property transactions and the characteristics of transactions on the stock market. Therefore, the problem posed for Vietnamese law today is the need to clearly define the nature of real estate business transactions conducted on the blockchain technology platform. According to the team, in order to determine the nature of these transactions, it is necessary to adhere to the principle of technological neutrality. Accordingly, real estate business transactions are made easier on the blockchain technology platform, not because of the blockchain technology that causes the nature of real estate business transactions to be transformed. The next issue of the law will be to review relevant regulations such as notarization, ownership certificates for co-owners of real estate, etc. in order to create favorable conditions for these transactions.

*Second*, ensure the safety of IDs of individuals involved in real estate transactions.

Currently, Vietnamese law has regulations on electronic identification and electronic authentication. However, with the risks in information security and cybersecurity, the use of electronic identifiers can seriously affect the rights and interests of related entities.

To solve this problem, it is possible to work towards a solution so that the Blockchain is linked to an official digital ID, which only allows transactions with legitimate access. There is also a need to work towards the possibility of using a cross-border connection ID. At that time, domestic actors could connect to other national blockchains to enhance cross-border transactions. However, even when implementing this type of blockchain, there are certain challenges that need to be solved. For example, creating a better mechanism to control the true consent of the parties by biometric analysis or developing a full blockchain environment to ensure that information about a transaction is properly understood through a computer.

**Third**, complete the legal corridor of smart contracts.

Many countries around the world have adjusted and applied smart contracts using digital technology in the conclusion and implementation of areas such as traditional contracts due to the impact of the Industrial Revolution 4.0. However, in the Vietnamese legal system in general and the field of contract law in particular, smart contracts are a new issue that has not been recognized. Therefore, there are certain challenges, the following are some solutions to overcome the above shortcomings:

There is recognition of the legal value of smart contracts. Currently, the law is indirectly regulating legal issues related to smart contracts when meeting the criteria and conditions of an electronic contract or a legal transaction. Therefore, the problem of applying Smart Contracts in practice is very difficult because it can make businesses timid and afraid. To address the above situation, Vietnamese law should be adjusted in the direction of officially recognizing the legal value of Smart Contracts.

Provide specific instructions to determine the validity of the Smart Contract. After being recognized as legal, Smart Contracts need to have clearer regulations on their effectiveness to be able to apply to social practices. The Vietnamese government can refer to the US and Poland's treatment as issuing regulations on "Proof of Consent" or the State can continue to study the establishment of a specialized agency, carry out the registration, use to limit and manage the number of participants.

There are specific regulations on the issue of signing a contract. Currently, Vietnamese law does not clearly regulate the adjustment of the time of signing the contract and determining the place of signing the contract. Vietnam can refer to the provisions of Thai law in determining the time of signing to make reasonable supplements to the current regulations. Moreover, more open regulations should be put in place to solve problems related to the place of engagement.

There should be a regulation that allows competent state agencies to modify the blockchain in certain cases, such as when requested by a court. Knowing that modifying the blockchain is a difficult task to do in blockchain technology. Therefore, the law needs to allow the ability to modify the blockchain under certain circumstances.

There should be specific regulations guiding the implementation of the contract. Vietnamese law should be studied in a more specific way to find the appropriate provisions in the implementation of the contract. The key point to be able to find the answers to the problems and contradictions when going to learn the nature of the application. From there, it is possible to make legal provisions for the guidance on the implementation of Smart Contracts.

**Fourth**, ensure the legality of tokens in real estate tokenization. This is an opportunity for investors who want to establish the right to buy or rent property in the future. This legal guarantee also helps to

replace traditional paperwork, buyers and sellers of real estate can use tokens to make transactions in a certain process.

**Fifth**, perfecting the law on digital currency when participating in transactions Digital money management policy should aim to prevent illegal transactions and exchanges such as money laundering, terrorist financing, etc. Currently, digital currency has been exploited by subjects in many illegal activities because trading this type of asset is completely possible with the function of anonymity.

**Sixth**, the regulation of smart contract language should also be formed. Because the translation of the language from the smart contract language to the common language is necessary for the parties to the transaction, it is aimed at ensuring the legal rights and interests of the parties involved.

**Seventh**, clearly identify the problems in the implementation of blockchain in the blockchain, they include operational and strategic factors. Based on the specific local and national context should be included in the analysis when deciding on the application of blockchain.

In addition to solutions to improve the legal framework, it is necessary to simultaneously implement the following measures to facilitate the application of blockchain technology in the real estate business effectively. Details are as follows:

*On the side of state management agencies:*

- State management agencies need to have management over the application of blockchain technology in the fields of the economy in general and in the real estate sector in particular. The implementation of the state management function for the application of blockchain technology in the real estate sector will ensure the transfer of real estate in the best way, in order to protect the legitimate rights and interests of the parties.

- Competent state agencies need to build a unified electronic identification system. The current situation shows that there are too many databases containing electronic identifiers of individuals and organizations (National Population Database, Citizen Identification Database, National Immigration Database, other databases – Decree 59/2022). This situation can lead to the risk of inconsistency in the identification of an individual's electronic identity. Therefore, it is necessary to build a single database and state management agencies in accessible areas.

- State agencies also need to build a network of unified state management agencies in the field of real estate business, including transactions made on the blockchain technology platform to facilitate the recognition of the legality of transactions, of the entities involved in real estate transactions.

- The organization disseminates the law on real estate business through blockchain technology so that each individual and organization can understand the provisions of the law in order to best protect their legitimate rights and interests. Through the results of the survey analyzed in the study, the most important factor in deciding the application of blockchain technology in the field of real estate business is the understanding of blockchain technology and the application of blockchain technology in the field of real estate business. The greater the understanding, the deeper the decision making to apply this technology and vice versa. In addition, in order to fully protect the legitimate rights and interests of entities involved in real estate transactions on the blockchain technology platform, entities need to have a certain understanding of this issue as well as the legal issues raised, and the risks that may occur when participating.

*On the side of enterprises, organizations and individuals*

- Encourage funding from enterprises in enhancing legal access, especially in the era of the 4.0 industrial revolution, to help effectively apply blockchain technology in the field of real estate business,

both helping to achieve business goals and maximizing the protection of the legitimate rights and interests of the participants.

- Voting, honoring and rewarding enterprises and individuals who are entrepreneurs to perform well in building, protecting and implementing the law, in applying technology to business activities in accordance with the law; attracting and praising useful initiatives in supporting legal access and improving people's capacity to access the law.

- Strengthen and improve the efficiency of the customer care department and receiving channels to answer petitions, reflect, answer, advise and support issues related to the application of Blockchain technology in the field of real estate business and relevant laws.

- For each individual business, it is necessary to have an understanding of the law in the field of real estate business on the basis of blockchain technology. Thus, it is possible to protect its legitimate rights and interests to the maximum.

## **6. CONCLUSIONS**

In summary, the application of blockchain technology in the field of real estate business is a prominent trend in economies around the world and in Vietnam. Blockchain in the real estate business sector has brought many opportunities for the Vietnamese economy in general and businesses, such as reaching more customers everywhere in the world. The purpose of Blockchain technology application in the field of real estate business is to solve the problems of information transparency, eliminate the geographical gap between countries, and overcome the limitations of traditional transactions. The research team analyzed the legal issues arising when applying Blockchain technology in the field of real estate business, thereby drawing on the experience of a number of countries (EU, Spain, Netherlands, Ukraine, ...), conducted an analysis of factors affecting the decision to apply this technology in Vietnam to understand the actual situation and aim to complete the legal corridor in Vietnam. Specifically, the legality of smart contracts, the issue of identifying and securing the IDs of the parties involved, and some of the risks faced when jointly buying real estate on the blockchain technology platform are the main legal challenges faced by countries ahead in this field; The legal corridor and surrounding risks and understanding around the application of blockchain technology in the field of real estate business are two factors that strongly influence the decision to apply Blockchain technology in the field of real estate business in Vietnam. The results show that the legal corridor is an important barrier to the application of blockchain technology in the real estate business. Therefore, from the legislators; the state; each organization and individual needs to make changes to suit the development situation of the 4.0 industrialization revolution but still ensure the rights and obligations of the subjects, especially in the field of real estate business today, not only to ensure rights and obligations but also to overcome the limitations of the previous real estate business in legal terms. Although this study has used qualitative research methods combined quantitatively, the sample size can be considered modest when said that on a national scale, the disparity between countries ahead in the field of technology in the world (US, UK, Switzerland, ...) is developed countries compared to Vietnam as a developing country in terms of facilities, economic conditions, human factors. As a next step, future research efforts will focus on expanding the sample size and developing new data analysis techniques that account for the factors affecting the application of Blockchain technology in the real estate business, continuing to research to thoroughly solve the legal issues arising from the application of Blockchain technology in the real estate business. That way, the research results can be applied more effectively to Vietnam.

## **FACTORS AFFECTING GREEN BANKING IMPLEMENTATION IN VIETNAM: EMPIRICAL STUDY AT THE LISTED COMMERCIAL BANKS ON HO CHI MINH CITY STOCK EXCHANGE**

**Author: Nguyen Thi Thu Huyen<sup>1</sup>; Le Duong; Nguyen Ngoc<sup>1</sup>  
Mentor: Msc. Nguyen Bich Ngoc<sup>1</sup>; Dr. Dang Thi Minh Nguyet<sup>1</sup>**

**Abstract:** *In Vietnam, the number of studies on green banking is still quite modest. This is still an open field, with many gaps. Therefore, it is really necessary to study green banks to estimate the factors affecting the implementation of green banks in Vietnam, identifying the factors affecting the implementation of green banking. The results of study will help Government, commercial banks, financial institutions; businesses and people to understand the role and impact of green banks on the stable and sustainable development of businesses in particular and on the economy. The study was conducted with a dataset of 200 survey results. The study used the method of reliability analysis of the scale using Cronbach/Alpha coefficients, analyzing EFA (Exploratory Factor Analysis) and extracted variables for multivariate regression analysis. The results show that a positive impact of stakeholder pressure, supportive policies, potential benefits and macro factors on the implementation of green banking in Vietnam. At the same time, the research proposed a number of solutions to strengthen the implementation of green banking in Vietnam.*

**Keywords:** *Sustainable economy, green economy, green banking, green finance, sustainable development.*

### **1. INTRODUCTION**

Climate change, depletion of natural resources, polluted environment is affecting the world. According UN ESCAP, “Green Bank” is defined as the operations of banks, incentives for environmental activities and reduces carbon emissions, such as: encouraging customers to use green products, services; imposing environmental standards when approved loan or grant preferential credits for projects that reduce CO<sub>2</sub>, renewable energy... Other definition, Green Bank works like a traditional bank and provide superior service for investors and customers while implementing programs useful to the community and the environment. The green bank is not a pure business operation for corporate social responsibility (CSR), also not entirely pure business for profit; it is a new combination to ensure the harmonious and sustainable about the economy - environment – society.

After nearly 25 years since international integration, the economy of Vietnam has been recognized as one of the most successful developing countries in the world. However, facing the danger of environment, for developing countries like Vietnam, Green Bank is a new concept that requires the environmental protection and economic growth trade-offs. In Vietnam, since 9/2012, the Prime Minister has approved the “Vietnam Green Growth Strategy (VGGGS) for the period 2011-2020 with a vision to 2050”, in order to contribute to responding to climate change, reducing poverty and ensuring sustainable economic development, and the banking system is a link in the implementation of this national strategy through the implementation of “banking” green goods”. The VGGGS aims to increasing the resource-efficiency of the economy, and increase sustainability while achieving development and economic objectives. Vietnamese government also built Vietnam Green Growth Action Plan (VGGAP) in 2014. Sustainable development with green growth is becoming a common development trend of countries around the world because green growth can

---

<sup>1</sup> Thuongmai University.

simultaneously solve problems between growth and the environment-society, ensuring economic growth with environmental and social protection. Through the role of providing capital to the economy, banking system plays an important role in realizing green growth with mechanisms to encourage investment in environmentally friendly projects, banks have gradually implemented to become green banks. Therefore, it is necessary to research to come up with solutions to develop the implementation of green banking, contributing to the sustainable development of the banking system as well as the Vietnamese economy.

## 2. LITERATURE REVIEW

### *\* Green Bank*

Green banking is a sustainable bank whereby investment decisions need to look at the big picture and act in a way that benefits consumers, economically, socially and environmentally. At that time, there was a close relationship between the bank and economic, social and environmental factors. Banks can only develop sustainably if they adjust their interests with social and environmental interests (Imeson and Sim, 2010). Using this approach, the Indian Institute of Banking Technology Research and Development (IDRBT), defines green banking as a term for practices and guidelines that show a sustainable bank in terms of economic, environmental and social aspects (IDRBT, 2013). In a narrow sense, a green bank is a bank whose professional activities are aimed at encouraging environmental activities and reducing carbon emissions within the bank as well as outside the banking system.

Approached in both directions, green banking is defined as “An ethical, socially responsible bank and a practical bank. In addition, it is certain that the green bank offers green products, supports activities that do not create risks to the environment and protect the environment. Moreover, it is the responsibility of the green bank to protect the planet from climate change, the greenhouse effect and reducing air quality, with the goal of ensuring practical economic development.”

### *Levels of green bank*

Kaeufer (2010) launched green banking under the perspective of providing green banking and financial services. At the same time, Kaeufer (2010) came up with a 5-level green banking model, namely:

- **Level 1:** Carry out side activities, by sponsoring «green» events and participating in public activities (most banks are at this level);

- **Level 2:** Separating project development and business activities, in which the bank develops separate green products and services (accounting for only a small proportion) to add to the portfolio of traditional banking products;

- **Level 3:** Systematic business operations, in which most of the bank’s processes and products comply with the “green” principle, the bank’s organizational structure is designed to support the “green” impact on 4 levels: people, processes, principles and purposes;

- **Level 4:** Strategic ecosystem balancing initiative, green banking activities are not limited to single operations but are expanded into networks, alliances, community dialogues, or ecosystems to achieve the sustainability of social-environmental and financial factors;

- **Level 5:** Proactive ecosystem balancing initiative, in which green banking activities are similar to level 4 but carried out in a proactive, purposeful manner, rather than responding to external changes like strategic initiatives at level 4.

Thus, only at levels 4 and 5, the green banking model is reflected in the bank’s long-term business strategy, meeting both social and environmental standards, ensuring sustainable development and having spillover effects on other economic sectors in the green growth model.

*\* Determinants of Green Bank Adoption in Commercial Banks in Malaysia (2018)*

The study was conducted by Dhamayanthi and Teresa Chirute with a sample of 160 employees, customers and stakeholders from banks in Kuala Lumpur, Malaysia. The study addresses the determinants of green banking adoption in the banking sector in Malaysia. The author used quantitative research methods. At the end of the study, the authors outlined the factors affecting the application of green banking in the banking sector in Malaysia including: (i) Concern for the environment, (ii) Stakeholder pressure, (iii) Supportive policies, (iv) Economic factors, (v) Loan demand.

The author came to the conclusion that adopting green banking is not only about becoming environmentally friendly, but it also brings benefits, such as: minimizing risks as well as costs of banks, contributing to the overall benefits of the environment as well as improving the reputation of banks. Green banks support the bank’s commercial objectives on corporate social responsibility. Finally, it is important for the author to be aware of their responsibility to the environment as well as society and the economy so that they can participate and survive in the global market.

*Study on factors affecting green banking development in Vietnam (2019)*

The study was conducted by Ngo Anh Phuong (and guided by Dr. Tran Thi Thanh Tu). The study surveyed 155 samples. With the research objective: to develop scales, models and assess the impact of factors affecting the development of green banks in Vietnam in the context and actual conditions in Vietnam. The research results will suggest solutions for the government and banks in developing Vietnam’s green bank. Combining qualitative and quantitative methods in research. In particular, qualitative research methods are used to help perfect research scales and models. The author uses the in-depth interview method in qualitative research. The subjects interviewed by the author are 20 experts, managers and employees with extensive experience working in the banking sector in Hanoi and Ho Chi Minh.

The results of quantitative analysis show that the level of green banking development in Vietnam is at level 3. At the same time, through the analysis of factors affecting the development of green banks, there are 04 groups of impact factors including: macro factors (YTVM) have the greatest impact on the development of green banks in Vietnam, followed by the group of financial capacity factors of banks (RE), the group of state support policy factors on green banking development (CSHT) and finally the group of green investment demand factors of business organizations (NCDTX) that have an impact on the development of green banks in Vietnam. For the group of factors, macro factors (YTVM) have the greatest impact on the development of green banks in Vietnam (standardized beta factor of +0.479). For the group of financial capacity factors of banks (RE), there is the second largest impact on the development of green banks in Vietnam (standardized beta factor of + 0.202).

**3. RESEARCH HYPOTHESES AND RESEARCH MODELS**

From domestic and foreign research and combined with the current socio-economic context in Vietnam, the author proposes research hypotheses and research models of factors affecting the implementation of green banking in Vietnam including 5 elements: (i) Pressure from stakeholders, (ii) State support policies, (iii) Potential benefits, (iv) macro factors, (v) green investment needs of enterprises.

STT	Factor	Source
1	Pressure from stakeholders	Dhamayathi (2018)
2	Support Policy	Dhamayathi (2018)
3	Potential benefits	Dhamayathi (2018)
4	Macro factors	Ngo Anh Phuong (2019)
5	Green investment needs of businesses	Ngo Anh Phuong (2019)

**Research hypotheses:**

**H1:** Pressure from stakeholders has a positive impact on the adoption of Green Banking in Vietnam.

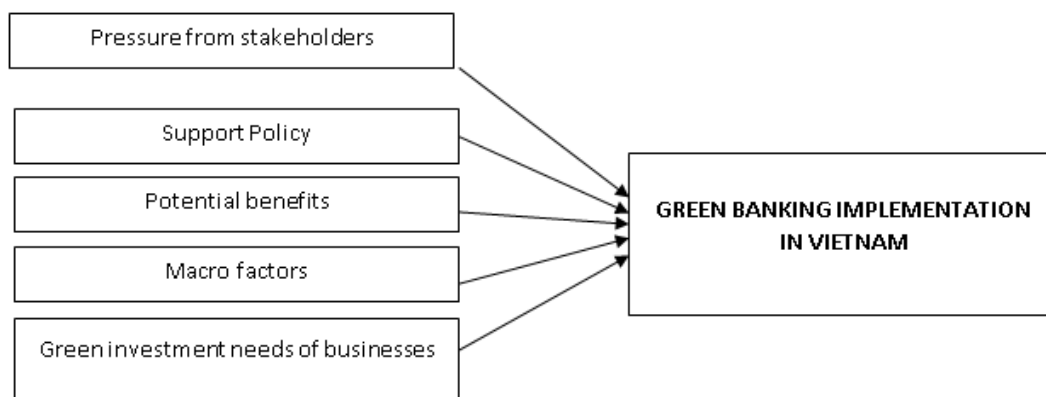

**H2:** The State's support policies have a positive impact on the implementation of green banking in Vietnam.

**H3:** The potential benefits have a positive impact on the implementation of green banking in Vietnam.

**H4:** Macro factors have a positive influence on the implementation of green banking in Vietnam.

**H5:** The demand for green investment of enterprises positively affects the implementation of Green Banks in Vietnam.

Based on the studied models, the author proposes the following research model:

*(Source: Proposed Research Group)*

## 4. RESEARCH METHODOLOGY AND RESEARCH DATA

### 4.1. Research methodology

+ Qualitative research methods:

Research is carried out at the table through documents, books, secondary data, legal documents and the previous researches on green banking and green bank model. Some in-depth interviews with bank leaders are also conducted to gain the personal perspectives on threats and opportunities for Vietnamese banks when launching green banking activities.

+ Quantitative research methods:

*Preliminary research:* Primary data collection using multiple-choice surveys.

The study uses questionnaires consisting of observed variables that are factors affecting green banking implementation in Vietnam. The Likert scale from 1 to 5 is used to measure these variables. From the survey form developed, by conducting a survey of officials and employees working at commercial banks listed on the Ho Chi Minh Stock Exchange. by analyzing the collected data to identify factors affecting the implementation of green banking in Vietnam. The sample selection method used is a non-probability convenient sampling method. The collected data will be processed using SPSS 20.0 software for validation of Cronbach's Alpha scale, EFA analysis, regression.

### 4.2. Research data

The respondents were commercial banks listed on the Ho Chi Minh Stock Exchange. Time range: study the current status of factors affecting the implementation of green banking in Vietnam using primary data collected through questionnaire surveys in the end of 2022. Since then, the study proposes a number

of recommendations to contribute to the development of green banks in Vietnam. Scope of space: Limited scope of research space are the listed commercial banks on the Ho Chi Minh Stock Exchange.

**Table 4. 1 Sample description statistics**

Information		Frequency	Percentage
Education	Intermediate	1	0,5%
	College	19	9,5%
	University	180	90%
Sum			100%
Years of experience in Banking industry	< 1 year	40	20%
	1 – 5 years	98	49%
	> 5 years	61	30,5%
	0	1	0,5%
Sum			100%
Type of bank	Joint Stock Bank	56	28%
	State commercial banks	144	72%
Sum			100%
Uptime of bank	< 5 years	5	2,5%
	5 – 10 years	13	6,5%
	> 10 years	182	91%
			100%

(Source: Data collected)

With 200 votes received, 93 votes were male, 107 votes were female, indicating that women have a greater level of interest in implementing green banking. The survey results showed 122 votes from 20-25 years old, 62 votes from 26-30 years old and 16 votes over 30 years old. The survey recorded 200 employees and specialists at commercial banks, of which the answers received the most from tellers with 24%, 14% were Telesales staff. Besides, there are many other positions such as credit support staff is 13.5%, risk management specialist is 10% and there are some other positions such as product developer, international payment staff, counselor, credit specialist, customer service staff, etc Business support specialists, financial analysts, personal account specialists, internal audit staff. However, a few did not disclose their positions, about 3.7%.

The research team received responses from surveyors working at different commercial banks. Typically, state-owned commercial banks such as Joint Stock Commercial Bank for Investment and Development of Vietnam (BIDV) with 37.5%, followed by answers from employees of Vietnam Joint Stock Commercial Bank for Industry and Trade (Vietinbank) with 28.1%, Joint Stock Commercial Bank for Foreign Trade of Vietnam (Vietcombank), Joint Stock Commercial Bank for Agriculture and Rural Development of Vietnam (Agribank) and some joint stock commercial banks such as Vietnam Technological and Commercial Joint Stock Bank (Techcombank), VP Bank, ACB, MB Bank, and some banks listed on the Ho Chi Minh Stock Exchange.

## 5. RESEARCH RESULTS

*\* Cronbach's Alpha confidence coefficient analysis*

The research team conducted face-to-face survey interviews and distributed online questionnaires designed through google forms of commercial banks listed on the Ho Chi Minh City Stock Exchange. At the end of the survey, the total number of valid responses was 200 votes. The survey is built based on

an overview of research works related to the topic and the actual context of the study, the observed variables are measured using the Likert scale with the following 5 levels of popularity: 1-Strongly disagree; 2-Disagree; 3-Normal; 4-Agree; 5-Totally agree. All valid samples are processed using SPSS software to conduct confidence analysis, correlation analysis, exploratory factor analysis, regression analysis, and hypothesis testing.

The selection of the observed variable and scale when the observed variables have a total variable correlation coefficient greater than 0.3 and Cronbach's Alpha coefficient greater than 0.6.

Cronbach's Alpha confidence coefficient results of the scales for each factor group are presented in the following table:

**Table 5.1 Summary of Cronbach's Alpha coefficients of scales**

STT	Observation variables	Item-total correlation
A. Stakeholder pressure (PRE) Cronbach's Alpha =, 0.914		
1	PRE1	0,769
2	PRE2	0,858
3	PRE3	0,891
4	PRE4	0,858
5	PRE5	0,565
6	PRE6	0,636
B. Support Policy (POL) Cronbach's Alpha coefficient: 0.930		
1	POL1	0,871
2	POL2	0,880
3	POL3	0,811
4	POL4	0,883
5	POL5	0,696
6	POL6	0,789
7	POL7	0,559
C. Potential Benefits (BEN) Cronbach's Alpha coefficient: 0.826		
1	BEN1	0,687
2	BEN2	0,646
3	BEN3	0,720
4	BEN4	0,059
5	BEN5	0,800
6	BEN6	0,729
D. Macro factors (MAC) Cronbach's Alpha coefficient: 0.891		
1	MAC1	0,732
2	MAC2	0,660
3	MAC3	0,622
4	MAC4	0,648
5	MAC5	0,687
6	MAC6	0,722
7	MAC7	0,744
E. Corporate Green Investment Needs (DEM) Cronbach's Alpha coefficient: 0.726		

1	DEM1	0,647
2	DEM2	0,539
3	DEM3	0,538
4	DEM4	0,592
5	DEM5	0,623
6	DEM6	0,049

(Source: Results extracted from SPSS)

*\* EFA Discovery Factor Analysis*

EFA factor analysis gives an independent variable with a loading factor of 0.5 that results in a factor rotation matrix table that examines the relationships between all variables in all different groups of factors in order to detect observed variables that upload multiple factors or observed variables that are different.

KMO and Bartlett’s test: The KMO coefficient = 0.644 is greater than 0.5 so factor analysis is appropriate with practical significance, Sig. (Bartlett’s Test) = 0.000 proves that the observed variables are correlated in the population, Eigenvalues >1 represents the variation explained by each factor that affirms the factor drawn to summarize the information best. A total extract variance of 61.367% (greater than 50%) indicates that EFA analysis is appropriate, according to Gerbing & Anderson (1998).

In order to identify, measure and assess the impact of 5 groups of factors on the implementation of green banks at commercial banks listed on the Ho Chi Minh Stock Exchange, the authors conducted multivariate regression model analysis and examined the indicators.

**Table 5.2. Rotating matrix table**

Rotated Component Matrix <sup>a</sup>					
	Component				
	1	2	3	4	5
POL1	,886

(Source: Results extracted from SPSS)

- R Square calibration: The corrected R square model result = 0.615 greater than 0.5 indicates that the model is good.

- The Sig. index of the F test determines the suitability of the regression model. The model results show that Sig = 0.000 (greater than 0.05), so the study's model is completely consistent.

#### \* Regression analysis

The multivariate linear regression equation is written from the results of the Table above as follows:

**Green bank implementation = const +  $\beta_1$ \*Stakeholder pressure (PRE) +  $\beta_2$ \*Support policy (POL) +  $\beta_3$ \*Potential benefits (BEN) +  $\beta_4$ \*Macro factors (MAC).**

Each relationship between the green bank implementation dependent variable and the independent variables is shown in the following normalized regression equation:

**Green Bank Implementation = 1.026 + 0.419\*Stakeholder Pressure (PRE) + 0.190\*Support Policy (POL) + 0.184\*Potential Benefit (BEN) + 0.093\*Macro Factor (MAC).**

The regression equation shows that the implementation of green banking at commercial banks listed on the Ho Chi Minh City Stock Exchange is influenced by four groups of factors: Pressure from stakeholders, Support policies, Potential benefits, Macro factors; reject the factor The need for green investment of enterprises. The degree of impact of each group of factors on customers' decision to accept and use services is different while other factors remain constant. The regression coefficients all bear the sign (+) representing independent variables that are positively related to the dependent variable. Comparing the impact of these 04 variables on the dependent variable Green banking implementation in Vietnam in descending order is as follows:

The Pressure from Stakeholders (PRE) factor group had the strongest impact ( $\beta = 0.419$ ), followed by the Supporting Policy factor group (POL) ( $\beta = 0.190$ ), the Potential Benefit factor group (BEN) ( $\beta = 0.184$ ) and the lowest was the macro factor (MAC). At the same time, the Beta > 0 coefficients show that

the independent variables act in the opposite direction with the dependent variable. This means that any one factor will make the deployment of green banking at commercial banks increase. Therefore, the hypotheses H1, H2, H4, H5 stated in the research model are accepted.

Model conformity assessment and verification: The regression results have corrected R2 and R2 values of 0.644 and 0.615, respectively, indicating a relatively high model suitability with 95% confidence. In other words, the independent variables of the model explain about 60% of the variability of dependent variables or 60% of green banking deployments at commercial banks listed on the Ho Chi Minh City Stock Exchange influenced by the above 4 groups of factors. The Durbin-Watson coefficient = 2.013, (in the range 1 – 3), demonstrates that there is no first-order sequence correlation in the model; test F has a value Sig.= 0.000 (< 0.05), so the model used is appropriate; the Tolerance coefficients > 0.0001 so all variables meet acceptance standards. The variance magnification coefficients VIF < 10 should have no linear multi-addition. The Sig. coefficient of 5 independent variables is all < 0.05, so 4 of the 5 independent variables are received.

**Table 5.3 Results of regression analysis**

Model	Unstandardized beta	Standad deviatin	Normalized Beta	T	Sig.	Error	VIF
System. number	1,026	0.241		4,254	0.000		
PRE	0.409	0.070	0.419	5,880	0.000	0.596	1,679
POL	0.162	0.052	0.190	3,093	0.000	0.799	1,252
BEN	0.161	0.059	0.184	2,706	0.000	0.653	1,531
MAC	0.064	0.053	0.093	1,203	0.000	0.505	1,679
DEM	0.066	0.072	0.079	,919	0.359	0.407	2,458

(Source: Results extracted from SPSS software)

## 6. EXCHANGES AND RECOMMENDATIONS

### \* *Government*

The Government needs to complete a stable legal policy framework, appropriate policies on taxes, fees and charges to support banks in providing green products and services on the one hand; On the other hand, encourage businesses to invest in environmentally friendly projects. Moreover, the Government and the State Bank of Vietnam need to cooperate with international organizations as well as experienced countries to develop common environmental policies to help commercial banks have a basis to gradually become more environmentally friendly, facilitating the emergence of green banks in Vietnam. In addition, the Government should include banking development goals in the national strategy on green growth.

### \* *State Bank of Vietnam (SBV)*

The research results show that pressure from stakeholders has a great impact on the implementation of commercial banks at commercial banks, so the SBV needs to make requirements on the deployment of green banks at commercial banks.

According to the research results, the State Bank raised the awareness of banks in spreading the implementation of green banking in other industries or fields. Training should be organized to strengthen the capacity of commercial banks and financial institutions in financial activities - green credit. The State Bank needs to raise the awareness of commercial banks about green banking, starting with raising the awareness of managers and senior leaders of banks so that they can plan accordingly. detailed and specific plans to establish green development strategies at each level suitable for each bank. In addition, as the

operating center of the banking system, the State Bank needs to issue specific policies and regulations to guide commercial banks to fulfill their responsibilities for environmental protection, especially through the implementation of green banking activities.

Support policies also make a very important contribution to the implementation of green banking, so the State Bank should have policies to support the development of green banking services, giving specific lists of areas, industries that need to be prioritized for support as well as limited in the green banking development strategy for commercial banks to refer to and serve as a basis in the credit granting process for projects; at the same time, there should be sanctions for commercial banks that provide credit for projects that have serious impacts on the environment and society. Actively apply technologies of the Fourth Industrial Revolution (Industry 4.0) in the innovation orientation of the banking industry. Continue to promote innovation and application of modern technologies by strengthening the integration of information technology in the state management of the State Bank of Vietnam.

Besides, in order to successfully implement the Green Banking Development Project towards sustainable development, it is necessary to mobilize the resources of the whole society. In particular, the banking industry is responsible for actively supporting the economic transition towards green growth and sustainable growth through the mechanism of mobilizing and providing capital for environmental protection projects. . There should be policies to support the application of technology in banks to evaluate green investments/projects.

*\* Commercial banks*

Commercial banks should consider green banking as a development strategy for their entire operations. Because green banking not only brings benefits such as avoiding paper-intensive procedures and using online transactions such as SMS, ATM... Paperless banking helps control deforestation but also benefits tax, the implementation of green banking helps to reduce costs, thereby reducing payable taxes.

Commercial banks will have to invest in a management system, create awareness for entrepreneurs about environmental and social responsibility, and help them carry out environmentally friendly business activities. Promote the application of Industry 4.0 technologies to service development, information data management to help limit human resources and infrastructure investment, help eliminate paper waste, save fuel, and reduce waste. printing costs, reducing carbon emissions. Actively propagate to the bank's customers about the benefits of green credit. In addition to businesses, the bank's customers are the bridge that brings green credit to the economy through its green investment activities. It is necessary to focus on building a strategic framework for green banking depending on its business orientation, market segments, products and target customers, and its capabilities and strengths; develop a strategic framework and roadmap towards green banking development at an appropriate level. It is necessary to develop and establish a comprehensive environmental and social risk management system; follow guidelines on environmental and social risk assessment, incorporating environmental risk assessment as part of the bank's credit risk assessment. It is necessary to establish a unit/department responsible for the implementation of environmental and social risk management.

**Conclusion**

Vietnam has identified "green growth" as an important content of sustainable development, ensuring fast and effective economic development and making an important contribution to the implementation of the National Strategy on climate change. Thus, the implementation of green banking is one of many steps to realize the development of a green economy, a sustainable economy. The State Bank and the Government

need to come up with reasonable policies to promote the implementation of Green Banking in banks across the country. Before the advantages, difficulties and barriers in the process of implementing and developing green banking, banks need to continue to promote their strengths and positive points, inherit the achieved achievements as well as consider, overcome the limitations to build and develop the green banking sector in particular and the sustainable Vietnamese economy in general. To build a civilized, rich, beautiful, prosperous and sustainable society.

Mentor: Vu Xuan Dung<sup>3</sup>

**Abstract:** *The article uses the Technology Use and Acceptance Model - UTAUT as a theoretical basis to study the factors affecting the online life insurance purchasing intention of people in Hanoi. Data was collected by conducting a survey of 480 observational samples in the form of an online survey via Google Forms. After removing 30 unreliable votes, 450 valid votes were obtained, 93.75% effective withdrawal rate. Data analysis was performed with the use of SPSS20 software. Descriptive statistical techniques, scale testing, exploratory factor analysis, multivariable linear regression with 6 factors divided into 27 observed variables. The results show that 3 factors including Social influence, Perceived usefulness, and Facilitating conditions all have a positive impact on the intention to buy online life insurance of people in Hanoi. Accordingly, the article proposed practical recommendations for businesses providing online life insurance services in Vietnam and state management agencies to develop this market.*

**Key words:** *Life insurance, online life insurance, UTAUT.*

### 1. INTRODUCTION

The 20th century was marked by the explosion of scientific and technological revolutions, the first of which was the explosion and penetration of information technology (IT). That is having a strong, profound, and comprehensive impact on all areas of socio-economic life, including the insurance sector. Technology is gradually changing the face of the insurance industry in a more positive and modern direction, creating convenience for users. Theoretically, buying and selling online insurance services is a method of product distribution formed in the environment of modern technology application, and also a transaction method that customers can choose based on their feelings and evaluation which is different from traditional methods of communication transactions. In practical terms, after the COVID-19 pandemic, the habit of purchasing insurance through direct contact has changed and the online insurance purchasing is tending to expand and develop. In Vietnam, insurance companies are also increasing the application of technology to diversify methods of reaching customers and distributing products, while enhancing the customer experience through online insurance products. According to a report by the Vietnam Insurance Supervision and Administration Department, up to now, there are 19 life insurance companies and 30 non-life insurance companies in Hanoi. To optimally increase sales and expand market share, insurance companies have started to offer online insurance services, which reduces transaction costs and increases the sales volume. However, life insurance products have their characteristics, so not all companies are ready to enter this playing field. In Vietnam, there are currently 10 online life insurance companies, including Bao Viet, Prudential, Manulife, AIA, FWD, Chubb Life, Dai-ichi Life, Generali, Hanwha Life and PVI. In particular, IBAOHIEM, the predecessor of the company is Bao Viet Online Insurance Sales Department, is still the leading unit in this field with cooperation with 20 original insurance companies spread across the country. Like most other companies, Prudential, one

<sup>1</sup> Student of class K56H3, Faculty of Banking and Finance, Thuongmai University.

<sup>2</sup> Student of class K56H3, Faculty of Finance and Banking, Thuongmai University.

<sup>3</sup> Lecturer of Faculty of Finance and Banking, Thuongmai University.

of the major insurance companies, invested in the development of the PRUOnline customer portal, the PruBot utility application, and its website to serve customers to buy online insurance. In addition, FWD and Manulife chose to confront each other on two major e-commerce platforms, Shopee and Tiki. Thus, it is undeniable that online channels are clear and growing trends. However, customers' intention to buy online life insurance depends on many factors such as Perceived usefulness, Perceived ease of use, Trust, Perceived risk, Social influence and Facilitating conditions. Therefore, building a model to measure and evaluate the influence of factors on customers' intention to buy online life insurance in Hanoi is an urgent issue for companies that have been providing services. Because, finding the answer to the above problem not only contributes to affirming an insurance product distribution method that adapts to the 4.0 technology era, but also helps insurance companies and managers to can improve business performance and develop the insurance market.

## **2. LITERATURE REVIEW AND THEORETICAL FRAMEWORK**

### **2.1. Literature review**

In the current digital technology era, the Internet opens up many potential markets for businesses, as well as useful and convenient products for consumers (Chiang Liu, 2016). There is a new and promising market like online life insurance. However, many consumers are not really interested in online transactions because they feel insecure, difficult to control and use.

Gebert-Persson, Sabine et al. (2019) carried out research called "Online insurance claims: when more than trust matters." The results of previous research on financial services suggested that Trust is always greater or equal to Perceived usefulness and Perceived ease of use in forming Attitudes towards acceptance of online insurance. The difference of this study is that it shows that the Trust attitude factor is only somewhat significant, the relationship is less binding between Trust and Intention to use online services. Meanwhile, the aspect of attitude towards technology including to Perceived usefulness and Perceived ease of use has a strong influence on intention to use online shopping.

Research by Huang, Wen-Shin, Chia-Tse Chang, and Wei Yeng Sia (2019) suggested that for relatively complex insurance products such as life insurance, Trust has the most positive impact; Perceived usefulness and Product engagement both had a significant positive effect on Attitude; Perceived risk has a significant negative impact on Attitudes; Attitudes and subjective norms have a significant positive impact on people's Intention to buy online insurance. As such, high-priced and long-term insurance may not be suitable for buying online because purchase intention relies too much on people's trust.

To find out the main factors affecting the intention to purchase online life insurance of Chinese customers, Jiang, Shi-jie et al. (2019) used a proposed theoretical model including the acceptance and using technology (UTAUT) combined with 2 external factors: Trust and Perceived risk. Data were collected from a field survey questionnaire with a sample size of 315 observations. The results show that customers' intention to buy online life insurance is significantly influenced by Performance Expectancy, Effort Expectancy and especially Social influence has the largest positive impact. In addition, Trust plays the role of both a fairly large direct positive factor affecting the intention to purchase online life insurance, and an indirect factor affecting through Perceived risk.

Nguyen Thanh Huyen et al. (2019) conducted a survey on customers' demand for online insurance and at the same time found out the factors that affect customers' intention and behavior to use online insurance services through a contract model UTAUT. Research results, Effort Expectancy and Facilitating Conditions do not influence the intention to use online insurance. This problem can be explained because customers mainly consider the benefits and risks of using the service rather than the way to buy the product on the

computer or phone. In addition, the research results also showed that Trust has an impact on Perceived risk, Performance Expectancy, Effort Expectancy.

Research by Nguyen Bich Ngoc et al. (2022) focused on understanding the factors affecting the acceptance of technology in online purchase of life insurance by customers, thereby proposing practical solutions for Vietnamese insurers. The results showed that when people have confidence in technology in online insurance, their intention to buy insurance will be positively affected. The benefits of technology and the way technology is used in online insurance will increase people's attitude toward accessing and buying insurance products through online channels. In terms of Attitude, if customers find online shopping to be trustworthy, it will increase their likelihood of accepting a purchase.

## **2.2. Theoretical framework**

### **2.2.1. Online insurance**

Online insurance is a convenient service as well as a new trend in the digital economy 4.0. According to Aarabi & Bromideh (2006), online insurance is the use of the Internet and IT in the development, distribution, and sale of insurance services. More specifically, online insurance is a method of signing insurance contracts by online channels. The use of the Internet ensures a better and more cost-effective transmission of information over a large area. It changed the role of insurance agents or brokers from an "insurance intermediary" to a "transmitter" for clients (Arora, 2003). Accordingly, customers don't need to go to the nearest insurance branch to buy or renew insurance packages; There is also no need to contact a local agent to purchase insurance policies on behalf of the customer. With online insurance, users can flexibly choose the product package that suits their needs without spending too much time and effort.

### **2.2.2. Factors affecting the intention to participate in online life insurance**

#### **Perceived usefulness**

Perceived usefulness is defined as "the degree to which a person believes that using a particular system would enhance his or her job performance" (Davis, 1989). Thus, Perceived usefulness in the article refers to the extent to which customers perceive that they will benefit when participating in online life insurance. The usefulness of technology has a key influence on consumer intention. If online consumers believe that this system will have a positive impact on their online shopping experience, then the intention to use this system will increase (Maher Taib Toukabri, 2021).

#### **Perceived ease of use**

According to Davis et al. (1989), Perceived ease of use is defined as "the degree to which a person believes that using a particular system would be free from effort." Ease of use includes both ease of learning and ease of use. This factor is related to the adoption of a system because an easy-to-use system requires less effort by the user, thus allowing them to allocate more resources to other activities, since that force is a finite resource (Radner & Rothschild, 1975). Perceptions will vary depending on the user's knowledge or previous experience with similar systems. Finally, Perceived ease of use can change over time. As users become more proficient in using a system, they may begin to find it increasingly easy to use.

#### **Trust**

Trust means "The willingness of an exchange partner to make oneself vulnerable to the actions of another party, in the expectation that the other party will perform a particular action" (Mayer et al., 1995). Trust is very important in the online environment, behavioral intentions as well as customer satisfaction are determined by security features (Meuter, et al., 2000). For insurances with high costs and relatively

complex policies such as life insurance, the belief factor has the greatest impact on attitude, while attitude positively affects the intention to participate in online life insurance (Huang & et al., 2019).

**Perceived risk**

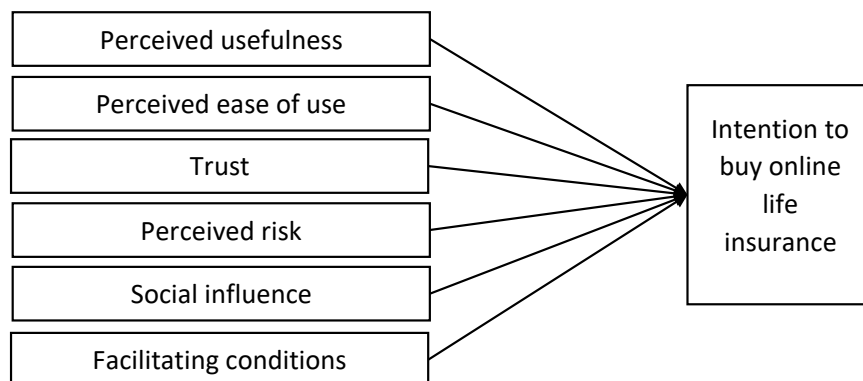

Perceived risk in this case refers to potential losses that users feel when participating in online life insurance. Featherman and Pavlou (2003) studied consumer acceptance of e-services from the perspective of Perceived risk. Research results have demonstrated that economic risk, functional risk, psychological risk, social risk, privacy risk, and time risk are the six dimensions that affect the using internet. Security risk is the privacy and safety policy of products and services, and discomfort or uncertainty about the use of a particular technology (Joshi & Bhatt). The risks associated with the e-commerce market mainly stem from the level of uncertainty regarding product performance, service delivery quality, privacy protection and technical difficulties encountered in purchasing process (Forsythe & Shi, 2003). At the same time, when Trust increases, Perceived risk decreases and risk perception has a negative impact on intention to use online banking (Nguyen Thanh Huyen & et al., 2019).

**Social influence**

Social influence is understood as “The degree to which an individual perceives that important others believe he or she should use the new system” (Venkatesh et al., 2003). Through the UTAUT model, Venkatesh has stated that social influence can have an impact on users’ intention to use technology. Social influence can originate from many different aspects such as family members, friends, partners or influence from celebrities, public figures, etc. This factor plays a role of motivating consumers to share views and insights about their service experience. According to Nielsen (2015), in 92% of purchases, consumers make decisions based on recommendations they receive from friends and acquaintances rather than other sources. This is especially important in the online context.

**Facilitating conditions**

Facilitating conditions is “The degree to which an individual believes that an organisations and technical infrastructure exist to support use of the system” (Venkatesh et al., 2003). Giao et al (2020) argue that the Facilitating conditions is the availability of resources such as documents or technology infrastructure that can assist in the use of new technology. When there are favorable conditions such as finance, equipment, knowledge, etc., consumers will be more likely to intend to participate in online life insurance.

**3. METHODOLOGY AND DATA**

**Research model**

The research model is built based on the Technology Use and Acceptance Model - UTAUT. On the basis of reference and inheritance of research by Huang & et al. (2019), the research model is added with

two additional factors: Trust and Perceived risk. Because Trust is a factor that has a strong direct positive impact on users' intention to buy online life insurance (Jiang, Shi-jie & et al., 2019); economic risks, functional risks, psychological risks, social risks, privacy risks and timing risks that affect consumers' use of internet services (Featherman, Mauricio S. , and Paul A. Pavlou, 2003). Besides, Davis (1989) assessed the Perceived usefulness to be similar to the Performance Expectancy of the UTAUT model. Meanwhile, Perceived usefulness is a familiar and convenient term for surveying. Therefore, the research uses Perceived usefulness instead of Performance Expectancy. Similarly, Effort Expectancy is replaced by Perceived ease of use in the Technology Acceptance Model - TAM. The research model is described as follows:

### **Hypotheses**

According to Gebert-Persson et al (2019), usefulness has a strong influence on the intention to use online insurance. Furthermore, Davis et al. (1989) and Quan et al (2021) all show that the perception of usefulness is a fundamental factor determining the intention behavior of users to use online payment methods in making purchases, such as payment by e-banking or e-wallets. Therefore, the following hypothesis is proposed:

*H1: Perceived usefulness has a positive impact on the intention to buy online life insurance of people in Hanoi.*

In his research, Dr. V. Uma Maheswari et al (2018) demonstrated that perceived ease of use is one of the two factors that have the greatest impact on users' intention to buy online life insurance. The easier the online life insurance service is to use, the higher the chances for customers to accept and purchase it. This is also supported by the majority of related studies. Therefore, the following hypothesis is proposed:

*H2: Perceived ease of use has a positive impact on the intention to buy online life insurance of people in Hanoi.*

According to the results of Jarvepaa and Tractinsky, consumer intention behavior can be influenced by beliefs in uncertain situations such as e-commerce on the Internet. For insurances with high prices and relatively complicated policies such as life insurance, the trust factor has the greatest impact on attitudes, and attitudes, in turn, have a positive impact on the intention to buy online life insurance (Huang & et al., 2019). Therefore, the following hypothesis is proposed:

*H3: Trust has a positive impact on the intention to buy online life insurance of people in Hanoi.*

Perceived risk is an important determinant of consumers' willingness to accept online banking services (Li & Bai, 2010). When studying the intention to take up insurance online of people in the Gujarat region, Parina Patel & Shivam Thakar (2022) showed that Perceived risk had a negative impact on online insurance acceptance. Therefore, the following hypothesis is proposed:

*H4: Perceived risk has a negative impact on the intention to buy online life insurance of people in Hanoi.*

Zhou et al (2010) examined the influence of social influence on users' adoption of mobile banking in China. The results show a positive effect of social influence on user's behavioral intention. The results are similar to the study of Nguyen Thanh Huyen & colleagues (2019) when considering the intention to buy online insurance of Vietnamese users. Therefore, the following hypothesis is proposed:

*H5: Social influence has a positive impact on the intention to buy online life insurance of people in Hanoi.*

Studies by Ajzen (1991), and Pushpa A et al. (2017) showed that favorable conditions have a direct influence on behavioral intention. When there are favorable conditions such as finance, equipment,

knowledge, etc., consumers will be more likely to intend to buy online life insurance. Given these considerations, the following hypothesis is proposed:

*H6: Favorable conditions have a positive impact on the intention to buy online life insurance of people in Hanoi.*

**Variable and Description**

All the items in the questionnaire were rated on a 5-point Likert scale ranging from 1 = strongly disagree to 5 = strongly agree. The scale or components measuring factors affecting people’s intention to buy online life insurance in Hanoi include the following variables:

**Table 1: Variable description**

Factor	Codes	Variable type	Description
Perceived usefulness	PU1	Independent	Purchasing online life insurance saves time
	PU2	Independent	Purchasing online life insurance saves travel costs
	PU3	Independent	It is possible to buy online life insurance anywhere
	PU4	Independent	Easy to compare and choose online life insurance products
Perceived ease of use	EU1	Independent	User-friendly online life insurance selling website interface
	EU2	Independent	Easily learn how to use an online life insurance selling website
	EU3	Independent	Easily query information
	EU4	Independent	The process of purchasing online life insurance is simple, clear and easy to understand
Trust	TR1	Independent	I believe online life insurance meets my expectations
	TR2	Independent	I believe that the information on online life insurance products is complete and accurate
	TR3	Independent	I believe that an online life insurance provider is always in the best interests of the customer
	TR4	Independent	I believe the website that sells online life insurance is trustworthy
Perceived risk	PR1	Independent	I am concerned that the online life insurance website collects too much of my personal information
	PR2	Independent	I am concerned that the online life insurance website will misuse my personal information
	PR3	Independent	I am concerned that my personal information is not secure on the sales site
	PR4	Independent	I am concerned that the payment may go wrong
Social influence	SI1	Independent	Most people around me take online life insurance
	SI2	Independent	Does the media affect my intention to buy online life insurance
	SI3	Independent	Does family influence my intention to buy online life insurance
	SI4	Independent	Friends influence my intention to buy online life insurance
	SI5	Independent	Colleagues influence my to buy online life insurance
Facilitating conditions	FC1	Independent	I have the funds and equipment to buy online life insurance
	FC2	Independent	I believe I have enough knowledge to buy online life insurance
	FC3	Independent	I will always find help if I have problems or questions during the process of buying online life insurance
Intention to buy online life insurance	IB1	Dependent	I intend to buy online life insurance when given the opportunity
	IB2	Dependent	I will likely to buy online life insurance in the near future
	IB3	Dependent	I will recommend my relatives to buy online life insurance

## Data

This study uses primary data sources through a survey of 480 observed samples distributed in 12 urban districts of Hanoi with 240 samples and 1 town, 17 suburban districts of Hanoi with 240 samples from November 2022 to January 2023. However, during the actual investigation, the authors only obtained 450 valid votes. Survey subjects are people aged 18 years or older, studying or living in Hanoi, have bought or intend to buy online life insurance. The survey sample was formed according to the convenient sampling method to collect information.

The data collection method used is a combination of face-to-face and online voting. Collected data are processed by SPSS20 with applied techniques including descriptive statistics of the survey sample, testing the reliability of the scale, exploratory factor analysis, correlation analysis and regression analysis using the OLS method.

## 4. RESULTS AND DISCUSSION

### 4.1. Descriptive Statistics

**Table 2. Sample Descriptive Statistic**

Description	Groups	Sample size N=450	
		Frequency	%
Gender	Males	175	38,9%
	Females	275	61,1%
Age	18 to 25 years old	92	20,4%
	26 to 35 years old	235	52,2%
	36 to 50 years old	81	18,0%
	over 50 years old	42	9,3%
Academic level	Lower than bachelor's degree	70	15,6%
	Bachelor's degree	336	74,7%
	Master's or higher degree	44	9,8%
Income (per month)	Below 10 million VND	95	21,1%
	10 to 20 million VND	229	50,9%
	20 to 30 million VND	108	24,0%
	over 30 million VND	18	4,0%
Status of taking online life insurance	Have been and are buying	118	26,2%
	have not bought yet	332	73,8%

Source: Calculations of the research team

According to the results of a random survey of 450 observations, the female response rate accounted for 61.1%, and the male response rate was 38.9%. The survey subjects were mainly from 26 to 35 years old, accounting for 52.2%, from 18-25 years old accounted for 20.4%, followed by the age group from 36-50 years old, accounting for 18.0% and finally over the age of 50 with the rate of 9.3%. The above figures show that most respondents to the survey are young people. Most of the respondents have bachelor's degree,

accounting for 74.7%, the rest are lower than bachelor’s degree (accounting for 15.6%) and master’s or higher degree (accounting for 9.8%). According to the survey results, more than half of the respondents have an average income of 10-20 million per month, accounting for 50.9%. The group of customers with incomes from 20-30 million and below 10 million have 24.0% and 21.1% respectively. The group of customers with incomes over 30 million per month accounted for the lowest proportion of 4%. According to statistics, the survey results on the status of buying online life insurance show that the majority of respondents have not purchased life insurance online (accounting for 73.8%). Meanwhile, the number of respondents who have purchased online life insurance only accounted for 26.2%.

**Table 3. Descriptive statistics of variables**

	<b>N</b>	<b>Minimum</b>	<b>Maximum</b>	<b>Mean</b>	<b>Std.Deviation</b>
PU1	450	1	5	4.56	.763
PU2	450	1	5	4.59	.733
PU3	450	1	5	4.56	.791
PU4	450	1	5	4.42	.825
EU1	450	2	5	4.25	.865
EU2	450	2	5	3.96	.790
EU3	450	2	5	3.91	.812
EU4	450	2	5	3.94	.822
TR1	450	1	5	3.64	.978
TR2	450	1	5	3.45	1.046
TR3	450	1	5	3.46	1.001
TR4	450	1	5	3.70	.940
PR1	450	1	5	3.34	1.006
PR2	450	1	5	3.29	.931
PR3	450	1	5	3.40	.949
PR4	450	1	5	2.92	.805
SI1	450	1	5	3.71	1.049
SI2	450	1	5	3.65	1.053
SI3	450	1	5	3.39	1.134
SI4	450	1	5	3.41	1.112
SI5	450	1	5	3.32	1.088
FC1	450	1	5	3.82	.924
FC2	450	2	5	3.90	.800
FC3	450	1	5	3.82	.840
IB1	450	1	5	4.10	.919
IB2	450	1	5	3.93	1.027
IB3	450	1	5	3.91	1.080

Source: Calculations of the research team based on SPSS software

The results of descriptive statistics show that the observed variables of Perceived risk and Social influence have an average value of over 3.0 with a rather small standard deviation, around 1%. This means that respondents about online life insurance services rate these factors at an average level. Similarly, the observed variables of Trust, Facilitating conditions and Intent to buy online life insurance have a mean value of over

3.7 with a standard deviation of less than 1%. This means that respondents about online life insurance services rate these factors above average. The observed variables Perceived usefulness and Perceived ease of use had the average value above 4.0 with standard deviation less than 1%. This shows that respondents about online life insurance services surveyed rated the usefulness and ease of use at a good level.

#### 4.2. Cronbach's alpha analysis

**Table 4. Reliability Statistics**

Scale	Cronbanh's Alpha
Perceived usefulness	0,901
Perceived ease of use	0,679
Trust	0,860
Perceived risk	0,834
Social influence	0,802
Facilitating conditions	0,791
Intention to buy online life insurance	0,831

Source: Calculations of the research team based on SPSS software

All the Cronbach's Alpha values of the scales in the research model are greater than 0.6. Therefore, all observed variables are accepted and will be used in the next factor analysis.

#### 4.3. Exploratory factor analysis (EFA)

\* Exploratory factor analysis for independent variables:

**Table 5. KMO and Bartlett's Test for independent variables**

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		0,853
Bartlett's Test of Sphericity	Approx. Chi-Square	4809,086
	df	276
	Sig.	.000

Source: Calculations of the research team based on SPSS software

With the coefficient KMO = 0.853 (> 0.5), it can be confirmed that the factor analysis for the independent variables is appropriate. The sig value. = 0.000 < 0.5 in Bartlett's test means that there is a basis to reject the hypothesis  $H_0$  that the independent variables are not correlated with each other in the population.

**Table 6. Total variance explained for independent variables**

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	5.986	24.942	24.942	5.986	24.942	24.942	3.230	13.460	13.460
2	2.915	12.147	37.089	2.915	12.147	37.089	3.046	12.693	26.153
3	2.610	10.876	47.965	2.610	10.876	47.965	2.702	11.257	37.410
4	1.893	7.889	55.854	1.893	7.889	55.854	2.699	11.244	48.654
5	1.401	5.838	61.692	1.401	5.838	61.692	2.240	9.333	57.988
6	1.182	4.924	66.616	1.182	4.924	66.616	2.071	8.629	66.616
7	.810	3.375	69.991						

8	.794	3.308	73.299						
9	.605	2.520	75.819						
10	.572	2.383	78.202						
11	.546	2.277	80.478						
12	.523	2.177	82.656						
13	.481	2.004	84.660						
14	.473	1.970	86.630						
15	.438	1.826	88.456						
16	.405	1.686	90.142						
17	.367	1.531	91.672						
18	.357	1.487	93.159						
19	.347	1.445	94.605						
20	.315	1.314	95.919						
21	.277	1.152	97.071						
22	.266	1.106	98.177						
23	.252	1.051	99.228						
24	.185	.772	100.000						

Source: Calculations of the research team based on SPSS software

Eigenvalues = 1,182 > 1 represents the variation explained by each factor, then the factor extracted is the best summary of information. Total variance extracted is 66.616% > 50% meets the requirements. This indicates that 66.616% of the variability of the data is explained by 6 factors.

**Table 7. Rotated component matrix for independent variables**

	Component					
	1	2	3	4	5	6
PU2	0,886					
PU1	0,872					
PU3	0,863					
PU4	0,798					
TR2		0,820				
TR3		0,793				
TR1		0,723				
TR4		0,651				
SI5		0,500				
PR1			0,846			
PR2			0,827			
PR3			0,812			
PR4			0,762			
SI2				0,860		
SI1				0,823		

SI3				0,697		
SI4				0,516		
FC1					0,795	
FC2					0,784	
FC3					0,742	
EU4						0,762
EU1						0,696
EU3						0,688
EU2						0,650

Source: Calculations of the research team based on SPSS software

The final rotation matrix results show that there are 24 observed variables grouped into 6 factors . The factor loading coefficients of 24 observed variables are all greater than 0.5 and there is no case that any variable uploads both factors at the same time with the loading coefficients close to each other, showing a correlation. The high correlation between the observed variable and the factor or the variation in the observed variable is mainly explained by the factor.

From the results of EFA analysis, it can also be seen that there is a change in the position of the observed variable SI5. The new group of factors includes TR2, TR3, TR1, TR4, SI5. The group of factors reflects consumers' trust in online life insurance, which can be understood as trust in a specific object, such as trust in e-commerce or trust in an online life insurance provider. Colleagues can influence intention to use insurance online through sharing experiences and product information with each other. If a consumer's co-worker has successfully used online insurance, it will help consumers trust the safety and reliability of the online insurance product, thereby increasing their likelihood of using it. This product also increased. Therefore, the group of factors is still kept the original name as "Trust" and there is no change in the research model.

Six independent factors extracted from EFA factor analysis are kept as original, only changed in number of observed variables as follows: Perceived usefulness factor (PU) includes PU2, PU1 , PU3, PU4; Beliefs (TR) include TR2, TR 3, TR1, TR4, TR5; Perceived risk (PR) includes PR1, PR2, PR3, PR4; Social influence (SI) includes SI2, SI1, SI3, SI4; Facilitation (FC) includes FC1, FC2, FC3, and Ease of Use Perception (EU) includes EU4, EU1, EU3, EU2.

**\* Exploratory factor analysis for dependent variables:**

**Table 8. KMO and Bartlett's Test for dependent variable**

<b>Kaiser-Meyer-Olkin Measure of Sampling Adequacy.</b>		<b>0,725</b>
Bartlett's Test of Sphericity	Approx. Chi-Square	517,301
	df	3
	Sig.	.000

Source: Calculations of the research team based on SPSS software

With the KMO value = 0.725 ( $> 0.5$ ), it can be confirmed that the factor analysis for the dependent variables is appropriate. The sig value. = 0.0000 in the Bartlett test  $< 0.5$  means that there is a basis to reject the hypothesis  $H_0$  that the dependent variables are not correlated with each other in the population.

**Table 9. Total variance explained for dependent variable**

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %
1	2.252	75.071	75.071	2.252	75.071	75.071
2	.388	12.928	87.999			
3	.360	12.001	100.000			

Source: Calculations of the research team based on SPSS software

Eigenvalues = 2,252 > 1 represents the portion of variation explained by each factor, then the derived factor has the best information summary significance. Total variance extracted is 75.071% > 50% is satisfactory. This indicates that 75.071% of the variability of the data is explained by one factor.

**Table 10. Rotation matrix of dependent variable**

	Component
	1
IB1	0,870
IB2	0,870
IB3	0,860

Source: Calculations of the research team based on SPSS software

The results of the factor rotation matrix have extracted 1 factor from 3 observed variables with the cumulative extracted variance of 75.071%, the factor loading coefficients are all greater than 0.5. Therefore, the observed variables of this dependent variable scale meet the requirements for the next correlation analysis.

**4.4. Pearson correlation**

**Table 11. Correlations**

		IB	PU	TR	PR	FC	EU	SI
IB	Pearson Correlation	1	.424**	.469**	.133**	.436**	.007	.602**
	Sig. (2-tailed)		.000	.000	.005	.000	.883	.000
PU	Pearson Correlation	.424**	1	.379**	.074	.295**	.204**	.133**
	Sig. (2-tailed)	.000		.000	.117	.000	.000	.005
TR	Pearson Correlation	.469**	.379**	1	.048	.523**	.194**	.506**
	Sig. (2-tailed)	.000	.000		.314	.000	.000	.000
PR	Pearson Correlation	.133**	.074	.048	1	.141**	.066	.169**
	Sig. (2-tailed)	.005	.117	.314		.003	.165	.000
FC	Pearson Correlation	.436**	.295**	.523**	.141**	1	.154**	.349**
	Sig. (2-tailed)	.000	.000	.000	.003		.001	.000
EU	Pearson Correlation	.007	.204**	.194**	.066	.154**	1	-.038
	Sig. (2-tailed)	.883	.000	.000	.165	.001		.420
SI	Pearson Correlation	.602**	.133**	.506**	.169**	.349**	-.038	1
	Sig. (2-tailed)	.000	.005	.000	.000	.000	.420	

Source: Calculations of the research team based on SPSS software

Based on Pearson correlation coefficient and sig value (Table 11), it shows that the independent variables (PU, TR, PR, FC, SI) are positively correlated with the dependent variable IB with small statistical significance more than 5%. The variable EU was excluded because the significance level of this variable with IB is greater than 0.05, that is, it is not significant in the research model.

#### 4.5. Regression results and discussion

##### \* Model Summary

**Table 12. Model Summary**

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin-Watson
1	.712 <sup>a</sup>	.507	.501	.61728	2.073

a. Predictors: (Constant), SI, PU, PR, FC, TR

b. Dependent Variable: IB

*Source: Calculations of the research team based on SPSS software*

With the adjusted R square coefficient of 0.501, it shows that the explanatory level of the model is 50.1%. In other words, 5 independent variables in the research model explain 50.1% of the variation of the dependent variable.

##### \* The fit of the regression model

To test the suitability of the overall linear regression model, we use the results of the F test. The F test in the analysis of variance considers whether or not there is a linear relationship between the dependent variable and the whole population set of independent variables.

**Table 13. ANOVA**

	Model	Sum of Squares	df	Mean Square	F	Sig.
1	Regression	173.889	5	34.778	91.272	.000 <sup>b</sup>
	Residual	169.179	444	.381		
	Total	343.068	449			

a. Dependent Variable: IB

b. Predictors: (Constant), SI, PU, PR, FC, TR

*Source: Calculations of the research team based on SPSS software*

The results of ANOVA analysis show that the F value is 91,272, which is statistically significant with very small sig. value (Sig. = 0.000 < 0.05). This means that the regression model used in this study is consistent with the actual data collected at the 5% statistical significance level.

##### \* regression results and discussion

**Table 14. Coefficients**

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		B	Std. Error	Beta			Tolerance	VIF
1	(Constant)	-.437	.248		-1.761	.079		
	PU	.388	.047	.303	8.306	.000	.834	1.199
	TR	.020	.049	.018	.398	.691	.551	1.813
	PR	.004	.039	.003	.092	.927	.952	1.050
	FC	.198	.049	.163	4.085	.000	.696	1.437
	SI	.514	.041	.495	12.522	.000	.709	1.410

a. Dependent Variable: IB

*Source: Calculations of the research team based on SPSS software*

According to the results of the regression analysis, the variance inflation factor (VIF) reached the largest value of 1.813, and all were less than 10. This shows that the variables are independent, there is no closely correlation among variables, so there is no multicollinearity.

The sig. value (p-value) of regression coefficients  $\beta_1$ ,  $\beta_5$ ,  $\beta_6$  are all less than 0.05. This means that 3 independent variables including Social influence, Perceived usefulness and Facilitating conditions all have significant explanatory meanings for the dependent variable Intent to buy online life insurance.

The results of the regression analysis showed that the model explained 50.1% of the influence of the research factors on the intention to buy online life insurance of people in Hanoi. Of the six factors analyzed, three are statistically significant.

Social influence (SI) has a positive effect on Intention to buy online life insurance (IB). This result is similar to the findings of Jiang, Shi-jie et al. (2019). The results also indicate that the Intention to buy online life insurance will be influenced by the people they know around them, such as family members, friends and colleagues. Especially with the ability to impact quickly, strongly and widely, communication has a great role in influencing the behavioral intentions of consumers.

Perceived usefulness (PU) has a positive effect on the Intention to buy online life insurance. This result supports the study results of Gebert-Persson, Sabine et al (2019). This shows that the inherent benefits of online insurance compared to traditional insurance have attracted increasing customer purchases and this trend will continue to grow rapidly in the digital industrial age.

Facilitating conditions (FC) has a positive effect on Intention to buy online life insurance. This result is similar to the research results of Ajzen (1991), Pushpa A et al (2017) when they suggested that favorable conditions have a direct influence on behavioral intention. When there are favorable conditions such as finance, equipment, knowledge, etc., consumers will be more likely to intend to buy online life insurance.

Thus, there are 3 original research hypotheses (H1, H5, H6) that are accepted with statistical significance less than 5%. The Standardized regression equation is written as:

$$IB = 0.495*SI + 0.303*PU + 0.163*FC$$

Based on the regression coefficient, it can be seen that the factor that has the most influence on the Intention to buy online life insurance of people in Hanoi is Social influence, followed by the factor Perceived usefulness and finally the Facilitating conditions.

## 5. CONCLUSIONS AND RECOMMENDATIONS

### 5.1. Conclusion

From the analysis of the above test results, it can be concluded that, there are many factors affecting the Intention to buy online life insurance of people in Hanoi, in which, the study has identified three main influencing factors including: Perceived usefulness, Social influence and Facilitating conditions. All three factors have the same direction influence and explain 50.1% of the change of Intention to buy online life insurance of people in Hanoi. However, influences of these factors are not the same. The factor that has the strongest influence on the Intention to buy online life insurance of people in Hanoi is Social influence, followed by Perceived usefulness, and finally Facilitating conditions. Meanwhile, Perceived ease of use as well as Trust, Perceived risk had no impact on intention to take life insurance online.

### 5.2. Recommendations

#### \* Recommendations for businesses providing online life insurance services

#### *Recommendations are based on the factor “Social influence”*

Through the research results, we can also see that the factor “Social influence” is assessed with an average level ranging from 3.39 to 3.71. This is still a rather low rating, so online life insurance providers

need to take measures to promote positive social impacts and improve people's assessment of this group of factors. The following recommendations should be considered:

- Increase the experience factor for customers through “seeing and hearing”, presenting the benefits of online life insurance with specific examples, from some relatives and acquaintances who have participated and receive payment benefits from online life insurance so that customers feel more convinced, the rate of intention to buy is also higher.

- Develop an effective marketing strategy, quickly update promotional programs on the media with a large number of visitors such as social networks and online newspapers to reach many different potential customers.

- Service providers also need to pay attention to programs such as cross-selling, old customers refer to new customers. Also, invest in promotion programs to attract and develop new customer sources, incentive factors to maintain existing customers.

#### ***Recommendations are based on the factor “Perceived usefulness”***

Most users are interested in the usefulness and convenience that online life insurance brings. The survey results show that the average value of the factor “Perceived usefulness” is at a high level, ranging from 4.42 to 4.59. However, in order to have a long-term strategy to increase the competitiveness of enterprises in this field, enterprises still have to take measures to further enhance the positive effects of usefulness of online life insurance. Therefore, some proposed solutions are as follows:

- Enterprises need to diversify the portfolio of business insurance products, complete and accurate product information for the needs of comparing and selecting products as well as updating the necessary information of customers.

- It is necessary to simplify procedures and automate operations to reduce the time customers participate in insurance.

- Expand transaction links with many partners, especially convenient sites, strengthen links with banks and payment acceptors to help users more conveniently in transactions.

#### ***Recommendations are based on the factor “Facilitating conditions”***

Based on the research results, the average value of the factor “Facilitating conditions” is above average, the lowest is 3.82 and the highest is 3.90. Although this factor has a small impact, it is also one of the factors that positively affects the Intention to buy online life insurance of people in Hanoi. Therefore, creating more favorable conditions for consumers is a necessity for every business providing this service. Suggestions are made as follows:

- Enterprises also need to have a training plan to improve the quality of human resources and professional qualifications of officers and employees, through which the handling of customer requests is done quickly and accurately.

- Online life insurance businesses need to improve their technology infrastructure regularly and have policies to support arising problems in the best way.

- It is necessary to establish and build a database of customer information in order to specifically classify customers to have a suitable working method for each customer group.

#### **\* Recommendations for state management agencies**

- Completing the legal provisions related to online life insurance, building a complete and safe legal corridor for both groups of subjects, which are insurance businesses and customers when participating in online life insurance activities. insurance trading.

- Improving information technology infrastructure is also a necessity. Information technology infrastructure is the connecting highway for the development of online services.

### 5.3. Limitations of the study and future research directions

With the topic “Factors affecting the intention to buy online life insurance of people in Hanoi” there are still certain limitations. Firstly, the study uses convenient sampling methods in Hanoi, so there are limitations on the generalizability of the study. Second, the new research model shows a part of the factors affecting the intention to buy online life insurance. However, besides those factors, there are many other factors that affect the intention to buy online life insurance. Therefore, further studies may use more factors for further testing. Third, the study has not mentioned the actual use of online life insurance. This is also a problem for further research.

## IMPACT OF FINANCIAL LEVERAGE ON THE FINANCIAL PERFORMANCE OF VIETNAMESE MANUFACTURING LISTED FIRMS DURING THE COVID PERIOD

**Author: Tran Thi Tra My<sup>1</sup>, Phung Hoang Dao<sup>1</sup>, Chu Thanh Dat<sup>1</sup>, Tran Duc Kien<sup>1</sup>, Le Thanh Hien<sup>1</sup>**

**Mentor: Nguyen Thi Lien Huong<sup>1</sup>**

**ABSTRACT:** *One of the most important issues of corporate financial management is the financial decision or deciding the level of financial leverage of the enterprise. This study aims to evaluate the impact of financial leverage on financial performance in enterprises in the processing industry in Vietnam. Data were collected from 163 enterprises over a period of 7 years with 1295 observations. Research methods OLS, REM, and FEM were used. The research results show that financial leverage has a negative impact on the financial performance of the business and Covid-19 has a negative impact on financial performance. From there, the study provides management implications to improve the financial performance of the business.*

*Keywords: financial performance, financial leverage, total asset turnover, revenue growth, enterprise*

### 1. INTRODUCTION

Financial efficiency is an economic category, that expresses economic development in depth, reflecting the level of exploitation and use of resources in the process of reproduction, to realize business goals, with spend the least amount of money and get the best results. The essence of financial management efficiency is to reflect the quality of production and business activities, and the level of use of resources to achieve the goal of profit. Financial results not only show the level of production but also help find ways to increase results and reduce costs, to improve the operating efficiency of the business.

Financial leverage measures the extent to which borrowed funds are used to finance the assets of a business with the goal that the income from the assets will be greater than the cost of borrowing. The use of financial leverage is likened to a “double-edged sword”, because, on the one hand, it is a tool to help businesses increase profits for shareholders (Shaked and Plastino, 2012). However, on the other hand, using leverage also creates a fixed debt cost burden, increasing the level of risk for the business. Each business, depending on the characteristics of the industry or different stages of development, will have different leverage strategies. For example, firms with short production and business cycles tend to use a higher proportion of short-term debt. Our businesses that are in the development stage often use more loans to invest in expanding production and business, improving competitiveness and position in the market. In contrast, in periods of economic recession and difficulties, businesses often limit the use of loans to minimize payment risks.

Although there have been many studies on the impact of financial leverage on the financial performance of enterprises, the research results are not consistent and there are no similar studies in the food and beverage industry in Vietnam. Therefore, this study was conducted to add more empirical evidence for this relationship.

In addition to the Introduction, the study includes the contents of the Theoretical Framework, Research Methods, Results and Discussion.

## **2. THEORETICAL FRAMEWORK AND LITERATURE REVIEW**

### **2.1. Theoretical framework**

#### **2.1.1. Pecking order theory**

The pecking order theory (Myers and Majluf, 1984) suggests that when firms use financing tools, they tend to set priorities for using these sources of funding. More specifically, when there is a need to use capital, businesses will consider all available funding sources and choose the least expensive source of funding (Brealey et al., 2012). The order of precedence suggested by this theory is as follows: first, firms should use internal equity (usually from retained earnings), then debt, and lastly use debt. using capital raised from outside. As a result, high-margin companies often maintain low debt ratios because they tend to use financing that comes from retained earnings. Income from retained earnings is considered a low-cost source of financing while the costs of debt or equity issuance are higher. Thus, according to pecking order theory, the more financially efficient firms are, the lower the leverage ratio will be because it prefers to use retained earnings financing for operations. his motion.

#### **2.1.2. Trade-off theory**

To obtain an optimal debt ratio, a business must trade off the benefits of using debt and the risks of liquidity or bankruptcy if it uses too much debt. When a business borrows, the interest on the loan reduces the taxable income of the business, thereby creating tax savings. However, at the same time, businesses also face fixed funding costs. If the business is not efficient, the income is not enough to cover the debt obligations, and the business easily falls into the situation of insolvency and may lead to bankruptcy. Thus, under the condition that the firm's asset and investment decisions are constant, the firm's optimal debt ratio will be achieved when there is a balance between the benefits of debt and the costs associated with it. loan debt. Also, according to Myers (2001), one of the advantages of the trade-off theory is that it explains why firms do not keep a high debt ratio.

#### **2.1.3. Representative theory**

Another theory often used to explain the relationship between financial leverage and the financial performance of firms is agency theory. In fact, there may be a conflict between the interests of three parties: shareholders – creditors, and corporate managers. Managers will always act in their own interests, which sometimes conflicts with the interests of shareholders. In this case, agency costs will be incurred. Agency costs are the portion of value that a firm loses due to disagreements in the interests of its stakeholders (Jensen & Meckling, 1976). According to this theory, the use of high financial leverage will reduce agency costs, thereby increasing the financial efficiency of the business. This is because increasing the proportion of debt will increase the risk of insolvency and personal losses for managers: such as salary reduction, bonus, or reputation deterioration (Grossman & Hart, 1982). Besides, large debt also puts pressure on managers to use cash flow efficiently to cover interest expenses (Jensen, 1986).

Thus, using financial leverage can help businesses reduce agency costs incurred between managers and shareholders of the enterprise. However, for conflicts between shareholders and creditors of the enterprise, financial leverage increases agency costs, leading to a decrease in the financial performance of the business. Shareholders, because they want to bring the most benefit to themselves, may prefer to invest in riskier projects to earn high returns. However, this is not preferred by creditors because these projects can increase the creditor's risk of capital recovery. Therefore, high leverage will generate higher agency costs between creditors and shareholders, thereby having a negative impact on business performance.

#### **2.1.4. Signal theory**

Ross (1977) introduced signal theory. Ross (1977) argues that corporate managers can use capital structure and dividends to give signals about the future development prospects of the business. More specifically, the borrowing of businesses represents a positive signal of businesses about their future. The reason behind this is that the managers of the business will never put the business at risk of bankruptcy due to debt if they are uncertain about the future profitability of the business. Therefore, only businesses that have enough confidence in their ability to pay their debt obligations take loans, or in other words, only businesses that have firm confidence in their future profitability.

#### **2.2. Literature Reviews**

The impact of financial leverage on the financial performance of enterprises has been studied by many studies. However, the direction of impact in this relationship was found to be quite diverse. Ali et al. (2019) investigated the impact of factors on the profitability of listed companies in Malaysia for 4 years from 2012 to 2014. The results of the study show a negative relationship between financial leverage and corporate profitability. The reason that analysts give is that the more debt the business uses, the more vulnerable the business will be to bankruptcy and financial risks. Syed Shah (2013) used a sample of 35 listed companies from the Food Manufacturing sector of KSE. The study was conducted to understand the relationship between financial leverage and financial performance. The main variable used to test the hypothesis includes the independent variable as financial leverage and the dependent variable as the financial performance of sugar companies listed in KSE. Debt to equity ratio is used to measure financial leverage while financial performance is measured by Return on assets. The results of the study showed mixed results. There is a positive relationship between the debt-to-equity ratio and return on assets and revenue growth and a negative relationship between the debt-to-equity ratio and earnings per share. As a result, Sugar Companies listed on Karachi Stock Exchange can improve their financial performance by using leverage to a considerable extent and can contribute to boosting the economy.

Research by Ullah, A., Pinglu, C., Ullah, S., Zaman, M., & Hashmi, S. H. (2020) shows that the nexus between capital structure, firm-specific factors, macroeconomic factors, and financial performance in the textile sector of Pakistan. According to a study by Atta et al. (2020) analyzes the role of capital structure in the financial performance of 90 textile and garment companies in Pakistan (PSX) in the period 2008–2017. The study measures capital structure including variables: debt to equity, total debt to total assets and financial performance measured by ROE. The results show that the variable debt-to-equity structure (D/E) has a negative and significant relationship with ROE while the asset turnover ratio and firm performance show a positive relationship. negative relationship and not statistically significant. However, the control variable for firm size has a significant and negative impact on firm performance. Meanwhile, the ratio of total debt to total assets, which has an insignificant relationship with financial performance (ROE) holds true for agency theory (Jensen & Mecking, 1976).

Gul, S., & Cho, H. R. (2019) argues that an increase in short-term debt to assets leads to increased default risk while an increase in long-term debt to assets leads to a decrease in default risk. The study also shows that size, tangibility, and ability to pay interest are also important determinants of default risk.

Besides, there are also a few studies that find a positive correlation between debt and financial performance of enterprises (Javeed and Tabassam, 2018; Banafa, 2015).

#### **Research situation in Vietnam**

Research by Doan, N. P. (2014). Impact of capital structure on financial performance of enterprises after privatization in Vietnam. Doan (2014) studied the impact of capital structure on the financial results of

enterprises after equitization. The data includes 217 companies listed on the Vietnam Stock Exchange in the period 2007-2012. The independent variables used in this study include short-term debt, long-term debt, total debt, and dependent variables measuring performance including ROA and ROE. The study shows a negative relationship between capital structure and business performance at 1% significance level. Regression results show that long-term debt has a positive impact on ROA and ROE while short-term debt and total debt have a statistically negative impact on business performance after equitization. ROA and ROE.

Research by Phan, T. H. (2016) shows the Effect of capital structure on business results of industrial manufacturing enterprises. Phan (2016) also studies the impact of capital structure on the business results of industrial enterprises. The author uses ROA and ROE as dependent variables to show business results, independent variables are capital structure, business size, growth rate, structure of tangible fixed assets, business risk. enterprises, state ownership and Tobin's Q. Research using OLS, FEM and REM methods shows that the negative impact of capital structure factors on business results of enterprises is very certain and possible. statistical significance. This result is consistent with many other studies such as Zeitun, Tian, and Keen (2007), Trinh and Nguyen (2013). This means that the firms in the sample observe that increasing debt reduces operating efficiency.

Research by Le, T. M. P. (2017). The relationship between capital structure and financial performance in manufacturing enterprises. Le (2017) studies the impact of capital structure on financial performance by using audited financial statements of 219 companies listed on the Vietnamese stock market for the period 2010-2015. The study applies two research methods: correlation analysis and regression analysis on panel data. The author chooses the dependent variable as ROE, the independent variable as size, capital structure, solvency, asset structure, growth rate. Research results show that capital structure for all production groups has a positive impact on firm performance.

Research by Bui, D. T. (2017). Impact of capital structure and working capital on the financial performance of small and medium-sized enterprises. Bui (2017) studies the influence of capital structure and working capital on the financial performance of small and medium enterprises. The author uses data collected from 1,032 small and medium enterprises in Ho Chi Minh City in the period 2006-2014. Using ROA and ROE as dependent variables and different independent variables including average debt to average total assets; average short-term debt to average total assets (SDA) and average long-term debt to average assets (LDA), days receivable (ACR); inventory date (ICP), payable date (APP) and cash cycle ( $CCC = ACR + ICP - APP$ ). The author uses GMM regression method for analysis. According to the regression results, variable DA positively affects ROE and ROA. More specifically, the variable SDA has a positive effect on ROA and ROE. The results show that the use of short-term debt in the capital structure has an impact on increasing the financial performance of enterprises. For the LDA variable, the regression results show no evidence of the impact of LDA on ROE and ROA.

Research by Dao, T. T. B., & Ta, T. D. N. (2020). A meta-analysis: capital structure and firm performance. Dao and Ta (2020) aim to investigate the relationship between capital structure and firm performance using a meta-analytic approach. The authors confirm that firm performance is negatively related to capital decisions, which favors the agency cost trade-off model and pecking order theory.

Research by Nguyen, H. T., & Nguyen, A. H. (2020). The impact of capital structure on firm performance: Evidence from Vietnam. Nguyen and Nguyen (2020) use panel data of a research sample consisting of 488 non-financial companies listed on the Vietnamese stock market for a period of 6 years, from 2013 to 2018. The method used is the generalized least squares (GLS) method. In this study, company performance is measured by return on equity (ROE), return on assets (ROA) and earnings per share (EPS).

The ratios of short-term debt, long-term debt, and total liabilities to total assets are representative of capital structure. Firm size, growth rate, liquidity and the ratio of fixed assets to total assets are the control variables in the study. The empirical results show that capital structure has a statistically significant negative impact on firm performance. In addition, this effect is stronger in SOEs than in non-SOEs in Vietnam.

Research by Ngoc, N. M., Tien, N. H., & Thu, T. H. (2021). The Impact of Capital Structure On Financial Performance of Logistic Service Providers Listed On Ho Chi Minh City Stock Exchange. Research by Ngoc et al (2021) on the relationship between capital structure and performance of 30 logistics enterprises listed on the Ho Chi Minh Stock Exchange. HCMC (HOSE) period 2012 - 2019. Applying quantitative method (with Pool OLS, FEM, REM and FGLS models), the research results demonstrate that capital structure has a negative impact on profitability. represented by the company's ROA. With financial performance measured by ROE, the study does not show the statistical significance between the impact of capital structure on the profitability of logistics enterprises in this period.

Research by PHAM, C. D. (2020). The effect of capital structure on financial performance of Vietnamese listing pharmaceutical enterprises. This study examines the impact of capital structure on financial performance of 30 pharmaceutical companies listed on the Vietnamese stock market in the period 2015 - 2019. The study uses ROE as the dependent variable and four independent variables. including self-financing ability, financial leverage, long-term assets and debt-to-asset ratio, control variables such as firm size, fixed asset ratio, and growth rate. Using the method of least squares regression (OLS), the results show that the financial leverage ratio (LR), long-term asset ratio (LAR) and debt to total assets (DR) ratio are related. positively related to the performance of the business, while the self-financing ratio (E/C) has the opposite effect. to return on equity (ROE).

Although there are many studies with diverse content and approaches, conducted in many different areas and periods, however, with the strong economic fluctuations after the COVID-19 pandemic. and Vietnam's particular developing economy, there has not been a comprehensive study on this issue. Most of the studies focus on countries with developed economies, abundant capital in periods of stable environment, not affected by social isolation. Vietnam with an economy on the rise, from 2002 to 2020, GDP per capita increased 3.6 times, reaching nearly 3,700 USD. While the COVID-19 epidemic took place strongly, Vietnam still maintained a positive growth in 2019, GDP increased by 7.02%, in 2020 by 2.91%, in 2021 by 2.58%. At the same time, Vietnam is a potential country to continuously receive abundant FDI capital. In addition, there has not been any research on the relationship between capital structure and performance of multi-sector manufacturing enterprises - an important factor promoting Vietnam's economy.

Based on the theoretical basis and research overview, the authors put forward 2 research hypotheses

*H1: Financial Leverage affects the financial performance of the enterprise.*

*H2: The Covid shock affects the financial performance of enterprises.*

### **3. RESEARCH METHOD**

#### **3.1. Samples and data**

To test the influence of these factors on the capital structure of listed companies, the study uses data from companies listed on the Ho Chi Minh City Stock Exchange and the Hanoi Stock Exchange in the period 2014-2021. These enterprises have different sizes and assets belonging to the manufacturing industry. As a result, the sample includes balance sheet data of 163 manufacturing enterprises for 8 years. Balanced tabular data with 1296 observations.

The use of panel data has many advantages over other data types such as time series data, and cross-sectional data. Enhanced panel data captures the number of observations of the sample, which limits model defects such as multicollinearity. Panel data also contains more information than other data which makes it possible to study the dynamics of changes in cross-units over time.

The data on enterprises is collected from the annual reports of enterprises at Vietstock’s database.

**3.2. Research model**

Based on the theoretical background and overview of previous research, this study proposes the research model as described in Table 1 below:

The variables used and the scales of variables in the model are inherited from previous studies, besides, the model also adds the state ownership variable due to the characteristics of Vietnamese enterprises when being equitized with state-owned enterprises.

The independent variable is capital structure, which is measured by a measure: debt ratio (LEVERAGE). The calculation of the debt ratio is based on the book value of the business because the book value is easier to calculate and more stable than the market value of equity and debt.

Control variables are firm factors, including firm size (SIZE), growth rate (GROWTH), total asset turnover (TURNOVER), state ownership (STATE), and COVID-19 context (COVID).

$$\text{Model 1: } ROA_{i,t} = \beta_0 + \beta_1 \text{LEVERAGE}_{i,t} + \beta_2 \text{SIZE}_{i,t} + \beta_3 \text{GROWTH}_{i,t} + \beta_4 \text{TURNOVER}_{i,t} + \beta_5 \text{STATE}_{i,t} + \beta_6 \text{COVID} + \varepsilon_{i,t}$$

$$\text{Model 2: } ROE_{i,t} = \beta_0 + \beta_1 \text{LEVERAGE}_{i,t} + \beta_2 \text{SIZE}_{i,t} + \beta_3 \text{GROWTH}_{i,t} + \beta_4 \text{TURNOVER}_{i,t} + \beta_5 \text{STATE}_{i,t} + \beta_6 \text{COVID} + \varepsilon_{i,t}$$

Variables in the research model include 6 financial ratios that were transformed and computed from the original data. All variables are measured by percentage units. These variables were described in detail in Table 1

**Table 1. The list of variables in models**

Index	Variable name	Description	Measure
<b>Dependent variables</b>			
1	ROA	Return on Asset	Annual net Income/Total Assets
2	ROE	Return on Equity	Annual net Income/ Shareholder Equity
<b>Independent variables</b>			
1	LEVERAGE	Financial Leverage or Debt Ratio	Total Liabilities/ Total Assets
2	TURNOVER	Asset Turnover	Net Sales/Total Assets
3	SIZE	Firm size	Logarit of total asset
4	STATE	State Owner	Get value 1 if the enterprise is state-owned, 0 if the enterprise is not state-owned
5	COVID	Covid context	Get value 1 in covid years, get value 0 in other years
6	GROWTH	Sale Growth	(Sales in the current period- Sales in the previous period)/ Sales in the previous period

**3.3. Research methods**

As usual, for the panel data regression model, there are 3 commonly used methods: the least squares estimator model (Pooled OLS), the Fixed Effect Model (FEM) and Random Effect Model (REM). The Pooled OLS model is a model that cannot control each individual characteristic of each enterprise in the study, while the two models FEM and REM overcome this drawback. Therefore, the authors decide to use the FEM model and REM model, then use the Hausman test to determine whether the FEM model or REM model is suitable for research.

## 4. RESULTS AND DISCUSSION

### 4.1 Data description

The study uses panel data collected information of 163 enterprises in the manufacturing industry in the period from 2014 to 2020. This dataset was obtained from audited financial statements and annual reports that were published on the website <https://vietstock.vn/>.

**Table 2. Summary of statistics**

Variables	Observation	Mean	Standard deviation	Min	Max
ROA	1295	0,657044	0,692572	-0,2974155	0,7836998
ROE	1295	0,11533	0,1429616	-1,874727	0,9821288
LEVERAGE	1295	0,4568216	0,2031236	0,0026735	0,9669253
SIZE	1295	27,36115	1,497454	23,70761	32,81413
TURNOVER	1295	1,288175	0,7600385	-0,0011286	5,906429
GROWTH	1295	2,168696	31,93691	-1,000268	926,42
STATE	1295	0,3263889	0,4690724	0	1
COVID	1295	0,25	0,4331799	0	1

The average ROA of manufacturing enterprises is 65.7%, the lowest is -29.74% and the highest is 78.37% and the standard deviation of ROA is 69.26%. The average ROE is 11.53%, the lowest is 14.3%, the highest is 98.21%, the standard deviation is 14.3%. The average debt ratio is 0.46, the maximum is 0.97 times and the lowest is 0.0027 times of total assets. Firm size ranges from 23.7 to 32.8, standard deviation 1.5, and mean 27.36.

### 4.2. Correlation Matrix

The significance of the Pearson correlation coefficient is to test the linear correlation between the dependent variable and the independent variables and identify the possibility of multicollinearity between the independent variables when they are strongly correlated with each other. .

After identifying two variables with a linear correlation (with a significance level of 5%), the Pearson correlation coefficient (r) will range from -1 to 1 with the following values:

-  $|r| < 0.1$ : The pair of variables has a very weak correlation. When  $|r|$  The closer to 0, the weaker the linear correlation.

-  $0.1 \leq |r| < 0.3$ : The pair of variables has a weak correlation.

-  $0.3 \leq |r| < 0.5$ : The pair of variables has a mean correlation.

-  $|r| \geq 0.5$ : The pair of variables has a strong correlation. When  $|r|$  The closer to 1, the stronger the linear correlation. A value approaching 1 is a positive correlation, moving to -1 is a negative correlation.

**Table 3: Correlation Matrix**

	ROA	ROE	LEVERAGE	SIZE	TURNOVER	GROWTH	STATE	COVID
ROA	1,0000							
ROE	0,7955	1,0000						
LEVERAGE	-0,3756	-0,1169	1,0000					
SIZE	0,0641	0,1320	0,2921	1,0000				
TURNOVER	0,2405	0,2353	0,0344	-0,2637	1,0000			
GROWTH	0,0489	0,0537	0,0170	0,1690	-0,0277	1,0000		
STATE	0,1330	0,0956	-0,0880	-0,0707	0,1025	-0,0136	1,0000	
COVID	-0,0518	-0,0810	-0,0323	0,0694	-0,0879	-0,1176	-0,0999	1,0000

*In the table above, correlation values are explained as follows at 5% significance level:*

- With two dependent variables ROA and ROE, there are two independent variables LEVERAGE and COVID showing negative correlation with moderate and weak level. The remaining 4 independent variables are positively correlated with ROA and ROE variables.

- Between the two dependent variables ROA and ROE, there exists a strong positive correlation

#### 4.2. Results

Firstly, the fixed effect model (FEM) is applied, and its results reveals that, with the Prob>F = 0.000, the FEM is more suitable than OLS in both ROA and ROE models. After that, we conduct the random effect model (REM) along with the Breusch and Pagan Lagrangian test and found that with a low p value of 0.000 in both two models with ROE and ROA, REM is more suitable than OLS in all the two models.

**Table 4: OLS regression with dependent variable ROA and ROE**

Variable	OLS regression with dependent variable ROA		OLS regression with dependent variable ROE	
	Coef.	P - value	Coef.	P - value
LEVERAGE	-0,1584	0,000	-0,1449	0,000
SIZE	0,0134	0,000	0,0264	0,000
TURNOVER	0,0291	0,000	0,0569	0,000
GROWTH	0,0001	0,319	0,0001	0,276
STATE	0,0109	0,002	0,0178	0,025
COVID	-0,0086	0,024	-0,0256	0,003
Cons	-0,2663	0,000	-0,6142	0,000
R <sup>2</sup>	0,2853		0,1454	
Prob > F	0,0000		0,0000	

**Table 5: REM regression with dependent variable ROA and ROE**

Variable	REM regression with dependent variable ROA		REM regression with dependent variable ROE	
	Coef.	P - value	Coef.	P - value
LEVERAGE	-0,1478	0,000	-0,1410	0,000
SIZE	0,0151	0,000	0,0366	0,000
TURNOVER	0,0227	0,000	0,0391	0,000
STATE	0,0037	0,481	0,0097	0,458
COVID	-0,0112	0,000	-0,0319	0,000
Cons	-0,3085	0,000	-0,8671	0,000
R <sup>2</sup>	0,2832		0,1217	
Prob > F	0,0000		0,0000	
Wald Chi2 (5)	31,84		9,39	

**Table 6: FEM regression with dependent variable ROA and ROE**

Variable	FEM regression with dependent variable ROA		FEM regression with dependent variable ROE	
	Coef.	P - value	Coef.	P - value
LEVERAGE	-0,1496	0,000	-0,1353	0,000

SIZE	0,0136	0,000	0,0272	0,000
TURNOVER	0,0256	0,000	0,0506	0,000
GROWTH	0.0063	0,157	0.0139	0,178
STATE	-0.0101	0,000	-0.0271	0,000
COVID	-0,2694	0,000	-0,6306	0,000
Cons	-0,1496	0,000	-0,1353	0,000
R <sup>2</sup>	0,2832		0,1457	
Prob > F	0,0000		0,0000	
Wald Chi2 (5)	256,19		107,36	

Similar to the dependent variable ROA, the value of F test Prob > F = 0.0000 concludes that the regression model for the dependent variable ROE is also statistically significant. In addition, with p-value = 0.478 > 0.05, the GROWTH variable is also not statistically significant in this model. However, the independent variables explained only 12.27% of the variation of the dependent variable ROE.

At the 5% level of significance, the remaining independent variables are all statistically significant, specifically as follows:

- The LEVERAGE variable has a negative effect on the ROE variable. When LEVERAGE is increased by 1 unit, ROE decreases by 0.1410 units, other things being equal.

- The SIZE variable has a positive effect on the ROE variable. When SIZE is increased by 1 unit, ROE increases by 0.0365, other things being equal.

- The variable TURNOVER has a positive effect on the ROE variable. When TURNOVER is increased by 1 unit, ROE increases by 0.0390 units, other things being equal.

- The STATE variable has a positive effect on the ROE variable. When STATE is increased by 1 unit, ROE increases by 0.0097, other things being equal.

- The variable COVID has a negative effect on the ROE variable.

#### 4.3. Model selection test

The variance is the phenomenon where the residuals or errors of the model after the regression do not follow a random distribution and the variances are not equal. This violates the assumption of the linear regression model that the variance of the errors should be the same.

If the model only has variable variance error, the OLS estimate is still an unbiased and consistent estimator, although not the most efficient estimator. Because, in this case, the variance of the error cannot be minimized. Then, the regression coefficients and F-tests of the model become unreliable, and conclusions based on these tests will not be accurate.

The model uses Breusch - Pagan test to determine whether the regression model has variable variance or not. The results of the test for the two dependent variables ROA and ROE both return p-value = 0.0000 < 0.05, proving that both models encounter variable variance, and the OLS model is not suitable to estimate the above two variables.

**Table 7: Model selection test**

Test	Model - ROA	Model - ROE
LM Test	Chi2 (1) = 159,92 P-value = 0,0000	Chi2 (1) = 157,45 P - value = 0,0000
Hausman Test	Chi2 (5) = 0,00 P - value = 0,0000	Chi2 (5) = 0,04 P - value = 0,4111
Selection Model	REM	

The study uses Hausman Test to determine that the FEM and REM models are suitable for the dependent variables ROA and ROE. The results of the two tests for the dependent variable ROA and ROE both show p-value > 0.05, P = 1,000, concluding that there is no difference between the REM model and the FEM model.

Therefore, we choose the REM model used in the study to regress for two dependent variables ROA and ROE.

**4.4. Multicollinearity test**

Multicollinearity is a phenomenon where the independent variables are strongly correlated with each other. The regression model occurs with multicollinearity, which will cause many indicators to be skewed, leading to the results of quantitative analysis no longer giving much meaning.

The variance exaggeration factor VIF was used to determine the correlation between the independent variables, the strength of those correlations, and to identify multicollinearity.

The value of the VIF coefficient starts from 1 and has no upper limit with the following values:

- $1 \leq VIF < 2$ : There is no correlation between the independent variables and no multicollinearity.
- $2 \leq VIF < 5$ : There is a relative correlation between the independent variables and the possibility of multicollinearity.
- $5 \leq VIF < 10$ : There is a large correlation between the independent variables and there is a high possibility of multicollinearity.
- $VIF \geq 10$ : Surely multicollinearity occurs.

**Table 8: Multicollinearity test**

Variable	VIF	1/VIF
SIZE	1,23	0,813661
LEVERAGE	1,12	0,891705
TURNOVER	1,11	0,904612
GROWTH	1,04	0,958543
COVID	1,03	0,967739
STATE	1,03	0,972118
Ý nghĩa của VIF	1,09	

**4.5. Result**

**Table 9: Results**

	ROA	ROE
LEVERAGE	-	-
SIZE	+	+
TURNOVER	+	+
GROWTH	?	?
STATE	+	+
COVID	-	-

Thus, with the two hypotheses given at the beginning of the study, through the data analysis process, hypothesis H1 is rejected: Debt ratio positively affects the financial performance of the business, accepting the hypothesis. Theory H2: The Covid shock affects the financial performance of enterprises.

## 5. CONCLUSION

After descriptive statistics and analysis of a sample linear regression model of 163 manufacturing enterprises listed on the stock exchange from 2014 to 2021 to find the relationship between capital structure and corporate financial performance. We have two regression models as follows:

$$\text{Model 1: ROA} = -0.2694 - 0.1496*\text{LEVERAGE} + 0.0136*\text{SIZE} + 0.0256*\text{TURNOVER} + 0.0063*\text{STATE} - 0.0101*\text{COVID}$$

$$\text{Model 2: ROE} = -0.6306 - 0.1353*\text{LEVERAGE} + 0.0272*\text{SIZE} + 0.0506*\text{TURNOVER} + 0.0139*\text{STATE} - 0.0271*\text{COVID}$$

With the research results, the relationship between debt-to-asset ratio, enterprise size, total asset turnover, growth rate, state ownership, and COVID-19 has been shown. Other results were obtained with the expectation that financial leverage would have a significant impact on financial performance as measured by ROA, and ROE.

Financial leverage has a negative effect on financial performance. Hypothesis 1 is accepted.

The increase in debt increases costs, income must be deducted to pay debts, reducing profits, and reducing the efficiency of enterprise asset use. The results imply that both long-term and short-term debt are relatively expensive for firms in the manufacturing industry and this negative of debt with its profitability, the associated risk that outweighs the tax benefits, using Using long-term debt is no longer an effective tax shield but, on the contrary, increases the cost burden leading to reduced profit.

This result is similar to the results of Abor (2005), Ebaid (2008), Mahfuzah Salim and Dr.Raj (2012), Ullah (2020), Ngoc (2021), Chi (2018), along with many Research by other authors Balakrishnan and Fox (1993), Majumdar et al. (1999), Gleason et al. (2000), Tian and Zeitun (2007), Abbasali Pouraghajan (2012), Osuji Casmir Chinaemerem and Odit Anthony (2012). 2012), Mahfuzah Salim and Raj Yadav (2012), and Muhammad Umar et al. (2012) that financial leverage will negatively affect the financial performance of enterprises.

This can be explained for a few reasons as follows. First, according to agency cost theory, borrowing will reduce agency costs between owners and managers, with creditors acting as supervisors of the business in the use of capital. However, in Vietnam, this role of the creditor has not performed well, so borrowing does not reduce agency costs between owners and managers (Le & Phan, 2017). Therefore, borrowing a lot will increase financial costs and reduce the financial efficiency of enterprises.

Second, compared to the stock market, the debt market in Vietnam develops slowly, so listed companies in the manufacturing industry in the study period often raised capital by issuing shares instead of issuing debt. If enterprises raise capital from outside, they often must borrow from banks, so they cannot take advantage of the tax shield from debt issuance (Tianyu, 2013; Le & Phan, 2017).

In addition, studies on the impact of financial leverage on profitability have mixed results when conducted in developed and developing countries. Most of the studies are done in developed countries, and the relationship between capital structure and corporate profitability is positive, conversely, for developing countries and emerging markets like Vietnam it is a positive relationship. reverse system. Studies in developing countries such as Salim and Yadav (2012); Thien Vu (2013); Le and Phan (2017) also agree with the results of this study.

In addition to the results on the relationship between financial leverage and financial performance of manufacturing firms listed on the stock market, the findings on the influence of the remaining control variables in the model. The figure is also statistically significant.

Variables of firm size, total asset turnover, and state ownership have significant positive effects on the financial performance of enterprises. However, the growth rate variable in this study is not statistically significant.

The size of an enterprise has an impact on financial performance because the larger the production enterprise, the more advantages it has in terms of economy and market, attracting investors and businesses, and easy access to capital sources. Sponsorship leads to an increase in corporate profits as well. Besides, total asset turnover has a positive impact on the profitability of the business.

The variable COVID has a negative effect on the profitability of the company in the manufacturing sector. The entire social isolation to prevent the COVID epidemic caused the production and business activities of enterprises to stall, causing great economic losses and reducing the efficiency of capital use. At the same time, not making a profit during COVID but still having to pay production costs: warehousing costs, etc., making it difficult for businesses to make a profit.

## DEFINING AND MEASURING FINANCIAL LITERACY OF YOUNG ADULTS: A CASE OF VIETNAM

**Authors:** Bui Nhat Quang<sup>1</sup>, Do Huy Phuc<sup>1</sup>, Ma Ngoc Huong Giang<sup>1</sup>, Pham Thanh Hung<sup>1</sup>  
**Mentor:** Phan Huu Nghi<sup>1</sup>

**ABSTRACT:** *The role of financial literacy in the context of integration, globalization, and economic development has garnered growing appreciation in both developed and developing economies to meet the requirements of the prevalence and sophistication of current financial products. This study posits a composite definition for financial literacy - a multidimensional concept with four components, namely financial attitude, financial behavior, financial knowledge, and financial skill – via the synthesis from previous studies before attesting such a measurement using quantitative data processing methods. The study used an online questionnaire to collect primary data, with a sample size of 521 young adults aged 18 to 30 residing in Vietnam. The reflectiveness of financial literacy through the abovementioned components is confirmed using Structural Equation Modeling approach. The results show that all four assumed components possess statistically significant correlations with financial literacy, in which financial behavior displays the greatest correlation, followed by financial skill, financial knowledge, and finally financial attitude.*

**Keywords:** *financial attitude; financial behavior; financial knowledge; financial literacy; financial skill; young adults.*

### 1. INTRODUCTION

As the global financial system progresses, financial products are becoming increasingly popular, diverse, and intricate. Such a notion begs for a certain level of knowledge for economic actors to effectively utilize these instruments and avoid potential issues. Hence, understanding financial concepts and being able to recognize financial tools are crucial for individuals in making financial decisions. The OECD (2022) notes that evaluating financial literacy is an essential aspect of a successful national financial education strategy. Studies have demonstrated that low financial literacy levels result in debt management and investment problems (Lusardi and Tufano, 2009), reduced stock market participation (van Rooij et al., 2011), inadequate retirement planning (Lusardi and Mitchell, 2014), and difficulties in accumulating and managing assets (Hilgert et al., 2003). Moreover, financial literacy is essential for managing cash flow and evaluating credit, mortgage, and bill payment behavior (Potrich et al., 2015). Therefore, research on financial literacy is of paramount importance for individuals and the global economy as a whole. Young people, in particular, should be a focus, as the financial challenges they confront are of higher severity due to their limited capacity both materially and mentally to recover from poor financial decisions (Lusardi et al., 2010). According to Lusardi et al. (2010), research on youth financial literacy is especially important for policymakers. Timely assessments of young people's financial literacy can facilitate devising efficient financial education programs targeted at youth and assist lawmakers in protecting young consumers.

Extant research on the financial literacy of young Vietnamese individuals is both limited and lacking in depth. Currently, there is no consensus on the definition and content of financial literacy, with some authors deem it as a single concept while others view it as encompassing three, four, or five aspects. This discrepancy complicates the creation of an accurate scale for measuring financial literacy, resulting in a significant research gap. To address this gap, the authors of this study sought to establish a unified definition

<sup>1</sup> National Economics University.

of financial literacy and develop a scale based on a theoretical synthesis of prior domestic and international studies. Primary data on factors measuring Vietnamese youth's financial literacy were collected over three months (September to December 2022), focusing on individuals aged 18-30 from various regions of Vietnam. Data were collected through self-administered online questionnaires, yielding a total of 521 valid responses.

This study's structure comprises five sections. Following the introduction highlighting the rationale, an overview of research on financial literacy and its components is presented. Subsequently, the research methods used and a summary of the results and comparisons to previous studies are discussed, from which conclusions and some policy implications are drawn.

## **2. THEORETICAL FRAMEWORK AND RESEARCH HYPOTHESES**

### **2.1. Definition of financial literacy**

The term "financial literacy" is derived from "finance" – the management of money and "literacy" - the ability of humans to read and write (Zarcadoolas et al., 2006), which ability encompasses both understanding (knowledge of words, symbols, and basic mathematics) and applying (reading, understanding, calculating) this knowledge to daily life. Hence, "literacy" has been developed and expanded in other fields (Huston, 2010) such as information technology (computer literacy - Wecker et al., 2007); medicine (health literacy - Baker, 2006); communication (media literacy - Potter, 2010). Nonetheless, there was no consensus on the exact definition and components of financial literacy (Ouachani et al., 2021; Priyadharshini, 2017; Dewi, 2020). According to Huston (2010), most of the studies up to that point did not assert a specific definition of financial literacy. Furthermore, the phrase "financial literacy" is often used interchangeably with "financial education" and "financial knowledge" in both media and academia (Huston, 2010). It is conspicuous that the duplication of such inherently different concepts is misleading and confusing as financial knowledge is an integral component, but not encompassing, of financial literacy (Huston, 2010; Potrich et al., 2015; Dwiastanti, 2015; Dewi et al., 2020).

Since the 1990s, the extant study has proposed concepts in either a single dimension (the ability to use and understand concepts) or a combination of several components to assess the level of financial literacy (financial behavior, financial knowledge, financial attitudes, financial skills, financial confidence, etc.). These concepts will be compiled and classified according to their generality, thereby synthesized into an overarching concept in this research. The first study ever on financial literacy was published by Noctor in 1992, in which this concept was defined as the ability to make effective judgments and decisions regarding the use and management of money. This definition has since been used by researchers worldwide to this day by several researchers such as Oseifuah (2010), Gale and Levine (2010), and Bird (2008).

Bowen (2002) proposed that financial literacy should be regarded as the ability to understand financial terms and concepts necessary for everyday life. Similarly, Bumcrot (2013) and Fox et al. (2005) deemed financial literacy simply as understanding basic financial concepts in general; while Kadoya and Khan (2020) further highlighted that those concepts should be of interest rates, inflation, risk, and diversification. To sum up, these researchers focus on the financial knowledge aspects of financial literacy, although such an interpretation ensues several problems in developing a measurement scale for financial literacy regarding the fundamental difference between financial literacy and financial knowledge (Potrich et al., 2015). These definitions of financial literacy do not address the long-term goal aspect of financial literacy but focus on knowledge or behavior (effective decision-making) in the short term of the subject, different from multi-dimensional definitions of financial literacy.

The definition of financial literacy should be approached from a multidimensional perspective (Huston, 2010). Multidimensional financial literacy concepts not only have a broader scope than one-dimensional ones, including various aspects of financial literacy such as knowledge, attitude, skills, confidence, etc. but also address the goals that enhancing financial literacy aims towards. Specifically, that goal revolves around making effective financial decisions (Stolper & Walter, 2007; Kefela, 2011) as well as improving financial well-being (Hung et al., 2009; Miller et al., 2009). Such goals can be achieved by combining one's knowledge and understanding of basic financial concepts to form positive financial behaviors (Kefela, 2011) or in combination with financial skills demonstrated by computational abilities (Hastings et al., 2013).

Studying the relationships between components of financial literacy among Generation Y, Hung et al. (2009) postulated that financial literacy is the combination of both financial knowledge of basic financial concepts and the ability to apply that financial knowledge - financial skill - to managing budget spending effectively and improving financial wellbeing. According to this definition, financial literacy encompasses financial knowledge, financial skills, financial behavior, and their coordination to ultimately achieve financial well-being. The inclusion of these three components of financial literacy is supported by numerous studies, for example, Felipe et al. (2017), Potrich et al. (2015), and OECD (2022). Moreover, these studies also refer to a mutual outcome of "financial well-being" - the satisfaction with one's current living standards and financial independence - not relying on another individual financially (Brüggen et al., 2017). For further elaboration, Miller et al. (2009) also mentioned financial satisfaction as a goal but encompassed confidence as a component of financial literacy. Accordingly, financial literacy is the combination of understanding financial products with consumer confidence in tolerating risks and seizing opportunities to make effective decisions to enhance their financial well-being. The confidence and risk aspects in the world of finance are also addressed in the studies on the definition of financial literacy by Remund (2010) and Huston (2010).

From these definitions, the authors propose a composite definition for financial literacy as a combination of financial knowledge, financial skill, financial attitude, and financial behavior that help people make informed decisions to strive toward the goal of financial well-being. Therefore, via evaluation of knowledge of financial concepts, skills in handling financial information, positive financial attitudes toward money, and positive personal financial management behaviors, researchers can construct an effective measurement of the level of financial literacy for each individual. Such a method is also employed by other researchers in an attempt to quantify financial literacy. For example, Atkinson and Messy (2012), Felipe et al. (2017), OECD (2022) used financial knowledge, financial attitude, and financial behavior, Smit (2021) and Hung (2009) used financial knowledge, financial attitudes, financial behaviors, financial skills, and financial well-being.

## **2.2. The dimensions of financial literacy**

### **2.2.1. Financial attitude**

The concept of financial attitude refers to the emotions and opinions of each individual against financial matters, which have a direct effect on their subsequent behaviors and decision-making (Rai et al., 2019). One of the fundamental factors to assess an individual's level of financial literacy is their financial attitude (Priyadharshini, 2017; OECD, 2022). According to Khuc The Anh (2020), a person who appreciates short-term financial gains more than accumulation for the future also tends to rarely consider investments, setting aside a reserve for emergencies or making long-term financial plans. Apropos the spending habits of Asian students on a large scale, Shahryar and Tan (2014) concluded that the influence of financial attitudes on financial literacy is obvious. This result was further supported by Potrich et al. (2014, 2016) when performing an analysis on the same group of subjects in Brazil as well as Rai et al. (2019) when evaluating

the level of financial literacy of women working in India. According to Bhushan and Medury (2014), in order to raise the level of financial literacy of the economy as a whole, first of all, policies should begin with improving how people perceive money in particular and their perspectives on financial topics in general.

**H1: Financial literacy of Vietnamese young adults is reflected by their financial attitude.**

### **2.2.2. Financial behavior**

Financial behavior is a collection of human financial behaviors related to financial decisions and cash flow management. This is a basic and essential dimension of financial literacy (OECD, 2013), which is closely related to other contents. According to Atkinson and Messy (2012), positive financial behavior is also often associated with a congruous, long-term mindset and a notable level of financial knowledge about economic topics. In addition, the higher the level of financial literacy, the more positive and wiser the financial behavior of the subject is. This is manifested in a wide array of financial behaviors including retirement planning (Lusardi and Mitchell, 2007, 2011), saving (Widjaja et al., 2020; Lusardi and Mitchell, 2007), stock market participation (Van Rooij et al., 2011; Yamori and Ueyama, 2022), investment decision making (Ozdemir et al., 2021; Alaaraj and Bakri, 2020), personal finance management (Ansar et al., 2019; Bhargava et al., 2017). Therefore, it can be concluded that financial literacy shares a close correlation with financial behavior.

**H2: Financial literacy of Vietnamese young adults is reflected by their financial behavior.**

### **2.2.3. Financial knowledge**

Financial knowledge refers to an individual's understanding of financial issues and concepts. While financial knowledge is an important part of financial literacy, this concept is often used interchangeably with financial literacy (Huston, 2010). Using this approach, Lusardi and Mitchell (2007) developed a measurement of financial literacy by questions related to basic concepts such as interest rate calculation, understanding of compound interest, inflation, and risk diversification. This measure has since been used by many studies as a standard for measuring financial literacy when designing questionnaires. The correlation between financial literacy and financial knowledge is also reflected in the studies towards a positive approach such as Hung et al. (2009), Rai et al. (2019), Potrich et al. (2014, 2015, 2016), and Khuc The Anh (2020). Accordingly, it can be concluded that financial knowledge is one of the important factors in evaluating and proposing appropriate policies to help improve an individual's financial situation (Khuc The Anh, 2020).

**H3: Financial literacy of Vietnamese young adults is reflected by their financial knowledge.**

### **2.2.4. Financial skill**

Financial skill is the ability to apply existing financial knowledge to strive for a certain outcome, namely to make sound financial decisions and achieve financial well-being. According to Falahati et al. (2011), when individuals can manage daily expenses and make use of credit and saving, they are regarded as possessing financial skills as they can manage different financial aspects of their lives. The ability to manage financial resources can conduce to personal financial well-being. Financial skill is a less commonly mentioned component in financial literacy studies than the above constitutes. However, in recent years, there have been more and more studies recognizing the importance of the ability to apply financial knowledge to this practice when constructing a comprehensive financial literacy measure. Hung et al. (2009) combined financial knowledge, financial behavior, and financial skill to assess the level of financial literacy of millennials in the US. Similarly, Smit (2021) has also included financial skills in the financial literacy measure for college students, with financial skill that not only regulates financial knowledge and financial behavior but also has a direct effect on how different actors respond to varying economic fluctuations.

#### H4: Financial literacy of Vietnamese young adults is reflected by their financial skill.

##### Research method

The study opted for random sampling in view of unbiased results and accurate representation the target population (Collis and Hussey, 2003). This method allows all subjects in a population to have the opportunity to partake and become a part of the sample. The measurement instrument is a self-monitoring questionnaire, divided into five different sections, covering general personal information and then four components of financial literacy:

- Financial knowledge scale is developed by Van Rooij et al. (2011); Potrich et al.(2015); Smit (2020); OECD (2022). It consists of 6 true/false questions related to inflation, financial markets, risk, interest rates and diversification. The result will be the objective financial knowledge of respondents, quantified by the number of correct answers. Each question of financial knowledge is measured as a binary variable, with 1 denoting a correct answer and 0 denoting a false answer.

- Financial attitude scale is developed by Khuc The Anh (2020), Smit (2021), OECD (2022). It is a collection of different statements that carry attitudes towards money and lifestyle in general. Respondents were asked to indicate their level of agreement with these assertions, using a 5-point Likert scale where (1) indicates complete disagreement and (5) indicates complete consensus.

- Financial behavior scale is developed by Potrich et al. (2015); Smit (2021); Schokey (2002); OECD (2022). This is a set of several behaviors such as bill payment, spending habits, emergency money, and long-term budgeting. Respondents were asked to indicate how often they performed these financial behaviors, using a 5-point Likert scale where (1) indicates never and (5) indicates always.

- Financial skill scale is developed by Van Rooij et al. (2011); Potrich et al. (2015); Smit (2021); OECD (2022). It comprises 6 multiple-choice questions about basic calculations, time value of money, compound interest and money illusion to determine if respondents can apply their financial knowledge to real-life situations. Each financial skill question is measured as a binary variable, with 1 denoting a correct answer and 0 denoting a wrong answer.

The study uses the Structural Equation Modeling method to evaluate the latent variable without the observed indicator variable FL (Financial literacy), latent variables reflecting FL are financial attitude. (FA), behavioral finance (FB), financial knowledge (FK), and financial skill (FS). Validity of measurement model is established by assessing convergent and discriminant validity. For convergent validity, the study examines standardized factor loadings, average variance extracted, and composite reliability. Apropos discriminant validity, HTMT and Fornell & Larcker method are employed. Data were processed using RStudio 4.2.1.

##### Results and discussion

#### 4.1. Descriptive statistics

Through 1068 accesses to the questionnaire, 631 attempts were completed, yielding a response rate of 59.08%. After accounting for outliers, the official sample had 512 responses, amounting to an effective response rate of 81.14%.

**Table 1: Descriptive statistics**

Demographic		Number	Frequency
Gender	Male	234	45.70
	Female	278	54.30
Education level	Primary education	18	3,52
	Secondary education	318	62,11
	Tertiary education	150	29,30

	Post-graduate	26	5,08
Marital status	Single	458	89,45
	Married	54	10,55
Employment status	Do not work	135	26,37
	Work part-time	238	46,48
	Work full-time	139	27,15
Income per month	Below 1 million VND	58	11,33
	1 million to 5 million VND	254	49,61
	5 million to 10 million VND	117	22,85
	More than 10 million VND	83	16,21

## 4.2. SEM results

### 4.2.1. Confirmatory factor analysis results

Confirmatory factor analysis was performed on the sample collected using structural equation modeling (weighted least square mean and variance adjusted estimator) in *lavaan* package from R4.2.1. We assessed the fitness of a second-order reflective model with the first-order reflective model consisting of 4 latent constructs and their respective indicators.

**Table 2: Validity assessment results**

	1.	2.	3.	4.
<b>1. Financial Attitude</b>	0.53 <u>0.82</u>			
<b>2. Financial behavior</b>	0.34 (0.43)	0.50 <u>0.81</u>		
<b>3. Financial knowledge</b>	0.20 (0.20)	0.19 (0.21)	0.51 <u>0.88</u>	
<b>4. Financial skill</b>	0.22 (0.34)	0.18 (0.45)	0.42 (0.53)	0.54 <u>0.86</u>

Note: values in bold are average variance extracted; values underlined are composite reliability; values in brackets are HTMT index; values with no special formatting are squared correlations between latent variables.

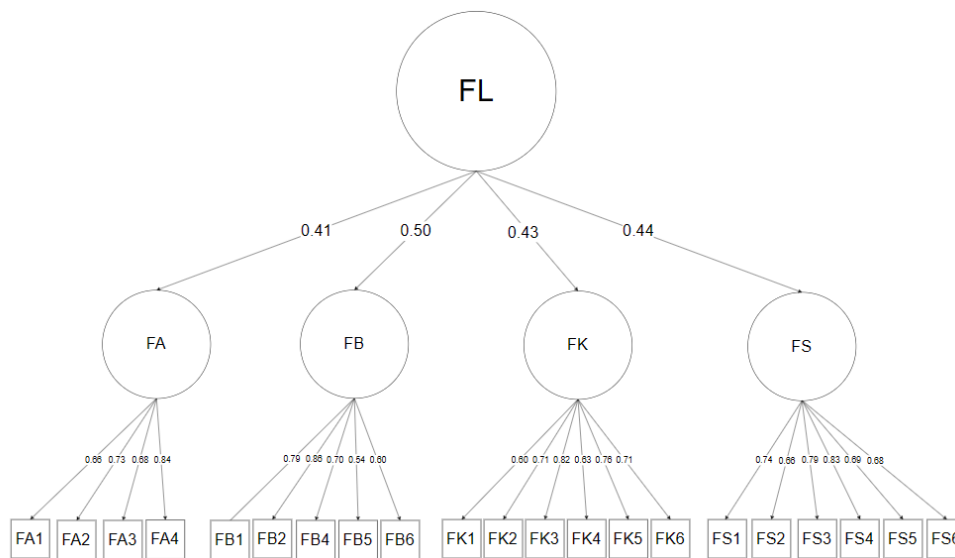

Source: Data processed

The table results show that the HTMT indices between the indicators are all below the threshold of 0.85 ensuring the distinction between the indicators (Henseler et al., 2015). According to the Fornell-Larcker method, AVE of all latent variables is greater than the squared correlation coefficient of that latent variable with the remaining latent variables. Hence, the correlation of each variable with itself is greater than that of other latent variables, ensuring discriminant validity to perform the next analysis steps. Convergent validity was evidenced by average variance extracted  $>.50$  and composite reliability  $>.70$  (Garver and Mentzer, 1999; Hair et al., 2009) for all constructs. All items exhibited a significant loading on their designated observed indicators, with the standardized loadings ranging from 0.50 to 0.89 - qualified for further analysis (Truong and McColl, 2011; Hulland, 1999). There is also evidence of a good model fit with  $\text{Chisq/df} = 1.93 < 2$ ;  $\text{CFI} = 0.992$ ,  $\text{TLI} = 0.992$ ,  $\text{GFI} = 0.995$ ,  $\text{RNI} = 0.992$ ,  $\text{IFI} = 0.993$ ,  $\text{AGFI} = 0.993$ , all have satisfied the condition that greater than 0.95;  $\text{RMSEA} = 0.048 < 0.08$ ;  $\text{PNFI} = 0.71 > 0.5$ . Thresholds follow those proposed by Hair et al. (2009); Schumacker and Lomax, (2004, 2010).

Since the criteria of validity have been met, this research concluded the measurement model is fully compliant with the requirements.

#### 4.2.2. Path analysis results

Figure 1: SEM model

Source: Data processed

##### a. Financial literacy is reflected by financial attitude.

The results from the model show that the correlation coefficient of financial literacy with financial attitude is 0.41 with  $p$ -value = 0.000. This means that financial literacy is positively reflected by financial attitude. This is also the conclusion of Potrich et al. (2014, 2016), Shahryar and Tan (2014), Rai et al. (2019), Priyaharshini (2017), OECD (2022). When consumers feel less financially constrained, they tend to perceive themselves as having an enhanced financial position (Sharma and Keller, 2017), thus modifying their financial behaviors accordingly. In other words, the more accurately a subject assesses the fluctuations within the economy, the more positive his ability to understand and invest in savings is. Therefore, improving financial attitude can boost the level of financial literacy (Vohs and Baumeister, 2011). Moreover, to improve the overall level of financial literacy economy-wide, policymakers need to commence with improving the way people see money and financial topics (Bhusan and Medury, 2013).

##### b. Financial literacy is reflected by financial behavior.

The results from the model show that the correlation coefficient of financial literacy with financial behavior is 0.50 with a  $p$ -value = 0.004. This means that financial literacy is positively reflected through financial behavior. This is also the result of Lusardi and Mitchell (2007, 2011), Ozdemir et al. (2021). Financial behavior is a collection of human financial behaviors related to financial decisions and cash flow management. The better the financial behavior, the higher the financial literacy level. Financial behavior is reflected in activities undertaken or avoided by the individual that can either manifest as positive or negative. Atkinson and Messy (2012) remarked that how a person behaves will have a significant effect on their financial well-being. Positive financial behavior is also often associated with long-term thinking, coupled with a significant level of understanding of economic topics. Accordingly, positive financial behaviors of individuals enhance their financial literacy and their level of financial satisfaction (Staten and Johnson, 2010), whereas negative financial behaviors like largely depending upon credits and loans to pay for daily expenses weaken their financial well-being.

##### c. Financial literacy is reflected by financial knowledge.

The results from the model show that the correlation coefficient of financial literacy with financial knowledge is 0.43 with a  $p$ -value = 0.000. This means that financial literacy is positively reflected through financial

knowledge. This result is similar to the previous conclusions of Hung et al. (2009), Rai et al. (2019), Potrich et al. (2014, 2015, 2016), and Khuc The Anh (2020). Thus, for Vietnamese young adults, financial knowledge is one of the factors reflecting financial literacy, or high financial literacy is expressed through correspondingly high financial knowledge. When someone is knowledgeable about financial matters, their ability to invest and save is better and consistent with their purposes. (Khuc The Anh, 2022). Kempson (2009), upon studying financial capability and its components, concluded that financial knowledge serves as the basis for the ability to effectively handle everyday financial issues and to make sound decisions accordingly. The acquisition of such financial knowledge is present in several manners: either directly from experience, education, and training, or indirectly via passive instillation of family, friends, media, and surrounding financial information.

**d. Financial literacy is reflected by financial skill.**

The results from the model show that the correlation coefficient of financial literacy for financial skill is 0.44 with a p-value = 0.001. This means that financial literacy is positively reflected by financial skill. The importance of financial skills is evidenced by the positive or negative consequences that an individual might experience, given their level of financial skills (Smit, 2021). A good set of financial skills enable individuals to make informed decisions about their money and minimize their chances of being misled when faced with financial matters. (Priyadharshini, 2017). Personal financial problems can be caused by a lack of basic financial skill in preparing a budget and an inability to understand credit and investment instruments or other financial products. The lack of financial literacy of individuals is one of the reasons leading to financial crises (Lusardi and Mitchell, 2011). Financial skill can be improved through a variety of approaches, including education, training, and mentoring. Improvements in financial skill can also be made by raising basic financial skill, such as preparing budgets and gathering financial information (Lusardi and Mitchell, 2011).

**Table 3: Hypotheses conclusions**

Hypothesis	Relationship	Path coefficient	p-value	Conclusion
H1	FL → FA	0.41	0.000	Accepted
H2	FL → FB	0.50	0.004	Accepted
H3	FL → FK	0.43	0.000	Accepted
H4	FL → FS	0.44	0.001	Accepted

*Source: Data processed*

Thus, from the four results above, this research concludes that financial literacy is reflected by four components including financial attitude, financial behavior, financial knowledge, and financial skill, or hypotheses from H1 to H4 are accepted. In particular, the relationship between financial literacy and financial behavior is the strongest, followed by financial skill and financial knowledge, and lastly financial attitude.

**Conclusion and policy implications**

In conclusion, by synthesizing definitions from extant domestic and foreign research, this study has drawn a composite definition for the concept of financial literacy - a combination of financial knowledge, financial skill, financial attitudes, and financial behavior- enabling people to make sound decisions and strive for financial satisfaction. This approach is a theoretical complement to future studies on the topic of financial literacy, an extension of the two current major traditional approaches which only take into account financial knowledge or include three components, namely financial knowledge, financial attitude, and financial behavior. In practical terms, based on the results from the quantitative model, the study has confirmed the simultaneous reflectiveness of the four components, in which financial behavior and financial skill, respectively, have the greatest impact on financial literacy, followed by financial knowledge and lastly financial attitudes.

From these results, the authors propose some policy implications with an aim to improve financial literacy for Vietnamese youth, with a focus on financial education at both governmental and local levels.

*First*, the central government needs to account for the education and enhancement of financial literacy of Vietnamese youth in the long run. At the same time, it should be made crystal clear that the purpose of improving financial knowledge and skills for young people is to facilitate a positive attitude change towards finance, hence enabling them to make sound decisions and positive financial management behaviors based on this knowledge.

*Second*, there should be training classes for lecturers - the leading force in imparting financial literacy to young people - with quality, in-depth understanding of financial literacy and its significance for young people and the Vietnamese economy in general.

*Third*, there should be seminars and talk shows to share, orient, and nurture positive financial behaviors for young people such as budget planning, paying bills on time, and avoiding bad credit and other debts.

*Fourth*, local authorities need to develop mobilizing programs imparting a positive financial attitude for young people in the local and promote information and communication on financial literacy and the role of youth in finance.

## A RESEARCH ON THE IMPACT OF FINANCIAL INDICATORS ON EARNINGS MANAGEMENT – EMPIRICAL EVIDENCE IN LISTED FIRMS ON THE STOCK MARKET IN VIETNAM

**Author: Le Thanh Ngan<sup>1</sup>, Dinh Thanh Bao<sup>2</sup>, Phung Thi Hong Nhung<sup>2</sup>,  
Tran Thi Thuy Vy<sup>2</sup>, Nguyen Thi Kim Long<sup>2</sup>  
Mentor: Nguyen Thi Thu Nguyet<sup>3</sup>**

**ABSTRACT:** *In the context that Vietnam's stock market is volatile as it is now, investors need to develop a careful and thorough strategy. Many factors affect the investment portfolio decision, one of which is the profit target on the business's income statement. It may also be what motivates managers to implement "Earnings management" to attract investors to participate. To learn and evaluate more about the factors affecting "Earnings management", the research team carried out the topic "Research on the impact of financial indicators on earnings management - Empirical evidence" in companies listed on the Vietnamese stock market. By quantitative research method, the research team collects secondary data from 173 companies listed on the Vietnam stock market in the period from 2017 to 2021. From the theoretical basis and previous studies, the group has included six indicators in the model of financial indicators affecting "Earnings management". Among them, the team found that there are two indicators that previous studies have not paid attention to, namely, "Dividend Payment Ratio" and "Sustainable Growth Rate". The obtained results show that there are two variables that have a positive impact on "Earnings management", that is: "financial leverage and return on equity". While other variables such as: "return on assets, company size, sustainable growth rate and dividend payout ratio" do not affect earnings management. Based on the obtained results, the research team makes recommendations to state agencies, listed companies and investors to identify and control Earnings management by looking at abnormal fluctuations in financial indicators.*

**Key words:** *Earnings management, financial indicators, listed firms, Viet Nam*

### 1. INTRODUCTION

Profit is considered one of the most important and concerned factors by many stakeholders, and reflects the financial performance and growth prospects of an entity. It can be seen that profit is both a goal and a driving force to promote effective development of enterprises. Therefore, enterprises in general and listed companies in particular have/ can perform the act of adjusting financial activities in important periods to serve management. This leads to users of information misinterpreting the actual financial situation of the business, affecting the decisions of many parties.

There are many definitions of Earnings management given by researchers around the world. Each researcher has a different view of Earnings management, but all lead to the same end result in the financial information provided to the outside of the enterprise being changed by the management methods. According to Schipper (1989): "Earnings management is the adjustment of profits to achieve a previously set goal of the manager"; it is "a deliberate intervention in the process of providing information. finance to achieve personal goals". According to Akers et al. (2007): "Earnings management as managers' efforts to influence or "manipulate" the income statement using a special accounting method, which recognizes non-recurring items, delay or expedite the recognition of revenue or expense transactions, or use other methods designed to affect short-term income." According to Beneish (2001) and Jiraporn et al. (2008), Earnings management aims at the interests of stakeholders by enhancing the value of the information provided to the outside.

<sup>1</sup> UEH University, Email: nganle.31201020598@st.ueh.edu.vn

<sup>2</sup> UEH University.

<sup>3</sup> UEH University, Email: thunguyet4497@ueh.edu.vn

There have been many domestic and foreign researches on the factors affecting the behavior of earnings management.. In the world, there are studies like that of Priharto & Rahayu (2019) with the topic “Determinants of Earnings Management and Its Implication on the Integrity of the Financial Statement” and the results calculated by the author are that financial leverage has a strong and positive impact on financial management, whereas audit size and quality have a negative impact on earnings management. Sadeghi & Zareie (2015) study on “Relationship Between Earnings Management and Financial Ratios At The Family Firms Listed In The Tehran Stock Exchange” and the research results give: “general ratio, quick ratio, receivables turnover, working capital, working capital to goods ratio, inventory turnover, return on capital ownership, return on sales, return on invested capital, return on assets, debt ratio and debt settlement ratio” have a positive impact on earnings management, conversely ratio of debt to equity and debt to assets” has a negative impact on earnings management, while “interest coverage ratio” has no impact on earnings management.

The question is whether some famous income manipulation identification models in the world are suitable for Vietnam. According to Pham (2012), the Modified Jones adjust model test to identify and detect the income management behaviors of enterprises listed on the Ho Chi Minh Stock Exchange (HOSE) because of the measurement coefficient of R2 is 3.8%. Meanwhile, R2 is 1.6% (Nguyen and Pham, 2015), R2 is 46.3% (Dechow et al., 1995), R2 is 89.6% (Kothari et al., 2005). In Vietnam, many related studies have also been carried out such as those of Tran Thi Thuy Kieu (2021), Le Thi Phuong Trinh (2019), Tran Thi Kim Ngan (2019), Nguyen Thi Thanh Ha (2017), ... with different sample size, scope and earnings management measurement model gave different results.

The research team found that there are no empirical studies in Vietnam testing the variables “Dividend payout ratio” and “Sustainable growth rate” affecting the behavior of earnings management. Meanwhile, these are also two important variables to evaluate the capacity of enterprises.

Based on the above bases, the research team will determine the influencing financial ratios and consider the level of impact on the earnings management in Vietnam with empirical evidence in 173 companies listed on Vietnam’s stock market including HOSE, HNX and Upcom (except for banks, insurance companies, and financial institutions due to different accounting regulations) in the period 2017-2021. Through this study, users of the Financial Statements of listed companies have a better overview in making economic decisions. Also through the findings, several recommendations are made to reduce earnings manipulations and improve financial data in the financial statements of listed companies.

The topic’s specific objectives are as follows:

- Determine the influencing factors & measure the impact of financial ratios on earnings management.
- Provide empirical evidence from companies listed on the Vietnamese stock market.
- Contributing and further improving the earnings management research database in Vietnam.
- From there, propose solutions to limit the behavior of earnings management in the process of managing Vietnamese enterprises that adversely affect the stock market as well as support appropriate decision making for stakeholders such as countries, investors, listed companies, audit firms.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Earnings management classification**

#### **2.1.1. Classification of Earnings management**

Previous studies have shown that earnings management behavior is often implemented by managers through the following two ways: one is to choose accounting policies, and the other is to govern rising economic transactions.

### **2.1.1.1. Earnings management through a selection of accounting policies**

Corporate managers can practice earnings management through the selection of accounting policies in some items to benefit themselves and lead to the quality of the information presented on The financial statements will be reduced.

Some researches have indicated that: Moyer's study (1990) examined the correlation between the choice of accounting policy and the capital adequacy ratio at banks. Research by McNichols & Wilson (1988) investigates the profitability management of managers by taking advantage of General Accepted Accounting Principles (GAAP). Keating & Zimmerman's (1990) study on "change of depreciation policy with tax and promotion of investment opportunities".

### **2.1.1.2. Earnings management through dominating rising economic transactions**

The researches of Roychowdhury (2006), Cohen et al. (2010) and Zang (2011) are the leading studies on earnings management through adjusting the "policies that govern discounts, activities, etc. sold on credit, costs incurred by the company". The results show that managers implement one or more of the above ways to implement earnings management. The administrator can apply for a special discount program or relax the terms of the credit policy to increase revenue if the set revenue target has not been achieved near the end of the accounting period. These acts are through arising economic transactions to make profit adjustments because the ultimate purpose of these acts is to govern cash flows resulting in revenue and related expenses being adjusted according to expectations.

## **2.2. Some Earnings management techniques**

### **2.2.1. Earnings management through an accrual basis**

#### **2.2.1.1 "Cookie jar reserve" technique**

Cookie Jar accounting is a method used by unethical company managers to influence financial statements (Keiso, 2012). The company will create a "Cookie Jar" (cake jar) for the purpose of "saving" profit. The "Cookie Jar" is made up of provisions, pre-recognition of expenses, and deferred revenue recognition.

"Cookie Jar" usually takes the form of a cumulative liability account. "Cookies" credited to the account the actual liability is not owed to anyone. For example, when estimating warranty liability, a manager may report \$110 when only \$100 is claimed. An additional \$10 reduces current earnings but gives managers the opportunity to increase reported earnings in future periods by reducing their estimate of a virtual liability.

#### **2.2.1.2 The "take big bath" technique**

Big bath is an accounting term defined by a company's management team that intentionally manipulates its income statements to make poor results even worse in order to make future results look better. It's often done in a relatively bad year so that a company can artificially raise the next year's earnings. Recording as many expenses as possible during the period during which the transfer takes place will show better operating results in the coming years (Jones, 2011).

#### **2.2.1.3 The technique of "Big Bet on The Future"**

"Big bet on the future" - this is a strategy of betting on the future through mergers, acquisitions, and acquisitions. All expected future returns are wagered at present. Therefore, in the future, if the actual profit is higher, the company will continue to make a profit, otherwise it will suffer a loss.

The company "bets on the future" through the application of loopholes in the provisions of accounting standards to record all future profits in the current year.

#### **2.2.1.4. Remove the array of inefficient operations (“Throw out” a problem child)**

This technique involves the manager’s judgment to remove a subsidiary when the group’s earnings are dragged down by the underperforming or inefficient subsidiary for the purpose of saving or improving financial and revenue results, include: the complete liquidation of a subsidiary, severing a subsidiary or creating a special purpose entity (SPE) to exchange financial assets and equity. During this process, earnings can be changed in various ways, such as by selling a subsidiary, or transferring or exchanging shares.

As a result, tax-adjusted net profit or loss is reported in the current financial statements, and thus the company distributes earnings to shareholders who are perpetual investors (Burgstahler & Eames, 2006).

#### **2.2.1.5 Applying new accounting regulations (Introducing new standards)**

Accounting standards enhance the transparency of financial reporting in all countries. New laws and regulations are enacted as a result of business changes. The principles can be adjusted without the profit being changed. When each new accounting standard is issued, it takes a long period of two to three years for every converting business to adopt that standard. The early voluntary adoption of new accounting standards can be an opportunity for earnings management.

Example of changing the depreciation method from the discounted balance to the straight-line method.

#### **2.2.1.6 Write off of long time operating Assets**

This involves management’s discretion in selecting write-off methods and periods, changing the method of estimating the salvage value or changing the asset type or usage.

Recorded expenses for long-term assets used during the period are recognized through amortization and depreciation. For example, the administrator can optionally prescribe the method of reducing assets: write down by term, according to the estimated residual value.

### **2.2.2 Earnings management through rising economic operations**

L. Sun & Rath (2010) claim that managers can use earnings management to move profits to an earlier or later accounting period through actual transactions. By arranging actual current-year transactions, a firm can also influence its revenues, even though those transactions might not ultimately be advantageous to the business.

Driving sales with pricing and credit policies. Businesses may drop their selling prices, relax their credit policies, issue invoices in advance to record revenue, or enter into “returnable sales” contracts in an effort to boost sales. The second strategy is to make public a plan to raise selling prices at the start of the following year. For instance, an automaker announced plans to raise selling prices beginning in the first quarter of 2013 in order to quickly turn a profit in the fourth quarter of 2012. This trick allows the company to increase profits this year but may decrease them over the next few years and the increase in selling price next year will also reduce the company’s competitiveness in the market.

Cutting useful costs such as research and development (R&D), advertising costs and equipment maintenance costs can be a way to increase profits but are also critical to the long-term growth of the business, so this solution can be a sacrifice of potential future profits.

Selling productive investments: the company can sell profitable investments to increase profits for the current year. Therefore, applying the above method means that the company voluntarily forgoes the potential for large returns from these investments in the following years.

### **2.3. Motivation for Earnings management**

According to Watts and Zimmerman (1990), the motivation of earnings management may stem from the need to raise capital (beautify financial statements to attract investors), the board of directors wants to increase salaries, bonuses or promotions. Because of good business results, or possibly because of the political cost hypothesis, businesses practice earnings management in order to avoid government intervention or enjoy tax incentives. According to Burgstahler and Eames (2006), earnings management

behavior increases when it meets the expectations of analysts and forecasters in management. Bergstresser and Philippon (2006) show that managers tend to manage earnings in an upward direction when they have stock options to increase their personal wealth.

It can be seen that the main motivations for earnings management behavior include: benefits based on contracts based on profit data on financial statements, owner's expectations and capital markets, government tax and legal regulations.

## **2.4. Foundational theories for earnings management**

### **2.4.1. The signal theory**

Signaling theory was originally developed to clarify information asymmetries in the labour market; the theory that the existence of information asymmetry can also be considered as a reason for good companies to use financial information to send signals to the market.

Information released by managers to the market reduces information asymmetry and is considered a good sign. Managers engage in earnings management to create a smooth and growing earnings stream over time that will allow them to influence stock prices. In summary, when information asymmetry exists, signal theory offers an equilibrium.

A number of studies have investigated the signaling effect on reported earnings and concluded that performance measures, namely: profitability, firm size and liquidity, drive managers involved in earnings management from "Watson A. Shrivess P. Marston C. Voluntary disclosure of accounting ratios in the UK. Signaling theory suggests that when a company's performance is good, managers will signal the company's performance to investors, stakeholders and the market by making public statements which inferior companies cannot. By increasing disclosure, directors expect to get more benefits: better reputation and increased value of the company. In contrast, companies with poor performance may choose to remain silent rather than disclose unsatisfactory performance.

### **2.4.2 The agency theory**

Agency theory, also known as authorization theory, finds differences in interests and unbalanced information structures between employers and employees when considering the relationship between these two objects. The interests of the owner (shareholder) can be harmed by the actions of the representative (manager) when the representative takes actions for the purpose of maximizing his or her personal interests.

Earnings management occurs when managers and executives of a company try to perform acts with the purpose of changing or affecting the output of financial statements by manipulating non-cash payments or choose suitable accounting policies to change accounting profits in their favor (Healey, 1985; Holtahaisen, Larcher & Sloan, 1995).

In the relationship between managers and shareholders, information imbalance often occurs to the disadvantage of shareholders. The managers can make decisions to maximize personal benefits instead of maximizing corporate value.

In the relationship between shareholders and creditors, the information imbalance takes place to the disadvantage of the creditor. Managers can adopt different accounting policies to implement Earnings management and increase the market value of the business to receive favourable terms in their debt contracts.

## **3. RESEARCH METHODS**

### **3.1. Proposed research and research hypotheses**

The authors choose a research model based on the results obtained from domestic and foreign studies and present the background theory to explain Earnings management. The authors consider the following relationships:

- **Financial leverage ratio (donbay):** research by Jelinek (2007) and Wasimullah et al., (2010), Safe Lazzem et al. (2017) expect a relationship between financial leverage use and governance earnings on an accrual basis. Accordingly, the authors hypothesize that the more leveraged firms use, the higher the level of earnings adjustment (**hypothesis H1**).

- **Return on total assets (ROA):** studies by (Sadeghi & Zareie, 2015), (Tran Thi Kim Ngan, 2019), (Ngo Hoang Diep, 2019) show a positive ratio between ROA and Earnings management. However (Gill et al., 2013), Kothari et al. (2005) showed an inverse ratio. Considering the agency theory and the signal theory, the authors hypothesize that there is an inverse relationship between the ROA variable and the level of earnings management (**hypothesis H2**).

- **Size:** The larger the company, the more profitable it is expected to be. Therefore, companies promote earnings management to achieve the desired level of profit. Research by (Le Thi Phuong Trinh, 2019), (Nguyen Dinh Huy, 2017) and (Phan Thi Thanh Trang, 2015) show that company size and Earnings management have a positive relationship. The authors hypothesize that the larger the firm size, the higher the level of earnings management (**hypothesis H3**).

- **Sustainable growth rate (benvung):** represents the maximum growth rate with current resources or sales that the business can achieve without increasing equity or increasing debt ratio. Achieving a “sustainable growth rate” is the goal of enterprises, from which businesses tend to “manage profits”. Therefore, the authors hypothesize that the larger the company’s “sustainable growth rate”, the higher the level of earnings management (**hypothesis H4**).

- **Return on equity(ROE):** the higher the ROE ratio, the better, showing how effectively the company has used its capital and how profitable it is. Therefore, businesses can implement Earnings management to achieve the desired ROE. Research by Sadeghi & Zareie (2015) also shows that the results between “Return on equity” and Earnings management have a positive impact on each other. The authors hypothesize “Return on equity” is higher the level of earnings management (**hypothesis H5**).

- **Dividend payout ratio (cotuc):** this is one of the factors that help attract investors, so this can motivate businesses to implement Earnings management. The authors hypothesize that the higher the dividend payout ratio, the higher the level of earnings management (**hypothesis H6**).

**Table 3.1 Proposed Research Hypotheses**

Hypothesis	Content	Expected
H1	The more “financial leverage” a company uses, the higher its ability to manage earnings.	+
H2	The higher the “return on total assets”, the lower the ability to manage earnings	-
H3	The larger the “company size”, the higher the ability to manage earnings.	+
H4	The higher the “sustainable growth rate”, the higher the ability to manage earnings	+
H5	The higher the “return on equity”, the better the ability to manage earnings	+
H6	The higher the “dividend payout ratio”, the better the ability to manage earnings	+

### 3.2. Measurement of variables in the research model

#### 3.2.1. Measure the dependent variable

To measure the level of accrual-based earnings management, the research team used the technique of the adjusted Jones model of P. M. Dechow et al. (1995), used in many studies and evaluated as appropriate in Vietnam. Nam and used in research papers by Nguyen Thi Thu Nguyet 2022, Nguyen Thi Kim Cuc and Pham Thi My Linh 2018, Trinh Hiep Thien and Nguyen Xuan Hung 2016...

According to the model of P. M. Dechow et al. (1995), the research team calculates the total accrual (TAit) of each enterprise according to the formula:

$$TAit = (\Delta CAit - \Delta CASHit) - (\Delta CLit - \Delta RLTPit) - DEPit$$

Then, the authors used SPSS to run the data by industry and determine the octal accrual (DA) as the remainder of the equation:

$$\frac{TAit}{Ait-1} = \alpha \frac{1}{Ait-1} + \beta1 \frac{\Delta REVit - \Delta ARit}{Ait-1} + \beta2 \frac{PELit}{Ait-1} + \beta3 \frac{ROAit}{Ait-1} + \epsilon t$$

In there:

- ΔCAit: Volatility of short-term assets in year t
- ΔCASHit: Movement of money in year t
- ΔCLit: Volatility of short-term debt year t
- ΔRLTPit: Short-term loan volatility
- DEPit: Depreciation and allocation
- Ait-1: Book value of the company’s total assets at year t-1
- ΔREVit: Change in revenue between year t and t-1
- ΔAR: Change in receivables between year t and t-1
- PPEit: Value of tangible fixed assets at year t
- εt: Represents abnormal accruals DA ROA: DA
- ROA: after-tax return on total assets

**3.2.1. Measure the independent variable**

**Table 3.2 Measurement of independent variables**

Numerical order	Variable name	Variable symbol	Measurement formula
1	Financial leverage ratio	donbay	donbay = Liabilities year t/equity year t
2	Return on total assets	ROA	ROA = Profit in year t/total assets in year t
3	Company size	size	size = log(total assets)
4	Sustainable growth rate	benvung	benvung = ROE * (1- Dividend payout ratio)
5	Return on equity	ROE	ROE = Profit in year t / equity in year t
6	Dividend payout ratio	cotuc	cotuc = Dividends/profit after tax

(Source: group of authors)

**3.3. Research paper design**

**3.3.1. Research sample**

The study selects a sample by non-random sampling method; that is, companies listed on the stock market can get all the information they need to collect, except for companies in the finance, banking and insurance industries. Dangerous because companies have distinct characteristics. The data is taken from active and listed companies for the period 2017-2021.

**3.3.2. Data collection**

Data is collected from the company’s financial statements: <https://cafef.vn/> and <https://www.cophieu68.vn/>

### 3.3.3. Data analysis:

Through SPSS and Excel software, the research team uses the following analytical techniques to process data to test the impact of financial indicators on Earnings management.

#### 3.3.3.1. Descriptive statistics:

Briefly describe the basic characteristics and related properties of data through ratios such as mean (means), maximum and minimum values (max, min), and standard deviation (std), ...

#### 3.3.3.2. Correlation analysis

Pearson correlation analysis to test the linear correlation between dependent and independent variables and detect multicollinearity problems when independent variables are strongly correlated with each other. The closer the correlation coefficient is to 1 or -1, the stronger the correlation between the two variables, and the closer it gets to 0, the weaker the correlation between the two variables.

#### 3.3.3.3. Multivariate regression analysis

##### **Perform OLS analysis, then test the model's defects through the following assumptions:**

##### *(1) Assuming that the variance of the error is constant:*

When performing multivariable linear regression, the assumption is to assume that the variance of the error does not change. If variance occurs, the results of the regression equation will be inaccurate and reduce the quality of the linear regression model.

To evaluate whether the regression model violates this assumption, the research team relies on the Scatter Plot plot between the normalized residuals and the normalized prediction value as in the assumption of a linear relationship. If the percentiles are fairly uniformly distributed above and below the zero axis, then as X increases or decreases, it is reasonable to assume that the variance of the error is constant.

##### *(2) Assumptions about the model's normal distribution*

The distributive property of residuals is a sufficient condition to determine the significance level of P-value in statistical tests: T-test, F-test. There are two methods used to test the assumption about the normal distribution of the residuals: the graph method and the arithmetic test method. The research team used the method to test the assumption of the normal distribution of the residuals.

##### *(3) Assume no correlation between residuals*

The research team used Durbin - Watson test to check the autocorrelation problem. Durbin Watson test (Durbin Watson test) is a statistical test performed to find the correlation between residuals or errors after estimating the regression test equation from the observation results about independent and dependent variables. To simplify, the research team used the empirical Durbin-Watson test rule.

- If  $1 < d < 3$ , the model has no autocorrelation.
- If  $0 < d < 1$ , the model has positive autocorrelation.
- If  $3 < d < 4$ , the model has negative autocorrelation.

##### *(4) Assume there is no correlation between the variables (no multicollinearity)*

“Linear correlation between two variables is a correlation where when representing the observed values of two variables on the Oxy plane, the data points tend to form a straight line.” According to Gayen (1951), “in statistics, researchers use the Pearson correlation coefficient (symbol r) to quantify the closeness of the linear relationship between two quantitative variables. If either or both variables are not quantitative variables (qualitative variables, binary variables, etc.), we will not perform Pearson correlation analysis for these variables.” The Pearson correlation coefficient r ranges from -1 to 1:

- “If r gets closer to 1, -1: the stronger the linear correlation, the closer it is. Moving towards 1 is a positive correlation, and moving to -1 is a negative correlation.
- If r gets closer to 0, the linear correlation is weaker.
- If r = 1: absolute linear correlation, when represented on a scatter plot, the points represented will merge into a straight line.
- If r = 0: there is no linear correlation. At this point, there will be two situations. One, there is no relationship between the two variables. Second, there is a nonlinear relationship between them.

If the model encounters violations according to the above assumptions, the OLS regression model is not suitable.

### 3.4. Research Process

Step 1: This study explores and synthesizes foreign and domestic research related to the topic “the impact of financial indicators on Earnings management”. Define the scope, audience and objectives of the research paper.

Step 2: Overview of theoretical bases and background theories related to the concept, classification, techniques and motives of Earnings management, theories related to financial indicators and their impact on Earnings management profit.

Step 3: Determine the research model and the scale for the research variables based on the results of the two steps above.

Step 4: Collect data from companies listed on the Vietnam stock market through 2 websites: <https://cafef.vn> and <https://www.cophieu68.vn>. Perform statistics to test the model and research hypotheses.

Step 5: Analyze the statistical results, draw conclusions and make recommendations to stakeholders in determining, evaluating and controlling the management’s profit on the financial statements

## 4. RESULTS AND DISCUSSION

### 4.1. Research results

#### 4.1.1. Descriptive statistical analysis results

**Table 4.1 Descriptive statistics of independent variables**

		Statistics						
		ROE	ROA	don bay	cotuc	benvung	size	DA
N	Valid	866	866	866	866	947	866	865
	Missing	179	179	179	179	98	179	180
Mean		,0938	,0592	1,305	-,07077	,0782	9,5335	,0000
Std. Deviation		,3788	,1456	1,533	4,6389	,3778	3,1007	,5925
Minimum		-8,661	-1,779	,003	-88,941	-8,661	4,200	-7,3249
Maximum		3,081	2,959	17,820	42,605	3,371	13,491	6,4681

The average level of Earnings management is 0, the highest is 6,468, and the lowest is -7.325. The average ROE is 0.094, the highest is 3.081, and the lowest is -8.661. The average ROA is 0.059, the highest is 2.959, and the lowest is -1.779. The average L/E leverage is 1.305, the highest is 17.82, and the lowest is 0.003. The average dividend payout ratio is -0.071, the highest is 42,695, and the lowest is -88,941. The average sustainable development rate is 0.078, the highest is 3,371, and the lowest is -8.661. The average company size is 9,533, the highest is 13,491, and the lowest is 4.2.

## 4.1.2. Correlation analysis results

Table 4.2 Correlation matrix between variables

	Sig. (2-tailed)	,096	,148	,182	,361	,191	,068	
	N	865	865	865	865	865	865	865

\*\* . Correlation is significant at the 0.01 level (2-tailed).  
\* . Correlation is significant at the 0.05 level (2-tailed).

The research team considers the correlation between the variables to serve as a basis for regression analysis and to identify and eliminate variables where multicollinearity occurs.

The analysis results show that the Pearson correlation coefficient between the variables is relatively low (less than 0.6), so multicollinearity is very unlikely.

## 4.1.3. Results of regression analysis

## 4.1.3.1. Table ANOVA

Table 4.3 Results of ANOVA. analysis

		ANOVA <sup>a</sup>				
Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	2,525	2	1,262	3,617	,027 <sup>b</sup>
	Residual	300,861	862	,349		
	Total	303,386	864			

a. Dependent Variable: DA
b. Predictors: (Constant), donbay, ROE

In order to assess the fit of the regression model, the research team used the F test to test the hypothesis  $H_0: R^2 = 0$ . The results show that

$Sig = 0.027 < 0.05$ : Reject hypothesis  $H_0$ ; that is,  $R^2 \neq 0$  statistically significant, and the regression model is suitable.

4.1.3.2. Table Model Summary

**Table 4.4 Model Summary Analysis Results**

Model Summary <sup>b</sup>					
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Durbin- Watson
1	,091 <sup>a</sup>	,008	,006	,59078514	1,895
a. Predictors: (Constant), donbay, ROE					
b. Dependent Variable: DA					

The measure of the fit of the linear regression model commonly used is the coefficient of determination  $R^2$  (R square). When most of the data points are concentrated close to the regression line, the  $R^2$  value will be high; if the data points are scattered far away from the regression line,  $R^2$  will be low.

The results from the Model Summary Table show R Square and Adjusted R Square to assess model fit. Adjusted R Square = 0.006 shows that the independent variables selected for regression analysis affect 0.6% of the variation of the dependent variable, the remaining 99.4% due to out-of-model variables and random error.

Durbin-Waston d-test value:  $d=1.895$ . Since  $1 < d < 3$ , the model does not have autocorrelation.

4.1.3.3. Table Coefficients

**Table 4.5 Coefficients. analysis results**

Coefficients <sup>a</sup>								
Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		B	Std. Error	Beta			Tolerance	VIF
1	(Constant)	-,051	,029		- 1,766	,078		
	ROE	,133	,057	,085	2,332	,020	,862	1,160
	donbay	,030	,014	,077	2,110	,035	,862	1,160
a. Dependent Variable: DA								

The research team used the t-test (student) to evaluate whether the regression coefficients of the independent variables were significant in the model or not. Hypothesis  $H_0$ : The regression coefficient of the independent variable  $X_i$  is 0. Test results:

After removing the variables with Sig value  $> 0.05$  and running the model again, the remaining two variables ROE and donbay, had Sig  $< 0.05$  (SigROE = 0.02; Sigdonbay = 0.035), so the research team rejected the hypothesis. Theory  $H_0$ , that is, the regression coefficients of the ROE and donbay variables are statistically different from zero in the model, and the variables ROE and donbay affect the dependent variable.

Based on the regression coefficients in the table, the research team has built a standardized regression equation:

$$DA = 0,085 \times ROE + 0,077 \times donbay + \varepsilon$$

The regression results show that when ROE increases to 8.5%, Earnings management will increase to a new level (excluding the impact of financial leverage). When financial leverage L/E increases to 7.7%, Earnings management will increase to a new level (excluding the impact of ROE).

**4.1.3.4. Variance magnification factor VIF**

**Table 4.5 Coefficients . analysis results**

Coefficients <sup>a</sup>								
Model	B	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		Std. Error	Beta				VIF	
1	(Constant)	-,051	,029		-1,766	,078		
	ROE	,133	,057	,085	2,332	,020	,862	1,160
	donbay	,030	,014	,077	2,110	,035	,862	1,160

a. Dependent Variable: DA

“VIF is an index to evaluate the phenomenon of collinearity in the regression model. The smaller the VIF, the less likely there is to be multicollinearity. Conversely, when the VIF is large (greater than 10), the possibility of multicollinearity is very high.” (Pham Loc, 2022)

In the analysis results table, the VIF coefficients of the independent variables are all less than 2, so the data does not violate the multicollinearity assumption.

**4.1.3.5. Histogram. Normalized Residual Frequency Histogram**

**Figure 4.1 Histogram. Normalized Residual Frequency Histogram**

From the results of the graph, we see that Mean ≈ 0, standard deviation Std. Dev ≈ 1, the value columns of the residuals have a bell-shaped distribution, so the distribution is approximately normal, from

which the research team concludes that the assumption of the normal distribution of the residuals is not violated. In the model, Mean =  $-7,93E - 17 \approx 0$ , standard deviation is  $0,999 \approx 1$

**4.1.3.6. Biểu đồ Scatter Plot kiểm tra giả định liên hệ tuyến tính**

**Figure 4.2 Scatter Plot**

If the distribution data points are concentrated around the zero coordinate line and tend to form a straight line, although it is not clear because the mining data set is the resource index, it is mainly differentiated from 0 to 1. In this case, the research team accepts that the assumption of a linear relationship is not violated.

**4.2. Results of the discussion**

The results show that out of 6 independent variables included in the model, there are two variables that affect earnings management. Both ROE and donbay variables have a positive impact on earnings management.

Table 4.6 Summary of hypothesis testing results

Hypothesis	Content	Expected	Regression results
H1	The more “financial leverage” the company uses, the higher the level of earnings management.	+	+
H2	The higher the “return on total assets”, the lower the ability to manage profits	-	0
H3	The larger the “company size”, the higher the ability to manage profits.	+	0
H4	The higher the “sustainable growth rate”, the higher the ability to manage profits	+	0
H5	The higher the “return on equity” the better the ability to manage profits	+	+
H6	The higher the “dividend payout ratio”, the higher the ability to manage profits	+	0

The model test results support hypothesis H1 and H5, and no statistical relationship is found in hypotheses H2, H3, H4, H6.

With the results supporting the hypothesis H1 and H5, the experimental data model results show that in the period from 2017 to 2021:

- The higher the “financial leverage” (L/E), the higher the level of Earnings management.
- The higher the ROE, the higher the level of Earnings management.

Based on the signal theory, the research team makes a judgment on hypothesis H1 that the more leverage the company uses, the higher the level of earnings management. The research results show that the above statement is appropriate, and the test results are consistent with the research hypothesis. This result is also supported by previous studies of (Sadeghi & Zareie, 2015), (Tran Thi Thuy Kieu, 2021). This proves that in the period from 2017 to 2021, companies on the stock exchange in Vietnam tend to implement earnings management through the use of debt instruments (leverage index  $L/E$ ).

Based on the theory of signals and the theory of agency, the research team makes a statement about hypothesis H5 that the higher the return on equity, the higher the level of earnings management. The research results show that the above statement is appropriate, and the test results are consistent with the research hypothesis. This result is also supported by previous studies of (Sadeghi & Zareie, 2015), (Nguyen Thi Phuong Hong, 2016), (Nguyen Thi Thanh Ha, 2017). This proves that in the period from 2017 to 2021, companies on the stock exchange in Vietnam tend to implement Earnings management through the use of ROE.

## 5. CONCLUSION

The research results from the model show that from 6 independent variables selected: Return on capital (ROE), Return on total assets (ROA), Liabilities to equity (donbay), Payout ratio dividend (cotuc), sustainable growth rate (benvung), company size (size). There are two variables that have a positive impact on the level of earnings management: Return on capital (ROE) and Liabilities on equity (donbay).

The study has achieved the objective of identifying financial indicators that affect Earnings management and the extent of influence on Earnings management of companies on the Vietnam stock exchange. There are two variables that have a positive impact on the level of Earnings management: Return on capital (ROE) and Liabilities on equity (donbay).

Thus, compared with previous studies in Vietnam on the impact of financial indicators on earnings management, by expanding the observational data on HOSE from 2017 to 2021, the results showed that only The amount of leverage ( $L/E$ ) affects Earnings management

## THE FINANCIAL CONTAGION EFFECTS OF THE GLOBAL COVID-19 PANDEMIC: EVIDENCE FROM FINTECH AND TRADITIONAL FINANCIAL MARKETS

**Author: Luong Bao Thanh Khoa<sup>1</sup>, Vu Thang Thinh<sup>2</sup>, Vu Xuan Loc<sup>2</sup>**

**Mentor: Nguyen Khac Quoc Bao<sup>3</sup>**

**ABSTRACT:** *In this, we investigate the contagion effect of the global Covid-19 pandemic in terms of the shift in mean spillover, volatility spillover, and time-varying correlation between Asian emerging stock and Bitcoin, as well as between stock and altcoins. The tri-variate GARCH-BEKK models are estimated, which include Covid-19 related dummies corresponding to the Covid-19 arrival date, the panic index, the media hype index, and the sentiment index. The time-varying correlation obtained through the DCC-GARCH model between two markets is under investigation to examine the transmission mechanism of the contagion effect and the safe-haven properties of Bitcoin and altcoins during various contexts of the Covid-19 pandemic. Our results indicate that both Bitcoin and altcoin cannot serve as a safe haven against Asian emerging stock markets in most contexts of this rapidly escalating pandemic, as we find evidence of the presence of a contagion effect, both in terms of a shift in mean spillover, volatility spillover, and dynamic correlation, between Asian emerging stock markets and cryptocurrency markets since the appearance of the Covid-19 pandemic. Especially, this contagion effect becomes more obvious in the high panic period, the high media hype period, and the negative market sentiment period. Additionally, we also provide evidence in support of the investor-induced contagion hypo during various turmoil context of the Covid-19 pandemic. We find that the source of the contagion effect between the stock market and the cryptocurrency market is the wealth effect. Furthermore, there is heterogeneity among the bitcoin and altcoin markets in how the global Covid-19 pandemic affected their respective relationship with the Asian emerging stock market.*

**Keywords:** *Covid-19 pandemic, fintech, Bitcoin, altcoin, financial markets*

### 1. INTRODUCTION

In recent years, trade barriers and restrictions on international capital flow have been gradually removed. In addition, the scope and scale of information technology have expanded dramatically, thus encouraging the globalization of the traditional financial market, such as stocks, bonds, and foreign exchanges. This phenomenon has contributed to greater global financial integration and provided investors, corporations, and economies with a wide range of opportunities and strategic benefits. However, extraordinary financial integration is usually associated with an increasing volatility spillover and a financial contagion effect, thus increasing the vulnerability of the investor to systematic risk arising from domestic or global factors (Ahmed, 2021a), especially during crisis or uncertainty periods.

The financial technology (Fintech) and its integration with traditional financial market have attracted the interest of policy makers, researchers, financial institutions, and investors around the world. According to Chen et al. (2019), cybersecurity, mobile transactions, data analytics, blockchain, peer-to-peer (P2P), robo-advising and the internet of things (IoT) are the seven subcategories that can be used to categorize fintech. The dramatic surge of interest in FinTech over the past few years has highlighted the need for a better understanding of the implications of FinTech in various aspects of the financial system. Our

study contributes to the knowledge of blockchain-related aspects of fintech and contributes to the body of knowledge on asset diversification by taking into account the investment capabilities of cryptocurrencies, including Bitcoin and altcoins, and their connections to traditional markets.

The topic's specific objectives are as follows:

i. Examine the safe haven properties of cryptocurrencies against Asian emerging stock markets during various contexts of the Covid-19 pandemic.

ii. Examine the existence of the contagion effect between the cryptocurrency markets and the Asian emerging stock markets during various turmoil periods of the Covid-19 pandemic.

iii. Verify whether the contagion effect between the Asian emerging stock market and the cryptocurrency market sources from the wealth effect or portfolio rebalancing mechanism.

iv. Test whether there is a heterogeneity among the bitcoin and altcoin markets in how the global Covid-19 pandemic affected their respective relationship with the Asian emerging stock market.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Literature on the connectedness between Bitcoin, altcoins, and other financial markets**

Cryptocurrency assets appear to be a potentially attractive investment asset from the perspective of portfolio diversification due to their low connection with traditional financial assets, their capacity to store value, and their independence from monetary policy. (Colon et al., 2021; Shahzad et al., 2021), hence, cryptocurrencies can take the role of a hedge, safe haven, or diversifier in the investors' portfolio and can be included in the variety of tools available to investors to hedge some of the market-specific risk. There are two main streams of research on the interconnectedness between cryptocurrencies and other financial markets. The first stream of interest focuses on modelling the relationship between cryptocurrencies and other traditional financial assets such as bonds, stocks, foreign exchange, or commodities, etc., and attempt to analyze their correlation as well as the return spillover and volatility spillover aspect. The second stream of interest focuses on the potential shift in the linkage or transmission mechanism between cryptocurrencies and other traditional markets during turmoil periods and examines the question of whether the relationship between cryptocurrencies and other mainstream assets changes over time. These are useful factors that can help investors, portfolio managers, and financial institutions make decisions about portfolio allocation, risk management, and hedging strategies.

### **2.2. The Interdependence between Bitcoin, altcoins, and traditional financial markets**

Corbet et al. (2018) employed the generalized decomposition methodology to examine the spillover of return and volatility in three popular cryptocurrencies, namely Bitcoin, Ripple, and Litecoin, and a variety of other financial assets. The results indicated that these three cryptocurrencies are isolated from other traditional assets such as gold, stock, or bond indices, thus providing short- and long-term investors with opportunities for diversification. Guesmi et al. (2019) used the DCC-GARCH model to identify the conditional cross effect and volatility spillover between Bitcoin and other mainstream financial tools and indicate that Bitcoin offers a low correlation with financial assets. Giudici & Abu-Hashish (2019) reached a similar conclusion, which confirms that Bitcoin could offer diversification and hedging benefits for financial investors. Furthermore, using an ADCC model and a non-temporal test, Urquhart & Zhang (2019) demonstrated that Bitcoin can be used as an intraday hedge tool for the CHF, EUR and GBP, but also as a diversifier for the AUD, CAD, and JPY and as a safe haven for the CAD, CHF, and GBP. The diversification benefits of cryptocurrencies for traditional financial assets such as stock, bond, currency, oil, gold, etc.

can be explained by Ciaian et al. (2016) 's finding that long-term fluctuations in the price of bitcoin are unrelated to macroeconomic and financial developments on a global scale and are instead largely influenced by supply/demand dynamics in the bitcoin market, as well as characteristics unique to digital currencies, such as the currency's appeal to investors.

### 3. RESEARCH METHOD

#### 3.1. Data set

The GARCH model was estimated for two biggest market capitalizations of cryptocurrencies, namely Bitcoin and Ethereum, which represent the altcoin market; and 8 Asian emerging stock indices: China (SSEC), Thailand (SETI), Philippines (PSEI), Indonesia (JKSE), India (S&P BSE100), Taiwan (TSE 50), Malaysia (KLSE), and Parkistan (KSE 100).

#### 3.2. Models for testing the hypotheses

##### 3.2.1. Hypotheses tested for the safe haven properties of Bitcoin and Altcoins

Hypo 1: Bitcoin does not provide safe haven properties against Asian emerging stock markets during various contexts of the Covid-19 pandemic.

Hypo 2: Ethereum does not provide safe haven properties against Asian emerging stock markets during various contexts of the Covid-19 pandemic.

##### 3.2.2. Hypo tested for the contagion effect between the the cryptocurrency market and the the stock market

We employ two different methodologies to estimate the contagion effect and to gauge the transmission mechanism of the contagion effect between the stock market and the cryptocurrency market. First, research developed the BEKK-GARCH model to test these hypotheses based on previous studies by Caporale et al. (2021). The second methodology is based on the DCC-GARCH model to test for the contagion effect, as proposed by Rigobon (2003, 2019). These two models are given to analyze the existence of a contagion effect between bitcoin/ethereum and Asian emerging stock markets in the context of the global Covid-19 pandemic.

##### 3.2.3. Hypo tested for the transmission mechanism of the contagion effect between the the cryptocurrency market and the the stock market

Hypo 5: Investor-induced contagion effect between Asian emerging stock market and Bitcoin market sources from the wealth effect mechanism

If contagion effect between Bitcoin and Asian emerging stock markets speard by investor wealth constraints rather than by the need for portfolio rebalancing, the dynamic correlation between these two markets is higher during turmoil periods than during tranquil periods. To test that there is a significant increase in correlation between stock and Bitcoin during the turmoil periods, the null hypo is for no contagion:

$H_{0,5}$ : The dynamic correlation between the stock and Bitcoin during turbulent periods related to the Covid-19 pandemic is equal to its correlation in the calm period:

$H_{1,5}$ : The dynamic correlation between the stock and Bitcoin during turbulent periods related to the Covid-19 pandemic is higher than its correlation in the calm period:  $\rho_{13c} > \rho_{13nc}$

Hypo 6: Investor-induced contagion effect between Asian emerging stock market and Bitcoin market sources from the portfolio rebalancing mechanism

If contagion effect between Bitcoin and Asian emerging stock markets speard by portfolio rebalancing

channel, the dynamic correlation between these two markets is lower during turmoil periods than tranquil periods, that is,

$H_{0.6}$ : The dynamic correlation between the stock and Bitcoin during turbulent periods related to the Covid-19 pandemic is equal to its correlation in the calm period:  $\rho_{13c} = \rho_{13nc}$

$H_{1.6}$ : The dynamic correlation between the stock and Bitcoin during turbulent periods related to the Covid-19 pandemic is lower than its correlation in the calm period:  $\rho_{13c} < \rho_{13nc}$

Hypo 7: Investor-induced contagion effect between Asian emerging stock market and altcoin market sources from the wealth effect mechanism

In a similar spirit, to examine whether the wealth effect is the transmission mechanism of the contagion effect between stock markets and altcoin markets during Covid-19 turmoil periods, we use t-tests to evaluate whether there is a significant increase in the dynamic correlation between stock and altcoin as follows:

$H_{0.7}$ : The correlation between stock and altcoin during the turbulent period related to the Covid-19 pandemic is equal to its correlation in the tranquil period.  $\rho_{23c} = \rho_{23nc}$

$H_{1.7}$ : The correlation between stock and altcoin during turbulent periods related to the Covid-19 pandemic is higher than its correlation in the tranquil period.  $\rho_{23c} > \rho_{23nc}$  If the null hypotheses  $H_{0.7}$  are rejected, we conclude that the investor-induced contagion effect between Asian emerging stock market and altcoin market sources from the wealth effect mechanism

Hypo 8: Investor-induced contagion effect between Asian emerging stock market and altcoin market sources from the portfolio rebalancing mechanism

$H_{0.8}$ : The dynamic correlation between the stock and altcoin during turbulent periods related to the Covid-19 pandemic is equal to its correlation in the calm period:  $\rho_{23c} = \rho_{23nc}$

$H_{1.8}$ : The dynamic correlation between the stock and altcoin during turbulent periods related to the Covid-19 pandemic is lower than its correlation in the calm period:  $\rho_{23c} < \rho_{23nc}$

## 4. RESULTS AND DISCUSSION

We next analyse other turmoil periods within the Covid time to provide more detail on the hedge and safe haven ability of Ethereum. The result reconfirms that Ethereum does not provide hedge or safe haven properties for all Asian emerging stock markets, as the constant  $m_0$  shows a positive relationship between Ethereum and stock indices in most Asian emerging countries with significance at the 1% level and the coefficient  $m_1$  is positive significant or insignificant together with a positive value of sum parameters in most countries during the high panic, high media hype, or negative sentiment periods. Except for the case of Pakistan, in more extreme market conditions of the Covid-19 pandemic where the panic index or the media hype index is high or the sentiment index turns negative after the appearance of the Covid-19 pandemic, Ethereum remains a strong hedge property for the Pakistan stock market; however, it cannot be considered as a safe haven for KSE 100 during the high panic period and the negative sentiment period. The insignificant coefficients  $m_1$  together with a negative value of sum parameters in the context of the high media hype period in Pakistan show that Ethereum can only provide a weak safe haven effect for the Pakistan stock market during the high media hype period. In general, Ethereum does not provide a hedge or safe haven property for Asian emerging stock markets in almost times of extreme market conditions related to the Covid-19 pandemic.

## 4.2. Empirical results on the contagion effect

### 4.2.1. Contagion effect in terms of a change in time-varying correlation

Note: The mean of pairwise conditional correlations between Bitcoin and stock ( $\rho_{13}$ ) for sub-samples in tranquil periods is reported in Mean DCC in tranquil period, whereas the mean of pairwise conditional correlation for subsample in turmoil period is reported in Mean DCC in turmoil period. The difference in DCC is calculated from the mean of the turmoil period minus the mean of the tranquil period. The null hypo of equal correlation means between DCC in a tranquil period and DCC in a tranquil period is tested (H0: Correlation in turmoil period = correlation in tranquil period) against the alternative (H1: Correlation in turmoil period  $\neq$  Correlation in tranquil period). The rejection of the level of null at the 1%, 5%, and 10% is indicated by \*\*\*, \*\*, and \* respectively.

The estimated time-varying correlation between the Asian emerging stock market and the Ethereum market is, on average, higher during the Covid period than during the pre-Covid period in seven out of eight nations of the sample (Table 4.3) . This difference is statistically significant in five cases, including the Philippines, Indonesia, India, Taiwan and Pakistan. A comparison of three subperiods suggests that statistically significant increase in time-varying correlation between stock and Ethereum during turbulence periods related to the Covid-19 pandemic has become more common in the high panic period and negative sentiment period, which were rare during high media hype period. To be more specific, the significant increase in conditional correlation between Ethereum and stock is recognized in six out of eight countries (except China and Malaysia) during high panic period, five out of eight countries (except China, India and Malaysia) during negative sentiment period, whereas only two out of eight countries (Thailand and Taiwan) during high media hype period.

#### 4.2.2. Contagion effect in terms of a change in mean spillover and volatility spillover

To test the adequacy of the models, we perform multivariate generalizations of the Ljung-Box Q to test serial correlation in the mean of standardized residuals and a test for multivariate ARCH effects of standardized residuals. The Ljung-Box Q test of 10 lags rejects the null hypo of no serial correlation in the standardized residual in only three cases. The test for multivariate ARCH effects cannot reject the null hypo that standardized residual series are mean zero, not serially correlated, and with a fixed covariance matrix in all estimated models. Therefore, the residuals of the multivariate model are serially uncorrelated and show no remaining ARCH effects. Overall, the findings show that all estimated models fairly accurately reflect the evolution of conditional means and variances of stock and cryptocurrency returns, as well as their interactions using the selected specification VAR-GARCH(1,1).

Notes: \*\*\*, \*\*, and \* denote significance at levels of 1%, 5%, and 10%. Standard errors (not reported) are calculated using the quasi-ML method of Bollerslev & Wooldridge (1992), which is robust to the distribution of the underlying residulas. LB(10) indicates the Ljung-Box autocorrelation test for ten lags in the standardized residual. ARCH indicates the multivariate ARCH effects test in the standardized residual. The full set of results is available upon request.

For the full sample period with a dummy DCOV (Table 4.4), the following points are noteworthy. The parameter estimates for the conditional means of eight Asian emerging countries in the full sample period suggest a statistically positive significant spillover in mean from the stock markets to the Bitcoin market for six countries, except for the Philippines and Pakistan. Similarly, the estimation parameters of the spillover mean from the stock markets to the Ethereum market are positive and significant for six countries, except for the case of the Philippines and Pakistan. Furthermore, the Covid-19 pandemic has been found to affect the dynamic links between the Asian emerging stock market and the cryptocurrency market, as indicated by the significant parameters measuring the change in mean spillover from stock to Bitcoin and from stock to Ethereum. In particular, there is a downward shift in the parameter that measures the mean spillover effect (negative contagion) from stock to Bitcoin in seven countries in which three out of them, including India, Taiwan, and Malaysia ( $\beta_{13d} = -0.520$ ;  $-0.448$ ; and  $-0.754$  respectively) are significantly at the 1% and 5% level, and from stock to Ethereum in six countries in which three countries including Indonesia, India, and Malaysia are significant at 5% and 10% level ( $\beta_{23d} = 0.304$ ;  $-0.472$ ; and  $-0.843$  respectively). Therefore, there is evidence of contagion effect in terms of a shift in mean spillover during Covid time from stock to Bitcoin in India, Taiwan, and Malaysia and from stock to Ethereum in Indonesia, India and

Malaysia. This finding suggests that investors in these countries react to the Covid-19 turmoil period by diversifying; therefore, they prefer to reduce the relative proportion of cryptocurrencies compared to stock in their portfolio. Except for the case of the Philippines, the parameter estimates for the shift in mean spillover from stock to Bitcoin and from stock to Ethereum in Covid period are positively significant ( $\beta_{13d} = 0.388$ ;  $\beta_{23d} = 0.393$ ), which may indicate that Philippines’s investors considered stock and digital currency as diversified assets, and classify them in risky asset classes, thus, in turmoil period, investors may choose to reduce investment propotion of these two assets in their portfolio and move to other less-risky assets.

LB(10) indicates the Ljung-Box autocorrelation test for ten lags in the standardized residual. ARCH indicates the multivariate ARCH effects test in the standardized residual. The full set of results is available upon request.

Table 4.5 represents the estimated result when the Panic index indicator is included in the model for the Covid-19 subsample. The estimated parameters of the mean spillover from the stock to Bitcoin are positively significant for the Philipines ( $\beta_{13} = 0.220$ ); and negatively significant for India ( $\beta_{13} = -0.126$ ). Additionally, estimates of the mean spillover from stocks to Ethereum are negative and significant for India ( $\beta_{23} = -0.308$ ) and positive significant for the Philippines and Pakistan ( $\beta_{23} = 0.365$ ; and 0.228 respectively). In particular, on days when the panic index is high, there is a significant and upward shift in the parameter that represents the spillover in mean running from stock to Bitcoin in Philippin and Pakistan ( $\beta_{13d} = 0.191$ ; and 0.168 respectively); and from stock to Ethereum in Thailand, Malaysia and Pakistan ( $\beta_{23d} = 0.397$ ; 0.458 and 0.114 respectively). Furthermore, downward shifts in the mean spillover parameter from stock to Bitcoin have been observed in India ( $\beta_{13d} = -0.282$ ); and from stock to Ethereum in India ( $\beta_{23d} = -0.033$ )

have been observed. For Korea and Thailand, the spillover in the mean from the Pakistan stock market to the Bitcoin market, as well as the spillover in the mean from the Thailand stock market and Malaysia to the Ethereum market was only recognized in a high panic period during Covid time.

Table 4.6 represents the estimated result when the Media Hype index indicator is included in the model for the Covid-19 subsample. The estimated parameters of the mean spillover from the stock market to the Bitcoin market are positive and significant for Thailand, the Philippines and Taiwan ( $\beta_{13} = 0.555$ ; 0.174 and 0.300, respectively); and negative and significant for India ( $\beta_{13} = -0.132$ ). Furthermore, the estimated parameters of the mean spillover from Asian stock to Ethereum are positively significant for Thailand and Taiwan ( $\beta_{23} = 0.612$  and 0.235 respectively); and negatively significant for India and Pakistan ( $\beta_{23} = -0.465$  and -0.875). In the high media hype period, there is a negative contagion in the mean run from stock to Bitcoin in Thailand, India, and Taiwan ( $\beta_{13d} = -0.742$ ; -0.165; and -0.494, respectively); and from stock to Ethereum in Thailand and Taiwan ( $\beta_{23d} = -0.705$ ; and -0.374, respectively). Furthermore, there is a positive contagion in the mean movement of the stock to Bitcoin in Pakistan ( $\beta_{13d} = 0.329$ ) and from stock to Ethereum in three countries, including Philippines, India and Pakistan ( $\beta_{23d} = 0.411$ ; 0.294 and 1.146, respectively).

Table 4.7 represents the estimated parameter values when the dummy that represents the negative sentiment period is included in the model for the Covid-19 subsample. The estimated parameters of the mean spillover from the stock to Bitcoin are positive and significant for the Philippines, India and Pakistan ( $\beta_{13} = 0.821$ ; 0.604 and 0.330, respectively). The estimated parameters of the mean spillover from Asian stocks to Ethereum are positively significant for 5 Asian countries, including Thailand, Philippines, India and Pakistan ( $\beta_{23} = 0.477$ ; 3.731; 2.046 and 0.449 respectively); and negatively significant for Indonesia ( $\beta_{23} = -0.589$ ). In the negative sentiment period, there is a negative contagion in the mean running from the stock to Bitcoin in the Philippines, Indonesia, India and Pakistan ( $\beta_{13d} = -0.483$ ; -0.364; -0.959; and -0.547 respectively); and from the stock to Ethereum in Thailand, Phillipines, India, and Pakistan ( $\beta_{23d} = -0.231$ ; -3.244; -2.401 and -0.541, respectively). There is a positive contagion in the mean flow from stock to Bitcoin in Thailand ( $\beta_{13d} = 0.224$ ); and from stock to Ethereum in Indonesia ( $\beta_{23d} = 0.292$ ).

### 4.3. The transmission mechanism of the contagion effect between the stock market and the cryptocurrency market during the Covid-19 period

We extract the dynamic correlation for each pair of assets using the standardized residual return produced by the DCC-GARCH model for the pair of Bitcoin-stock and Ethereum-stock. During both turmoil and tranquil periods related to the Covid-19 outbreak, we examine the investor-induced contagion hypo and assess whether this contagion impact is caused by the wealth effect or the portfolio rebalancing effect. As proposed by Boyer et al. (2006) and Petmezas & Santamaria (2014), for investor-induced contagion to hold through the wealth effect hypo, Bitcoin-stock correlation ( $\rho_{13}$ ) or Ethereum-stock correlation ( $\rho_{23}$ ) must increase in turmoil periods. In contrast, for investor-induced contagion sourced by the portfolio rebalancing to hold, these correlation must reduce in turmoil periods.

**Table 4.8: T-test for the contagion channel between the Ethereum market and the Stock market**

	China	Thailand	Philippines	Indonesia	India	Taiwan	Malaysia	Pakistan
Panel A: Pre-Covid and Covid Period								
Mean DCC in tranquil period	0.0439	0.1137	0.0573	0.0478	0.0359	0.0204	0.0070	-0.0110

Reject Ho ( $\rho_{23c} < \rho_{23nc}$ )								
Panel C: Low and High-Media Hype Period								
Mean DCC in tranquil period	0.0442	0.1004	0.0576	0.0526	0.0557	0.0290	0.0066	-0.0089
Mean DCC in turmoil period	0.0449	0.1344	0.0612	0.0479	0.0603	0.0360	0.0075	-0.0076
Different in Mean DCC	0.0007	0.0340	0.0036	-0.0047	0.0046	0.0070	0.0009	0.0013
Reject Ho ( $\rho_{23c} > \rho_{23nc}$ )		***				***		
Reject Ho ( $\rho_{23c} < \rho_{23nc}$ )				**				
Panel D: Positive and Negative Sentiment Periods								
Mean DCC in tranquil period	0.0440	0.0870	0.0516	0.0477	0.0549	0.0300	0.0097	-0.0109
Mean DCC in turmoil period	0.0447	0.1264	0.0603	0.0514	0.0580	0.0337	0.0060	-0.0055
Different in Mean DCC	0.0006	0.0394	0.0086	0.0036	0.0031	0.0037	-0.0037	0.0054
Reject Ho ( $\rho_{23c} > \rho_{23nc}$ )		***	*	*		**		**
Reject Ho ( $\rho_{23c} < \rho_{23nc}$ )								

Note: The mean of pairwise conditional correlations between Ethereum and stock ( $\rho_{23}$ ) for sub-samples in tranquil periods are reported in mean DCC in tranquil period, whereas the mean of pairwise conditional correlation for sub-sample in turmoil period are reported in mean DCC in turmoil period. The difference in DCC is calculated from the mean of the turmoil period minus the mean of the tranquil period. The first null hypo of equal correlation means among DCC in tranquil period and DCC in tranquil period is tested (H0: Correlation in turmoil period = correlation in tranquil period) against the alternative (H1: Correlation

in turmoil period > Correlation in tranquil period). The second null hypo of equal correlation means among DCC in tranquil period and DCC in tranquil period is tested ( $H_0$ : Correlation in turmoil period = correlation in tranquil period) against the alternative ( $H_1$ : Correlation in the turmoil period < Correlation in the tranquil period). Rejection of the null at the 1%, 5%, and 10% level is denoted by \*\*\*, \*\*, and \* respectively.

To take into account that the transmission mechanism between Asian merging stock market and Ethereum market may vary over time, Table 4.13 represents the result of the T-test for testing the investor induced contagion between Asian stock market and Ethereum market sourced by the wealth effect and portfolio rebalancing hypo, respectively. The results of the T test indicate that the significant increase in the dynamic correlation between stock and Ethereum in turmoil periods is recognized in 5 countries (except China, Thailand, and Malaysia) during the Covid period, 6 countries (except China and Malaysia) during the high media hype period, 2 countries including Thailand and Taiwan during the high media hype period and 5 countries (except China, India, and Malaysia) in the negative sentiment period. The volatile nature of DCC between stock and Ethereum estimates, especially during various turmoil contexts in the global Covid-19 pandemic, suggests that the transmission mechanism of the contagion effect between stock market and Ethereum market is through the wealth effect in most cases. The change in the correlation between the Indonesia stock market and the Ethereum market can be considered as an exception as it decreases significantly during the high media hype period. Therefore, for this specific case, the contagion effect is the result of a portfolio rebalancing effect.

## 5. CONCLUSIONS

The Covid-19 pandemic has wreaked havoc on economies around the world and has had a significant impact on the global financial market. The global health crisis affects not only country-specific risk, but also systemic risk, which is why its impact on the linkage between financial assets has piqued the interest of economists, investors, and policy makers. Financial markets around the world have responded to the global spread of the Covid-19 pandemic by increasing risk and changing cross-market links, and emerging Asian stock markets and cryptocurrency markets are no exception.

In this study, we analyze both the presence of the contagion effect and the transmission mechanism that causes contagion between the emerging Asian stock market and the Bitcoin and altcoin market under various turbulent periods related to the Covid-19 pandemic. This is necessary to understand the shift in mean spillover, volatility spillover, and dynamic correlation between traditional equity markets and cryptocurrency markets, which represent, for the Fintech revolution, during the turbulent periods of Covid-19. It can also provide an explanation for the volatility of digital currencies, which has recently puzzled both academic researchers and investors. Furthermore, our research aims to complement the results of previous studies on the benefits of hedge, safe haven, and diversifier of cryptocurrency by assessing whether Bitcoin and Ethereum can be used as hedge, safe haven, or diversifier against emerging Asian stocks, in the different contexts of the global health crisis, and conditional on relevant Covid new-related indicators.

According to the literature, assets become more connected during economic downturns. The global Covid 19 pandemic offers an unprecedented opportunity to further explore this consideration (Bekaert et al., 2009; Hartmann et al., 2004; Lee et al., 2011). Recently, the role of cryptocurrencies, including Bitcoin and altcoins, as an investment shelter during a market crash such as the global Covid-19 pandemic has been recognized in academia. There is a stream of research that argues that cryptocurrencies failed to prove their hedging and safe haven probability during the Covid-19 pandemic (Dutta et al., 2020; Lahmiri & Bekiros, 2020; K. Q. Nguyen et al., 2021; Yarovaya et al., 2021). Therefore, from the financial asset perspective, cryptocurrencies have not

yet demonstrated their safe haven capability during any large-effect economic crisis and recession (Conlon & McGee, 2020; Corbet, Larkin et al., 2020a, 2020b). Other studies support the argument that bitcoin and altcoins can be considered a safe haven for financial assets in the context of the Covid-19 pandemic (Corbet et al., 2021; Diniz-Maganini et al., 2021; Goodell & Goutte, 2021; Huang et al., 2021). This research is different from previous investigations, as we examine the present of the contagion effect as a shift in return spillover, volatility spillover, and time-varying correlation from the Asian emerging stock market to the cryptocurrencies market in the context of the Covid-19 global pandemic.

## ANALYSIS OF FACTORS INFLUENCING INVESTMENT DECISIONS IN THE VIETNAMESE STOCK MARKET OF STUDENTS IN HO CHI MINH CITY

**Author: Nguyen Mai Lien<sup>1</sup>, Nguyen Thi Kim Ngan<sup>1</sup>, Tran Phan Thuy Tien<sup>1</sup>, Luong Tuong Vy<sup>1</sup>**

**Mentor: Ha Van Son<sup>1</sup>**

**ABSTRACT:** *The Vietnamese stock market has experienced significant growth, attracting individual investors, including young students. This study examines the factors influencing investment decisions among Vietnamese students in the stock market, using SPSS 20.0 software to evaluate the reliability of measurement scales and to test the accuracy of the model. Through surveys and statistical analysis, the results of the study showed that factors including overconfidence, herd behavior, risk attitude, firm image, accounting information, neutral information, advocate information and personal financial needs had a positive impact on the investment decisions of Vietnamese students in the stock market. The research also indicates the level of investment and the intentions of students in investing in the Vietnamese stock market. The research provides insights for academic and practical purposes, benefiting students, businesses, and government agencies. Practical solutions are proposed to enhance investment decisions, market stability, and attract investment for listed companies on the stock exchange.*

**Keywords:** *stock market, investment decision, financial behavior.*

### 1. INTRODUCTION

In the past two decades, the Vietnam stock market has experienced remarkable growth, with securities trading accounts surging from 400 at its launch in July 2000 to 4,946,316 accounts as of March 31, 2022. This surge highlights the market's appeal as a significant investment channel, especially for individual investors. While the market still exhibits characteristics of a developing market, Vietnam has been steadily integrating into the global economy. The stock market serves as a vital component of the Vietnamese economy, mobilizing medium and long-term capital for economic growth. The rapid development of the Vietnam stock market has garnered attention both regionally and globally. Notably, the stock market in Vietnam has experienced robust growth. Data from the State Securities Committee shows a significant increase in mobilized capital. For instance, mobilized capital rose from 40 trillion VND in 2006 to 320 trillion VND in 2019. Even in the challenging first half of 2020, the stock market mobilized approximately 107 VND. Despite obstacles, such as oil price fluctuations and supply chain disruptions in the supply chain due to conflicts between Russia and Ukraine, the Vietnamese stock market demonstrated relatively high growth.

The main challenge for individual investors in the stock market is the potential risks associated with investing. These risks make decision-making and timing of investments difficult. Factors like financial influences and investor behaviors have a significant impact on investment decisions. Limited knowledge, skills, and experience pose additional challenges for students, who are known for their dynamism and adaptability. Limited capital can lead to a cautious mentality, fear of risks, and a tendency to follow the majority for safety. Therefore, it is crucial for individual investors to carefully evaluate market factors and understand the overall market situation. This analysis is essential for managers in developing strategies to attract and restore the Vietnamese stock market.

---

<sup>1</sup> University of Economics Ho Chi Minh City.

Understanding investor psychology and conducting research on factors influencing investment decisions, particularly among students, is crucial for businesses in today's global landscape. The Behavioral Finance Theory by Victor Ricciardi & Helen K. Simon (2000) examines how behavioral finance affects the investment decisions of individual investors. Another study by Hussein A. Hassan Al-Tamimi (2005) explores factors influencing investment decisions in the UAE's financial market, which can be relevant to Vietnam's stock market. Empirical research in Vietnam, across various sectors and the economy, has identified financial factors impacting investment decisions on the HOSE Stock Exchange. For instance, Nguyen Thi Ngoc Diep and Nguyen Minh Kieu found that expected profit, dividend policy, dividend payout ratio, and stock price significantly influence individual investors' decisions, with the dividend payout ratio having the greatest impact. Proposed solutions aim to enhance investors' decision-making abilities and assist businesses in attracting investments. Nguyen Thi Mai's research on behavioral factors during COVID-19 in the Vietnamese stock market shows that demographic characteristics and the pandemic have significant influences. Factors such as investment experience, age, and education level positively impact investment decisions, while gender does not play a significant role. The study also highlights the presence of emotional decision-making, herd mentality, and overreactions, potentially influenced by the pandemic and market changes. This research has implications for enhancing investment performance and understanding investor psychology for securities companies in Vietnam. However, research on the specific topic of financial factors and behavior's impact on individual investors' decisions remains limited in Vietnam.

In summary, identifying the factors that impact investment decisions is of utmost importance in the current economic situation in Vietnam. Therefore, our research team has undertaken a study titled "Analysis of factors influencing investment decisions in the Vietnamese stock market of students in Ho Chi Minh City". The primary objective of this study is to analyze and understand the factors influencing investment decisions of students in Ho Chi Minh City when participating in the Vietnamese stock market. By identifying these factors and assessing the level of impact of these factors, we aim to propose solutions to enhance students' investment decision-making abilities, attract investments for businesses, and provide recommendations for government support.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Definition**

#### **2.1.1. Individual investors**

Individual investors are individuals who participate in investment activities across different market segments to achieve desired benefits. Specifically, individual investors are investors who buy and sell securities for their own accounts through traditional or online brokerage firms or other types of investment accounts (Hayes, 2020). Their involvement is crucial for exploring investment opportunities, supporting business development, and driving economic and social progress in any economy (Guo et al., 2017)

#### **2.1.2. Investment decision**

Investment is the allocation of resources for medium or long-term purposes with the expected effectiveness of recovering investment costs and achieving high profits. While making decisions, we are influenced by various factors and change our behavior. This also occurs in the decision-making process of investors (Akbar et al., 2016). In reality, the financial decisions of investors are influenced by internal and external behavioral factors, and research on financial behavior has developed rapidly in recent years (Shefrin, 2000; Wärneryd, 2001).

## **2.2. Factors affecting the investment decision of individual investors**

### **2.2.1. Overconfident**

Numerous studies, including Trivers (1991), have highlighted how people tend to be overconfident, overestimating their abilities and exaggerating their knowledge. This behavior is particularly prevalent in stock investing, where overconfident investors often misjudge information accuracy and misinterpret its meaning due to cognitive limitations. Overconfidence leads to higher risk-taking as investors concentrate on familiar stocks and rarely diversify (Campbell et al., 2004; Lichtenstein et al., 1982). Consequently, overconfident investors trade more frequently and achieve lower average returns (Oden, 1999). Overconfidence also often underestimates the volatility of risky assets or overestimates their accuracy (Baker & 11 Nofsinger, 2011). While overconfidence can boost certain aspects of professional performance and enhance advancement opportunities (Oberlechner & Osler, 2004), it remains a human characteristic rather than a market characteristic (Oden, 1998). Market efficiency is influenced by various participants, leading to excessive trust and overconfidence among investors (Waweru et al., 2008). Even if you are a good analyst, it does not mean you will be a successful trader.

### **2.2.2. Herd behavior**

The herd behavior in financial markets is defined as the behavioral trend of investors following the actions of others (Bikhchandani and Sharma, 2001; Banerjee, 1992). Based on the observed actions of others, individuals generate their own behaviors, or in other words, imitate the actions of others (Hwang and Salmon, 2004). The herd behavior can create market inefficiency and speculative bubbles. In general, investors who follow the herd behavior behave like prehistoric humans, who have some knowledge and information about their environment and are grouped to support each other and achieve safety (Carporelli et al., 2004, p. 223). Investors who follow herd behavior aim to minimize perceived risks, especially when investing significant capital. Additionally, the herd behavior also depends on the types of investors, for example, individual investors tend to follow the herd behavior more in making investment decisions than organized investors (Goodfellow, Bohl & Genka, 2004, p. 213). It is important to note that the prevalence of herd behavior may differ between individual and institutional investors (Goodfellow, Bohl & Genka, 2004).

### **2.2.3. Risk attitude**

Researchers now focus on the risk attitude of individual investors alongside fundamental and technical analysis to understand their stock trading behavior. Risk and uncertainty influence crucial economic decisions, emphasizing the need to understand and predict economic behavior. Risk is an unwanted outcome associated with uncertainty, making stocks riskier due to market volatility. Nowadays, the stock market always has its ups and downs. This makes stocks riskier, and volatility is measured in very precise ways (such as variance, standard deviation, and beta (Ly, 2010)). Prospect theory is often used to explain investors' risk attitudes. Weber, Blais, and Betz (2002), who support prospect theory, show that people are risk-seeking when facing losses. Risk attitudes depend on factors like age, income, gender, education, and experience

### **2.2.4. Firm image**

The firm image plays a crucial role in understanding how a company achieves its goals and objectives, impacting the investment decisions of individual investors. Numerous studies, such as Robert A. Nagy and Robert W. Obenberger [21, p. 67] (1994) and Al-Tamimi (2006) in the UAE, have demonstrated the positive influence of firm image on stock investment decisions. Epstein's (1994) research also revealed that companies with a strong image in terms of culture, reputation, product quality, and social responsibility positively affect individual investors' choices. Furthermore, the research model by Le Hoang Anh, Nguyen

Ho Phuong Thao, and Phan Thi Nhu Hieu highlights that firm image has the greatest impact on investment decisions of individual investors in the stock market of Hue city.

#### **2.2.5. Accounting information**

Before making investment decisions, investors usually pay attention to accounting information such as the ability to sell stocks, expected earnings, financial reports, dividends, stock prices, expected dividends, and past stock information (Hussein, 2006). And if a company discloses complete accounting information, individual investors will have more confidence in the company, and investment trends will be higher (A. Nagy & W. Obenberger, 1994).

#### **2.2.6. Advocate information**

For new investors entering the stock market, who have little experience and time to keep up with the daily volatility of the stock market, using a brokerage and advisory services is entirely reasonable, especially for students. According to the AL - Anood Bin Kalli's research, opinions from advisors affect the investment decisions of individual investors, including: advice from brokers; opinions from family members; opinions from colleagues, and friends; opinions from shareholders in the company; advice from market analysts, finance (Al-Tamimi & Kalli, 2009). However, Nagy and Obenberger (1994) believed that recommendations from brokers, individual brokers, family members, or colleagues are rarely taken into account. In addition, religious reasons, recommendations on "opinions and supporters" are socialpsychological factors of the market that have little influence on investors' decisionmaking (AL - Tamimi, 2006; Sultana and Pardhasaradhi, 2012; Chong and Lai, 2011; Merikas et al., 2011) but in the views of Hussein A. Hassan AL - Tamimi and Anood Bin Kalli, 2009 are the opposite, the authors believe that religion has a significant influence on investment decisions in the UAE and rumors have the least influence. In addition, recommendations from supporters such as brokerage firms, friends, and acquaintances are considered the most influential factor in the study of investor behavior in Malaysia (Chong and Lai, 2011). According to Nilsson (2008), Riedl and Smeets (2017), and Gutsche et al. (2019), relatives' knowledge and advice can positively impact individual investment decisions by sharing insights about popular stocks and future investment portfolios. Therefore, interactions between family members, acquaintances, and friends can be an important source of information for individuals before making investment decisions (Hong et al., 2004; Gutsche & Zwergel, 2020).

#### **2.2.7. Neutral information**

Information that investors can search and refer to on stock forums, from the media, and from securities company reports before making investment decisions is called neutral information. The factors of neutral information prioritized when making trading decisions: the volatility of the stock index, news from forums, the media, and from government decisions and announcements, economic indicators (GDP, interest rates, etc.), the market price of listed securities, and the percentage of state-owned shares held (A. Hassan Al-Tamimi & Kalli, 2009). According to Aamir Sarwar & Ghadeer Afaf (2016), factors related to neutral information such as information about price volatility mean the change or fluctuation in price due to the difference between supply and demand on a trading day. When searching for information about market fluctuations, news in the press, information from the Internet, recent price changes, and information about government holders are important for investors (Shafi, 2014). Other studies such as Robert A. Nagy and Robert W. Obenberger (1994), Hussein A. Hassan Al-Tamimi (2006) also confirmed that this neutral information directly affects investment decisions. Therefore, investors will not make investment decisions without market-supported information sources.

### **2.2.8. Personal financial needs**

One of the desires of investors when investing in the stock market is to benefit from the price difference of stocks. At the same time, investors also aim to profit from dividends, unlike the benefit from price differences which can only be realized at the maturity date and only a certain percentage is received. The need for financial investment among investor groups by age is not the same and varies with each stage of age. For young investors, the stock market is a suitable investment channel with flexible initial capital according to each person's financial capacity. At the same time, young investors have more time to learn, make mistakes and correct losses. Therefore, they can accept higher risks to achieve their goals (in terms of knowledge or finance). Conversely, for older investors, they tend to seek stable investment opportunities with low risk. They are afraid when faced with high risks as time does not allow them to correct their mistakes as desired. The study by Robert A. Nagy and Robert W. Obenberger (1994) identified 6 component factors within the group of personal financial factors. The attractiveness of other investment markets including: Necessary diversification; low risk; expectation of failure in international financial markets; comfort with credit funds; expectation of failure in domestic financial markets.

## **3. RESEARCH METHOD**

### **3.1. Sampling**

According to the research by Hair et al. (2006), to conduct exploratory factor analysis (EFA), the minimum sample size should response the formula:  $n \geq 5x$  ( $n$  is the sample size,  $x$  is the number of observed variables - the number of measurement questions in the survey table), the authors developed a model consisting of 39 observed variables, so it is:  $n \geq 5 \times 39 = 195$ . Therefore, the minimum sample size required to ensure the representativeness and accuracy of the research is 195 samples.

### **3.2. Data collection method**

The data was collected in raw form by gathering information on survey forms. The group approached students in Ho Chi Minh City through social media and conducted the survey via a link attached to an online survey developed on the Google Forms. The statistical sampling method Snowball Chain is often used when there is wide distribution and sharing among students and others, helping to save time in data collection and selecting appropriate subjects.

The questionnaire used a Likert scale with a level of agreement ranging from 1 to 5 with specific scores: 1 = "Completely disagree", 2 = "Disagree", 3 = "Neutral", 4 = "Agree", 5 = "Completely agree".

After collecting survey responses, the research data was screened and non-standard responses were eliminated, and processed using SPSS 20.0.

### **3.3. Method to test the Reliability of Variable**

The Cronbach's Alpha coefficient is a statistical test of the degree of consistency among items in a measurement scale (Hoang Trong & Chu Nguyen Mong Ngoc, 2008). This coefficient evaluates the reliability of the measurement scale based on the variance of each observation and the correlation of each variable with the score of the total remaining variables in the measurement (George and Malley, 2003). There are two points to note when analyzing the Cronbach's Alpha coefficient:

First, testing the reliability of the entire measurement scale. According to Nunnally & Bernstein (1994), Cronbach's Alpha coefficient is good if it is from 0.8 to 1, 0.7 to 0.8 is acceptable, while 0.6 to 0.7 is the requirement for new researches. However, if the Cronbach's Alpha coefficient is too high (above 0.95), it indicates that many variables in the measurement scale measure the same concept of the research.

Second, testing the reliability of each observed variable by Corrected Item-total Correlation - which indicates the degree of close relationship between observed variables in the factors and dependent variables. When a measuring variable has a correlation coefficient - total adjusted correlation  $\geq 0.3$ , the variable is satisfactory (Nguyen Dinh Tho, 2013).

### 3.4. Method to test the Exploratory Factor Analysis

Exploratory Factor Analysis (EFA) is a mutually dependent multivariate analysis aimed at reducing a set of interdependent variables into a new set (new factors) with fewer variables to identify the necessary variables for the research problem (Hair et al., 2010). The new set of variables still contains meaningful information and is complete compared to the original set of variables. We will use the Principal Component Analysis and Varimax to group all the factor.

In the EFA method, the criteria for selecting appropriate variables are as follows:

According to Kaiser (1974), the KMO coefficient is an index used to evaluate the suitability of the factor. This coefficient must be  $\geq 0.5$  with Sig.  $\leq 0.05$  significance level.

Factor loading is a coefficient that reflects the correlation between the observed variable and the factor. The higher the factor loading coefficient, the higher the correlation between the observed variable and the factor, and in contrast. If the Factor Loading  $< 0.5$  in EFA, it will be eliminated to ensure the value of the homogeneity coefficient between variables.

Finally, we should ensure that the Total Explained Variance  $\geq 50\%$  and Eigenvalue  $\geq 1$ .

### 3.5. Regression Analysis

Multiple linear regression analysis is an extension of simple linear regression and is used when predicting the value of a dependent variable based on the values of two or more independent variables. All observed variables when analyzing correlation will be analyzed by multiple linear regression according to the regression equation. In this case, we will figure out whether the Investment Decision has a multiple linear relationship with 8 independent variables. The multiple linear regression is shown below:

$$QD = \beta_0 + \beta_1 TT + \beta_2 DD + \beta_3 RR + \beta_4 HA + \beta_5 KT + \beta_6 NI + \beta_7 YK + \beta_8 NC + \varepsilon$$

In which:

Dependent Variable

- QD: Investment decision

Independent Variable

- TT: Overconfidence
- DD: Herd Behavior
- RR: Risk Attitude
- HA: Firm Image
- KT: Accounting Information
- NI: Neutral Information
- YK: Advocate Information
- NC: Personal Financial Needs

In the multiple linear regression analysis, we should follow these criteria:

- Adjusted coefficient of determination (R<sup>2</sup>): This is a measure of the percentage of variation in the dependent variable that is explained by the independent variables, taking into account the sample size and the number of independent variables in the multiple regression model. The higher the R<sup>2</sup> value, the greater the explanatory power of the regression model (Hair et al., 2010). Typically, we choose a mid-range level of 0.5 to 1 as a good model, while a value below 0.5 indicates an inadequate model.

- Independence of residuals: The Durbin-Watson statistic (d) is used to test the autocorrelation of adjacent residuals (first-order autocorrelation). If this statistic is close to 2, the residuals are uncorrelated.
- Test of the significance of regression coefficients  $\beta$  using the t-test in multiple regression to evaluate the importance of factors. The larger the coefficient  $\beta$ , the more important the independent variable is to the dependent variable.
- Significance value (Sig): If the Sig value of the t-test for the regression coefficient of an independent variable is less than 0.05, we conclude that the independent variable has an effect on the dependent variable.
- Variance inflation factor (VIF) in the model: If the VIF of a predictor is greater than 10, the variable has little explanatory value for the variation of the dependent variable in the multiple regression model (Hair & ctg, 2006, cited in Nguyen Dinh Tho, 2012).

### 3.6. Measurement Scale

The model of the research project was developed based on assumptions from 8 main groups of potential factors. The scale of a factor is defined as a set of observable variables that can measure, explain and reflect the characteristics of that factor. In the study, observed variables (scales) were constructed according to the formative construct and measured the degree of agreement based on the 5-point Likert scale.

Based on previous research models, this study base on the model of psychological factors affecting the investment decision of Ho Minh Phuc (2015), retaining three objective factors: Overconfidence, Herd Mentality, and Attitude towards risk. Based on the study of factors influencing individual investors in UAE (Hussein A. Hassan Al-Tamimi, 2006), the group suggested retaining these factors, which is appropriate because there is similarity between the stock markets of Vietnam and UAE (Nguyen Thi Ngoc Diep, 2011).

**Table 3.1: Description of variables in the research model**

Number	Name	Coding	Describe	Expectation	Source
Dependent variable					
1	Investment decision	QD	The commitment to invest in stocks or bonds with the expectation of future profit.”		Hussen A. Hassan Al-Tamimi (2005)
Independent variable					
1	Overconfidence	TT	The psychology in which investors are satisfied with their investment decisions on their own.	+	Waweru et al., 2008
2	Herd Behavior	DD	Investors’ behavior of imitating the majority of other investors.	+	Waweru et al., 2008
3	Risk attitude	RR	Investors’ behavior when an unexpected situation occurs.	+	Waweru et al., 2008
4	Firm image	HA	Analyzing the operations of a company to understand how it achieves its goals and objectives.	+	Waweru et al., 2008
5	Accounting information	KT	The reports provide interested parties with insights into the financial health of the company.	+	Robert A. Nagy and Robert W. Obenberger (1994)
6	Neutral information	NI	The information is publicly posted, easily accessible, and available for reference.	+	Robert A. Nagy and Robert W. Obenberger (1994)
7	Advocale information	YK	Providing knowledge and information from family, relatives, friends, or brokers to facilitate investment decisions that are faster, more accurate, and reduce risk.	+	Al Anood Bin Kalli (2009) Hussen A. Hassan Al-Tamimi (2005)
8	Personal financial needs	NC	Desiring to earn profits from an investor’s investment portfolio.	+	Robert A. Nagy and Robert W. Obenberger (1994)

## 4. RESULTS AND DISCUSSION

### 4.1. Results

The team issued a survey questionnaire via the online Google Form tool for students in various fields in Ho Chi Minh City from March to June 2022. Starting with the question “Have you invested or are you currently investing in the stock market?” to exclude recipients who do not participate in stock market investment. Those who answered “No” were directed to the end of the survey and thanked for their participations. We have collected 300 questionnaires which includes 271 suitable respondents (a response rate of 90%), however, we have already eliminated 17 unsuitable respondents. Therefore, the team collected 254 valid samples and used them for further analysis.

#### 4.1.1. Descriptive statistical analysis

**Table 4.1.1: Descriptive statistics of the surveyers' characteristics**

Feature	Frequency	Percentage
<b>Gender</b>		
Male	144	56.7%
Female	110	43.4%
<b>Major field</b>		
Economy - Society	153	60.2%
Technology - Engineer	83	32.7%
Other	18	7.1%
<b>Acedemic level</b>		
First – year student	20	7.9%
Second – year student	70	27.6%
Third – year student	107	42.1%
Fourth – year student	51	20.1%
Other	6	2.4%
<b>Monthly income</b>		
Under 1.000.000	19	7.5%
From 1.000.000 to 3.000.000	88	34.6%
From 3.000.000 to 5.000.000	108	42.5%
Above 5.000.000	39	15.4%

**Table 4.1.2: Descriptive statistics of the engaging in stock market of the surveyers**

Level of spending on investments	Frequency	Percentage
Under 1.000.000	73	28.7%
From 1.000.000 to 2.000.000	119	46.9%
From 2.000.000 to 3.000.000	42	16.5%
Above 3.000.000	20	7.9%
<b>Time of participation in the stock market</b>		
Above a year	115	45.3%
From 1 to 2 years	87	34.3%
Above 2 years	52	20.5%
<b>Level of understanding of the stock market</b>		
Very bad	14	5.5%
Bad	32	12.6%
Neutral	122	48.0%

Good	56	22.0%
Very good	30	11.8%
<b>Sources of knowledge about the stock market</b>		
Participate in securities courses	91	35.8%
Being trained in school	102	40.2%
Being guided by others	161	63.4%
Self-research	173	68.1%
Reading books	1	0.4%
<b>Intentions of student investors</b>		
Definitely not	8	3.1%
No	28	11.0%
Uncertain	76	29.9%
Yes	70	27.6%
Definitely yes	72	28.3%

**4.1.2. Reliability test using Cronbach's Alpha**

After testing the Cronbach's Alpha for the first round, we decided removing the variable DD4 (to achieve a higher Cronbach's Alpha value) and RR5 (because the item-total correlation coefficient was less than 0.3). Then we conducted the second Cronbach's Alpha reliability test, the results showed that all measurement scales achieved acceptable reliability. Therefore, the remaining 37 variables will be used in the EFA analysis steps.

**Table 4.1.3: Results of the second round of testing of the scales using Cronbach's Alpha.**

Component	Scale Mean if Item Deleted	Scale Variance if Item Deleted	Corrected Item-Total Correlation	Cronbach's Alpha if Item Deleted
<b>Overconfidence (TT)</b>	Cronbach's Alpha = .818			
TT1	11.28	6.596	.667	.758
TT2	11.24	7.031	.587	.794
TT3	11.30	6.094	.680	.751
TT4	11.28	6.512	.625	.777
<b>Herd behavior (DD)</b>	Cronbach's Alpha = .838			
DD1	11.67	6.594	.644	.721
DD2	11.69	5.976	.689	.694
DD3	11.67	6.007	.702	.687
<b>Risk attitude (RR)</b>	Cronbach's Alpha = .878			
RR1	15.83	24.979	.569	.547
RR2	15.87	24.867	.616	.538
RR3	15.89	24.355	.597	.533
RR4	15.86	24.384	.585	.551
<b>Firm image (HA)</b>	Cronbach's Alpha = .900			
HA1	19.77	18.675	.755	.878
HA2	19.84	19.493	.711	.885
HA3	19.79	19.105	.748	.880
HA4	19.84	19.319	.706	.886

HA5	19.81	19.405	.698	.887
HA6	19.80	19.057	.751	.879
<b>Accounting information (KT)</b>	Cronbach's Alpha = .887			
KT1	16.13	12.414	.792	.846
KT2	16.16	13.596	.709	.866
KT3	16.17	13.016	.722	.863
KT4	16.20	13.515	.691	.870
<b>Neutral information (NI)</b>	Cronbach's Alpha = .881			
NI1	16.24	11.820	.698	.861
NI2	16.22	11.914	.723	.854
NI3	16.13	11.942	.763	.846
NI4	16.30	11.973	.731	.853
NI5	16.31	12.122	.669	.867
<b>Advocate information (YK)</b>	Cronbach's Alpha = .803			
YK1	7.49	3.974	.651	.729
YK2	7.35	4.093	.641	.739
YK3	7.26	3.867	.655	.724
<b>Personal financial needs (NC)</b>	Cronbach's Alpha = .929			
NC1	15.90	17.159	.820	.912
NC2	15.92	17.380	.819	.912
NC3	15.87	17.255	.801	.916
NC4	15.88	17.203	.820	.912
NC5	15.89	17.524	.810	.914
<b>Decision-making (QD)</b>	Cronbach's Alpha = .883			
QD1	8.24	3.604	.786	.822
QD2	8.22	3.693	.778	.830
QD3	8.24	3.859	.755	.849

#### 4.1.3. Exploratory factor analysis (EFA)

##### 4.1.3.1. EFA analysis for independent variables

**Table 4.1.4: KMO and Bartlett's test results for independent variables**

<b>KMO and Bartlett's Test</b>		
<b>Kaiser-Meyer-Olkin Measure of Sampling Adequacy</b>		<b>.941</b>
Bartlett's Test of Sphericity	Approx. Chi-Square	5614.343
	df	595
	Sig.	.000

The test results showed that the KMO index is  $0.941 > 0.5$ , so the research data is suitable for conducting factor analysis. Bartlett's test has a result of 5614.343 with a significance level of  $\text{Sig} = 0.000 < 0.05$ . Therefore, the variables are correlated with each other and meet the condition for factor analysis, so the hypothesis that the correlation matrix between variables is uncorrelated is rejected.

**Table 4.1.5: Factor matrix with Principal Varimax method.**

	Factor							
	1	2	3	4	5	6	7	8
HA6	.779							
HA1	.761							
HA3	.724							
HA5	.716							
HA4	.704							
HA2	.683							
NC2		.784						
NC1		.782						
NC3		.772						
NC4		.761						
NC5		.753						
KT1			.809					
KT4			.752					
KT5			.751					
KT3			.737					
KT2			.727					
NI2				.717				
NI3				.695				
NI4				.685				
NI1				.673				
NI5				.613				
RR3					.818			
RR1					.777			
RR4					.754			
RR2					.728			
TT3						.751		
TT1						.750		
TT4						.733		
TT2						.716		
DD3							.743	
DD1							.728	
DD2							.706	
YK3								.784
YK2								.740
YK1								.716
Eigenvalues								1.080
Extraction Sums of Square Loadings								71.632
Extraction Method: Principal Component Analysis								
Rotation Method: Varimax with Kaiser Normalization								
Rotation converged in 7 iterations								

The Principal Components analysis with Varimax rotation shows that the initial 37 observed variables are extracted into 8 meaningful factors that best summarize the information; the Eigenvalue coefficient is  $1.080 > 1$ . The result also indicates that the extracted variance of 71.632% shows that 71.632% of the data variability is explained by 8 factors that comply with the evaluation standard of the factor extraction method.

#### 4.1.3.4. EFA factor analysis for dependent variables

**Table 4.1.6: KMO and Bartlett's test results for dependent variables.**

KMO and Bartlett's		
Kaiser-Meyer-Olkin Measure of Sampling Adequacy		<b>.744</b>
Bartlett's Test of Sphericity	Approx. Chi-Square	410.412
	df	3
	Sig.	.000

After conducting EFA, 3 observed variables of the "Investment decision" scale were grouped into 1 factor, and no observed variables were excluded. The EFA test result showed that the KMO coefficient was 0.744, indicating that the research data was suitable for factor analysis. The Bartlett test had a result of 410.412 with a significance level of Sig. = 0.000 < 0.05. Therefore, the variables were correlated with each other and met the conditions for factor analysis, and the hypothesis of the correlation matrix between variables being uncorrelated was rejected.

**Table 4.1.7: Summary table of cumulative variance eigenvalue for dependent variables.**

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings		
	Total	% Variance	Cumulative %	Total	% of Variance	Cumulative %
1	2.431	81.048	81.048	2.431	81.048	81.048
2	.308	10.265	91.312			
3	.261	8.688	100.000			

After conducting the EFA for the dependent variables using Principal Components with Varimax rotation, the results showed that the total extracted variance was nearly 81%, indicating that these 3 factors explain 81% of the variability in the data. The Eigenvalue scores of the factors were high (>1). All observed variables had factor loading scores >0.5.

**Table 4.1.8: Factor matrix of "Investment decision"**

Component	Factor
	1
QD1	.907
QD2	.903
QD3	.891

The results of the analysis of the observed variables are divided into 8 unique factors and 1 dependent factor. Therefore, the results of the EFA factor analysis to determine the factors obtained from the observed variables are consistent with the initial proposed research model.

#### 4.1.4. Linear regression analysis

##### 4.1.4.1. Model fit assessment

**Table 4.1.9: Summary of the regression model**

Model	R	R <sup>2</sup>	Adjusted R <sup>2</sup> square	Std. Error Of the Estimate	Durbin - Waston
1	.814 <sup>a</sup>	.662	.651	.55354	2.077
a Predictors: (Constant), NC, TT, KT, YK, RR, HA, DD, NI					
b Dependent Variable: QD					

The adjusted R<sup>2</sup> coefficient has a value of 0.651 > 0.5, meaning that about 65.1% of the variance in investment decisions is explained by 8 independent variables: Overconfidence, Herd behavior, Risk

attitude, Firm image, Accounting information, Neutral information, Advocale information and Personal financial needs. The remaining 34.9% of investment decisions are explained by other factors.

**4.1.4.2. Testing the goodness of fit of the model**

**Table 4.1.10: ANOVA table for testing the goodness of fit of the model.**

Model	Sum of Squares	df	Mean square	F	Sig.
Regression	97.147.132	8	18.391	60.023	.000 <sup>b</sup>
Residual	75.070	245	.306		
Total	222.202	253			
a. Predictors: (Constant), NC, TT, KT, YK, RR, HA, DD, NI					
b. Dependent Variable: QD					

In the ANOVA table, we can see that the F-value of 60.023, calculated from the R2 value with a Sig. value of 0.00, is very small, indicating that the regression model fits the data well and can be used.

**4.1.4.3. Regression Weight Test**

**Table 4.1.11: Regression Weight Table.**

Model		Unstandardized Coefficients		Standardized Coefficients	t	Sig.
		B	St. Error	Beta		
1	(Constant)	-.372	.213		-1,748	.082
	Overconfidence - TT	.155	.053	.137	2.916	.004
	Risk attitude - RR	.133	.047	.133	2.807	.005
	Herd behavior - DD	.111	.052	.107	2.109	.036
	Firm image - HA	.142	.056	.132	2.529	.012
	Accounting information – KT	.180	.051	.171	3.516	.001
	Neutral information – NI	.194	.063	.176	3.083	.002
	Advocate information – YK	.116	.046	.117	2.484	.014
	Personal financial needs - NC	.111	.048	.122	2.323	.021
a. Dependent Variable: QD						

In table 4.1.12, the results of the regression coefficients are shown. If Sig. < 0.05, which is equivalent to 95% confidence level and  $|t| > 2$ , then the factor is accepted, meaning that it has an impact on investment decisions. At the same time, the standardized Beta coefficient of the 8 independent variables is greater than 0, indicating that these independent variables have a positive impact on the dependent variable. In addition, all independent variables have a Sig. value less than 0.05, indicating that they are statistically significant in the model and reject the H0 hypothesis that the independent variables have no positive correlation with the dependent variable.

The regression coefficient is presented in two forms: unstandardized and standardized. Because the unstandardized regression coefficient (B) depends on the scale of measurement, we cannot use it to compare the impact of independent variables on the dependent variable in the same model. The standardized regression coefficient (Beta) is the coefficient that has been normalized for variables, so we can use it to compare the impact of independent variables on the dependent variable. The larger the weight of this variable, the stronger its impact on the dependent variable.

Therefore, the linear regression equation is as follows:

$$QD = .137*TT + .133*RR + .107*DD + .132*HA + .171*KT + .176*NI + .117*YK + .122*NC + \epsilon$$

## 4.1.4.4. Test of multicollinearity phenomenon

**Table 4.1.12: Multicollinearity statistics table.**

Model		Multicollinearity phenomenon	
		Tolerance	VIF
	(Constant)		
	Overconfidence – TT	.626	1.598
	Risk attitude - RR	.610	1.638
	Herd behavior - DD	.533	1.877
	Firm image - HA	.510	1.962
	Accounting information – KT	.582	1.718
	Neutral information – NI	.422	2.367
	Advocate information – YK	.619	1.616
	Personal financial needs - NC	.502	1.992

According to the table of multicollinearity statistics, the VIF coefficients of the independent variables have values ranging from 1.598 to 2.367 (all of them are less than 10). Therefore, it can be concluded that the model does not suffer from multicollinearity.

**4.2. Discussion**

Through the analysis, the study yielded the following results:

- Descriptive statistics on the survey sample characteristics to gain a better understanding of the subjects.
- Assessment of the reliability of the scale using Cronbach's Alpha coefficient, which showed that all variables had high reliability after removing those that did not meet the requirements.
- Exploratory Factor Analysis (EFA) identified 8 independent variables that impact a dependent variable, including Overconfidence (TT), Herd behavior (DD), Risk attitude (RR), Firm image (HA), Accounting information (KT), Neutral information (NI), Advocate information (YK), and Personal financial needs (NC).
- Multivariate regression analysis and hypothesis testing confirmed that investment decisions are influenced by the 8 factors mentioned above. Among them, Neutral information (NI) has the greatest impact on investment decisions.

**5. CONCLUSION**

The research offers valuable insights into the factors influencing investment decisions, particularly among students in the Vietnamese stock market. It successfully integrates psychological and social factors, providing a comprehensive understanding of the decision-making process.

The research model suggests that there are eight variables that have a positive impact on students' investment decisions. These variables encompass psychological factors such as overconfidence, risk attitude, and personal financial needs, as well as social factors including firm image, advice from advocates, neutral information, accounting information, and herd behavior. This represents a novel approach to the subject matter, as previous studies predominantly concentrated on either psychological or external factors in isolation. Moreover, this study overcomes limitations by analyzing both financial and psychological factors affecting individual investors, thus offering a more comprehensive understanding of the decision-making process, specifically among students in the present context.

One key finding of the research is the importance of neutral information in shaping investment decisions (= 0.176). This reflects that students' investment decisions are heavily dependent on information from the Government, social networks, past information, etc. Because students are the generation that grew up in the online world, the huge advantage of being able to capture information leads to the fact that when

the information is positive, student investors will tend to become more confident and invested. The second most influential factor on students' investment decisions is Accounting Information (= 0.171). The study also proves that the remaining factors also play a positive role in the investment decision.

In general, the topic can contribute a theoretical basis and solid arguments for managers to succeed in providing effective solutions, improving investment situations, especially in information asymmetry, along with promoting the strong development of Vietnam's stock market:

- For individual investors, the research emphasizes the importance of acquiring knowledge and skills in finance, understanding personal financial needs, and maintaining a balanced level of confidence. This highlights the need for investors to be well-informed and equipped with the necessary tools for effective decision-making.

- In terms of government policies, the study suggests enhancing credit for domestic businesses, ensuring strict regulations on securities margin trading, investing in advanced technology for securities companies, and imposing penalties for providing false information. These measures aim to create a more stable and reliable investment environment, fostering investor trust and confidence.

- The research also provides recommendations for joint-stock companies to enhance their attractiveness to investors. Transparency, positive image-building, attractive dividend policies, and expanding business areas are identified as key strategies to attract investors and create long-term value.

- Educational institutions, especially schools, should actively promote stock market knowledge among students. This can be done through initiatives like stock trading competitions, comprehensive training courses, and workshops to increase students' awareness and understanding of the stock market. By fostering financial literacy and investment skills early on, educational institutions can empower students to make informed financial decisions in the future.

The study on investment decisions in the Vietnamese stock market provides valuable insights but has limitations. It focused only on students and investors in Ho Chi Minh City, limiting the generalizability of the findings. Future research should include a more diverse sample from different regions of Vietnam to enhance understanding. Additionally, exploring the interaction between psychological and social factors and investigating other variables not covered would be beneficial. Addressing these limitations will improve the efficiency and knowledge of the stock market in Vietnam, benefiting investors, policymakers, joint-stock companies, and educational institutions. Future studies should also expand the sample size to include investors of all ages and from various cities. Furthermore, deeper exploration of the practical application of fundamental analysis and examination of the impact of significant events like the COVID-19 pandemic and oil price volatility would provide valuable insights.

## ECONOMIC POLICY UNCERTAINTY AND INVESTMENT DECISIONS: DO BUSINESS CHARACTERISTICS MATTER?

**Author: Vo Dinh Que Chau<sup>1</sup>, Tran Thi Kim Ngan<sup>1</sup>, Nguyen Thi My An<sup>1</sup>,  
Nguyen Thi My Hiep<sup>1</sup>, Nguyen Van Hung<sup>1</sup>  
Mentor: Ho Thu Hoai<sup>1</sup>**

**ABSTRACT:** *This study is conducted to examine the impact of Global Economic Policy Uncertainty (GEPU) and China Economic Policy Uncertainty (China EPU - CEPU) on the size and efficiency of Vietnamese business investment. The research sample is collected through a 10-year period, from 2012 to 2021, including 190 firms listed on the Hanoi Stock Exchange (HNX) and the Ho Chi Minh City Stock Exchange (HOSE). After analyzing the research data, the authors draw a conclusion that uncertain global and China economic policies can inhibit the expansion and, at the same time, reduce the efficiency of business investment. In addition, the study also classifies the research sample into different groups based on specific characteristics, including business ownership, level of capital concentration, industry properties, and firms headquarter location, in order to investigate whether the influence of GEPU and CEPU differs for each business in these groups.*

**Keywords:** *Economic policy uncertainty, investment, efficiency*

### 1. INTRODUCTION

Economic policy uncertainty (EPU) rises from the fact that the government's policies and legal framework remain ambiguous and unclear, making investors and other businesses feel concerned and delay investment because of the risk of market uncertainty. In Vietnam, the national economy has dealt with several challenges from its volatile sides. Following a short time of stabilization at a low level since 2014, the EPU index suddenly increased again, with the reason being explained by the influence of the Covid-19 pandemic. However, in the second quarter of 2022, the volatility index of Vietnam's economic policy rose sharply again. The return of this index is explained by external influences such as the increase in global inflation, or the FED's interest rate policy putting pressure on the exchange rate. Along with that, there are problems related to the corporate bond market, leading businesses not to issue bonds to raise capital. The economic situation in Vietnam has suffered from many adverse effects of economic policy uncertainty, first on the financial system and then on the economy. Therefore, to reduce the uncertainty of economic policies, policymakers need to ensure transparency, consistency, and feasibility, thereby creating a foundation for the development and implementation of economic policies.

Currently, studying the impact of EPU on business investment activities as well as other activities is attracting many authors' attention (Li, Guo, & Chen, 2021). Most studies agree that elevated EPU has an inverse impact on investment (Gulen & Ion, 2016; Julio & Yook, 2012; Li & Yang, 2015). In addition, the reduction in investment, employment, and consumption by businesses and households is also found to be strongly related to high EPU (Gulen and Ion, 2016, Baker, Bloom, and Davis, 2016). Business investment activities are the most affected if there is a change in the EPU since rising EPU could slow down economic recovery and, make it difficult for governments to predict and at the same time increase investors' perception of risk and create negative sentiment among investors.

---

<sup>1</sup> University of Economics Ho Chi Minh City.

From the aforementioned background, the authors conduct this study to examine the influence of EPU on business investment from the perspective of investment size and efficiency, in order to help businesses make rational decisions in different cases, limit the risks that businesses and government may face due to the impact of economic policy uncertainty. Therefore, the paper will in turn address the following specific objectives:

- i. Investigate the impact of global EPU and China EPU on the size and efficiency of business investment.
- ii. Explore the difference in the impact of global EPU and China EPU on businesses with different characteristics, including types of ownership, industry properties, level of capital concentration, and headquarter location.
- iii. Recommendations for businesses and managers to enhance investment performance optimally and effectively.

The research will be presented in three main directions. Firstly, we will examine the impact of the Global and China EPU index on business investment. China was chosen for the study among other nations since it is one of Vietnam's main trading partners. In recent years, the trade economy between Vietnam and this economy has been constantly developing, so any fluctuation in EPU of this country, and also the world, could directly affect Vietnam's economy. Secondly, our study will expand further by focusing on both the size and efficiency of business investment, and at the same time, explain the changes in investment behavior of firms through two categories: underinvestment and overinvestment. Lastly, the research will divide the research sample into 4 different groups of firms, according to types of ownership, industry properties, level of capital concentration, and firms headquarter location to examine the differences in the effect of EPU on each business of these groups.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Theoretical basis**

#### **2.1.1. Theories related to the business investment decisions**

Investment decisions of firms are decisions related to the total value of assets of the firm or the value of each part of assets (short-term and long-term assets) to orient long-term operations. Investing activity is sacrificing certain present value in exchange for uncertain (but greater) value in the future. This is an important factor that could directly affect the businesses since it creates value for the firm.

In the economy, investments take various forms. These include investing in fixed assets such as factories, machinery, and transportation to boost production capacity. Liquid asset investment involves raw materials and goods with changing volumes over time. Strategic investment aims to develop business strategies for increasing market share and competitiveness. Meanwhile, modernization investment concentrates on upgrading machinery and equipment to reduce costs and improve product quality. Expansion investment can be made for new businesses or by expanding production capacity for existing products. Replacement investments involve replacing outdated equipment to enhance operational efficiency. When making investment decisions, factors like interest rates, economic growth, wage, depreciation costs, and inflation's impact on the project should all be considered.

As an organization, when making an investment decision, it is necessary to carefully consider three closely related principles in investment decisions, including maximizing business value, considering the value of money over time, and risk-return trade-off. Making wise investment decisions will raise the

company's worth, which will increase the owner's asset value as well. On the other hand, if the incorrect investment choice is made, the business's value would drop, harming the owner's good.

### **2.1.2. Theories related to economic policy uncertainty**

There have been many economic-financial theories that suggest the causes of uncertainty in the economy, such as epidemics, terrorist attacks, financial crises, etc. One of the causes that has attracted much attention recently is economic policy uncertainty (EPU), which arises from the uncertain policies of the government (Baker et al., 2016). There are three components to the EPU, including uncertainty in the designation of policymakers, how monetary and fiscal policies are set, and the effect these new policies can bring to the economy. During the gubernatorial election period, the EPU can increase when the public is unsure about who will come up with new policies, when business managers cannot predict the imposition of new policies, or how new trade sanctions might affect their business activities (Mordfin, 2014). During this time, firms are required to carefully pay attention to the business environment in which their company operates, to be able to make prudent decisions and help minimize risks when investing. Since the EPU has a particularly negative impact on operational performance and the development of the economy, the ability to understand, analyze, and deal with this uncertainty is critical and indispensable for businesses.

The measurement of economic policy uncertainty is substantially crucial, especially when we want to assess its impact on various subjects. Baker et al. (2016) introduced a text-mining approach to construct media-based volatility indices. The index was built by the authors from two main sources of information. They analyzed phrases expressing economic policy uncertainty in articles, quantifying their frequency and sentiment using machine learning techniques. Additionally, they considered deviations in forecasted values of key economic indicators and variations among economic forecasters' perceptions. This comprehensive index provides valuable insights into the dynamics of economic policy uncertainty and its consequences on the economy and its participants.

However, one of the disadvantages of the text mining method is that it depends on media control and government interference. As a result, these indicators can change as the government deliberately alters the level of media control. To solve this problem, Jurado, Ludvigson & Ng. (2015) proposed alternative indicators reflecting the performance of the real economy and financial markets based on big data mining, as well as measuring the volatility of economic policy through two sets of data. Large data reflects the overall economic situation, including 132 indicators, whereas 147 indicators reflect different aspects of the economy. Market and business conditions include data from 155 US firms regarding daily sales and profits.

## **2.2. Previous empirical studies**

### **2.2.1. Previous research on the impact of EPU on the size and efficiency of business investment**

Several past researchers have investigated the effect of EPU on the size and efficiency of business investment. Using sample data of Chinese firms from Q1/2003 to Q4/2012, Y. Wang, et al. (2014) found that increasing EPU constrains businesses to scale up investments. In addition, those firms with the goal of expanding market share will be more sensitive, making businesses more cautious in maintaining their branches in other locations. In addition, the research results show that state-owned enterprises will be less affected by economic policy uncertainty than other businesses. T. Liu et al. (2022) also examined the influence of China's economic policy uncertainty (EPU) on business investment decisions, with the final results showing that an increase in EPU will make firms reduce their investment.

Using the measurement developed by Baker, Bloom, and Davis (2013), Gulen and Ion (2015) explored a strongly negative relationship between the degree of policy volatility and business capital investment.

Therefore, they drew a conclusion that the uncertainty of policies increases the benefits from investment delay, leading to firms' limiting expansion of investment. Furthermore, by using data collected from China, India, Japan, Pakistan, Singapore, and South Korea, Farooq, et al. (2022) discovered that EPU has an inverse effect on business investment, implying that an increase in economic policy uncertainty will discourage investment behavior because the risk of failure will increase during these times.

Sustainable development in the period of economic volatility is an extremely important factor, related to the survival of businesses. Guo, et al. (2020) examined the impact of economic policy uncertainty (EPU) on the investment value and profitability of 389 Chinese businesses and found that economic policy uncertainty could limit the profitability and size of business investment. Consequently, to promote investment and enhance operational efficiency, it is crucial for the government to minimize policy changes that can cause businesses to delay their investments. By providing a stable operating environment, businesses can effectively adapt new policies and make timely investment decisions.

Based on the results drawn from several previous research above, the authors formulate a research hypothesis about the relationship between economic policy uncertainty and the size of business investment as follows:

***Hypothesis H1: Economic policy uncertainty reduces the size of business investment.***

Meanwhile, according to Liu, Zhou, and Liu (2022), after testing the sample consisting of different Chinese businesses, the final results showed that the uncertain economic policy exacerbates the situation of overinvestment and underinvestment, thereby limiting the improvement of the efficiency of firm investment. Correspondingly, using a sample of businesses from 24 countries over the 2001–2020 period, Muhammad Ilyas and Muhammad Tahir Suleman (2022) investigated that, on the one hand, countries with low investor protection drive the negative effect of EPU on investment efficiency. On the other hand, countries with strong investor protection neutralize the adverse impact of EPU on their investment efficiency.

To find an empirical explanation of how EPU affects investment inefficiency, S. Akron et al. (2022) collected data from 5,836 Europe firms and separated them into 2 different groups: overinvested and underinvested firms. The results stated that, in terms of investment inefficiency, the impact of uncertainty is negative to the overinvested businesses and positive to the underinvested businesses due to asymmetric information. Another point that is taken into consideration is, uncertainty was also found to make business investment decisions better and improve the performance of firms.

From the empirical results concluded from previous research, the authors process to develop the second hypothesis as follows:

***Hypothesis H2: Economic policy uncertainty reduces the efficiency of business investment.***

**2.2.2. Studies related to the impact of EPU on business investment with different characteristics**

Bianco, et al. (2013) studied the relationship between uncertainty and investment of Italian private businesses. The results drawn from the research concluded that family business investments are more influenced and sensitive to uncertainty than non-family businesses, due to the higher risk aversion of family businesses. Furthermore, AzAzhar, Abbas, Waheed, & Malik (2019) also examined all non-financial businesses listed in Pakistan to investigate the impact of ownership structure and management on investment efficiency. They deduced that businesses are likely to get a higher level of investment efficiency when considering the decrease in the concentration level of the business, as explained by the stress for corporate management and the lower expected returns.

---

In their research conducted to examine the impact of EPU on business investment in Australia from a sample of 391 firms in the period between 2022 and 2017, Wu, et al. (2020) discovered a positive association between EPU and the investments of businesses located in small states. However, the EPU influence on the investment activities of businesses located in large states is found to be insignificant. The conclusion that businesses in small states are more affected by EPU can be explained as due to the lack of economic development in small states, as well as the poor management structure which can make it hard for these businesses to respond to instability. Cui, et al. (2021), with a sample of 15030 observations over an 11-year period, from 2007-2017, also found the state ownership factor can weaken the effect of EPU on investment because SOEs (State-owned enterprises) are likely to be prioritized for protection by the government and have easier access to external financing.

Furthermore, Q. Kong, et al. (2022) carried out their study to investigate the association between EPU and the investment of Chinese firms. After analyzing their findings, the authors deduced that macro-policy uncertainty inhibits firms investment size and efficiency, whether the firms are operating in polluting or non-polluting industries. However, the influence is greater on firms belonging to the heavy-polluting industries.

Based on the results drawn from the research above, the authors proceed to develop the research hypothesis as follows:

*Hypothesis H3a: There is a difference in the impact of economic policy uncertainty on the investment of state-owned, private, FDI, and other businesses.*

*Hypothesis H3b: There is a difference in the impact of economic policy uncertainty on polluting and non-polluting businesses.*

*Hypothesis H3c: There is a difference in the impact of economic policy uncertainty on businesses with high capital concentration and low capital concentration.*

*Hypothesis H3d: There is a difference in the impact of economic policy uncertainty on businesses whose headquarters locate in non-central areas.*

### 3. RESEARCH METHOD

#### 3.1. Research data

The research sample of this research is collected from 190 Vietnamese businesses listed on the Hanoi Stock Exchange (HNX) and the Ho Chi Minh City Stock Exchange (HOSE) from 2012 to 2021. Data on the economic policy uncertainty (EPU) index is gathered by the authors from the website [policyuncertainty.com](http://policyuncertainty.com). The annual EPU is calculated by calculating the average of the 12 monthly EPUs provided by the website over the research period. Other data related to firms are collected from their published financial statements and annual reports.

#### 3.2. Research models

##### 3.2.1. The impact of economic policy uncertainty (EPU) on the size and efficiency of business investment

Firstly, the authors study the effect of economic policy uncertainty on the size of business investment. Based on the research of Huang, Lu, and Huang (2021), the model used to examine the impact of EPU on investment size is built as follows:

$$SCALE_{ijt} = \alpha_0 + \alpha_1 \cdot EPU_{ijt} + \alpha_2 \cdot SIZE_{ijt} + \alpha_3 \cdot AGE_{ijt} + \alpha_4 \cdot CF_{ijt} + \alpha_5 \cdot STRUC_{ijt} + \alpha_6 \cdot ROA_{ijt} + \alpha_7 \cdot RISK_{ijt} + \lambda_j + \mu_t + \varepsilon_{ijt} \quad (1)$$

in which, the subscripts  $i, j, t$  describe the business, industry, and research year, respectively. The dependent variable SCALE represents the investment size of the business, which measurement will be explained in detail below. EPU is the main independent variable which (comprises Global EPU and China EPU), showing the uncertainty of economic policy. The control variables including business size (SIZE), number of years operating since IPO (AGE), operating cash flow (CF), asset structure (AS), return on total assets ratio (ROA), and financial risk (RISK) are also added to examine the impact on the size of business investment. In addition,  $\lambda_j$  represents the industry fixed effect,  $\mu_t$  represents the time-fixed effects, and  $e_{ijt}$  is the residual of the model.

Secondly, after testing the influence of EPU on the investment scale of the business, the research also examines the impact on the investment efficiency after referencing the research of Q. Kong, et al. (2021) via the model as follows:

$$\text{EFFICIENCY}_{ijt} = \alpha_0 + \alpha_1 \cdot \text{EPU}_{ijt} + \alpha_2 \cdot \text{SIZE}_{ijt} + \alpha_3 \cdot \text{AGE}_{ijt} + \alpha_4 \cdot \text{CF}_{ijt} + \alpha_5 \cdot \text{STRUC}_{ijt} + \alpha_6 \cdot \text{ROA}_{ijt} + \alpha_7 \cdot \text{RISK}_{ijt} + \lambda_j + \mu_t + \varepsilon_{ijt} \quad (2)$$

### 3.2.2. Evaluating heterogeneity in the impact of economic policy uncertainty (EPU) on investment of businesses

Besides, to analyze the heterogeneity, the authors have classified the businesses into 4 different groups, including: firms with different types of ownership (State-owned Enterprises - SOEs, Private firms, Foreign-Invested firms, and Other firms), industry properties (Heavy polluting industries and Non-heavy polluting industries), level of capital concentration (Firms with high concentration of capital and firms with low capital concentration), firms headquarter location (Whose headquarters locate in non-central areas) and conduct the regression for these groups using model (1) and (2).

Specifically, on business ownership, firms with a share ownership ratio of more than 50% belonging to the State will be classified as “State-owned enterprises”. Besides, FDI firms are classified by consulting the list of foreign-invested businesses collected from the State Securities Commission (SSC). Regarding the classification of heavy polluting/non-heavy polluting firms, based on Appendix II to Decree 08/2022/ND-CP, the research classifies firms operating in the fields which are likely to cause environmental pollution at level I, including mineral processing, cast iron, steel, pulp, and paper production, chemicals, chemical fertilizers, textiles, garment, oil and gas, natural gas, and coal-fired power generation are heavy-polluting firms. Firms with capital concentration levels greater than the median value of the sample will be classified as having high capital concentration, whereas firms with capital concentration lower than the median value will be classified as having low capital concentration. Lastly, firms with their headquarters not located in 4 cities: Hanoi, Da Nang, Can Tho, and Ho Chi Minh are considered non-central.

### 3.3. Description of variables

#### 3.3.1. Dependent variables

**SCALE - Investment size.** *When making investment decisions, businesses must consider the size of the project. With large-scale projects, they have to face higher risks and unpredictable events in the future and must prepare a large investment capital. Additionally, it is necessary to have professional skills in using specific calculation methods. After referring to the studies of Huang, Lu, and Huang (2021), Kong, et al. (2022), the research has determined to measure the investment size of the business by taking the sum of (Net fixed-assets; Net intangible assets; Other assets) divided by total assets:*

$$\text{SCALE} = (\text{Net Fixed Asset} + \text{Net Intangible Asset} + \text{Other}) / \text{Total Assets}$$

**EFFICIENCY - Investment efficiency.** Before deciding to invest, it is necessary to evaluate the effectiveness under different aspects, especially from a financial perspective. Besides opening up opportunities for investors, investment projects can also bring unpredictable disadvantages, therefore, businesses must carefully evaluate before making the decision to invest or not. After referring to the work of Richardson (2006), Xin, Zheng, and Yang (2007), Huang, Lu, and Huang (2021), and Kong, et al. (2022), the research uses the absolute value of residuals from the following two investment scale models to measure the efficiency of business investments:

$$SCALE_{ijt} = \alpha_0 + \alpha_1 \cdot GROWTH_{ijt} + \alpha_2 \cdot LEV_{ijt} + \alpha_3 \cdot CASH_{ijt} + \alpha_4 \cdot LnAGE_{ijt} + \alpha_5 \cdot SIZE_{ijt} + \alpha_6 \cdot RETURN_{ijt} + \alpha_7 \cdot IvSCALE_{ij,t-1} + \sum Industry + \sum Year + \varepsilon_{ijt} \tag{3}$$

$$SCALE_{ijt} = \alpha_0 + \alpha_1 \cdot TOBINQ_{ijt} + \alpha_2 \cdot CASH_{ijt} + \alpha_3 \cdot LnAGE_{ijt} + \alpha_4 \cdot SCALE_{ij,t-1} + \sum Business + \sum Year + \varepsilon_{ijt} \tag{4}$$

$\varepsilon_{ijt}$  is the residual that the research needs to estimate. The larger the absolute value of the residuals from models (3) and (4), the higher the level of investment inefficiency of the business.

There is also the value of the residual  $\varepsilon_{ijt}$  from model (3) to assess the level of underinvestment and overinvestment of the business. Specifically, businesses with a positive residual value will be evaluated as overinvested (OVER), whereas a business with a negative residual value means that the business has not taken advantage of the capital to carry out all of the potential projects and will be assessed as underinvested (UNDER).

### 3.3.2. Independent variable

Economic Policy Uncertainty (EPU) is considered as an index measuring the volatility of world economic policies developed by Baker, et al. (2016) with data from 20 developed countries in the world. The variable EPU is a fairly new variable in empirical research on economic factors in general and investment in particular. An increase in the EPU means that investment decisions in equity are higher than those in financial assets, thereby reducing the risk suffered, and at the same time providing the foundation for businesses to have contingency strategies in place when similar situations arise (Yan Zhao, Kun Su, 2022).

**Table 3.1. Description of variables**

<i>Dependent variables</i>		
SCALE	Investment scale	(Net Fixed Assets+Net Intangibles + Other Assets)/Total Assets
EFFICIENCY	Investment efficiency	Absolute value of residuals from models (3) and (4)
OVER	Overinvested businesses	Positive residual value from model (3)
UNDER	Underinvested businesses	Negative residual value from model (3)
<i>Independent variable</i>		
EPU	Economic Policy Uncertainty	
<i>Control variables</i>		
SIZE	Business size	ln(Total assets)
AGE	Age of the business	ln(Year of research - Year of IPO)
CF	Cash flow from operating activities	(EBIT + Depreciation – Tax)/Total assets
AS	Asset structure	(Fixed assets + Inventory)/Total assets
ROA	Return on total assets	Net profit/Total assets
RISK	Financial risk	Liabilities/Total assets

*Source: Authors' collection*

### 3.4. Research methods

Firstly, we perform descriptive statistics to find the mean, standard deviation, maximum value, and minimum value of the research sample. Next, the Pearson correlation matrix was conducted to find out the relationship between the dependent variables, independent variables, and control variables in the research. Secondly, the Ordinary Least Squares (OLS) model was used to process the research data. The OLS model has been used for data analysis in previous studies by Kong, et al. (2022). The OLS regression model has the following functional form:

$$Y_{it} = \beta_0 + \beta_1 X_{1,it} + \beta_2 X_{2,it} + \dots + \beta_k X_{k,it} + \varepsilon_{ij}$$

In addition, the random effects model (REM) and fixed effects model (FEM) are also used to control for industry fixed effects and time fixed effects.

The random effects model (REM) has the form of a regression function as follows:

$$Y_{it} = \beta_0 + \beta_1 X_{1,it} + \beta_2 X_{2,it} + \dots + \beta_k X_{k,it} + v_i + \varepsilon_{ij}$$

in which,  $v_i$  are unobservable factors that change between subjects but are constant over time

The fixed effects model (FEM) has the form of a regression function as follows:

$$Y_{it} = \beta_0 + \beta_1 X_{1,it} + \beta_2 X_{2,it} + \beta_3 Z_i + \varepsilon_{ij}$$

$$Y_{it} = \beta_1 X_{1,it} + \beta_2 X_{2,it} + \alpha_i + \varepsilon_{ij}$$

in which  $\alpha_i$  are factors that vary between subjects but are not observable and do not change over time.

In order to choose which method is optimal among the three methods above, the study performed F-test and Hausman Test. Then, the research proceeds to test the violation of the model hypothesis. On checking multicollinearity, the authors utilize the correlation matrix and the results of the Variance Magnification Factor (VIF), specifically, the values of the correlation coefficients between the variables exceed 0.8 indicating that those variables are highly correlated with each other and there is a possibility of multicollinearity in the model. In addition, Breusch-Pagan test and Wooldridge test were also used to test the existence of heteroskedasticity and autocorrelation. Lastly, the Feasible Generalized Least Squares (FGLS) method is utilized to overcome the heteroskedasticity and autocorrelation problems occurring in the model.

On the other hand, to test the robustness of the research model, the authors use two-stage regression model (2-Stage Least Squares - 2SLS) and the instrumental variable (Instrumental Variable - IV) in order to overcome the endogeneity of the research variable, ensuring that the research results provided are consistent and reliable.

## 4. RESULTS AND DISCUSSION

### 4.1. Descriptive statistics

**Table 4.1. Descriptive statistics**

Variable	Obs	Mean	Std. Dev.	Min	Max
SCALE	1,900	0.5260006	2.951028	0	72.3294
EFFICIENCY	1,900	0.0925838	0.3880225	0.0003189	5.376628
GEPU	1,900	5.160471	0.3261291	4.663147	5.768465
CEPU	1,900	5.770543	0.6550507	4.735295	6.674402
SIZE	1,900	27.55337	1.629295	23.6367	33.69104

AGE	1,900	2.086913	0.4606799	0.1015175	3.064159
CF	1,900	0.0753431	0.1468228	-0.4913819	1.39701
AS	1,900	42.64342	462.1052	0	7482.773

RISK	1,900	0.5008384	0.2828644	-0.3460092	7.133735

Source: Authors' calculation

Table 4.1 presents the descriptive statistics results. SCALE receives the mean value of 0.5260006, illustrating more than 50% of the assets of the businesses in the sample are long-term assets. In addition, the large standard deviation shows that the mean of SCALE cannot accurately assess the firms in the years from 2012 to 2021, for example, there is too big a difference between the largest value and minimum value. EFFICIENCY has a standard deviation of 0.3880225 with the minimum and maximum values are 0.0003189 and 5.376628, respectively. Meanwhile, GEPU has an average value of 5.160471, fluctuating from 4.663147 to 5.768465. The small fluctuation range shows that the global EPU maintains a stable level with little volatility. Besides, the maximum and minimum values of CEPU are 4.735295 and 6.674402, respectively. In recent years, due to the impact of the Covid-19 epidemic, China's economic policy uncertainty will have a great impact on the global economy. That is reflected in the fact that China's EPU is more volatile than the global EPU through the fluctuation range of them.

Source: Authors' calculation

In general, the dependent variables (SCALE and EFFICIENCY) and the main independent variable (GEPU and CEPU) were not correlated with each other. However, the Global Economic Policy Uncertainty and the China Economic Policy Uncertainty have a positive correlation with each other at the 1% statistical significance level, the correlation is 0.9518 (>0.8), indicating that multicollinearity may exist in the model. In addition, business size (SIZE) is negatively correlated with the business's investment efficiency at the 5% statistical significance level and positively correlated with GEPU and CEPU at 1% statistical significance.

### 4.3. The impact of economic policy uncertainty (EPU) on the size and efficiency of business investment

In columns (1) and (2), the regression coefficients of GEPU and CEPU are -0.0136 and -0.0118, respectively, and significant at a 1% level, which implies that when other factors remain constant, GEPU increases by 1 percentage point will make investment size decrease by 0.0136 percentage points, and when CEPU increases by 1 percentage point, investment size will decrease by 0.0118. This demonstrates that the size of Vietnamese business investment is massively affected by the China economic policy uncertainty - a border country and an important trading partner in most manufacturing businesses.

AGE is also one of the factors that reduce the size of business investment. This often arises from competition for market share among businesses in the same sector during periods of economic policy uncertainty, which is in agreement with Q. Nguyen and H.T. Kim (2023). The only factor that increases the size of business investment is the firm size, meanwhile, business risk is found to have a negative association with investment scale.

Additionally, results from columns (3) - (6) on the effects of EPU on investment efficiency show that both global EPU and China EPU have positive impacts on business investment efficiency, no matter how EFFICIENCY is measured. Besides, the age of the business is also found to adversely influence investment efficiency. As a corporation age, investment policies and risk tolerance have already been maintained for a considerable amount of time. As a result, when businesses experience economic policy disadvantages, their investment alternatives will eventually become less effective than those of younger firms.

From the results from columns (7) and (8), it can be concluded that when considering two different types of businesses, the underinvestment businesses will be more sensitive to EPU compared to the overinvestment ones. This is partly based on the Catch-up Effect when underperforming businesses will take advantage of the benefits of adjusted economic policies to create value for their businesses. However, overinvested businesses are found to be more sensitive than those in the other group when it comes to the effect of asset structure (AS).

### 4.4. Endogeneity test

To further address the endogeneity problem, we continue conducting the 2SLS regression to estimate the impact of EPU on the investment, using alternative EPU index as instrumental variables. Based on the approach from Peng, et al. (2018) and Wu, et al. (2020), we decided to use the US and Korea EPU in

building the instrumental variable. Regression results using instrumental variables GEPUhat and CEPUhat are presented in Table 4.4.

**Table 4.4. Endogeneity test with instrumental variable regression (2SLS)**

	Investment scale		Investment efficiency		Overinvestment		Underinvestment	
	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)
	Scale		Efficiency		Scale		Efficiency	
GEPUhat	-0,067**		0,1931***		0,5067***		0,0067***	
CEPUhat		-0,0413**		0,1086**		0,2896**		0,0208*

_cons	-0,0657	0,0079**	-0,2036**	-0,0553*	-2,9136**	-1,9581	0,0051***	0,0577***

Note: \*, \*\*, \*\*\* represent statistical significance at 10%, 5% and 1%, respectively

Source: Authors' calculation

Table 4.4 presents the regression results from the 2SLS model. Except for the investment size, the coefficients of GEPUhat and CEPUhat are positive and statistically significant. Specifically, the regression coefficient of GEPUhat and CEPUhat are -0.067 and -0.0413 and statistically significant at 1% level for investment size, implying that other things being constant, a 1 percentage point increase in global and China economic policy uncertainty will cause firms to reduce their investment scale by 0.067 and 0.0413 percentage points, respectively. This indicates that the instrumental variables selected in this study are strongly correlated with endogenous variables. Regression results for GEPUhat and CEPUhat, which are considered in this study, are generally in agreement with the estimates in Table 4.3. Therefore, the results estimated above are robust and free from endogeneity problems.

#### 4.5. Impact of economic policy uncertainty (EPU) on the size and efficiency of business investment by different business's characteristics

##### 4.5.1 Impact of economic policy uncertainty (EPU) on the size and efficiency of business investment by types of ownership

First, examine the effects of global economic policy uncertainty (GEPU) and China economic policy uncertainty (CEPU) on investment size, the results show that both global and China EPU have inverse effects on the investment size of businesses with different ownership structures. GEPU and CEPU are found to have the least influence on the investment scale of state-owned enterprises. A possible reason for this difference is that SOEs have better access to government subsidies and external financing through guarantees and policy support from the government. Therefore, changes in macroeconomic policy uncertainty have less impact on their investment behavior. Furthermore, because governments at all levels have an advantage in mobilizing SOEs, they tend to give priority to interfering in the operations of SOEs, especially their investments when there is uncertainty in local policy and increased demand for steady growth. (Li, Xu, & Wang, 2021).

Next, examining the influence of GEPU and CEPU on the efficiency of business investment shows that the regression coefficients of both GEPU and CEPU are positive and statistically significant in the sample of state-owned businesses, private businesses, and foreign-invested businesses, while other businesses are not affected. Having the largest regression coefficients demonstrates that global policy uncertainty (GEPU) and China economic policy uncertainty (CEPU) have a substantially adverse impact on the efficiency of private business investment.

#### 4.5.2. Impact of economic policy uncertainty (EPU) on businesses' investment scale and efficiency by industry properties

The results of testing the impact of economic policy uncertainty on the size and efficiency of business investment by industry properties are presented in Table 4.6. The results show that the global EPU and the China EPU both have major influences on the size and investment efficiency of the firms operating in heavily polluted industries. Specifically, the regression coefficients of GEPU and CEPU are -0.057 and -0.034 and significant at 1% level, respectively, implying that other factors remain unchanged, global and China EPU increase of 1 percentage point will cause firms to reduce their investment size by 0.057 and 0.034 percentage points, respectively. In contrast, GEPU and CEPU improve the investment efficiency of firms. The regression coefficients of GEPU and CEPU are both positive and statistically significant at 1%, implying that when the uncertainty of global and China economic policies increases, it will reduce the investment efficiency of businesses. For businesses operating in non-heavy polluting sectors, the impacts of GEPU and CEPU on investment efficiency are negligible. Regarding the investment scale, GEPU and CEPU are found to have positive associations.

In this study, we use the share ownership ratio of the largest shareholder of the firm to measure the degree of equity concentration and divide the data set into 2 categories: firms with high equity concentration and firms with low equity concentration. The degree of equity concentration is determined by adjusting the share ownership ratio according to the industry characteristics, external environment, and internal performance of the company (Li, 2017). It can be seen that the EPU has varying effects on the investment choices made by businesses, depending on their equity concentration level.

GEPU and CEPU are found to have significant impacts mostly on the investment size and efficiency of firms with low equity concentration. These results indicate that policy uncertainty has a stronger inverse impact on the low capital concentration firms. This is explained by the fact that the low level of capital concentration means that the ownership of the company is more dispersed, which reduces the cost of the firm's investment decisions and increases the potential for conflicts, interests between shareholders and managers, leading to inefficient investments. As firm ownership becomes more dispersed, the costs of corporate investment decisions increase and there is a potential for conflicts of interest between shareholders and managers, resulting in ineffective investment (Yu & Wang, 2019; Zhong, Ran, & Wen, 2009).

#### ***4.5.4. Impact of economic policy uncertainty (EPU) on businesses' investment scale and efficiency after excluding businesses located in non-central areas***

The result shows that GEPU and CEPU both have adverse impacts on the businesses located in non-central areas. Comparing the mean and absolute values of the coefficients, it can be concluded that both GEPU and CEPU have a statistically negative relationship with the investment of overinvested businesses. The coefficients of GEPU and CEPU are both significant at the 5% significance level. The uncertainty of the global and China economic policy also do not improve the investment efficiency of overinvested businesses when the regression coefficients of GEPU and CEPU were both positive and statistically significant at 1% level, showing that when the uncertainty of global and Chinese economic policies increases, it will have a negative effect on the investment efficiency of overinvested businesses. The results showed that because overinvested firms usually have investment size larger than others, or operate in key industries, or are frequently involved in huge and complicated projects, EPU thus has a greater impact on these business investment decisions. Furthermore, economic policy uncertainty might raise the risk of businesses overinvesting in complicating project management, and capital recovery. Because it diminishes the project's desirability, it influences investment decisions.

## **5. CONCLUSION**

### **5.1. Conclusion**

In this study, the authors examine the impact of Global economic policy uncertainty and economic policy uncertainty of China - one of the main trading partners of our country - on the size and efficiency of Vietnamese business investment using the economic policy uncertainty index. The research results show that, on the one hand, GEPU and CEPU both have negative impacts on the size and efficiency of business investment, because when the economic policies are not stable, firms may have to face greater risks in the process of raising capital, and it is more challenging for managers in the process of analyzing and evaluating projects, and firms would limit their expansion invest to reduce risk (Huang et al., 2021). On the other hand, GEPU and CEPU are also found to have a positive effect on the overinvestment or underinvestment state of firms. The more uncertain the economy is, the more serious the firm's overinvestment or underinvestment situation will be. Results from the robustness test also show a similar effect of GEPU and CEPU on investment size and efficiency, demonstrating the robustness of the regression model. Moreover, the study also classifies the businesses into different groups, including types of ownership, industry property, level of capital concentration, and firms headquarter location, with the results showing that there is a difference between the effects of EPU on the investment of each business in these groups.

### **5.2. Limitations**

This study has only tested using the Global and China economic policy uncertainty index, but not measuring and testing the impact of Vietnam EPU because of difficulties in collecting the data. Moreover, the data collected on the financial statements of businesses is not consistent from year to year within the timeframe of the research because of the "double entry" nature of transparency and accuracy in ethical principles of accounting. Because businesses may tend to switch accounting units from year to year, the figures in the financial statements may have large and small differences, leading to the research results may be slightly different in terms of data but does not significantly affect the accuracy of hypothesis testing.

### **5.3. Recommendations**

Drawing from the above findings, the authors propose a number of solutions with the aim of limiting the impact of global EPU and China EPU on Vietnam's economy. Firstly, the government and businesses must pay close attention to monitoring the fluctuations of the world economic policies, as well as those countries that play an important role in our economy, like China. Especially in the period of 2020-2021 when the Covid-19 pandemic was spreading, proactively capturing, and evaluating information at the right

time can help Vietnam become more flexible in issuing information, in order to support and encourage firms in developing and expanding their investment scale. Secondly, the government must keep enhancing its policies and fostering the conditions that encourage businesses to grow, scale up, and increase investment effectiveness. However, in doing so, it is crucial to take into account the ownership structure and unique traits of each industry and business in order to implement the proper policies.

## DEVELOPING A Z-SCORE MODEL TO PREDICT THE LIKELIHOOD OF BANKRUPTCY FOR REAL ESTATE COMPANIES IN VIETNAM'S STOCK MARKET

Nguyen Van Cong Thanh<sup>1</sup>, Vo Thi Kieu Oanh<sup>1</sup>,  
Pham Thi Quynh Oanh<sup>1</sup>,  
Mentor: Le Ngoc Luu Quang

**ABSTRACT:** *The Z-Score model and numerical analysis approach serve as the theoretical foundations on which the authors' study is built. Its objective is to create an appropriate bankruptcy risk prediction model for real estate companies listed on the Hanoi and Ho Chi Minh City stock markets. The research paper collects secondary data from financial statements. A total of 72 companies were sampled and divided into two groups: 'Good' businesses that operating normally and financially stable, and 'Bad' businesses that are in danger of bankruptcy. Based on the chosen financial indicators, the authors developed a new Z-Score model. This model allows for the categorization of risks associated with real estate firms listed on stock exchanges.*

**Keywords:** *Z-Score, bankruptcy, real estate, stock market*

### 1. WHY CHOOSE THE TOPIC

Bankruptcy is an observable phenomena that doesn't exclude any businesses in a market economy. Therefore, predicting the likelihood of bankruptcy is always a crucial task to assist investors in creating strategies to promptly modify firm operations.

The General Statistics Office claims that the business sector has been adversely affected by the severe fourth wave of Covid-19 breakout, stringent lockdowns, and protracted distancing (particularly in Q3/2021). Nearly 55 thousand businesses suspended operations for a period of time in 2021, up 18% from the previous year; 48.1 thousand businesses ceased operations while undergoing dissolution procedures, up 27.8%; 16.7 thousand businesses completed dissolution procedures, down 4.1%, of which 14.8 thousand businesses had capital scales of less than VND 10 billion, down 4%; and 211 businesses with capital scales of over VND 100 billion, did not dissolve. Every month, on average, around to 10,000 companies leave the market because they are unable to "resist" the Covid-19 pandemic's brutality.

Finding a tool to quickly anticipate the risk of bankruptcy of businesses is crucial to be able to offer warnings to investors and assist businesses adjust as a result of the bankruptcy of thousands of firms as well as thousands of other businesses facing the danger of bankruptcy. The turn is more appropriate. The study of bankruptcy forecasting has been studied extensively across the globe in the context of risk management and credit rating. However, there is still little use of these models for predicting in Vietnam. Additionally, the predictive power of these models in the Vietnamese real estate market hasn't been thoroughly examined in many empirical research.

In order to predict the likelihood that a company would file for bankruptcy, a variety of models are available. Some of these models include Altman's Z-Score model, Ohlson's O-Score model, and KMV model. In particular, the Z-Score model, which is used in the majority of nations, is regarded as a pioneer model for predicting bankruptcy risk in the future.

<sup>1</sup> University of Economics, Hue University.

After more than 2 years of the Covid-19 pandemic, which has not yet recovered, the real estate market continues to face challenges due to strict control policies on capital flows, causing the supply to fall drastically, high prices that, on average, are above the purchasing power of the majority of low-income people, but liquidity that is almost “immobile”. In most areas, the real estate price level has climbed as well, continually setting a new price level. When prices are consistently driven up but market liquidity does not follow suit, the possibility of a real estate “bubble” starts to surface. After the Covid-19 epidemic, the domestic economic market experienced fluctuations, and business in the real estate sector had an impact on bank investments as well. This demonstrated the importance of credit ratings in comparison, and how timely information can help banks make better investment decisions. The authors chose the study “Developing a Z-score model to predict the likelihood of bankruptcy for real estate companies in Vietnam’s stock market” in order to help improve the efficient operation of real estate enterprises by forecasting the bankruptcy risk of these enterprises.

## **2. RESEARCH OVERVIEW AND RESEARCH METHODOLOGY**

### **2.1. Research overview**

Numerous studies have been done in Vietnam to determine how well the Z-score model predicts the possibility that real estate businesses listed on the Vietnamese stock exchange would file for bankruptcy. For instance, Vo Van Nhi and Hoang Cam Trang (2013) investigated the connection between 85 enterprises listed on HOSE in the 2011 accounting period’s profit adjustment behavior and bankruptcy risk. Leuz & Associates’ (2003) and Altman’s Z-index model’s (2000) analyses of profitability adjustment behavior and corporate bankruptcy risk were merged by the author. The study sample was chosen by the authors to include HOSE-listed firms, enterprises that must submit financial statements, and other company kinds. Because the author evaluates the standard deviation measurement based on a formula that defines the adjusted behavior of profits for 5 consecutive years, the financial statements of the chosen firms must be published on the HOSE website with data for at least 5 consecutive years from 2007 to 2011. The findings demonstrate that the level of profit adjustment is inversely correlated with the risk of bankruptcy, i.e., the company with the lowest average profit adjustment will have a lower risk of bankruptcy (in the safe zone), and companies with high or very high average profit adjustment will be warned that they are at risk of bankruptcy or bankruptcy.

Korol (2013) analyzed data from 185 Warsaw Stock Exchange businesses and 60 Mexican, Argentina, Peruvian, Brazilian, and Chilean enterprises. Each business is evaluated based on the absolute value of 14 financial indicators as well as the change in these indicators. The author examined over 400 studies from around the world devoted to corporate bankruptcy forecasting models to determine how effective statistical methods (DA analysis and decisional trees) and artificial intelligence techniques (ANN) are in predicting the bankruptcy of businesses in the United States, Latin America, and Central Europe one year and two years before bankruptcy. The CART model beat the ANN model for Latin American enterprises by 4.35 percentage points in the year before bankruptcy (96.66% vs 92.31%) and 3.97 percentage points in the two years before default (95% vs 91.03%). The difference in efficiency gains between the CART and ANN models was even greater in Central European companies: 11.05 percentage points in the year before the financial collapse (96.23% vs 85.18%) and 14.61 percentage points in the previous two years of bankruptcy (88.68% vs 74.07%). The author demonstrated that bankruptcy in dynamic and uncertain marketplaces such as Latin America may be efficiently forecast using a population of 60 Latin American enterprises.

In addition to employing the KMV-Merton model, our country has published a number of research papers on the model in order to anticipate default risk and other sectors of the economy. Nguyen Thi Tuyet

Lan (2019) used the O-score model, as well as quantitative research methodologies and logit analysis techniques, to get a more thorough understanding of the variables influencing the bankruptcy of specific firms in the construction sector that are publicly traded. The study analyzed data from 109 businesses listed on the HOSE and HNX exchanges during a 13-year period, with a sample size of up to 1417. Following an examination of the survey sample, it was discovered that two factors contribute to the enterprise's bankruptcy risk: total debt to total assets has the same impact as the enterprise's bankruptcy risk, and the rate of return on total assets has the opposite effect. This study does not contain linear multi-additive flaws, is not deviated, and is effective since the correlation coefficient is less than 0.8. This article also offers several corporate governance strategies, such as increasing business efficiency or changing debt ratios as the business grows. Empirical study on the factors influencing bankruptcy risk for particular organizations is required since it represents the circumstances in which enterprises find themselves.

Hoang Thi Hong Van's research from 2020 used the Z-Score model to evaluate the model's accuracy in predicting the performance of Vietnamese businesses by gathering data from 30 active businesses at the time of the study. The study data comprises all joint stock firms that were liquidated or dissolved by decision of the Court in accordance with rules between 2012 and 2019 and delisted from the Ho Chi Minh Stock Exchange (HOSE) and the Hanoi Stock Exchange (HNX). The study's findings indicate that the Z-Score model is 70% accurate in predicting enterprise bankruptcy in Vietnam two years out and 76.67% accurate one year out. When using the Z-Score model of Altman et al. (2007) to forecast bankruptcy enterprises one year in advance, the model can achieve average accuracy 76.67% (high accuracy, ability to predict bankruptcy 1 or 2 years in advance). The ROA (Return on Assets), also known as the return on total assets, in the non-bankrupt group ranges from 4% to 5.5%, more than double that of bankrupt enterprises (only about 2%). Similar to the ROE (Return on Equity), return on equity or return on capital is an indicator used to evaluate the health of the business. For businesses that are operating normally, the ROE is typically about 11.2% higher than the bank interest rate, while in the group of bankrupt companies the ROE is typically less than the interest rate on bank loans. According to studies, the group of insolvent businesses has much worse ROA and ROE than those that are still functioning, and their average asset value growth is also lower than that of operating businesses. In order to examine and evaluate the financial status and the "health" of the firm and make the best investment decisions, financial analysts and users of financial information can utilize the Z-Score model.

## 2.2. Research methodology

Data sources include credible websites like investing.com and coffee F.

Information is gathered from the financial accounts of real estate businesses that are listed on stock markets, including balance sheets and business performance.

Using studies on anticipated sample sizes from Hair, Anderson, Tatham, and Black (1998) as a guide. The minimal sample size is thus five times the total number of variables that were observed. The research team chose the sample size of 72 companies because, according to reliable information sources, there are 72 listed real estate companies that have a sufficient number of highly accurate financial indicators that the team needs to gather in order to conduct the research and satisfy the requirements of the aforementioned sample selection theory when the number of variables depends on the equation. Five variables make to the final sequence.

The group first chose 10 independent variables that essentially covered all categories of fundamental financial indicators (such payments, profitability, ...). From then, the group discovered that 5 variables had the best distinguishability and the largest association with the Z-dependent variable.

The rationale behind choosing this study model is because there are other models available for predicting a company's risk of bankruptcy, each with its own benefits and drawbacks. Examples include Altman's Z-Score model, Ohlson's O-Score model, and the KMV model. In particular, the Z-Score model, which is used in the majority of nations, is regarded as a pioneer model for predicting bankruptcy risk in the future.

Describe how this model allows for forecasting and why: The study team used data from real estate company indicators to create this Z-score model, which is appropriate for both the specific features of the local real estate market and the economic climate of Vietnam. Additionally, because the data was acquired in 2021, it more accurately represents studies that used data from earlier times that are no longer applicable to the current situation.

Following the selection of the observed sample using the aforementioned criteria, the research calculates the financial metrics for each firm in the chosen sample. Calculate the chosen indicators next, then split the businesses into two groups.

To describe and evaluate data in a generic fashion, perform selected statistical descriptions of certain typical values of independent variables, such as mean, maximum value, minimum, and standard deviation. The study that follows will be influenced by these ideals.

The study evaluates two hypotheses the difference in group mean and the equality of group variance to make sure that the research data support the hypotheses and that the analysis's findings are statistically significant. On the SPSS program itself, Box's M and Wilks Lambda tests were run. The analysis results may be justified if the mean hypothesis for the groups is met and the variance between the groups is equal (Hoang Trong, 2008).

Following the completion of the aforementioned tests and fulfillment of the model's hypothesis, the research will evaluate the analysis data collected using the Discriminant Analysis command in the SPSS program. Structural Correlation Coefficient, Normalized Canonical Coefficient, Unnormalized Canonical Coefficient, and Model Classification outcomes are some of the analysis outcomes for all variables.

The study further chooses the financial variables that have the strongest correlation with the dependent variable (Z-score) and then conducts an analysis in accordance with the stated steps, i.e., done with all 10 variables, with the goal of identifying financial factors that are crucial for performing the classification of businesses in the sample.

The final phase in the estimation process of the categorization model for real estate firms in Vietnam is to remark on the model's complete and incomplete features, as well as its benefits and drawbacks, given the time and resources available for study. As a result, the study will offer advice to state management organizations and identify areas for further research.

The following is how the research model is presented:

$$Z_i = D_1 X_{1i} + D_2 X_{2i} + D_3 X_{3i} + \dots + D_n X_{ni} \quad (3.1)$$

### 3. RESEARCH RESULTS

#### 3.1. Selecting indicators and filtering for highly reliable indicators

The target groups that will be used are quantitative. Each spending group takes from 2-3 indicators as a representative and fully reflects the efficiency and risks of the business.

**Bảng 3.1. Tests of Equality of Group Means**

	Wilks' Lambda	F	df1	df2	Sig.
Current Ratio	,905	7,308	1	70	,009
Quick Ratio	,919	6,132	1	70	,016
Cash Ratio	,986	,961	1	70	,330
Debt to equity ratio	,982	1,292	1	70	,260
Self-financing rates	,982	1,292	1	70	,260
ROA	,430	92,701	1	70	,000
ROE	,336	138,048	1	70	,000
EPS	,462	81,546	1	70	,000
P/E	,921	6,033	1	70	,017
P/B	1,000	,002	1	70	,961

The results of the table above show that of all 10 variables included in the model, 5 variables when considered separately are capable of distinguishing between 2 groups. These are the variables ROA, ROE, EPS, Current Ratio, and Quick Ratio.

### 3.2. The shortened Z-Score model for real estate enterprises is listed on the Ho Chi Minh City and Hanoi stock exchanges.

In this section, we conduct a closer test of these 5 variables to form a reduced function and check whether the correct ratio of this new model is more accurate. The analysis steps are: (1) Group variance testing; (2) Group average accreditation; (3) Normalized Canonical coefficient; (4) Structural correlation coefficient; (5) Canonical coefficient is not normalized; (6) Classification results.

#### ➤ Group variance verification

**Bảng 3.2. Overall test of variance of two groups**

Dependency variable Z	
Overall variance test of two groups (Box's M)	
F-value	9,049
Probability	0,000

(Source: Author's Data Processing)

Often, researchers want to retain the hypothesis that variance between groups is equal so that their study stands. For 5 selective variables, the value  $F = 9.049$  and the p-value is recorded 0.000. We have grounds to reject the  $H_0$  hypothesis, i.e. the variance of the 2 groups is different. However, with a sufficiently large sample size, the variance of the two groups is not considered too important (Burns, 2008).

**Table 3.3: Specific values**

Eigenvalues				
Function	Eigenvalue	% of Variance	Cumulative %	Canonical Correlation
1	2,674 <sup>a</sup>	100,0	100,0	,853

a. First 1 canonical discriminant functions were used in the analysis.

(Source: Author's Data Processing)

The results from above show that a specific value of 2.674 represents a very good distinguishability of the newly formed function and it accounts for 100% of the variance that explains the cause. Also, the value of the correlation coefficient between the dependent variable Z and the selective new variables is 0.853.

This is quite a high value when the perfect correlation value is 1,000. The square of this coefficient,  $(0.853)^2 = 0.7276$ , shows that 72.76% of the variance of the dependent variable (Z-score) is explained by this model. This proves that the newly formed function also has good distinguishability.

➤ **Group average accreditation**

**Table 3.4: Group average inspection**

Wilks' Lambda				
Test of Function(s)	Wilks' Lambda	Chi-square	df	Sig.
1	,272	87,838	5	,000

(Source: Author's Data Processing)

We have enough statistical evidence to refute the H0 hypothesis that the average overall of the differentiated function is equal, or in other words we conclude that the average groups have significant distinctions.

➤ **Normalized Canonical Factor**

As mentioned above, the Canonical coefficient normalizes the importance of variables through the absolute magnitude of the normalization coefficient of each variable. With five new variables, normalized Canonical coefficient values are presented in the following table.

**Table 3.5: 5-variable normalized canonical coefficients**

Discriminant Function Coefficients	
	Function
	1
Current Ratio	,249
Quick Ratio	-,053
ROA	,484
ROE	,909
EPS	-,244

(Source: Author's Data Processing)

➤ **Structural correlation coefficient**

**Table 3.6: 5-variable structural correlation coefficient**

Structure Matrix	
	Function
	1
ROE	,859
ROA	,704
EPS	,660
Current Ratio	,198
Quick Ratio	,181

(Source: Author's Data Processing)

The above structural correlation coefficient is arranged in descending order of absolute values of independent variables. The structural correlation coefficient of the above five variables has 5 variables that are all positive, proving that these 5 variables have a same-dimensional relationship with the dependent variable Z.

➤ **Unnormalized Canonical coefficients**

Similar to normalized canonical coefficients, unnormalized canonical coefficients indicate the contribution of each independent variable to the distinguishing function of the master function. These coefficients can be used to evaluate the special contributions of each variable and as such, can be interpreted as unnormalized beta coefficients in multivariate regression equations. Since the non-normalized canonical coefficient is just as significant as the unnormalized beta coefficient in keeping the raw values of the variable for calculation, the study proceeded to build a new distinguishing function on the basis of this coefficient. Details are presented in the following table:

**Table 3.7: 5-variable unnormalized canonical coefficients**

Canonical Discriminant Function Coefficients	
	Function
	1
Current Ratio	,191
Quick Ratio	-,046
ROA	,147
ROE	,195
EPS	-,173
(Constant)	-2,471

(Source: Author's Data Processing)

Thus, the newly built model takes the form:

$$Z = 0,191X1 - 0,046X2 + 0,147X6 + 0,195X7 - 0,173X8 - 2,471 \quad (3.2)$$

➤ **Classification results**

**Table 3.8. Classification Results<sup>a,c</sup>**

		Business ratings	Predicted Group Membership		Total
			bad	good	
<b>Initial sample</b>	Count	bad	47	0	47
		good	3	22	25
	%	bad	100,0	,0	100,0
		good	12,0	88,0	100,0
<b>Cross-examination</b>	Count	bad	46	1	47
		good	3	22	25
	%	bad	97,9	2,1	100,0
		good	12,0	88,0	100,0

In the initial sample section, businesses are categorized by function (3.3). During cross-examination, the SPSS software will develop a distinct function that will be separated from the review process. This process is repeated with each of the remaining cases. The cross-examination process proved more credible because of the argument that cases under classification should not be used as part of the classification process (Burns, 2008).

When we randomly categorize a new business into one of the two groups, we get the correct rate at 50%. The results help us improve the accuracy of random classification by up to 44.4%. In fact, distinguishability only needs to be improved to 25% is acceptable (Hoang Trong, 2008).

**Table 3.9. Functions at Group Centroids**

Business ratings	Function
	1
Bad	-1,176
Good	2,211

Thus the Z-value is in the range (-1.176 ; 2.211)

If  $Z \geq 2.211$ , then the business is in the comfort zone.

If  $-1.176 \leq Z \leq 2.211$ , then the enterprise is in the bankruptcy warning zone.

If  $Z \leq -0.969$ , then the enterprise is in the zone at risk of bankruptcy.

#### 4. CONCLUSION

The study has achieved its predetermined objective of finding the five indicators ROA, ROE, self-financing ratio, debt ratio, and cash payment ratio that are required input components to assess the risk level of real estate firms listed on the Vietnam Stock Exchange. From there, a Z-model based on 5 independent variables may be constructed, and defined Z-value intervals can be used to group the enterprise's risk level. The model's accuracy was 94.4%, a respectably high estimation result that served as a foundation for later research on variable selection and reduced variable combination selection.

The research contributes more theoretical groundwork and empirical research for subjects in the economy, especially investors, to have a basis for choosing real estate securities codes suitable to their investment preferences (high risk, low risk), given that the real estate industry is currently experiencing many difficulties.

## TESTING OF FAMA-FRENCH THREE-FACTOR MODEL FOR REAL ESTATE STOCKS IN VIETNAM

Pham Thi Kim Duyen<sup>1</sup>

Mentor: Nguyen Tuyet Trinh<sup>2</sup>

**ABSTRACT:** *This study provides empirical evidence for the applicability of the three-factor Fama - French model for real estate stocks listed on the Vietnam stock market with weekly data for the period from January 2017 to December 2021. The empirical results show that although CAPM is able to capture the section of average returns, the three-factor Fama – French model with size and value factor can do the job better and hence is useful in pricing the assets. In details, the market risk premium is positively correlated with the return of the portfolio, indicating that high return is a reward of high risk taking. The size premium is positively correlated with the portfolio returns of small firm stocks. The value premium (HML) has a positive coefficient for the portfolios having high BE/ME ratio and negative coefficient for the portfolios having low BE/ME ratio.*

*Keywords:* Fama - French 3 factor model; real estate stocks; stock rate of return.

### 1. INTRODUCTION

In 2021, real estate stocks account for 27% of market capitalization, which proves the importance of real estate stocks on the Vietnam stock market. Investors enter into stock market with an aim to generate high returns but it comes at a cost in the form of risk. In order to minimize risk, investors must estimate the rate of return of investment portfolio. Measuring the return of an individual stock is not easy, making it even harder to measure the return of an entire portfolio. Therefore, researchers around the world have developed models to estimate the rate of return of investment portfolios. A typical example is the Capital Asset Pricing Model (CAPM), which was designed in the 1960s by William Sharpe. The model is expected as an effective method to measure the expected returns of individual stock and portfolio. The increasingly complex development of the market, however, has gradually reduced the accuracy and efficiency of CAPM model. Meanwhile, the Fama - French model, which was developed in 1993, is considered as an improvement. The size premium and the value premium variable are added to increase efficiency in measuring the change in return of the portfolio. This paper empirically examines the standard CAPM along with the Fama-French three-factor model for the Vietnam real estate stocks. We also use the Fama–French three-factor model to measure and explain the change in returns of stocks in the Vietnamese real estate industry.

### 2. LITERATURE REVIEW

Maroney, Protopapadakis (2002) tested the Fama - French model on stock markets in 7 countries including Australia, Canada, Germany, France, Japan, the U.K and the U.S. The effects of firm size and value on stock returns were found in all markets. The test results showed that the effects of firm size and the BE/ME ratio are international characteristics.

Nima Billou (2004) compared and tested the effectiveness of CAPM and Fama – French three-factor models. The effectiveness was measured based on alphas and the mean of the absolute value of alphas. The

<sup>1</sup> University of Economics, Hue University, Student of class K53B Finance

<sup>2</sup> University of Economics, Hue University

results of the study showed that size premium variable and the value premium variable are very influential on the U.S stock market.

Elhaj Walid, Elhaj Ahlem (2007) tested the Fama-French model on the Tokyo Stock Exchange (TSE) between January 2002 and September 2007. The firm size factor and the rate of return were demonstrated to have a negative relationship while that of value factor and the rate of return was positive.

Al-Mwalla, Karasneh (2011) tested the efficiency of the Fama-French three-factor model on the Amman stock market. The study found a very strong and positive effect of the size and company value to the return on stock in Jordan.

Ferdian (2011) applied a three-factor model to measure the profitability of stocks on the Indonesian stock market. The research results show that in addition to beta coefficient (market risk), company size and value were also factors affecting the return of stocks. Market risk still remained the most important factor in the model.

V Eraslan (2013) has tested the Fama - French model on 365 stocks on ISE in the period 1/2003 - 12/2010. The research results show that the model is suitable in explaining the change of stock returns. The SMB scale offset variable is effective for small and medium sized portfolio returns. Meanwhile, the HML variable is effective with high BE/ME portfolio returns.

Vuong & Ho (2008) applied the Fama - French three-factor model to explore the factors affecting the profitability of stocks on HOSE. The research result showed that the portfolio of small-sized stocks has a higher return than the portfolio of large-sized stocks. This result was completely consistent with previous studies conducted on the stock market in developing countries. However, when considering the HML factor, this study had opposite results with the conclusion of Fama-French (1993). Specifically, the BE/ME ratio was negatively correlated with the returns of stocks.

Tran (2010) tested the suitability of the Fama-French 3-factor model for stocks listed on HOSE in the period from 12/2004 to 12/2007. The results showed that the factor of market return and the ratio of book value to market value (HML) were positively correlated with the return of stocks. However, in contrast to the results of studies conducted abroad, the size factor (SMB) is negatively correlated with the return of stocks, which made the return of large-cap stocks was high than the return on small-cap stocks.

In general, there have been many studies testing the efficiency of the three-factor Fama - French model in estimating the return on stocks and investment portfolios in Vietnam and abroad. However, as far as we may know, until now, there is no study in testing of Fama-French three-factor model for real estate stocks in Vietnam. This study makes an attempt to fill that gap in research for Vietnam stock market.

### 3. THEORETICAL MODEL

By conducting an empirical research in the period 1963 - 1990, Eugene Fama and Kenneth French found that beta was not the only variable that affected the return on stock or portfolio. They concentrated on two groups of stocks that tend to outperform the market. The first group was for small-cap (known as small-sized) stocks and the second one was for stock having high BE/ME ratio. Fama - French model was considered as an improvement of CAPM. On the basis of CAPM, Fama and French (1993) added the variables of firm size (measured by market capitalization) and company valuation (measured by book value to market value - BE/ME) to model to measure and explain changes in the return on stocks and portfolios. This model is called Fama - French Three-Factor Model. The model is expressed as:

$$R_i = R_f + \beta_i(R_m - R_f) + s_iSMB + h_iHML$$

In this equation:

$R_i$ : The return of stock  $i$ ;

$R_m$ : The market return;

$R_f$ : Risk free rate;

SMB (Small Minus Big): The size premium

HML (High Minus Low): The value premium

$s_p, h_i$ : the sensitivity coefficients of SMB and HML factors.

### 3. DATA

Prices of real estate stocks and Vn-Index are collected from the Website of Ho Chi Minh Stock Exchange between January 2017 and December 2021.

Book value of shares is determined based on equity and number of shares outstanding. Market capitalization is calculated based on number of shares outstanding and market price at the end of each year from 2017 to 2021. This data is obtained from the consolidated financial statements of real estate firms listed on HOSE. The Government bond yield is taken as the proxy for the Vietnam risk free rate which is collected during the period between January 2017 and December 2021 from the website <http://investing.com/>.

### 4. METHODOLOGY

The stock portfolios are built on the basis of two factors: company size and BE/ME ratio (Fama, 1993). The six categories: SM, SH, SL, BM, BL, BH are denoted as follows:

**Table 1: Portfolio construction to determine Fama-French Factors**

Size	BE/ME ratio		
	L(30%)	M (40%)	H (30%)
S	SL	SM	SH
B	BL	BM	BH

+ SMB (Small minus big) is the average return on small portfolios minus the average return on big portfolios:  $SMB = 1/3(SH + SM + SL) - 1/3(BH + BM + BL)$

+ HML (High minus low) is the average return on five value portfolios minus the average return on five growth portfolios.):  $HML = 1/2(SH + BH) - 1/2(SL + BL)$

+ Return of stock: The closing prices of stock are used to calculate the weekly return:

$$R_{i,t} = \ln(P_t/P_{t-1})$$

Where:

- $R_{i,t}$ : weekly return of stock  $i$
- $P_t$ : price of stock  $i$  for the last weekday
- $P_{t-1}$ : price of stock  $i$  for the first weekday

### 6. RESULTS

During the research period, there is no stock matching up to the portfolio BH (containing big-sized and high BE/ME ratio stocks). Therefore, I will conduct regressions of 5 portfolios including: BL, BM, SL, SM, SH.

#### 6.1. Regression results

The article uses the Augmented Dickey - Fuller test method (ADF, 1979) to check the existence of a unit root in all data series. At the 5% level of significance, the data series of variables are stationary.

**Table 2: Augmented Dickey – Fuller test results**

Variables	Augmented Dickey – Fuller test statistic	
	t - statistic	P – value
$R_m - R_f$	-11.15018	0.0000
SMB	-14.76527	0.0000
HML	-13.67195	0.0000
$BL - R_f$	-3.150877	0.0242
$BM - R_f$	-2.999590	0.0363
$SL - R_f$	-12.16028	0.0000
$SM - R_f$	-15.19780	0.0000
$SH - R_f$	-11.20770	0.0000
Test critical values	1% level	-3.455990
	5% level	-2.872720
	10% level	-2.572802

*(Source: Author's Data Analysis Results)*

Multicollinearity test is carried out to ensure that the independent variables can simultaneously explain the change of the dependent variable.

**Table 3: Correlation matrix between variables**

	$R_m - R_f$	HML	SMB
$R_m - R$	1.000000	0.365047	0.247891
HML	0.365047	1.000000	-0.124364
SMB	0.247891	-0.124364	1.000000

*(Source: Author's Data Analysis Results)*

The correlation coefficients between the explanatory factors are relatively low, none of the correlation coefficients is greater than 0.8 - a certain level of multicollinearity (Kennedy 1985). Therefore, the model does not have multicollinearity.

Before explaining the estimation results, we will conduct the autocorrelation test and error variance test.

**Table 4: Breusch-Godfrey autocorrelation test results**

No	Portfolio	P – value	Conclusion
1	BL	0.747478	No autocorrelation
2	BM	0.304791	No autocorrelation
3	SL	0.989571	No autocorrelation
4	SM	0.993171	No autocorrelation
5	SH	0.249278	No autocorrelation

*(Source: Author's Data Analysis Results)***Table 5: White test results**

No	Portfolio	P – value	Conclusion
1	BL	0.000002	Presence of heteroskedasticity
2	BM	0.003905	Presence of heteroskedasticity

3	SL	0.000071	Presence of heteroskedasticity
4	SM	0.000000	Presence of heteroskedasticity
5	SH	0.000001	Presence of heteroskedasticity

(Source: Author's Data Analysis Results)

The results of the Breush Godfrey Lagrange Multiplier test show that portfolios do not exist autocorrelation. However, all variances of the errors are not constant (Table 5). In order to fix this phenomenon, the author used the Robust Standard Errors Model (White 2008). This model accepts the variable variance, but the coefficients are recalculated without using the constant-variance hypothesis. The results are presented in Table 6.

**Table 6: Robust Standard Errors Model**

Variables	BL	BM	SL	SM	SH
Constant	0.017573*** (9.89)	0.0224*** (8.824)	0.0038*** (3.517)	-0.0148*** (7.236)	0.0213*** (9.716)
$R_m - R_f$	0.4918*** (10.286)	0.6833*** (10.151)	0.1211*** (3.995)	0.4411*** (10.747)	0.6129*** (10.290)
SMB	-0.2087*** (-3.613)	-0.0373 (-0.446)	1.1149*** (26.112)	0.7330*** (12.411)	0.9062*** (13.648)
HML	-0.4644*** (-8.247)	-0.0718 (-0.9345)	-1.0199*** (-29.303)	-0.032 (-0.5411)	0.5156*** (7.173)
R – squared	0.62	0.68	0.92	0.73	0.78
P-value	0.0000	0.0000	0.0000	0.0000	0.0000
Number of observations	260	260	260	260	260

Note \*\*\*, \*\*, \*: Significance level of 1%, 5% and 10%

(Source: Author's Data Analysis Results)

Most of coefficients are statically significant at 1% level. In terms of coefficient signs, the variable  $R_m - R_f$  has positive coefficients in all 5 portfolios. The variable SMB has positive coefficients in the small-sized portfolios SL, SM, SH, but those coefficients in the big-sized portfolios BL, BM are negative. The variable HML has positive coefficients in 4 out of 5 portfolios, but these coefficients in BM and SM are not statistically significant.

**6.2. Compare the fit of the capital asset pricing model (CAPM) and the Fama-French three-factor model**

**Table 7: Comparing R<sup>2</sup> of CAPM and Fama – French**

Portfolio	R-squared of CAPM	R-squared of Fama – French model
BL	0.38	0.62
BM	0.31	0.68
SL	0.17	0.92
SM	0.07	0.73
SH	0.28	0.78

(Source: Author's Data Analysis Results)

R-squared of CAPM is quite low, ranges from 0.07 to 0.3. It means CAPM only explains 7% - 38% of the variation of the returns of real estate stocks. Meanwhile, this figure in Fama - French model ranges from 0.62 - 0.92, the factors in this model explain 62% - 92% of the variation of the returns of real estate stocks.

## 7. DISCUSS RESULTS

### 7.1. Discussion on the applicability of Fama – French three – factor model on Vietnamese real estate stocks

Compared with the traditional CAPM model, the addition of the variables SMB (difference between average returns of small-sized and large-sized portfolios) and HML (difference between average returns of portfolios with high BE/ME ratio and those with low BE/ME ratio) significantly increased the R-squared value. Especially, the highest adjusted R-squared of CAPM is 38% while this figure of Fama-French model has risen to 92%. It is considered as a great improvement in the measurement of the expected return of stocks and investment portfolios. The Fama-French three – factor model is proved to be more effective than the CAPM in measuring and explaining the variation of the returns of Vietnamese real estate stocks. This result is consistent with Nima Billou (2004), Gregory Connor and Sanjay Sehgal (2001).

### 7.2. Discussion on regression results

The market risk premium ( $R_m - R_f$ ) has positive coefficients in all 5 portfolios ranging from 0.12 (SL portfolio) to 0.68 (BM portfolio). In addition, all categories are statistically significant at the 1% level. This shows that the market risk premium is positively correlated with stock returns and investment portfolio returns. This result is completely consistent with many previous studies such as: Maroney and Protopapadakis (2002), Elhaj Walid and Elhaj Ahlem (2007), Nima Billou (2004), L. Bretschger and F. Lechthaler (2012).

The size premium (SMB) has negative coefficients in 2 regression models with big-sized portfolios: BL (-0.2087) and BM (-0.0373), but positive coefficients in 3 regression models with small capitalization portfolios: SL (1.1149), SM (0.7330), SH (0.9062). All coefficients are statistically significant at the 1% level. This shows that the size premium is positively correlated with the rate of return of small-sized firms and negatively correlated with the rate of return of firms having high market capitalization. These results coincide with those of Fama and French (1993), V Eraslan (2013), L. Bretschger and F. Lechthaler (2012), but disagree with those of Tran Thi Hai Ly (2010). This may due to the characteristics of the Vietnamese market where big-sized companies often have a high state ownership rate.

The value premium (HML) has a positive coefficient in the regression model with portfolio SH which has a high BE/ME ratio and correlates inversely with the returns of the portfolio having low BE/ME ratio. These results are similar to those of Fama – French (1993), V Eraslan (2013), Vuong Duc Hoang Quan and Ho Thi Hue (2008).

By comparing the appropriateness of the capital asset pricing model (CAPM) and the Fama - French 3-factor model, it can be determined that the Fama - French model is more suitable in explaining the variation in the stock rates of return in the Vietnamese real estate industry. However, some assumptions of the Fama - French model are no longer relevant, which leads to potential misleading results. Besides, in Vietnamese stock market, it is hard to achieve the market efficiency, which reduces the applicability of asset pricing models.

## 8. CONCLUSION

This study has provided empirical evidence on the appropriateness of the Fama – French 3-factor model in explaining the rate of return of real estate stocks listed on the Vietnam market in the period from January 2017 to December 2021. In addition, the study also shows that the Fama - French model is more effective than the CAPM in measuring as well as explaining the change in the return of stock.

In the Fama- French three-factor model, the market risk premium is positively correlated with the returns of the portfolio, indicating that high return is a reward of high risk taking. The size premium is

correlated positively and negatively with the returns of small and the returns of small large firms respectively. The value premium is positively correlated with high BE/ME portfolios and negatively correlated with low BE/ME returns. Investors, therefore, should prioritize putting more small-cap value and BE/ME stocks into the portfolio in order to outperform market return in long-term.

## EVALUATING THE EFFICIENCY OF COMMERCIAL BANKS IN VIETNAM: AN APPLICATION USING DATA ENVELOPMENT ANALYSIS (DEA)

Do Thi Quynh Nhu<sup>1</sup>

Mentor: Le Viet Giap<sup>1</sup>

**ABSTRACT:** *This paper uses the data envelopment analysis (DEA) method to evaluate the performance of 30 commercial banks in 2021. It was a challenging year for the banking sector and the economy in Vietnam due to the significant impact of the Covid-19 pandemic. Specifically, this study uses three input variables (total net fixed assets, total expenses for employees, and raised capital) and two output variables (interest and cash equivalents and non-interest income and equivalents) to estimate the DEA efficiency score of Vietnamese commercial banks. Results show that the group of five banks with the highest efficiency were AGRB, OCB, NAB, VAB, and PGB. Thus, among these banks, four are joint-stock commercial banks and one is state-owned commercial bank. Despite the Covid-19 period, the average operational efficiency of the whole banking system remained high, reaching 81.02%. This study proved that Vietnamese commercial banks operated efficiently and reasonably utilized input resources in 2021. In other words, it also revealed that banks wasted approximately 18.98% of their inputs, indicating that many banks are still operating inefficiently.*

**Keywords:** *Covid-19, Commercial banks, Data Envelopment, Operational Efficiency.*

### 1. INTRODUCTION

Globalization, international economic integration, trade liberalization, and the continuous development of science and technology are prominent trends in the contemporary world economy. These conditions provide opportunities for developing countries but intensify competition in various economic sectors, including the finance and banking sector. Most commercial banks in Vietnam have small scales, limited financial capacity, management capabilities, and technological expertise compared to foreign banks. Additionally, the unpredictable development of the Covid-19 pandemic, along with the emergence of new variants, has further complicated the economic prospects and revealed certain aspects that impact the operations of banks. For instance, capital mobilization in 2020 increased by only 0.47% (a significant decrease compared to the 2.76% growth in 2019). As of the end of 2020, the credit outstanding balance of the banking system towards the economy increased by only 1.48% compared to the end of 2019, the lowest in nearly 15 years. The gross non-performing loan ratio also significantly increased to 7.31% at the end of 2021 from 5.1% at the end of 2020 (State Bank of Vietnam Annual Reports, 2019-2021). Despite facing many challenges due to the pandemic, this is also an opportunity for commercial banks to reflect on the limitations in their operations and explore new directions that align with market demands to thrive.

Commercial banks play an essential role in the economy. The banking sector is a vital channel for capital allocation to support business activities. Banks also contribute to maintaining and stabilizing the macroeconomy, controlling inflation, restructuring the economy after the epidemic, etc. In addition, commercial banks have been building the economy. Independence and self-reliance are associated with proactive and active international integration and improving people's living standards. Therefore, the economy will develop if the banking system is stable, safe, and efficient.

<sup>1</sup> University of Economics, Hue University.

In conclusion, evaluating the efficiency of the banking system in 2021 is significant in addressing lingering issues, effectively utilizing existing resources, enhancing competitiveness, and making policy decisions to maximize profits for the banks. It also aids government regulatory bodies in supporting the creation of favourable conditions for improved bank operations.

## 2. RESEARCH OVERVIEW

Efficiency is a term used in many fields and has various perspectives regarding operational efficiency, including overall operational efficiency and the efficiency of commercial banks. In general, if a bank achieves maximum output results under the given input conditions by optimizing its utilization, it is considered efficient. This argument can be understood from the following aspects. Firstly, operational efficiency must reflect the level of success that businesses or banks achieve in allocating their usable inputs and producing outputs to meet predetermined goals. The more significant the difference between these two factors, the higher the efficiency. Secondly, it includes generating profits or minimizing costs to enhance competitiveness with other financial institutions. Thirdly, it encompasses the probability of a bank operating safely. Therefore, both global and Vietnamese studies have applied the Data Envelopment Analysis (DEA) method to evaluate the operational efficiency of commercial banks.

Barbara Casu and Claudia Giardone (2011) applied an intermediate approach and two models, Stochastic Frontier Analysis (SFA) and Data Envelopment Analysis (DEA), to examine the relationship between competitiveness, concentration, and specific efficiency of commercial banks in the Euro area. The study found a non-linear relationship between competition and efficiency and other factors such as risk sensitivity, regulatory framework, and macroeconomic factors that could, directly and indirectly, influence this relationship. This could explain subsequent studies in the Euro area. Similarly, using the DEA model, Sherman and Gold (1985) assessed the operational efficiency of 14 bank branches in the United States. The study included three input variables: labour, workspace, and supply cost, and one output variable: the number of transactions. The research results showed that six branches operated less efficiently than other branches in the sample. Additionally, Miller and Noulas (1996) applied the Data Envelopment Analysis (DEA) method to estimate the efficiency of 201 large banks in the United States (banks with assets over 1 billion US dollars during the period of 1984-1990). Considering banks as intermediary organizations, the authors selected input variables such as total demand deposits, total time deposits, total interest expense, total interest paid, and output variables such as industrial loans, commercial loans, consumer loans, real estate loans, securities investments, interest income, and fee income. According to the authors, the average inefficiency (including pure inefficiency and scale inefficiency) of the 201 banks was over 5%. The research results also indicated that most banks with larger scales were experiencing decreasing efficiency as their scale increased.

Tran and Bhaiyat (2016) evaluated the efficiency of 31 Vietnamese commercial banks using the Data Envelopment Analysis (DEA) model for 2011-2014. The selected input variables were fixed assets, deposits, and employee expenses, while the output variables included loans, securities investments, and non-interest income. The analysis showed that the average technical efficiency of Vietnamese commercial banks was 87%, indicating that banks wasted 13% of their input resources. The average technical efficiency decreased in 2012 but then increased in subsequent years. In particular, the central and listed banks exhibited higher efficiency in their operations compared to non-listed commercial banks. The restructuring of banks during 2011-2015 yielded positive efficiency outcomes for some of the researched banks.

In addition, the Data Envelopment Analysis (DEA) model has also been extensively studied in Vietnam. Nguyen Thi Thu Thuong (2017) applied the DEA model to evaluate the efficiency of 21 banks

in Thai Nguyen province from 2011 to 2015. The selected input variables were deposits ( $X_1$ ), interest expenses for credit activities ( $X_2$ ), and expenses for other activities, including employee costs ( $X_3$ ). The output variables included loan amounts ( $Y_1$ ), income from credit activities ( $Y_2$ ), and income from other activities ( $Y_3$ ). The results showed that the banks utilized their input resources relatively efficiently, with an average technical efficiency score of 94%. The study also revealed that technological progress was the main factor contributing to changes in the Malmquist index. In addition to profitability/total assets, non-performing loans/total credit debt, and total assets, the number of enterprises positively impacted the technical efficiency of the banks in the province. In 2017, Tran Hoa Nha Truc applied the DEA model to evaluate the efficiency of Vietnamese commercial banks. The summarized results indicated an increasing trend in the efficiency of Vietnamese commercial banks during the period 2009-2012, followed by a gradual decline. The research results demonstrated that the business efficiency of Vietnamese commercial banks from 2009 to 2015 was relatively high. Factors reflecting the scale of bank operations contributed more to the overall operational efficiency than pure technical efficiency, suggesting that increasing the scale of operations would create conditions for improving operational efficiency. Using an intermediate approach, Ngo Dang Thanh (2010) also employed the DEA model to assess the resource utilization efficiency of 22 Vietnamese banks in 2008. The input variables in the study included salary expenses, interest expenses, and other equivalent expenses, while the output variables consisted of total assets, income from interest and equivalent sources, and other income. The study had the advantage of a larger sample size and a better selection of input and output variables compared to previous research, resulting in more specific and comprehensive evaluation results for the Vietnamese banking system.

Moreover, Thao and Quynh (2013) also conducted a study on the operational efficiency of Vietnamese commercial banks and used the DEA model with the following input variables: operating costs, interest expenses, and other similar costs; the output variables included interest income and other comparable earnings, and other income from business activities. The research results for 39 banks between 2008 and 2012 showed that the average technical efficiency (TE) was 92.84%, the average pure technical efficiency (PTE) was 96.2%, and the average scale efficiency (SE) was 96.56%. This indicates that scale efficiency contributes more to overall efficiency than pure technical efficiency, and the operational activities of the commercial banks did not achieve the expected efficiency. Finally, we cannot overlook the study by Nguyen (2008), who examined SFA method to assess factors influencing operational efficiency and DEA method to measure operational efficiency for 32 banks in Vietnam, including five state-owned banks, 4 joint-venture banks, and 23 commercial banks between 2001 and 2005. The research utilized an intermediary approach with selected variables in the DEA model, including two output variables and three input variables. The input variables were net fixed assets, total employee expenses, and total mobilized capital, while the output variables were interest income and equivalent earnings and non-interest income and equivalent earnings. This study is considered comprehensive in terms of the Vietnamese banking system and represents a new direction for researching operational efficiency methods in Vietnam today.

In conclusion, it is evident that the Data Envelopment Analysis (DEA) method has been widely employed in both domestic and international research to evaluate the operational efficiency of banks. However, most authors have focused on an intermediary approach, considering banks as financial intermediaries between depositors and borrowers and the selection of input and output variables based on the collected data sources. Each study proposes solutions to improve the operational efficiency of banks, thereby contributing to the sustainable development of the banking industry. This research will apply the DEA method to evaluate the operational efficiency of Vietnamese banks in 2021, which was a challenging year due to the impact

of Covid-19. The research sample will include 1 state-owned bank and 29 commercial banks representing the entire Vietnamese banking system, to identify new insights and directions in this period. Additionally, the DEA model allows for determining the relative efficiency of operating units within a complex system. It provides a comprehensive analysis of the relative efficiency of decision-making units (DMUs) with multiple inputs and outputs by estimating each DMU and its relative efficiency based on efficiency margins.

### **3. RESEARCH DATA AND METHODS**

#### **3.1. Research data**

The research data is collected from the financial statements of 30 Vietnamese commercial banks (Appendix 1) and the annual report of the State Bank for 2019-2021. There are currently 46 commercial banks in Vietnam, including 4 state-owned commercial banks, 31 joint-stock commercial banks, 9 banks with 100% foreign capital, and 2 joint-venture banks. Thus, the research sample, consisting of 29 joint stock commercial banks and 1 state-owned commercial bank, partly represents the entire Vietnamese commercial banking system in evaluating the performance of banks.

#### **3.2. Research Methods**

This study utilizes the Data Envelopment Analysis (DEA) model, which originated in 1978 with the “initiative” of Charnes, Cooper, and Rhodes. However, its foundation can be traced back more than 20 years earlier. In 1957, Farrell introduced the concept of applying the Production Possibility Frontier (PPF) as a criterion for assessing (relative) efficiency among companies within the same industry. According to this concept, companies that reach the limit are considered efficient (or more efficient), while those that fall below the PPF are deemed inefficient (compared to other companies). The DEA method (1978) later applied non-parametric linear optimization to construct the PPF based on known data about a specific group of companies (decision-making units - DMUs) and calculated efficiency scores for those companies. In 1984, Banker, Charnes, and Cooper improved the model by incorporating returns to scale in the calculations, providing a more specific view of the efficiency of analyzed DMUs. Since then, the DEA model has been widely applied and developed in analyzing efficiency/performance in various fields such as banking, insurance, education, healthcare, etc. According to the DEA model, the most efficient operating unit will have an efficiency score of 1, while the scores of inefficient units are determined by projecting them onto the efficiency frontier.

The principles of calculating and comparing the efficiency of DMUs are based on effectiveness, performance, or productivity measures used to compute/compare the corresponding outputs to the given inputs. For example, labour productivity can be calculated as the ratio of output (number of products) to labour input; return on investment can be measured as profit divided by capital invested, and so on. However, in practice, a business or production unit (DMU) typically uses a combination of input factors to obtain a range of output factors (multivariate model), and therefore, evaluating the efficiency of that DMU requires multiple different efficiency indicators. Because these efficiency indicators are constructed based on various factors in terms of nature and measurement, assessing the overall performance of each DMU and comparing between DMUs requires a common monetary measure.

The combined effect applied to multiple variables is calculated based on the individual effects as follows:

$$EF = 1 \text{ Output} / 1 \text{ Input}$$

$$EFF = \text{Total Outputs} / \text{Total Inputs}$$

If assuming a DMU utilizes  $m$  input factors  $x$  to produce  $n$  output factors  $y$  through a specific combination of inputs and outputs according to two corresponding weights  $v$  and  $u$ , then EFF can be calculated as follows:

$$EFF = \frac{u_1*y_1 + u_2*y_2 + \dots + u_n*y_n}{v_1*x_1 + v_2*x_2 + \dots + v_m*x_m}$$

EFF is the absolute efficiency of the DMUs. With the above formula, we can calculate the efficiency of each DMU sequentially. In cases where prices are not determined, it can be assumed that one input variable  $x_i$  or one output variable  $y_j$  will be assigned to a weight  $u_i$  or  $v_j$  based on the importance level of the input or output variable for each DMU. However, each DMU will have different evaluations regarding the importance of each input and output variable. Therefore, each DMU will now be different in terms of  $u$ ,  $v$ ,  $x$ , and  $y$ .

$$\text{Max}_{u,v} EFF_0$$

Within the conditions of:

$$EFF_0 = \frac{\sum U_{0m} Y_{0m}}{\sum V_{0k} X_{0k}} \text{ (DMU Efficiency score)}$$

$$EFF_j = \frac{\sum U_{jm} Y_{jm}}{\sum V_{jk} X_{jk}} \text{ (Efficiency score of all DMUs does not exceed 1)}$$

$$u_m, v_k \geq 0 \text{ (The "hidden prices" are non-negative)}$$

When applied to the efficiency calculation of an industry or a group of DMUs, it is necessary to study the set of all maximum efficient points, which will form the PPF curve. According to this curve, the DMUs lying on the PPF will have 100% efficiency, while other DMUs will have an efficiency lower than 100%. This represents the relative efficiency among the DMUs, different from the absolute efficiency determined by the formula mentioned above. However, this formula also serves as a basis for constructing the Production Frontier (PF) curve according to the following principle.

- PF is the set of all maximum efficient points of the DMUs, so it is necessary to determine these maximum efficient points.

- The efficiency calculation formula mentioned earlier shows that each DMU will have an optimal set of weights  $u$  and  $v$  to maximize its own efficiency. Therefore, it is necessary to find the optimal weights  $u$  and  $v$  for each DMU. This can be achieved by solving an optimization problem for each DMU according to the formula:

$$\text{Max EFF} (u, v)$$

Under the condition:  $EFF \leq 1$  for all DMUs (including the DMU under consideration). The study proceeds with other DMUs to find the optimal weights as well as the maximum efficient points for each DMU. With this calculation, the obtained PF curve will represent the best practice frontier, constructed based on the available actual data, because it is an optimization function that can be fully achieved by changing the weights  $u$  and  $v$ . This is different from regression functions, which are only estimates. The PF curve will form an enveloping (boundary) curve, and the observed actual data points lie within it. Therefore, the calculation model described above is known as the Data Envelopment Analysis (DEA). Particularly, the study uses the input-oriented constant return to scale DEA model to estimate the efficiency score of Vietnamese commercial banks.

*Choosing input and output variables:* An important characteristic of the banking industry is that it involves multiple inputs and outputs, making it crucial to determine the reasonable selection of inputs and

outputs for banks. However, there is currently no complete or clear theory or definition regarding identifying inputs and outputs for banks. According to Berger and Humphrey (1997), an intermediary approach may be the most appropriate for evaluating the operational efficiency of financial institutions because this approach considers both interest expenses, which typically account for 1/3 to 1/2 of the total operating costs of banks. Based on the collected data and suggestions from research findings by authors within and outside the country, the study has selected the following variables for the research model.  $K$  is the total net fixed assets of a commercial bank, which refers to the net book value of the fixed assets owned by the bank.  $L$  is total expenses for employees. DEPO is raised capital of commercial bank.  $Y_1$  and  $Y_2$  are interest and cash equivalents and non-interest income and equivalents, respectively.

Input variables		Output variables	
K	Total net fixed assets	$Y_1$	Interest and cash equivalents
L	Total expenses for employees	$Y_2$	Non-interest income and equivalents
DEPO	Raised capital		

#### 4. RESEARCH RESULTS

##### 4.1. Overview of Vietnamese commercial banks

- Charter capital

Figure 1: Charter capital of banks (Billion VND)

(Source: Author's summary)

As shown in the table above, the top 3 banks in terms of equity capital are BID, CTG, and VPB. In the first quarter of 2020, BID maintained its first position among the top 10 banks with the largest equity capital in the system, with nearly 40,220 billion VND, remaining unchanged from the end of 2020 to the end of 2021 at 48,057.51 billion VND. CTG, with an equity capital of 48,057.51 billion VND, held the second position, which is quite normal as it is one of the four major banks in terms of total assets. The third position is not held by the two giants VCB and AGR, but by VPB (45,056.93 billion VND). In 2021, VPB increased its charter capital from over 25,000 billion VND to 45,000 billion VND through a stock dividend at a rate of 80%. In 2022, VPB continued to plan a substantial increase in equity capital to nearly 80,000 billion VND through private placement for foreign investors and dividend payment or bonus shares from owner's equity to become the bank's largest equity capital.

On November 14, 2019, the Vietnamese Government issued Decree No. 86/2019/ND-CP regulating the legal capital of credit institutions and branches of foreign banks. The minimum legal capital of commercial banks is 3,000 billion VND. Based on Clause 3, Article 7, Circular 22/2019/NHNN, the charter capital must

not be lower than the legal capital. The order of 8 banks from low to high in terms of equity capital are PGB, SGB, Baovietbank, KLB, BVB, NVB, NAV, VBB, respectively. Despite complying with the regulations of banks, maintaining equity capital below 5,000 billion VND is a significant obstacle to developing asset scale according to regulations, ensuring the minimum capital adequacy ratio for expanding market share and operations. While there are no banks with equity capital below 3,000 billion VND, the scale of these banks is still relatively small compared to banks in the region and globally.

- **Non-performing loan ratio**

**Table 1: Non-performing loan (NPL) ratio of banks in 2021**

No.	DMUs	NPL	No.	DMUs	NPL	No.	DMUs	NPL
1	Baovietbank	4.94%	11	EIB	1.96%	21	OCB	1.32%
2	VPB	4.57%	12	KLB	1.89%	22	CTG	1.26%
3	VBB	3.65%	13	VAB	1.89%	23	SCB	1.10%
4	NVB	3.00%	14	MSB	1.74%	24	BID	1.00%
5	BVB	2.53%	15	SHB	1.69%	25	MBB	0.90%
6	PGB	2.52%	16	SSB	1.65%	26	TPB	0.82%
7	ABB	2.34%	17	HDB	1.65%	27	BAB	0.77%
8	VIB	2.32%	18	NAB	1.57%	28	ACB	0.77%
9	AGRB	2.04%	19	STB	1.50%	29	TCB	0.66%
10	SGB	1.97%	20	LPB	1.37%	30	VCB	0.64%

(Source: Author's summary)

From Table 1, Baovietbank has the highest non-performing loan ratio at 4.94%, followed by VPB and NVB, which are the second and third highest with non-performing loan ratios of 4.57% and 3.00%, respectively. The banks with the lowest non-performing loan ratios are VCB (0.64%), TCB (0.66%), BAB, and ACB (0.77%). The remaining banks also have relatively high non-performing loan ratios ranging from 0.8% to 4.57% as of the end of 2021. This causes a loss of capital for these banks, forcing them to pay interest on the capital leading to decreased profits. Moreover, the high overdue debt ratio undermines the credibility and trust in the financial strength of the banks, reduces their ability to mobilize capital, and, more seriously, may lead to liquidity risks, pushing the banks to the brink of bankruptcy and threatening the stability of the entire banking system. Depositors also risk not recovering their deposits and interest if the banks go bankrupt.

- **Return on asset (ROA)**

**Figure 2: ROA of Vietnamese commercial banks in 2021 (%)**

(Source: Author's summary)

As can be seen from Figure 2, TCB ranks first in terms of return on assets (ROA) at 3.65%, the highest among the Vietnamese banking system. It has increased by 0.55% compared to the same period in 2020 (3.1%). At this time, no member achieved a rate above 3%, and most were below the 2% threshold. The only five banks that achieved above 2% are OCB (2.61%), MBB (2.40%), VPB (2.38%), VIB (2.31%), and MSB (2.12%). The interesting point is that VCB, one of the three major state-owned banks, made it into the top 10 with a ROA of 1.60%. In contrast, CTG and BID lagged behind, ranking 17th and 22nd in the surveyed group of banks, with ROA in 2021 of 0.99% and 0.66%, respectively. We cannot overlook the three banks with ROA below 0.2%, which are NVB (0.002%), Baovietbank (0.10%), and SCB (0.17%), meaning they generate 0.2% or less profit from each unit of assets, indicating ineffective asset utilization. A high ROA often reflects efficient bank operations, a reasonable asset structure, and flexible allocation among different asset categories in response to economic fluctuations.

**4.2. Results of the Data Envelopment Analysis (DEA) model**

- **Descriptive statistics**

**Table 2: Descriptive statistics of variables (Unit: Billion VND)**

Variable name		Number of observations	Mean value	Standard deviation	Minimal value	Maximum value
Input 1	Total net fixed assets (K)	30	3,095.449	3,460.199	119.06	10,741.23
Input 2	Total employee expenditure (L)	30	3,374.516	3,505.096	305.68	14,111.2
Input 3	Raised Capital (DEPO)	30	319,364.4	418,465.9	18,105.49	1,542,504.38
Output 1	Interest and cash equivalents (Y1)	30	27,592.03	29,472.85	1,534.17	109,765.8
Output 2	Non-interest income and equivalents (Y2)	30	5,020.557	6,204.181	202.92	19,515.16

*(Source: Author's summary)*

AGR and BID have maintained the highest values for all 5 variables. AGR has 2 input variables and 1 output variable: total employee expenses (14,111.2 billion VND), mobilized capital (1,542,504.38 billion VND), and interest and equivalent income (109,765.8 billion VND). BID has 1 input variable and 1 output variable: net fixed assets (10,741.23 billion VND) and non-interest and equivalent income (19,515.16 billion VND). This is unsurprising as these two banks are among the top 4 banks in total assets. Regarding the smallest values: Baovietbank has 2 input variables: net fixed assets (119.06 billion VND) and total employee expenses (305.68 billion VND). SGB has 1 input variable and 1 output variable: mobilized capital (18,105.49 billion VND) and interest and equivalent income (1,534.17 billion VND). BVB has 1 output variable: non-interest and equivalent income (202.92 billion VND).

In addition, Vietnamese banks' primary income source is from mobilized capital. Most banks use mobilized capital for investment and business activities after establishing their capacity and reputation. Banks with appropriate strategies, credibility, and the ability to mobilize large capital are more likely to compete and expand their development rapidly, while the opposite is true. Furthermore, mobilized capital determines the payment capacity and high liquidity, ensuring credibility, developing business operations, engaging in competitive activities, and contributing to enhancing market position. The next source of income comes from interest and equivalent income, while non-interest income accounts for a very low proportion. This observation indicates the current focus of Vietnamese banks on credit income and the inefficient exploitation of non-interest income sources.

➤ **Data Envelopment Analysis (DEA)****Table 3: DEA model results**

No.	DMUs	Rank	Efficiency score	No.	DMUs	Rank	Efficiency score

15	VIB	15	0.8245	30	VBB	30	0.4949

*(Source: Author's summary)*

From Table 3, the highest efficiency in 2021 was achieved by five banks: AGRB, OCB, NAB, VAB, and PGB, all of which held the first position with an efficiency score of 1. However, despite having an efficiency score of 1, TCB and STB ranked second and third in the result table because the software rounded the number 1. The second group consists of nine banks with efficiency scores ranging from 0.8 to 0.98, indicating relatively high efficiency. The lowest group includes banks with efficiency scores ranging from 0.5 to 0.8. Among these banks, VBB had the lowest efficiency score of 0.4949.

In the first group, AGR is the only bank among Vietnam's "large four" banks to achieve optimal efficiency. In addition to having a large capital base and scale, the bank's indicators, such as ROA, ROE, and total profits, also rank between the 16th and 18th out of the 30 banks. VCB and BIDV lead in terms of capital base and consistently have their indicators in the Top 10, but they do not have optimal efficiency scores like the first group. Nevertheless, these two banks still rank 4th and 5th, which is relatively high, with efficiency scores of 0.9759 and 0.915, respectively. On the other hand, CTG falls into the lowest group, ranking 26th, far behind smaller-scale banks like OCB, NAB, VAB, PGB, TCB, and STB. With a restructuring plan allowed to span 10 years, but achieved in just 5 years, the distance to the target is no longer far. From 2017 to 2021, STB has recovered and resolved nearly 72,000 billion dong of non-performing loans and remaining assets, of which over 58,300 billion VND belongs to the plan, achieving nearly 68% of the overall plan. The on-balance-sheet non-performing loan ratio decreased from 6.81% to 1.47%. STB has continuously improved its system, elevated its management and operational capabilities, and significantly changed its business mindset to align with the market, contributing to the bank's efficient operations and sustainable growth. Despite a year of prolonged Covid-19 pandemic, TCB has maintained a very low non-performing loan ratio of 0.66%, with deposits reaching 314,752.53 billion VND in 2021, a 13.4% increase compared to the previous year-end (277,458.65 billion VND), and total operating income rising by 35.4% compared to the same period last year (Vietnam Technological and Commercial Joint Stock Bank's 2020 financial report). This observation reflects the success of the bank's management strategy and operational efficiency during this challenging period.

Therefore, it can be seen that not all banks with larger total assets operate more efficiently, and banks with smaller total assets are not necessarily unable to operate efficiently. From this, large banks need to assess their operational position and focus on further developing and improving operational efficiency. On the other hand, smaller banks need to address and enhance deficiencies in their systems, scale, management, and especially their business mindset to strive for optimal efficiency.

## 5. CONCLUSION

Regarding commercial banks' operational situation, registered capital reflects financial strength, ensures financial stability in banking operations, and builds public trust. The year 2021 marked significant milestones for the Vietnamese banking industry. According to statistics, the top three banks with the highest registered capital were BID, CTG, and VPB. While the registered capital of banks in the top 10 continuously increased and competed with each other, many Vietnamese commercial banks still have relatively small registered capital, limiting their ability to mobilize and supply credit to the entire economy. Typically, a bank is considered to be operating efficiently when its return on assets (ROA) is at least 0.9-1%. However, in 2021, as many as 14 banks had a ROA lower than 0.9%. This observation could result from non-performing investment or lending policies or high operating costs for the banks. Conversely, banks that meet or exceed the minimum ROA often reflect effective operations, have a reasonable asset structure, and exhibit flexibility in reallocating resources among asset categories in response to economic fluctuations. Moreover, the issue of non-performing loans is also alarming. Data from the State Bank of Vietnam (SBV) shows that the non-performing loan ratio reached 1.9% at the end of 2021 (an increase of 0.21 percentage points compared to the end of 2020). The increase in non-performing loans in the banking system was predicted due to the outbreak of the Covid-19 pandemic, especially, the fourth wave with the Delta variant in 2021, which caused significant losses to production, business activities, livelihoods, and people's lives. This increase also led to capital depletion in commercial banks, forcing them to continue paying interest on operating capital, resulting in decreased profits.

Regarding the operational efficiency of commercial banks, the study shows that the top five banks with the highest efficiency are AGRB, OCB, NAB, VAB, and PGB. In addition, among them, four are joint-stock commercial banks, and one is a state-owned commercial bank. Particularly, the average efficiency level in 2021 reached 81.02%. This finding indicates that Vietnamese commercial banks, in order to produce the same output, utilize 81.02% of their inputs. It demonstrates their effective operations and rational utilization of input resources, reflecting the level of success of these banks. However, compared to previous studies, the 81.02% efficiency level is considered low. For example, Tran and Bhaiyat's research (2016) reported an average technical efficiency of 87% for the period 2011-2014, Nguyen Thi Thu Thuong (2017) obtained an average technical efficiency of 94% for the period 2011-2015, and Le Phan Thi Dieu Thao and Nguyen Thi Ngoc Quynh (2013) for the period 2008-2012 reported an average technical efficiency of 92.84%, average pure technical efficiency (PTE) of 96.2% and average scale efficiency (SE) of 96.56%. In other words, it can be said that banks still waste approximately 18.98% of their inputs. Therefore, many banks are still not operating well and need to pay attention to the allocation of input resources to optimize output and achieve their defined goals. The more significant the difference between these two factors, the higher the efficiency. Moreover, the issue of non-performing loans has not been thoroughly resolved, and ROA is partly affected by non-performing loans and other factors, which is why some banks have a very low ratio.

**6. APPENDIX****Appendix 1. List of Vietnamese commercial banks in the study**

No.	Abbreviated name	Bank name	English name
1	ABB	NHTMCP An Bình	An Binh Commercial Joint Stock
2	BAB	NHTMCP Bắc Á	Bac A Commercial Joint Stock Bank
3	CTG	NHTMCP Công Thương Việt Nam	Vietnam Bank for Agriculture and Rural Development
4	BID	NHTMCP Đầu tư và phát triển Việt Nam	Joint Stock Commercial Bank for Investment and Development of Vietnam
5	ACB	NHTMCP Á Châu	Asia Commercial Joint Stock Bank
6	EIB	NHTMCP Xuất Nhập khẩu Việt Nam	Vietnam Commercial Joint Stock Export Import Bank
7	AGRB	Ngân hàng nông nghiệp và phát triển nông thôn	Vietnam Bank for Agriculture and Rural Development
8	BVB	NHTMCP Bản Việt	Viet Capital Commercial Joint Stock Bank
9	KLB	NHTMCP Kiên Long	Kien Long Commercial Joint Stock Bank
10	LPB	NHTMCP Liên Việt Post	Lien Viet Post Joint Stock Commercial Bank
11	MSB	NHTMCP Hàng hải Việt Nam	Vietnam Maritime Commercial Joint Stock Bank
12	NVB	NHTMCP Quốc Dân	National Citizen Commercial Joint Stock Bank
13	OCB	NHTMCP Phương Đông	Orient Commercial Joint Stock Bank
14	NAB	NHTMCP Nam Á	Nam A Commercial Joint Stock Bank
15	SCB	NHTMCP Sài Gòn	Saigon Commercial Joint Stock Bank
16	SHB	NHTMCP Sài Gòn - Hà Nội	Saigon Hanoi Commercial Joint Stock Bank
17	TPB	NHTMCP Tiên Phong	Tien Phong Commercial Joint Stock Bank
18	SSB	NHTMCP Đông Nam Á	Southeast Asia Commercial Joint Stock Bank
19	STB	NHTMCP Sài Gòn Thương Tín	Sai Gon Thuong Tin Commercial Joint Stock Bank
20	VBB	NHTMCP Việt Nam Thương Tín	Vietnam Thuong Tin Commercial Joint Stock Bank
21	VCB	NHTMCP Ngoại Thương Việt Nam	Joint Stock Commercial Bank for Foreign Trade of Vietnam
22	VIB	NHTMCP Quốc Tế	Vietnam International Commercial Joint Stock Bank
23	VPB	NHTMCP Việt Nam Thịnh Vượng	Vietnam Prosperity Joint Stock Commercial Bank
24	HDB	NHTMCP Phát triển TP.HCM	Ho Chi Minh City Development Joint Stock Commercial Bank
25	MBB	NHTMCP Quân đội	Military Commercial Joint Stock Bank
26	TCB	NHTMCP Kỹ thương Việt Nam	Vietnam Technological and Commercial Joint Stock Bank
27	SGB	NHTMCP Sài Gòn Công Thương	Saigon Bank For Industry And Trad
28	Baovietbank	NHTMCP Bảo Việt	Bao Viet Joint Stock Commercial Bank
29	VAB	NHTMCP Việt Á	Vietnam - Asia Commercial Joint Stock Bank
30	PGB	NHTMCP Xăng dầu Petrolimex	Petrolimex Group Commercial Joint Stock Bank

## A STUDY ABOUT THE EFFECT OF INTEREST RATE AND ASSET STRUCTURE ON STOCK PRICE RETURN OF COMMERCIAL BANKS IN VIETNAM

**Author: Tran Minh Quan<sup>1</sup>**

**Mentor: Duong Thi Hoai Nhung<sup>2</sup>**

**ABSTRACT:** *The purpose of this research was to determine the impact of interest rates and asset structure on the stock price return of commercial joint stock banks in Vietnam. The research data contains official World Bank statistics as well as aggregated data from the financial reports of 18 listed joint stock banks on the HOSE and HNX stock markets in Vietnam from 2013 to 2022. The research employed a quantitative approach, examining a regression model with panel data and a fixed effects model (FEM). The study gave valuable insights into the correlations between variables, revealing that interest rates as well as asset structure, including the proportions of cash, interbank deposits, loans, and investment to total assets, have a substantial impact on the stock price return of Vietnamese joint stock banks. As a result, recommendations for regulators, managers, and investors were made to achieve the best efficiency in management and investing.*

### 1. INTRODUCTION

Banks have consistently held an influential position in the national economy throughout history. One of the national economy's locomotives is the banking industry. As a result, bank stocks normally receive a lot of attention from stock market investors. Bank stock prices, on the other hand, tend to be more volatile due to their strong relationship to macroeconomic conditions (Gertler and Karadi, 2000). Many studies have demonstrated that interest rates are one of the macroeconomic elements that have a substantial impact on not only a bank's operations but also its stock value (DeYoung and Roland, 2001). And, in a specialised industry like banking, numerous factors must be addressed before making investment decisions, one of which is asset structure (Berger and Bouwman, 2009). Asset structure not only has a direct impact on profitability, but it also influences the bank's risk exposure (Fang and Wu, 2019). Many analysts have recently pointed out that the SVB bank incident was driven by pressure from the Fed's interest rate hikes and inefficient asset structure management. The question is what effect interest rates and asset structure have on the bank's operations, how investors interpret that relationship, and how stock prices tend to vary as a result. This is also the study's premise and inspiration. The goal of this study is to close the gap by evaluating and explaining the direct relationship between interest rates, asset structure, and the return on bank stocks from an economic and practical standpoint. Managers and investors will be able to draw more informed conclusions in the future.

Next, a literature review will be conducted to develop theoretical frameworks and hypotheses. From here, the research design phase commences. This analysis employs a quantitative approach with secondary data sources. After analysing and evaluating the data using various techniques to eradicate outliers, a regression model is created. This model is then examined for various flaws and modified so that the final model can best explain the stock price return's dependence on relevant factors. As presented in the preceding stages, recommendations are made to the relevant parties, and conclusions are derived.

## **2. LITERATURE REVIEW**

### **2.1. Overview of banking sector and stock market**

#### **2.1.1. Overview of banking sector in Vietnam**

Banking is a financial institution that has been in existence for a considerable period of time, dating back to the inception of commerce and economics. The contemporary banking system, as it is currently recognised, originated in Italy during the early Renaissance period. This development occurred specifically in affluent northern cities such as Florence, Lucca, Venice, and Genoa, as noted by Reinhart and Rogoff (2013).

The banking history of Vietnam is intricate and extensive, dating back to the colonial era when French banks established their presence in the region. It was not until the 20th century that a proper banking system emerged in Vietnam.

Nguyen and Tran (2019) assert that the inception of Vietnam's modern banking system can be traced back to the early 1900s, during the period of French colonial rule. After gaining independence in 1945, Vietnam's banking system was nationalised and the State Bank of Vietnam (SBV) was established in 1951. The State Bank of Vietnam (SBV) was responsible for overseeing and supervising all financial institutions operating within the nation's borders. During the socialist era spanning from the 1950s to the 1980s, the banking system underwent a reform whereby all banks were nationalised and came under state ownership. In the aftermath of economic reforms in the late 1980s, Vietnam initiated a process of economic liberalisation and welcomed foreign investment into its economy. The contemporary financial system in Vietnam is constituted by a combination of banks that are state-owned, jointly owned, and owned by foreign entities. The SBV, which serves as the regulatory body for the banking industry, has implemented several measures aimed at enhancing the efficiency and stability of the sector through modernization efforts. The present investigation will centre on commercial banks, given that they are the sole category of financial institution that possesses listed units on the stock exchange of Vietnam. Banks hold a central position within a nation's financial and economic framework, thereby rendering their influence on the stock market quite consequential.

#### **2.1.2. Overview of stock market**

##### *2.1.2.1. Concept of stock market*

The stock market comprises various individuals and entities that engage in the buying and selling of stocks, which symbolise their ownership interest in a particular company. The classification of stock markets is predicated upon three discrete variables, namely liquidity, transparency, and regulation, which result in the distinction of three distinct categories of stock markets.

According to Bodie, Kane, and Marcus (2019), the secondary stock market is commonly denoted as the "stock market" due to its high level of stock trading activity and the application of the law of supply and demand in determining stock prices. Several scholarly investigations carried out by credible sources have demonstrated that the consistent operation of the stock market plays a pivotal role in promoting economic development. The aforementioned phenomenon can be attributed mainly to its capacity to enable corporations to obtain capital and foster the effective distribution of resources in the economy. The present study, in line with Beck, Demirgüç-Kunt, and Levine's (2000) findings, illustrates that the stock market exerts three effects that foster the promotion of economic growth in a wider context: affording investment prospects, enabling enterprises to obtain capital, and enhancing corporate governance.

##### *2.1.2.2. The relationship between commercial bank and stock market*

The established link between the stock market and commercial banks is widely recognised. Levine and Zervos (1996) posit that commercial banks have the potential to make a substantial contribution to the expansion of stock markets through the provision of diverse services to investors. These services encompass

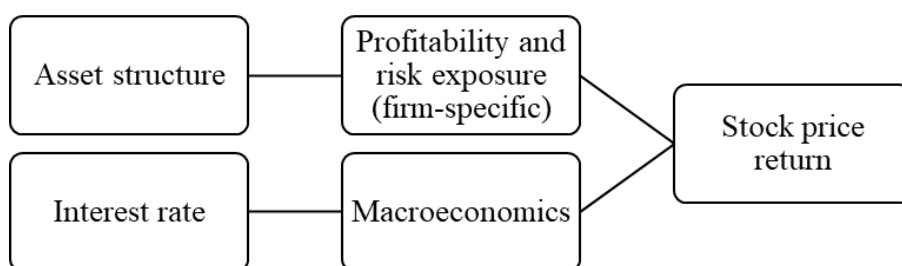

the facilitation of trading, the provision of finance, and the underwriting of securities. In general, there exists a symbiotic relationship between commercial banks and the stock market, wherein commercial banks assume a pivotal function in enabling the expansion and efficient functioning of stock markets.

## 2.2. Factors affecting stock price of banks.

### 2.2.1. Overview of factors affecting stock price of banks

Several scholarly investigations have been conducted to examine the variables that impact stock prices across various markets (Srinivasan & Sivakumar, 2013; Kurtdede et al., 2016; Vasilios Sogiakas et al., 2014; Muhammad Haseeb et al., 2016). In summary, the overarching inference can be specified as follows: the stock price is influenced by two primary categories of factors, namely macroeconomic factors and microeconomic or firm-specific factors. Studies have suggested that interest rates are among the most influential macroeconomic factors affecting stock price returns for commercial banks. The impact of interest rates on commercial banks is a multifaceted and intricate phenomenon that is contingent upon several factors, including the bank's risk profile, business model, and market conditions. The impact of interest rates on banks can manifest in various dimensions, including net interest margin, loan demand, credit risk, and investment portfolio, as posited by Demirgüç-Kunt and Huizinga (1999). Firm-specific factors pertain to the endogenous factors that impact the operational outcomes of a given firm. The assessment of commercial banks encompasses various aspects such as the institution's managerial practises, financial framework, asset calibre, and operational efficacy (Altunbas, Carbo-Valverde and Molyneux, 2011). Among these factors, asset structure holds significant importance. Berger and Bouwman (2009) posit that the asset composition of a financial institution plays a crucial role in determining the nature of its assets and the manner in which they are financed. In the banking industry, it is common for financial institutions to maintain a diversified portfolio of assets, including loans, securities, and cash. These assets are typically financed through a combination of deposits, borrowings, and other funding sources. The configuration of assets and funding sources can exert a significant influence on a bank's profitability and risk profile. This is due to the fact that assets and funding sources possess distinct levels of risk and return. Demirgüç-Kunt and Huizinga (2010) posit that the stock price performance of commercial banks is significantly influenced by their level of risk exposure.

In general, the performance of any given stock is influenced by two primary factors: macroeconomic conditions and the inherent attributes of the company. The present study aims to examine the impact of two distinct factors, namely interest rate as a macroeconomic factor and asset structure as a firm-specific factor, on the stock price return of banks operating in Vietnam.

**Figure 1.** The relationship between asset structure, interest rate and stock price return of commercial banks (Author, 2023)

### 2.2.2. The effect of interest rate on banks

Drawing upon the theoretical framework of marginal utility, initially proposed by John Rae in 1984 and subsequently developed by Eugen von Böhm-Bawerk in 1889 and Irving Fisher in 1930, it can be inferred that

the interest rate plays a pivotal role in shaping financial behaviour, particularly with regard to the allocation of funds. With low interest rates, people and entities tend to borrow and invest more. On the other hand, a high interest rate encourages cash flows to go into saving. These theoretical views about marginal utility are the foundation for future studies about the effect of interest rates on financial activities in general and banking operations in particular. According to Mishkin (2016), investment decisions are influenced by interest rates, which in turn have a significant impact on two key factors that are closely associated with banks, namely, profits generated from lending activities and the valuation of financial assets held by banks. Financial institutions generate income by engaging in lending operations, wherein they levy interest charges on loans that exceed the interest rates offered on deposits. Hence, the determination of banks' profitability is significantly influenced by the interest rates applicable to loans. DeYoung and Roland's (2001) research indicates that changes in lending rates have notable impacts on the profitability of banks. An increase in interest rates can potentially result in a decrease in net interest margin for banks. This is due to the fact that when interest rates rise, banks are required to pay higher rates on customer deposits and other funding sources. However, the interest rates on existing loans and assets may remain fixed for a certain period of time, as noted by Agoraki, Delis, and Pasiouras (2019). The negative impact of this phenomenon on bank profitability and stock returns has been documented in previous studies (Fung, Lin, and Mitchell, 2015; Akhigbe and McNulty, 2013).

Financial assets held by banks are also affected by interest rates. The discount rate, used for assessing diverse asset categories, exhibits a strong correlation with interest rates. Several studies have been carried out to investigate the relationship between interest rates and discount rates. The interpretation and theoretical frameworks applied to the relationship between the two can result in differing causal conclusions. Nonetheless, a prevalent observation that can be inferred from such studies is that there exists a strong link between interest rates and the discount rate (Thornton, 1982; Lucas, 1978; CFA Institute). Market interest rate fluctuations have an inevitable impact on the required rate of return for investment and the valuation of diverse assets. This, in turn, affects the returns of investors, including banks. In general, interest rates have an impact on many aspects of commercial banks, not only on operations but also on investing and financing. Consequently, it is possible to make predictions regarding the influence of interest rates on the stock value of the banking sector. The trajectory of the impact is contingent upon a multitude of intricate factors that are intricately linked to particular macroeconomic circumstances. Based on the previously mentioned research, it is possible to formulate a hypothesis that suggests a negative correlation between interest rates and the stock price return of banks. This correlation is believed to be due to the impact of high interest rates on reducing profitability and intrinsic value in valuation methods.

### **2.2.2. The effect of asset structure on banks**

The asset structure of commercial banks refers to the relative distribution of asset categories across the bank's financial statement in relation to the overall total asset. According to Pham's (2011) publication in the *Journal of Southeast Asian Economies*, the primary constituents of asset structure in Vietnam's commercial banks consist of the proportion of loans, investments, and cash and cash equivalents, which encompasses cash, reserves held at the central bank, and interbank deposits.

In Vietnam, loans comprise the predominant component of bank assets. Financial assets are created by banks to lend to borrowers, with the expectation that they will be repaid with interest within a specified timeframe. This constitutes the primary revenue source for banks, and they all aspire to stimulate its growth as it directly contributes to revenue expansion. According to Berger and Bouwman (2017), loans are comparatively more lucrative than other forms of assets. Banks that have a greater percentage of loans in their asset portfolio may possess superior capability to generate revenue and sustain profitability in the long run.

Investments are a means by which financial institutions allocate their capital to a variety of asset classes, including but not limited to equities, fixed-income securities, and other similar instruments. These financial instruments are used for either short-term trading or long-term investment purposes. There are two primary categories of assets: stocks and bonds. Distinct asset categories possess varying attributes, and their influence on profitability exhibits dissimilarities as well. In actuality, the predominant investment type held by commercial banks in Vietnam is bonds. Bonds are associated with distinct risks, including credit risk and interest rate risk. Credit risk pertains to the possibility of bond issuers defaulting and being unable to fulfil their obligation to pay the coupon and principal. On the other hand, interest rate risk refers to the likelihood of bonds losing their value in the event of a rise in interest rates in the market. The possession of bonds in a burgeoning economy such as Vietnam may be regarded as a prospective risk.

Banks maintain cash and cash equivalents in the form of highly liquid assets, including cash and treasury bills, to fulfil depositor withdrawal demands and facilitate new lending activities. (Rose, 2005). The aforementioned comprises three distinct categories: cash, central bank reserves, and interbank deposits.

The importance of cash as an asset for maintaining a bank's short-term liquidity cannot be overstated, as it serves as a means to satisfy payment obligations and accommodate customer withdrawals. According to Ozkan and Ozkan's (2015) argument, the effective management of liquidity risk requires the maintenance of an optimal cash ratio. As per the findings of Longstaff and Rajan (2018), cash serves as a crucial buffer for financial institutions, enabling them to address unforeseen requests for withdrawals and offset deficits during phases of economic turbulence.

Central bank reserves refer to mandatory deposits that banks must maintain with the central bank as a precautionary measure against potential risks, to meet currency requests from other banks, or to complete interbank transactions. Frost and de Haan (2016) posit that the lending practises and profitability of banks may be impacted by the interest rate on the reserves established by the central bank. The relationship between the reserve levels that banks maintain at central banks and their financial gains is complex and dependent on various factors.

Interbank deposits are indicative of the level of interbank market participation. Interbank loans and deposits play a crucial role in liquidity management, risk mitigation, payment assurance, and monetary policy transmission. However, the impact of interbank deposits can be either favourable or unfavourable. According to Tavakoli and Mohammadi (2019) and Cihak and Hesse (2010), interbank deposits have the potential to pose considerable risks for banks, specifically counterparty risk and systemic risk.

Generally, academic research supports the hypothesis that a bank's asset structure, specifically the proportion of liquid assets to total assets, can significantly impact its stock price. Nguyen, Nguyen, and Nguyen (2018) conducted a significant study in Vietnam. The study analysed Vietnamese banks listed on the Ho Chi Minh Stock Exchange between 2010 and 2017. Banks with greater liquid assets, such as cash and cash equivalents, had higher stock values. Banks with higher levels of liquid assets are believed to manage liquidity risk better and respond better to market changes. Banks with adequate liquid assets are perceived as better equipped to handle liquidity risk and adapt to market changes, potentially resulting in a higher stock value. Identifying the optimal asset structure is a challenge for bank managers due to the constantly changing economy.

### **2.3. Summary**

The unique role played by a bank gives rise to its distinctive operational characteristics when compared to other entities operating within the economy. The determination of a bank's stock value is

contingent upon not only fundamental macroeconomic factors such as inflation and interest rates, but also a unique factor that distinguishes it from other industries, specifically, the composition of its assets. The interest rate exerts a significant influence on the financial decisions made by both individuals and firms, thereby affecting the operations of commercial institutions. Investors assess the risk management capabilities of banks by analysing their asset structure as presented in their financial reports. This evaluation informs their expectations of the bank’s future activities and earnings. The phenomenon exerts a significant influence on the operations within the stock market and the assessment of stock values.

### 3. RESEARCH METHODOLOGY

#### 3.1. Research approach

The study uses a quantitative research method, with data presented in table form, including cross-sectional and time-series observations. According to Wooldridge (1997) and Khanh (2011), the common regression models with panel data are the pooled regression model, fixed effects model (FEM), and random effects model (REM). Using the pooled regression model with the ordinary least squares method is not appropriate because the estimation results are biased, often resulting in the problem of autocorrelation or the constraint of residuals, leading to a low Durbin-Watson statistic (Baltagi, 2005; Park, 2009). To choose between FEM and REM, Wooldridge (1997) used the Hausman test. This is a test developed by Hausman (1978) with a chi-square asymptotic distribution and used to test the hypothesis that the regression results of FEM and REM are not significantly different. If this hypothesis is rejected, then the conclusion is that REM is not appropriate, and in this case, FEM will be selected. The study uses the Hausman test to select the appropriate regression model. The selected model is then tested for common defects such as autocorrelation and heteroskedasticity and adjusted using robust standard deviations if necessary.

#### 3.2. Research hypothesis

Based on literature review, the research hypotheses are as following:

**Table 1. Research hypotheses and related studies**

Hypotheses	Previous studies
H1: There is a significant relationship between Interest Rate and Stock Price Return of commercial banks.	Fung, Lin, and Mitchell (2015), Drehmann and Juselius (2014), Thornton (1982)
H2: There is a significant relationship between the Proportion of Cash in Total Asset and Stock Price Return of commercial banks.	Longstaff and Rajan (2018)
H3: There is a significant relationship between the Proportion of Reserves at the State Bank in Total Asset and Stock Price Return of commercial banks.	Levine (2017)
H4: There is a significant relationship between the Proportion of Interbank Deposits in Total Asset and Stock Price Return of commercial banks.	Tavakoli and Mohammadi, (2019)
H5: There is a significant relationship between the Proportion of Loans in Total Asset and Stock Price Return of commercial banks.	Berger and Bouwman (2017)
H6: There is a significant relationship between the Proportion of Investments in Total Asset and Stock Price Return of commercial banks.	Bordo and Murshid (2016)

### RESEARCH MODEL

Based on research hypotheses, the proposed model is as following

$$APR = \beta_0 + \beta_1 IR + \beta_2 PC + \beta_3 PR + \beta_4 PD + \beta_5 PL + \beta_6 PI + \epsilon$$

In which variables are calculated in the following table:

**Table 2. Description of variables**

No	Variable	Acronym	Variable Definition
Dependent variable			
1	Stock price return	APR	
Independent variables			
1	Interest rate	IR	Collected from World Bank Data
2	Proportion of Cash	PC	
3	Proportion of Reserves in Central bank	PR	
4	Proportion of Interbank Deposits	PD	
5	Proportion of Loans	PL	
6	Proportion of Investments	PI	

### 3.3. Data

The data for this research is secondary data. The data will be collected directly from reputable sources. In terms of scope, the data will be filtered from 18 companies listed on the HNX and HOSE, as only the joint stock commercial banks on these two exchanges have stock prices determined by the laws of supply and demand and rationally reflect investor expectations. The time frame will be 10 years, from 2013 to 2022.

The following table shows the mean, standard deviations, minimum and maximum values of each variable in the dataset.

**Table 3. Descriptive analysis**

Variable	Mean	Std. Dev.	Min	Max
APR	0.094129	0.4273742	-0.5983087	2.19
IR	8.03871	1.003628	7	10.4
PC	0.9760139	0.3694267	0.3445246	1.830154
PR	2.948619	1.73739	0.6144737	10.31805
PD	10.81636	5.83569	0.7481409	25.31681
PL	62.8189	8.339069	36.31595	78.80603
PI	14.3087	4.871204	4.958703	26.52031

## 4. FINDINGS AND DISCUSSION

### 4.1. Correlation analysis

The study conducts correlation analysis by creating a correlation matrix of variables, which is presented in Table 4.

**Table 4. Correlation matrix**

	APR	IR	PC	PR	PD	PL	PI
APR	1.0000						
IR	-0.3408	1.0000					
PC	0.6040	-0.2817	1.0000				
PR	0.1380	-0.0359	0.1010	1.0000			
PD	-0.0358	0.2145	-0.1806	-0.1424	1.0000		
PL	0.4508	-0.2253	0.4219	0.0897	-0.1972	1.0000	
PI	-0.5665	0.1931	-0.4254	-0.0786	-0.1167	-0.3533	1.0000

Based on Table 4, at a significance level of 5%, the correlation coefficients between each pair of variables are all less than 0.7. This indicates that the likelihood of multicollinearity in the research model is low.

**4.2. Regression analysis**

The author conducted a Breusch-Pagan Lagrangian Multiplier test to choose between the OLS and REM regression models. After that, the Hausman test was used to select the appropriate regression model between FEM and REM. The results of these two tests are shown in the following table:

**Table 5. Results of tests for choosing model**

Test	Comparison	Chi-squared statistic	Prob.	Conclusion
Breusch-Pagan Lagrangian Multiplier	OLS vs REM	20.92	0.0000	REM
Hausman	REM vs FEM	1941.70	0.0000	FEM

According to Table 4, the Prob > Chi-squared statistics are less than 0.05 for both tests, indicating that the Fixed-Effect Model (FEM) is the most appropriate model for the dataset.

After identifying the most appropriate model, a test for time-fixed effects was conducted because it is reasonable to believe that macroeconomic conditions may vary from year to year and affect the return of bank stocks. Controlling for variables that are constant across entities but vary over time may be necessary because it eliminates the omitted variable bias caused by excluding unobserved variables that evolve over time but are constant across entities. The results show that time-fixed effects are necessary, but it also shows that in all variables, the variable PR is not statistically significant.

To check if the model suffers from common defects of linear regression, the Wooldridge test for autocorrelation and the modified Wald test for heteroskedasticity were conducted. The results show that time-fixed effects are necessary. Although the model does not suffer from autocorrelation, it suffers from heteroskedasticity. Therefore, robust standard deviation is used to address this issue. The final model result after being adjusted is as follows:

**Table 6. Final result of FEM**

Fixed-effect Model				
R-squared	Within	=0.8440	F(13, 17)	=255.87
	Between	=0.0772	Prob > F	=0.0000
	overall	=0.5402	Corr (u <sub>i</sub> , Xb)	=-0.5793
	Coefficient		t with Robust Std. deviation	P >
IR	-.1703346***		-3.09	0.007
PC	.5753158***		2.93	0.009
PD	-.0159352*		-2.10	0.051
PL	.01427**		2.13	0.048
PI	-.0470785**		-2.15	0.046
Dummy year variables	Yes			
Rho	.78840138			
F test that all u <sub>i</sub> = 0: F(17, 92) = 7.60			Prob > F = 0.0000	

Note: \*\*\*, \*\* and \* represent the statistic is significant at 1%, 5% or 10%.

The final result shows that all variables are statistically significant, except for the variable PD, which is significant at the 10% level with  $\text{Prob} > |t| = 0.051$ . The overall R-squared is 54.02%. Overall, 54.02% of the variance in stock return can be explained by factors such as interest rates, cash ratios, interbank deposits, loan ratios, and securities investment ratios. The model shows a moderate relationship between the dependent and independent variables.

The final regression equation is formed as following:

$$\text{Return} = \beta_0 - 0.170 \times \text{IR} + 0.575 \times \text{PC} - 0.016 \times \text{PD} + 0.014 \times \text{PL} - 0.047 \times \text{PI} + \alpha_i + \varepsilon_{it}$$

Where:

$\beta_0$ : the unknown intercept for each entity.

$\alpha_i$ : entity-specific fixed effect

$\varepsilon_{it}$ : overall error term

#### 4.3. Discussion of findings

The model's within-model R-squared is high at 84.4%. 84.4% of the variance in stock returns can be explained by the independent variables within each bank group. The model fits well for each bank, and there is a strong relationship between the dependent and independent variables. The model is applicable within each bank's time frame.

The between-model R-squared is low at 7.72%. The explanatory power of the differences between group means is very weak. Thus, the model may not be appropriate for comparing banks.

The study analysed secondary data from 18 joint-stock commercial banks in Vietnam from 2013 to 2022 using the fixed-effect model (REM). The results showed that a model with five factors had a significant explanatory rate of 54.02% on the dependent variable, stock price return. The research findings are as follows:

Lending interest rates in Vietnam from 2013 to 2022 have negatively impacted the return of commercial bank stocks. Interest rates have a dual effect on bank stocks, affecting profitability and pricing methods, as noted in the literature review. The finding can be attributed to the close relationship between lending interest rates and discount rates (Thornton, 1982; Lucas, 1978; CFA Institute). Most bank assets are financial assets. A high discount rate reduces the value of financial assets and stocks using pricing methodologies like the dividend discount model and the Gordon growth model. Lending interest rates are linked to the State Bank of Vietnam's policy rate for economic management. Vietnam's State Bank has implemented a restrictive monetary policy by increasing policy rates to control inflation. This has led to higher interest rates and a less optimistic investment climate, straining the bank's operations. In the latter half of 2022, due to the FED's interest rate increase, the State Bank of Vietnam raised the policy rate, resulting in downward stock market adjustments.

The cash-to-total assets proportion affects the commercial bank stock's return. Banks use cash to maintain liquidity and fulfil customer withdrawal requests. Ozkan & Ozkan (2015) emphasise the importance of maintaining adequate cash reserves for banks to ensure short-term liquidity. Cash holdings in Vietnamese joint-stock commercial banks range from 0.34% to 1.83% of total assets. A higher cash ratio within this range implies better liquidity, indicating the bank's risk management and internal capacity are relatively strong. Cash is a low-risk asset because it is not exposed to credit and market risks like loans or securities. A bank can enhance its financial stability and lower its risk profile by increasing its cash holdings. This indicator benefits investors and increases the value of banking stocks.

The reserve proportion at the State Bank of Vietnam does not affect the banking sector's stock return. A reserve helps banks operate stably, manage risk, handle unexpected losses and liquidity shocks, and fulfill obligations. This reserve decreases credit for lending and investment, causing opportunity costs. Reserves can have offsetting effects, making their overall impact complex. McLeay et al. (2014) argue that bank lending is not influenced by their reserves, and reserves do not significantly contribute to money creation. The authors propose that banks can create money by extending credit and that reserve availability does not limit their lending ability. Therefore, there is reason to believe that reserve levels do not necessarily impact bank operations. The impact of the reserve ratio at the State Bank of Vietnam on the value of stocks in Vietnamese banks is unclear due to offsetting positive and negative effects.

The proportion of interbank deposits to total assets negatively affects the banking sector's stock return. Interbank deposits have both positive and negative effects, as stated in the research review. This conclusion has two possible interpretations for Vietnamese joint-stock commercial banks. Firstly, it suggests a decrease in lending activity, leading to excess reserves and lower opportunity costs. It impacts the bank's risk management capacity. During liquidity crises or economic downturns, banks face challenges due to the counterparty risk involved in depositing funds at other financial institutions (Tavakoli & Mohammadi, 2019). Interbank deposits can create contagion risks if one bank defaults, which can quickly spread to other banks that have deposited with it. Default chain reactions can trigger systemic crises. Vietnamese joint-stock commercial banks often face significant liquidity problems. VietinBank, Agribank, DongA Bank, and SCB are among the banks that have undergone restructuring in recent years. A high interbank deposit ratio is concerning for the developing Vietnamese banking system due to high counterparty risk and inefficient lending with surplus reserves. These factors impact the bank's value and investors' assessment of its shares.

The loan-to-asset proportion positively affects the profitability of banking stocks. Lending is the primary revenue-generating activity for banks, and therefore, this outcome can be anticipated. A high proportion suggests strong lending activities for the bank, with potential for significant revenue and no opportunity costs from excess funds. Banks with higher loan levels can generate increased profits due to various factors. Banks earn interest income from loans. If a bank has a higher proportion of loans in its assets, it can generate more interest income. Banks can earn fees and commissions on loans in addition to interest income. Loans aid banks in diversifying their portfolios and mitigating risk. Banks can reduce their risk and exposure to any one borrower or sector by lending to a variety of borrowers in different sectors and industries. This can enhance banks' long-term profitability and stability. Higher loan levels in banks lead to increased profitability and intrinsic value, resulting in higher stock price returns. Vietnam's growing economy and increased investment prospects offer significant potential for expanding lending activities. Loan demand in Vietnam is increasing, especially in real estate, industry, trade, and services. Banks can increase profits by expanding lending activities, but they also face the challenge of increasing the value of their stocks.

The banking sector's stock return on equity is negatively impacted by the proportion of investments to total assets. The observed outcome can be explained by the predominant allocation of investments towards bonds in Vietnam, despite the theoretical inclusion of stocks. Vietnam's credit rating is low. Vietnam's sovereign credit rating as of September 2021 is B1 by Moody's, BB- by Fitch Ratings, and BB by Standard & Poor's. The mentioned ratings are classified as non-investment grade or "junk bond." Vietnamese corporations have not been assessed using global standards, leading to higher credit risk in the country. Several bond defaults and scandals have occurred, such as OceanBank's in 2015, VinaConex's in 2020, and multiple real estate companies' in 2022. Holding many bonds increases a financial institution's credit risk. Financial institutions often set aside provisions for bonds, affecting bank profitability. Greater

holdings require increased provisional allocation, especially due to the lack of transparency in Vietnam's bond market. These unfavourable indicators negatively affect the stock's appeal and value for shareholders.

## **5. RECOMMENDATIONS**

### **5.1. Recommendations for regulators**

The findings confirm that interest rates are crucial in determining banking activities and stock valuation. Interest rates are closely tied to the policy rate set by the State Bank of Vietnam. The State Bank of Vietnam must consider the impact of its policy adjustments on the banking-dominated stock market, in addition to its primary objectives of regulating inflation, managing monetary supply, and controlling exchange rates. Bekaert and Harvey (2003) suggest that a robust stock market can stimulate economic growth by promoting investment and spending. A strong stock market can offer businesses greater access to capital. The State Bank of Vietnam must be cautious and diligent when considering changes to interest rates. The State Bank of Vietnam has lowered the policy rate to help banks find borrowers, increase financial asset value, attract more capital to the stock market, and assist enterprises in raising funds.

The State Bank of Vietnam has set rules for reserve ratios based on time deposit categories and bank-held reserves. This model shows that the impact of the reserve-to-stock price return ratio is uncertain due to the opposing effects of positive and negative factors. Maintaining current minimum reserve ratio regulations is justifiable in the future. Changing these rules may have unpredictable consequences for the bank's operations.

The central bank must prioritise strategies that improve financial system transparency. This can reduce the risks associated with bonds and interbank transactions and increase investor confidence in the banking sector and the stock market.

### **5.2. Recommendations for bank managers**

Research shows a link between asset structure and stock price return, affecting profitability and risk exposure. Maintaining a stable stock value is crucial for discovering new investment opportunities and increasing the likelihood of successful fundraising. Bank managers must carefully analyse and improve asset structures tailored to each bank's unique characteristics based on macroeconomic conditions and long-term goals.

Different types of assets have different levels of impact. Banks primarily provide capital for investment, consumption, and production through lending. Banks must maintain a significant allocation of assets at all times, as loans are their primary source of income. Maintaining and growing this asset category is vital for the financial institution's stability, profitability, and growth.

In addition to revenue growth, banks must effectively manage risks. The allocation of cash, bond holdings, and other assets can indicate a bank's level of risk exposure. Banks must manage risks by identifying, measuring, monitoring, and controlling them to maintain acceptable levels.

Credit risk is a primary concern for banks when dealing with loans or bonds, as it involves the potential for borrowers to default. Banks use credit scoring, loan covenants, collateral, and loan loss provisions to manage credit risk. Vietnam's Credit Information Centre has comprehensive credit information, but international credit scoring systems have not been implemented. Credit risk remains a significant concern for Vietnam's banking industry.

Banks face market risk due to changes in interest rates, foreign exchange rates, and other market variables. This risk impacts stock prices. Banks need to employ hedging, diversification, and stress testing

to manage market risk. The risk management system in Vietnamese banks falls short of expectations, resulting in volatile stock groups with high returns but significant risks. To enhance bank stock value and attract investment, managers should prioritise research and risk management.

### **5.3. Recommendations for investors**

Investors should closely monitor the macroeconomic environment, including interest rate fluctuations, to make informed investment decisions due to the interdependence between the banking sector and the economy.

Investors must consider the balance sheet's asset structure in addition to monitoring financial performance. This enhances our understanding of financial performance and stock price fluctuations. Analysing a bank's asset composition is vital for making investment decisions in bank stocks. The asset composition of a financial institution can provide insights into its risk exposure, financial performance, and expansion potential. Banks with a high percentage of low-risk assets, like government securities, may have lower profits but are less likely to default. Financial institutions with a higher percentage of high-risk assets, like loans, may be more profitable but also more likely to default. Analysing a bank's assets can help stakeholders understand its solvency. Financial institutions with higher liquid asset ratios are better equipped to withstand market disruptions and maintain operations during times of financial stress.

Investors must understand different bank assets and their effects before making investment strategies in this sector.

### **5.4. Limitations**

The R-square values suggest that this model is better suited for tracking changes within a bank over time than comparing different banks. When making investment decisions based on interest rates and asset structure, the focus should be on whether the bank's stock is a better investment compared to the previous year, rather than comparing it to another bank's stock.

This study does not evaluate the asset's quality. Asset quality is a crucial factor to consider when evaluating a bank's assets. Asset quality pertains to a bank's loan portfolio and the probability of loan repayment. Banks with strong assets are typically viewed as more financially stable and less risky than those with weaker assets.

Credit risk is a major concern for banks, as it occurs when borrowers are unable to repay their loans. Banks with high NPLs may suffer losses and reduced financial performance. Banks with low-quality assets may encounter regulatory measures, harm to their reputation, and reduced customer trust.

Banks with high-quality assets are more resilient to economic downturns and market disruptions due to their lower risk of default. Banks with good asset quality can provide better interest rates to borrowers, which can lead to more lending and profits.

Asset quality is crucial for a bank's financial stability. Asset quality is closely monitored by investors and regulators to evaluate a bank's financial performance and risk profile. This model overlooks specific loan types, tenures, and other details that financial statements provide. Asset quality insights were not covered in this study.

## **6. CONCLUSION**

Interest rates and asset structure significantly affect the stock price returns of banks, according to the study. Interest rates directly affect bank profitability by impacting the cost of funds and income from loans and investments. The composition of assets, including cash, interbank deposits, loans, and investment

securities, affects the profitability and risk of bank stocks. Investors should evaluate risk and profitability factors to make informed decisions about investing in banks. Banks should monitor their asset structure and assess interest rate risk to improve long-term financial performance.

This study has established a basis for future research on the topic. Further research should address the limitations of this study to yield more practical and valuable insights for investors, regulators, and bank managers.

## SUPPLY CHAIN DISRUPTIONS AND FIRM OUTCOMES: EVIDENCE FROM SOUTHEAST ASIAN COUNTRIES

**Author: Bui Quynh Trang<sup>1</sup>, Nguyen Thi Giang<sup>2</sup>, Dinh Thi Hong Duyen<sup>2</sup>, Dang Thu Ha, Hoang Anh<sup>2</sup>**

**Mentor: Pham Ngoc Anh<sup>2</sup>**

**ABSTRACT:** *This study investigates the impact of supply chain disruptions on the performance of Southeast Asian businesses. The analysis is based on a panel dataset covering 6 countries from 2018 to 2021. We use the fixed effects (FE) model to estimate our baseline results and the difference-in-difference (DiD) estimation to better clarify the impact of the pandemic on corporate performance. Our overall results suggest a negative impact of supply chain disruption on corporate performance. However, in several cases, it has a beneficial influence on the business performance of enterprises in the Industry group. Our findings also show that the strictness of government policies to deal with the Covid-19 pandemic negatively affects businesses' revenue. Given these results, we propose a series of recommendations to assist firms in adjusting to and dealing with the risks and challenges arising out of supply chain disruptions.*

**Keywords:** *Supply chain disruption, Corporate performance, DiD.*

### 1. INTRODUCTION

Global supply chain plays an essential role in the economic integration of nations, and is considered the “artery” of the global economy. According to Chopra & Meindl (2016), the global supply chain refers to the network of suppliers, manufacturers, distributors, and retailers engaging in producing and distributing goods and services among different nations and regions. Participating in the global supply chain gives enterprises access to the low-cost labor force and raw materials, as well as financial support, market expansion, and government incentives (such as tax reduction), which furthermore creates an entry barrier and keeps these businesses in their current market positions (Manuj & Mentzer 2008).

Because of the interdependence of nations regarding raw materials, components, and finished goods, the global economy is becoming increasingly intertwined. The figures demonstrate a general surge in each nation's reliance on foreign inputs throughout time. For instance, Li et al. (2019) report that global supply chain (GSC) operations made up around 12.9% of the global GDP in 2017, a significant increase from 9.6% in 1995.

Ever since the outbreak of Covid-19, over 210 nations and territories have reported more than 759 million cases of infection and 6.8 million fatalities (WHO, 2023). Under the government's disease prevention efforts, supply chain disruptions caused by border closures, travel restrictions and workplace closures or social distancing have posed a particularly serious risk to the global supply chain. In other words, the pandemic has exposed the susceptibility of global supply chains to external shocks.

The protracted Covid-19 outbreak has witnessed variations in the degree of closure, the epidemic situation, the number of infections, recoveries, and even countermeasures among nations. Many tactics have been implemented to prevent epidemics from spreading through nations, including travel restrictions and halting the manufacture of certain goods in favor of essential goods, which caused some industries to disappear completely.

<sup>1</sup> Foreign Trade University, Email: [k59.2012150091@ftu.edu.vn](mailto:k59.2012150091@ftu.edu.vn)

<sup>2</sup> Foreign Trade University

Additionally, many production industries were delayed, containers that could not be delivered were jammed due to the customs requirements to prevent epidemics, etc. The uneven distribution of goods among regions has put pressure on the market, disrupting supply and demand chains and causing severe losses in all aspects, from the economy, culture, and tourism, to human life globally (La et al., 2020; Nguyen An, 2020).

In this study, we attempt to examine how supply chain disruption affects business results in Southeast Asia, which involves 11 countries cooperating with each other on many fronts, and having more geographical similarities than other regions. Although there has been a wide range of research papers on the effect of supply chain events with diverse methods around the world, little research has focused on quantifying the effect of supply chain disruption on the performance of enterprises in Southeast Asian countries. Furthermore, the contexts of most conducted studies do not include the Covid-19 epidemic, thereby not concerning the severity of the shutdown measures from the government.

This study makes three major important contributions. First, our paper expands and complements theories that emphasize the role of supply chains in the circulation and production of goods. Although the theories of the preceding authors are plausible, a reliable assessment of supply chain disruption's impacts is yet largely unexplored. As a result, we provide micro-level evidence on the impact of global supply, as well as wire disruptions on business outcomes in Southeast Asian nations, which are considered to be the region adjacent to China, the source of Covid-19. Second, the study contributes to the research direction concerning with the economic impact of the Covid-19 pandemic. The authors derive from previous theories and provide one of the earliest pieces of evidence showing how supply chain disruptions during the pandemic in various countries affected corporate revenue growth. In addition, regarding practical contributions, we provide a series of recommendations to assist firms in adjusting to and dealing with the risks and challenges arising out of supply chain disruptions.

Apart from the Introduction, our paper is structured as follows: Section 2 reviews the theory which helps to explain the effects of supply chain disruptions on firm performance, as well as a literature review of previous research. Section 3 illustrates the data and methodology used for analysis. Section 4 presents specific results and a discussion of such findings. Lastly, we conclude the overall research findings and propose some recommendations for firms to better adjust in the context of supply chain disruptions.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Theoretical basis**

Contingency theory emphasizes the importance and impact of situational factors on the performance of firms (Lawrence & Lorsch, 1967). This idea states that both internal and external aspects of the corporate environment will affect how a business makes optimal decisions and takes action (Helms, 2000). More specifically, contingency theory precisely explains how influencing factors and performance results relate to enterprise behavior and operation, as well as how situational factors affect such a relationship. According to Lawrence & Lorsch (1967), this theory is based on four fundamental aspects:

- There exists no optimal method for firms to handle every situation they confront.
- The companies' operating procedures and organizational structure must be appropriate for their environment.
- To ensure effective functioning, businesses need to establish a harmonious relationship between internal and external factors.
- The performance of the business will be enhanced if enterprises build a management structure adequate for the duties and nature of each task as well as particular environmental characteristics.

Contingency theory considers firms as open systems where information is exchanged throughout the input-output process (Schoonhoven, 1981). “Inputs” include relevant internal and external issues, while “process” indicates the organization’s behaviors towards these inputs. “Outputs” refer to the outcomes of processes, which aim to find out the appropriate procedures for an organization in response to environmental characteristics. Usually, these outputs refer to performance measurements. Thus, contingency theory forms a natural theoretical framework for elucidating the conditions that can lead to the development of proactive supply chain risk management (Grötsch et al., 2013).

We decided to use contingency theory to explain the effects of supply chain disruptions on firm performance. More specifically, based on this theory, the impacts on business outcomes of supply chain disruptions depend on the specific circumstances surrounding such disruptions, such as the degree of dependence on foreign inputs, or the strictness of the closure policy during the epidemic control period.

## **2.2. Literature review**

Much of the prior research demonstrates how the epidemic affects businesses and industries in a particular country. Ozgur et al. (2023) conclude that supply chain disruptions are more severe in businesses located in developed nations like the United States and the United Kingdom and less severe in nations such as New Zealand and Australia. However, when studying the impact of supply chain disruptions on companies in Central Europe during the early stages of the Covid-19 pandemic, Veselovská (2020) claims that there was not much difference among enterprises of different countries regarding their response to such disruptions.

Another strand of literature focuses on the impacts of supply chain disruption on different industries. In the research on the impacts of the Tohoku catastrophe, Arto et al. (2015) conclude that the industries most affected by this disaster are transportation equipment, base metals, fabricated metals, wholesale trade, financial intermediation, and other businesses. When studying the impact of supply chain disruptions attributed to the pandemic on Vietnam’s textile and garment industry, Nguyen Thanh Son (2022) concluded that this industry is adversely affected when output and manufacturing processes are disrupted along the value chain. EY’s report (2023) shows that the disruption caused by Covid-19 has impacted most sectors of the economy; however, besides the industries that are negatively affected by the Covid-19 epidemic, there are also sectors that have not been significantly affected and may even have benefited from it. Research by Veselovská (2020) confirms that some businesses were successful in adjusting their supply chains to the new circumstances brought on by the outbreak, thereby increasing their revenue. Considering Covid-19 as a global supply chain shock, Ersahin et al (2022) find that businesses facing higher supply chain risks will establish relationships with domestic suppliers and become closer to industry-leading suppliers.

Other researchers concentrate on the impacts of supply chain disruptions on firms’ financial situation. Businesses of different sizes suffer from different extents of effects, which last not only for a short time but also continue for a long period after disruptions occur (Baghersad & Zobel, 2020). Previously, when studying the effect of supply chain disruptions arising from the Covid-19 epidemic on the financial situation of businesses across 21 countries, Choudhury et al (2022) concluded that such disruption reduced the shareholder value of the business by 2.16% on average. According to the results of in-depth interviews with Vietnamese enterprises conducted by Nguyen Thanh Hieu et al (2020), a lack of raw materials caused the majority of such businesses to operate slowly. To illustrate, enterprises in the manufacturing industry rely heavily on imported raw materials, therefore, when a supply chain disruption occurs, they hardly have any backup plans and lack time to seek alternative supplies, causing operational disruptions and reduced revenue.

### 2.3. Hypotheses development

*H1: Stringency Index of lockdown policy has a negative effect of firms' corporate performance*

The Stringency Index measures the strictness of the government's restrictive policies to prevent the Covid-19 epidemic. We calculate a weighted average of the workplace closure Stringency index of all foreign countries providing inputs for each industry in the host country as a proxy for supply chain disruption. During the Covid pandemic, Barro et al. (2020) raise the issue of the trade-off between lives and goods, and it is clear that such trade-offs are inevitable as a result of efforts to combat the pandemic and prevent the spread of infection. Its spread has led countries to implement policies that reduce real GDP, especially through restrictions on travel and trade. Research by Lasha and Mohammed (2023) concludes that strict public policies to tackle the pandemic have significantly deteriorated the financial performance of companies. Besides, the impact of the blockade not only affects the performance of domestic companies but also negatively affects companies in other countries (Aslam et al., 2022).

*H2: The interaction between Stringency Index and the level of demand for foreign inputs has a negative effect on firms' corporate performance*

This is the interaction variable between Stringencyindex and highlyexposed (highlyexposed=1 if the company's demand for foreign inputs is higher than the 75th percentile, and =0 otherwise). Together with the overall increase in foreign input dependence, are the accompanying risks that can be felt throughout the chain if one node is disrupted. Industries and countries that rely heavily on foreign inputs will be more severely affected when supply chains are disrupted. If these industries and countries lack adequate and stable supplies of key inputs, they will face difficulty in producing and supplying goods. When subject to the same strict blockade or the same risk of supply chain disruption, industries with a higher degree of dependence on foreign inputs tend to have lower business results.

Based on previous research results, the hypotheses *H3, H4, H5, H6, H7, H8* relating to the relationship between the firm's control variables, namely Total assets, Total liability, Short-term investment, Tobin's Q, ROA, Total debt-to-equity- D/E and business results, are determined in Table 1 below.

### 3. DATA AND METHODOLOGY

We extract the panel data from available datasets: the firm data from World Scope with industrial code from Standard Industrial Classification (SIC) dataset, the Multi-regional Input-Output table (MRIO, ADB), and Stringency Index (Hale, 2021).

There are two approaches to determine the interdependence of the supply chain. The first method is "tear down", which analyzes the supply chain by analyzing the value of individual components for source companies and their countries. In the research on Iphone products by Xing & Detert (2010), the authors find that China contributed 3.6% to the final export value of Iphone from the US in 2009. Nevertheless, this approach heavily relies on particular types of goods and companies, which makes it difficult to draw generalizations about the function of global supply networks.

The second method is ICIO, a crucial instrument in global supply chain analysis. It is based on the use of transnational input-output tables to define the roles of countries and industries in the supply of goods. First proposed by Wassily Leontief (1936), the ICIO treats each industry in a country as an upstream supplier, providing inputs for the final product of another industry in the target country. The inter-industry transactions that take place both inside and between nations can be viewed comprehensively using the ICIO approach. This method also allows to assess the degree of dependence on foreign inputs of a country or industry. This makes it easier to understand the dependency and impact of supply chain disruption.

Hence, in this study, the authors use the transnational input-output table to calculate supply chain intensity, the degree to which an industry in a host country depends on foreign inputs, following an approach similar to that of Krugman et al. (1995) and Timmer et al. (2014). The formula is as follows:

$$SCI_{ci} = \frac{\sum_{k \neq c}^N Inputs_{ki}}{Outputs_{ci}}$$

Where  $i$ ,  $c$ ,  $k$  are the industry, host country, and foreign country of the input, respectively.  $SCI_{ci}$  is the total quantity of inputs required by industry  $i$  in the host country  $c$  from other nations (i.e. all countries  $k$  other than the host country  $c$  in the study group's dataset), scaled following the total output produced by industry  $i$  in the host country  $c$ .

In this study, the authors gathered information on foreign inputs and outputs of 35 sectors across 6 Southeast Asian countries from ADB's 2018 Input-Output table. According to ADB data, to create the final unit of output, each Southeast Asian country needs inputs from other industries in other nations. The Philippines, Thailand, and Malaysia are significantly reliant on foreign inputs, whilst Singapore, Vietnam, and Indonesia are less dependent. In general, in comparison to other industries, the production of leather, leather goods, and footwear, as well as transportation, electrical, and optical equipment, requires more foreign inputs.

Also, in this paper, the authors use workplace closures, the Stringency Index developed by Hale et al (2021), to capture the severity of supply chain disruptions. The index has a scale from 0 to 100, with 100 denoting the nation with the tightest workplace closure policies. The research team's approach is comparable to that of Ersahin et al (2022) and Li et al (2020). Specifically, to quantify supply chain disruptions, our team calculates a weighted average of the workplace closure stringency index of all foreign countries providing input for each industry in the host country. To account for differences in the importance of certain foreign countries for each sector input in the host country, we use the total amount of foreign inputs as the weight to calculate the Index. The weighted average Stringency Index is as follows:

$$\text{StringencyIndex}_{ict} = \frac{\sum_{k \neq c}^N \text{StringencyIndex}_{kt} \times \text{Input}_{ick}}{\sum_{k \neq c}^N \text{Input}_{ick}}$$

Where  $i$ ,  $c$ ,  $k$ ,  $t$  are industry, host country, foreign country of input, and time, respectively. is a weighted stringency index representing the supply chain disruptions faced by industry  $i$  in host country  $c$  at time  $t$ . This index is zero for 2018 and 2019, before the pandemic.  $\text{Input}_{ick}$  is the amount of input in dollars that industry  $i$  in the host country  $c$  needs from a foreign nation  $k$  in 2018 (pre-shock data from ADB's ICIO table).  $\text{StringencyIndex}_{kt}$  is the Workplace Closure Stringency Index of foreign country  $k$  at time  $t$ .

We consider using one of three estimation models: pooled regression model (POLS), fixed effects model (FE) and random effects model (RE). The result of the Lagrange test shows a better fit for RE than POLS. We use the FE model according to the result of the Hausman test. Besides, we also test the possible defects of the model. Furthermore, we conduct the Chow test to compare the indices by the least squares method and draw conclusions about the reliability of the model. In addition, we also use the difference-in-difference (DiD) to better clarify the impact of the pandemic on corporate performance.

Table 1 presents the variable measurement and expectations for each hypothesis according to previous studies we synthesized.

**Table 1. Variable measurement and hypothesis**

Variables	Description	Expectation	Sources
Log_ Net sales or revenues	Total revenue (US\$)		
Stringency Index	Stringency index	-	Aslam et al. (2022)
Stringency exposed	Stringency index correlated with exposure	-	
Log_ Total assets	Total assets (US\$)	+	Marimin et al. (2015) Rani Salamah et al. (2020)
Log_ Total liability	Total liability (US\$)	-	Tsangyao Chang (2010)
Log_ Short-term investment	Short-term investment (US\$)	+	Dritsaki (2004) Tiwari (2011)
ROA	Return on asset (ROA) (%)	+	Faisal et al. (2018)
Tobin's Q	Equals the market value of a company divided by its assets' replacement cost (Tobin's Q ratio) (%)	-	Mitra & Adhikary (2017)
Total debt-to-equity- D/E	Total debt on equity (D/E) (%)	-	Misman & Ahmad (2011)

## 4. RESULTS AND DISCUSSION

### 4.1. Summary statistics

**Table 2. Summary statistics**

Variables	Obs.	Mean	Sd.	Min	Max
Net sales or revenues	11,116	17.948	2.051	5.200	25.035
Stringency Index	11,116	31.877	32.035	0.000	67.800
stringency exposed	11,116	11.097	24.276	0.000	67.800
Total assets	11,116	18.757	1.943	8.904	25.737
Total liability	11,116	17.732	2.274	7.572	24.587
Short-term investment	11,116	20.098	4.851	0.000	31.133
Tobin's Q	11,116	3.516	116.580	-198.667	11,398.170
ROA	11,116	3.902	41.573	-3,428.500	134.784
Total debt-to-equity- D/E	11,116	95.137	1,868.014	-10,202.800	171,564

Source: Author's calculation from STATA

The minimum value of *Stringency Index* is 0.00 the maximum value is 67.8, the mean value is 31.877, and the standard deviation is 32.035.

The minimum value of *stringency exposed* is 0.00 the maximum value is 67.8, the mean value is 11.096, and the standard deviation is 24.276.

As can be seen from Table 2, the minimum value of *NET SALES OR REVENUES* is 5.200, which is an index of a firm from the Industrial group in Vietnam in 2018, while the maximum value is 25.035, one firm from Utility in Thailand in 2019, the mean value is 17.948, and the standard deviation is 2.051.

Regarding *TOTAL ASSETS*, the minimum value is 8.904, which is a firm from Industrial group in Malaysia in 2021, while the maximum value is 25.737. This is also a firm from Industrial group in Malaysia but in 2018, the mean value is 18.757, and the standard deviation is 1.943.

The minimum value of *SHORTTERM INVESTMENTS* is approximately 0. It comes from a firm in Industrial in Vietnam in 2019, the maximum value is 31.133, a firm of Transportation in Vietnam in 2021, the mean value is 20.098, and the standard deviation is 4.851.

Finally, the minimum value of Tobin’s Q ratio, the minimum value is -198.667, which comes from a firm of Other finance in Vietnam in 2019, the maximum value is 11398.170, an enterprise from Bank group in Indonesia in Vietnam in 2018, the mean value is 3.516, and the standard deviation is quite significant at the level of 116.580.

Regarding *RETURN ON ASSETS (ROA)*, the minimum value is -3428.5, the maximum value is 134; the expectation value is 3.902 and the standard deviation is quite significant at the level of 41.573.

**4.2. Sample descriptive statistics**

**4.2.1. Sample statistics by year and nations**

As can be seen from Figure 1 below, data collected from Vietnam contribute the largest part with 3093 observations, making up 27.82% of the total number of observations. Ranked second is Malaysia with 2704 observations, or 24.33% of the total number of observations collected. Observations in the case of Thailand and Singapore count for respectively 18.04% and 10.98% of the overall sample. The nation with the fewest observations in this paper is the Philippines with 520 observations.

**Figure 1: Number of observations in each nation**

*Source: Authors’ compilation*

**4.2.2. General industry classification**

Each company is ascribed with a SIC (Standard Industrial Classification) code, available on Worldscope. Such codes were developed by the U.S. government, and they are assigned in accordance with each business segment’s contribution to net sales or revenues, in descending order of importance. Furthermore, each company is given a General Industry Classification, which specifies whether it is an industrial, utility, transportation, banking, insurance, or other financial enterprise.

**Table 3. Industries statistics**

GENERAL INDUSTRY CLASSIFICATION	Total	Percent	Cum.
Industrial	8976	80.75	80.75
Utility	704	6.33	87.08
Transportation	541	4.87	91.95
Bank/Savings & Loan	9	0.08	92.03
Insurance	9	0.08	92.11
Other Financial	877	7.89	100.00

*Source: Authors’ compilation*

From the table above, it can be seen that the Industrial Sectors accounted for the highest proportion in this study with 8976 observations, 4 times higher than the other sectors combined. Ranked second

with a rate of 7.89% are 877 observations from other Financial sector. The Utility industry includes 704 observations, accounting for 6.33%, while such a number in the case of Transportation sector is 4.87%. The last two sectors are Banking and Insurance industries with the same ratio of 0.08% of the total sample.

#### 4.2.3. Stringency at home

The Stringency Index is a metric used to measure the tightness level of a country’s policies in response to the COVID-19 pandemic. This index is determined on a scale of 0 to 100, with a higher score indicating a stricter policy.

**Table 4. Stringency at home**

	<b>INO</b>	<b>MAL</b>	<b>PHI</b>	<b>THA</b>	<b>VIE</b>	<b>SIN</b>
Year 2020	62.18	59.36	71.30	48.81	61.44	50.44
Year 2021	58.15	69.10	72.81	55.54	69.13	48.96

*Source: Authors’ compilation*

Overall, it can be seen that the Stringency Index for Southeast Asian Countries has generally witnessed a downward trend from 2020 to 2021, suggesting that governments have become less stringent in their pandemic response policies over time. This could be due to factors such as increased vaccination rates or a decrease in the number of infection cases in some countries.

The Philippines has the highest Stringency Index for both 2020 and 2021, at 71.3 and 72.8 respectively, indicating that the government in this nation has taken more stringent pandemic response measures than other countries in the region. This may be because the Philippines had a relatively high number of COVID-19 cases and deaths compared to other Southeast Asian countries.

In both 2020 and 2021, Stringency Index is the lowest in Singapore, indicating that its government has taken less stringent pandemic response measures than its counterparts. However, it is worth noting that Singapore had a relatively low number of COVID-19 cases and deaths compared to other countries in the region, suggesting that their approach may be effective.

### 4.3. Discussion

#### 4.3.1. Baseline results

**Table 5. Regression results**

Variables	(1)	(2)	(3)	(4)
STRINGENCYINDEX	-0.00234*** (0.000199)	-0.00112*** (0.000202)		-0.0148*** (0.00965)

Note: Columns 1&2 presents the results of 6 Southeast Asian Nations in the sample. Column 3 shows the results of the pre-pandemic period (2018-2019). Column 4 illustrates the results of the post-pandemic period (2020-2021).

**Source: Author's calculation from STATA**

The results show that the Stringency index variable has a negative coefficient and is significant, which is consistent with the expectations of Aslam et al. (2022). This can be explained that if the Stringency index in the policy to deal with the Covid-19 pandemic is higher, countries will tend to limit trade and exchange; thus reducing revenue of enterprises.

The stringencyexposed interaction variable has a negative coefficient, which implies that in high-growth firms, the negative effect of disruption on firm performance is weaker than in low-growth firms.

As total assets increase, the revenue growth rate also increases. This result is similar to the study of Marimin et al (2015) when analyzing the growth of Islamic Sharia banks and getting the results that the bank's growth has increased along with the increase in assets.

The coefficient of the Total liabilities is positive, contrary to the author's expectation. However: "Debt can facilitate or determine economic growth depending on the level of debt" (Chang, 2010). Therefore, much corporate debt does not mean a decrease in firm revenue growth.

The coefficient of the investment variable in the short run is not statistically significant, which is contrary to the expectations of the author and Dritsaki (2004), and Tiwari (2011) when arguing that short-term investment not only helps promote private sector investment but also increase GDP in the long run.

The coefficient of the ROA variable is not statistically significant, which is entirely contrary to the author's expectations and the point of view of Faisal et al. (2018) when arguing that the larger the ROA, the better the financial performance because the rate of return is increasing.

The coefficient of the variable TOBIN's Q is negative, which is in line with the expectations of the authors and Mitra & Adhikary (2017). This can be explained that, if the company's Tobin's Q is more extensive, the company actively promotes investment, but during the Covid-19 period, the supply chain is disrupted; therefore, the company could not expand production resulting in negatively affected revenue.

The coefficient of the Debt-to-equity is negative, this is entirely consistent with the expectations of the authors and the study of Misman & Ahmad (2011). This means that the larger the company's percentage of liabilities, the slower its revenue growth. When a business has bad debt, it is forced to make provision for risks and record it as an expense, which will increase costs and reduce profits.

To measure the impact of supply chain-related factors on the company's revenue growth separately, the authors record the results in column 2. At this point, the stringencyexposed interaction variable does not affect the company's revenue growth. When removing the data for two years 2020 and 2021 (column 3), and two years 2018 and 2019 (column 4), the results show that in column 4, the severity index has

an effect. This shows that whether this policy is tight during the epidemic period will also contribute to economic growth. Therefore, firms need specific and clear development policies if they want to grow and recover the economy

#### 4.3.2. Difference-in-difference estimation results

To test our hypothesis that firms considered highly exposed to supply chain disruption would experience lower sales growth than lowly exposed firms, we employ difference-in-difference (DiD) estimation to examine the correlation between supply chain disruption and firm sales growth.

Where is the sales growth rate for firm  $f$  in industry  $i$  locating in country  $c$  at time  $t$ .  $year_1$  is a dummy variable that equals 1 if the observation time is in the pandemic period (2020-2021), and 0 otherwise.  $highlyexposed$  is also a dummy variable that equals 1 if the SCI of its industry exceeds the 75th percentile in the distribution of SCI in the home country  $c$  in 2018. The interacted variable between  $HighlyExposed$  and  $StringencyIndex$  is considered as  $StringencyExposed$ .  $StringencyIndex$  is the Weighted Average of the workplace closure index at time  $t$  of all input countries that provide goods to industry  $i$  in country  $c$  with the number of inputs from each input country used as weights.

**Table 6. Difference-in-difference estimation results**

Variables	(1)
$year_1$	-1.910***
	(0.701)
$highlyexposed$	-0.534***
	(0.0571)
$year_1highlyexposed$	1.700*
	(1.010)
$stringencyexposed$	-0.0282*
	(0.0158)
STRINGENCYINDEX	0.0288***
	(0.0109)
Constant	18.19***
	(0.0337)
Observations	11,116

Source: Authors' compilation

The coefficient of  $year_1$  is negative and significant, suggesting the downtrend in the firm's net sales or revenues following the time. This can be explained by the fact that the Covid-19 pandemic deteriorated from 2020 to 2021, harming the corporate performance of many firms in general.

The coefficient of  $year_1highlyexposed$  is positive and significant, showing that the pandemic can have a good impact on several firms' corporate performance. For instance, in Vietnam, Finance, Real estate and Food & Beverage still have effective performance, despite the Covid-19 pandemic.

Using DiD estimation, we conclude that the firm's revenue tends to decrease under the circumstances of the pandemic. However, several firms can still grow positively despite the influence of the pandemic. This can be explained that there may be other determinants that affect the growth of corporate performance, irrespective of the pandemic.

**4.3.3. Regression results by industry**

**Table 7. Regression results by industry**

	<b>Industrial</b>	<b>Utility</b>	<b>Transportation</b>	<b>Bank</b>	<b>Insurance</b>	<b>Others</b>
Stringency index	0.005***	-0.001***	-0.001***	-0.000***	-0.000***	-0.002***
stringencyexposed	0.003***	-0.000***	-0.000***	-0.000***	-0.000***	-0.001***
Stringencyathome	-0.005***	0.002***	0.001***	0.000***	0.000***	0.003***
Observations	8,976	704	541	9	9	877

*Source: Authors' compilation*

As can be observed from Table 5, there are apparent contradictions regarding the impacts of Covid-19 pandemic between firms of the Industrial sector and those from the other sectors, namely: Utility, Transportation, Bank, Insurance, and Others.

Specifically, regarding the Industrial sector, Stringency Index of lockdown policy poses a positive impact on corporate performance, whereas such a relationship between domestic Stringency (stringencyathome) and firms' outcomes is reversed. This may be due to the fact that the stricter the domestic lockdown measures, the less vulnerable the Industrial companies become when being exposed to an economic shock. As a result, the revenue of such businesses may not be severely affected. However, if the domestic country is strict in the lockdown policy in response to the Covid pandemic, enterprises in this industry will be incapable of finding materials sources, as well as face difficulty in exporting to potential markets. To be more specific, the Zero Covid policy of China, together with its extreme blockade, has worsened supply chain disruptions in Vietnam. A series of factories and warehouses were shut down, truck deliveries were delayed, and there was a shortage of container trucks... Consequently, Vietnamese businesses, which heavily depend on the Chinese market, are interrupted in both the export and import of raw materials. It can be seen that, without mentioning the Russia-Ukraine conflict, the shortage of raw materials supply due to the congestion of world seaports as well as the fluctuations in the epidemic in China has exposed the Industry sectors to significant difficulties.

Regarding the remaining sectors, Stringency index of lockdown measures exerts an adverse effect on business performance, while domestic stringency index (stringencyathome) poses a positive impact. Such relationships are contrary to those of the Industrial sector discussed above. This indicates that if the domestic Stringency index rises, it will be challenging for businesses, especially those in Utility and Transportation sectors, to seek raw materials sources, as well as to expand their market share. Compared to other sectors, Utility and Transportation are more susceptible to the economic shock during the pandemic. Regarding Transportation, it is reasonable that the profit of Transportation companies are acutely influenced. Due to the pandemic, supply chains are disrupted; airway, railway, seaway, and land transportation services are severely affected. Nevertheless, such an impact remains at a quite low level (0.001), which may be due to a relatively small number of such firms compared to the number of those in the Industrial sectors, thereby leading to a discrepancy in research results.

**5. CONCLUSION**

We studied 11,116 observations from 2018 to 2021 in order to answer the question of how supply chain disruption affects the performance of various firms in Southeast Asia. Our research results show that the higher the country's stringency index in the policy to deal with the Covid-19 pandemic, the more negatively businesses' revenue is affected. Control variables such as total assets and total liabilities have a positive influence, in contrast to Tobin's Q, D/E, which have a negative impact on revenue growth. Also according to the research findings, the stringency index of the blockade policy has a beneficial influence

on the business performance of enterprises in the Industry group, whereas the domestic stringency index shows the opposite effect. Other industry groups, however, exhibit these linkages in the opposite way.

Our research results indicate that it is crucial for firms to monitor and evaluate debt-related indicators and policies in reaction to the COVID pandemic, as well as alter their tactics to take into account differences in disease-prevention practices among regional and international countries. We propose some specific recommendations as follows.

First, businesses can establish strategic base locations to minimize risks associated with restrictions on cross-border mobility. This strategy requires a significant amount of restructuring, which is often appropriate for companies with worldwide infrastructure and may pose a long-term impact. However, blockades in different parts of a country may limit the effectiveness of this strategy.

Additionally, businesses can concentrate on creating a flexible supply station. To achieve this, it is advisable that companies diversify their material supply through multiple-sourcing or entering into flexible contracts with suppliers that allow them to adjust order quantities and delivery time windows.

Another option for businesses is to implement digital transformation throughout the entire operating system to improve supply chain agility. This aids businesses and organizations in getting a comprehensive picture of the entire value chain, from the processing of raw materials to final consumption.

Also, according to the findings, firms need to be more cautious when making investment decisions in the event of a supply chain disruption because investment in materials and equipment may result in a lower return on investment. Instead, employ a reuse strategy where assets are moved from underperforming sectors to assist stronger-performing areas in order to reduce waste.

Companies also need to modify their strategies to align with regional governments' pandemic response plans. This may entail changing product development, sales tactics, or marketing methods. For example, businesses can leverage the influence of social media, such as starting a trend on social networking sites to promote a sales promotion. This strategy does not necessitate large resources due to the fact that viewers will spread the word about the product.

In general, an unusual situation in the supply chain is characterized by a high level of uncertainty and a dearth of reliable information (Chen et al., 2010). In other words, if the information was readily available, timely, and highly accurate, the severity of the disruption would be lessened. As a result, it is necessary to give priority to employing modern technologies such as EDI (Electronic Data Interchange) or ERP (Enterprise Resource Planning).

There exists some shortcomings to this study. Due to limited available statistical data, we only studied 6 countries in Southeast Asia and the latest data is of the year 2021. In addition, as the severity of supply chain disruption in this paper is based on the industry's supply chain disruption, we only study single-industry companies. Future research may be particularly interested in the business performance of Southeast Asian businesses during the recovery period after the pandemic (from 2022 onwards). Therefore, we suggest a new direction based on forecasting the business performance of the business and then comparing it with the actual results.

## HOW DOES THE ACCESS TO FINANCE IMPACT BANK'S PROFITABILITY: THE CASE OF VIETNAM

**Author: Ngo Quang Tuan<sup>1</sup>, Do My Ha Trang<sup>2</sup>, Nguyen Duc Thang<sup>2</sup>, Le Phuong Anh<sup>2</sup>**

**Mentor: Nguyen Thu Thuy**

*ABSTRACT: Financial inclusion, especially the access to finance aspect, is considered as an important element in ensuring sustainable growth of a nation. To investigate the impact of the access to finance on profitability of the Vietnamese commercial banks, this paper applies Pooled OLS model for analysing the relationship between the access to financial services dimension (namely the number of ATMs, bank branches, point of sales) and bank profitability (measured by ROAE) during the period from 2011 to 2020. Moreover, the study also takes into account macro elements such as GDP, inflation rate as well as bank internal factors including bank size, liquidity and capital adequacy. The results show that branch expansion adversely influences the profitability of Vietnamese banks while no impact has been found from the number of ATMs and POSs. The importance of government supports is also expressed in implementing policies to improve the bank's profitability based on the enhancement of financial inclusion in the particular context of Vietnam.*

*Keywords: Financial Inclusion; Accessibility Aspect; Bank profitability; Commercial banks.*

### 1. INTRODUCTION

Commercial banks' primary function is to provide loans to borrowers and collect deposits from savers, hence, optimise capital distribution. Banks are also necessary for the payments system as funds transfer is processed through banks. Moreover, banks also generate money from the spread between interest revenue and expense, trading income, fees for customer services and financial product sales. Therefore, banks play a crucial part in ensuring the stability, efficiency and prosperity of the whole financial and economic system.

By improving the quality and access to financial services, the banking sector can allocate optimal resources while lowering the cost of financing, enhancing capital accumulation and economic growth. Simultaneously, banks can attract and maintain customers, thus improving their profitability. Financial inclusion can be used to measure supply of adequate and quality financial services. Financial inclusion refers to the accessible capabilities of individuals and institutions to useful and affordable financial products and services (The World Bank, 2011). The Global Partnership for Financial Inclusion (GPII) 2016 report suggests three aspects of financial inclusion including access to financial services, usage of financial services and quality of the products and service delivery. Banking sector is a driving force for financial inclusion activities while simultaneously, promoting financial inclusion helps enhance bank performance. As banks always consider profitability as a top priority during their operation, it is vital to improve bank profitability through factors such as financial inclusion.

After the COVID-19 pandemic, many individuals and businesses are negatively affected. The increased loan demands to recover business and production activities create an excellent incentive for commercial banks to enhance financial inclusion, contact all potential customers, increase financial performance and support the healing of the national economy.

<sup>1</sup> Foreign Trade University, Email: ngoquangtuan7801@gmail.com.

<sup>2</sup> Foreign Trade University.

Additionally, the Government has shown strong support and interest in financial inclusion implementation through plans and policies including Decision No. 2545/QD-TTg approving the Scheme on Non-Cash Payment Development in Vietnam for the 2016-2020 period; Decision No. 1726/QD-TTg approving the scheme on an increase of accessibility to banking services for the economy; the National Financial Inclusion Strategy to 2025, with a vision to 2030 signed by the Prime Minister in 2020.

These aforementioned emphasises the significance of this study in examining the impact of financial inclusion on bank profitability. Due to the limitations in public data and the specific context of the Vietnamese banking system, the study uses only accessibility dimension as a proxy of financial inclusion, including the number of bank branches, POS and ATMs. ROAE is used to evaluate bank profitability. The study also takes into account macro factors such as GDP, Inflation rate and bank-specific elements including bank size, liquidity, capital adequacy. To obtain the most accurate approximation, 200 observations are collected from 20 Vietnamese commercial banks from 2011 to 2020. The research uses Pooled OLS regression models and several postestimation tests including the variance inflation factor (VIF), the Breusch-Pagan, the Wooldridge and the Ramsay Reset test. To handle autocorrelation, the study applies the Newey-West method. This paper consists of six main parts. Section 1 is introduction. Section 2 reviews theoretical framework and literature. Section 3 focuses on data and methods. Section 4 discusses empirical results. Section 5 checks the robustness. Section 6 provides conclusions.

## **2. THEORETICAL FRAMEWORK AND LITERATURE REVIEW ON FINANCIAL INCLUSION AND BANK PROFITABILITY**

### **2.1. Theories**

Firstly, financial intermediation theory has been deployed to explore financial inclusion in various research publications (Kamal et al., 2021; Kalunda & Ogada, 2019 and Misati et al., 2019; ). It was implied that banks serve as a bridge between customers and the society. It concentrated on banks' contributions to the effective distribution of funds and the decrease of market friction. This can be taken to suggest that creating trustworthy information and lowering transaction costs result in financially sound institutions.

Secondly, the special agent theory will be used to examine how this relationship affects the goal of financial inclusion. This theory implied a special connection between the principal and the agent. The national authority is regarded as the principal, and local banks are regarded as the special agent.

### **2.2. Literature review of the impact of financial inclusion on bank profitability**

Numerous earlier studies have looked into the factors affecting banks' profitability around the globe. The factors that affect the performance of banks can be divided into two categories: macroeconomic variables (inflation, GDP growth rate) and bank-specific variables (capital adequacy, bank size and liquidity). According to Francis (2013), inflation has a negative effect on bank performance. However, Gul et al. (2011) suggested that external factors (GDP, inflation) significantly, positively influence on bank performance. Rachdi (2013) found that GDP, adequate capital, and liquidity had a beneficial effect on bank performance. As for adequate capital, it is indicated to significantly and positively contribute to bank performance (Kumar et al., 2020). In terms of liquidity, Kawshala and Panditharathna (2017) assumed an insignificantly negative influence on Sri Lankan bank profitability, however Bitar et al. (2020) concluded that liquidity is a key factor in determining the performance of Islamic banks. According to Kumar et al. (2021) and Al-Eitan et al. (2022), bank size is a key factor in determining profitability. Furthermore, bank size is asserted to have a significantly positive link with bank performance (Dietrich & Wanzenried, 2011).

Several studies have been undertaken using various databases to examine the correlation between financial inclusion and bank performance. As a result, there is controversy over the impact of financial inclusion metrics on bank profitability. Nonetheless, the majority of conclusions agreed on the critical impact of financial inclusion towards bank profitability. Al-Eitan, Al-Own, and Bani-Khalid (2022) used FE models and multiple linear regression model to analyze data from 13 banks in Jordan over a 10-year period, from 2009 to 2019) in order to look at indicators of financial inclusion. According to the study, bank profitability is significantly and negatively impacted by the volume of loan accounts as well as size of deposits, while the number of branches and ATMs had no noticeable impact. The support for this study about the value of financial inclusion in banks was simultaneously highlighted in the paper conducted by Kumar, Thrikawala, and Acharya (2021). A database containing 122 Japanese banks was studied by Kumar, Thrikawala, and Acharya in 2021. The authors used OLS, FE models, and GMM estimation techniques to demonstrate the significance of financial inclusion in economic activity since there is a positive correlation between bank profitability and the number of branches, despite the fact that the number of loan accounts and ATMs has no impact on bank profitability. Shihadeh et al. (2018), on the other hand, investigated the link between financial inclusion and Jordanian bank performance using an OLS regression model with annual data from 13 commercial banks from 2009 to 2014, indicating that the number of ATMs and credit cards increases bank profitability. In other words, the authors argue that financial inclusion can boost bank profitability.

Nonetheless, in the field of our research, only a few studies have been conducted on this topic to thoroughly examine the financial inclusion of Vietnam. Nguyen (2018) investigated the adverse effects of financial inclusion on monetary policies. Van et al. (2019) studied 159 countries, including Vietnam, to support the favorable association between financial inclusion as well as economic growth. Pham, Tran, and Vu (2020) emphasized the vital role of financial inclusion in the Vietnamese market by researching the impact of financial inclusion on other countries, specifically India, Brazil, and Malaysia. Despite its low mobile transaction volumes in comparison to other low- and middle-income countries, Tran, Nguyen, and Nguyen (2019) investigated the favorable influence of financial inclusion upon online payment transactions in particular. Vo et al. (2020) stated a link between financial inclusion and bank profitability, which they discovered when examining the impact of corporate social responsibility on loyalty among consumers in the Vietnamese bank industry. Furthermore, Vo and Nguyen (2021) investigated the impact of financial inclusion on Vietnam's bank performance as part of a database of 13 Asian emerging nations.

To sum up, the outcomes from a few papers which have been done to research the relationship between bank profitability and financial inclusion showed a mixed picture of relationships between financial inclusion indices and bank profitability, ranging from positively to negatively, significant to statistically insignificant.

### **Hypothesis development**

**The number of ATMs (ATM):** Itah and Ene (2014); Akhisar et al. (2015); Chaarani and Abiad (2018) discovered that ATMs might efficiently boost bank expansion. According to them, in recent years, many banks have attempted to expand their ATM network because this innovative technology is widely used by bank customers. As a result, the bank's financial performance improves, resulting in a competitive advantage.

**Hypothesis H1: There exists a statistical and significant relationship between the number of ATMs and bank profitability in Vietnam**

**The number of bank branches (BRANCH):** The development of bank branch networks, according to Shihadeh and Liu (2019); Farooq et al. (2021), leads to a rise in bank profitability. Kumar, Thrikawala,

and Acharya (2021) agreed with the same conclusion. According to them, a growth in the number of bank branches leads to an increase in the number of clients, which in turn increases deposits, loan portfolio, and risk diversification.

**Hypothesis H2: There exists a statistical and significant relationship between the number of bank branches and bank profitability in Vietnam**

**The number of POSs (POS):** Akhisar et al. (2015) used panel data methods to investigate electronic banking services in 23 developed and developing countries from 2005 to 2013. They discovered that the number of POSs had a considerable negative impact on ROE.

**Hypothesis H3: There exists a statistical and significant relationship between the number of POSs and bank profitability in Vietnam**

**Bank size (SIZE):** In terms of the bank size variable, Gul et al. (2011); Alper and Anbar (2011); Bhattarai (2017); Bitar, Pukthuanthong and Walker (2020) found out the significant positive relationship between bank size and ROE. They discovered that the number of POSs had a considerable negative impact on ROE.

**Hypothesis H4: There exists a statistical and significant relationship between bank size and bank profitability in Vietnam**

**Bank Liquidity (LIQUID):** In terms of liquidity, Rahman, Hamid, and Khan (2015) investigated the relationship between liquidity and bank performance in 25 Bangladeshi banks from 2006 to 2013. This encouraging finding is supported by Ebenezer, Oma, and Kamil (2017), as well as Bitar, Pukthuanthong, and Walker (2020).

**Hypothesis H5: There exists a statistical and significant relationship between bank liquidity and bank profitability in Vietnam**

**Capital adequacy (CAP\_AD):** Moving on to capital adequacy, Amahalu et al. (2017); Olalere et al. (2017) discovered that capital sufficiency has a favorable and significant impact on bank profitability. As a result, an increase in chosen banks' capital leads to an increase in return on equity. It implies that banks should use shareholder cash to improve bank performance and increase returns.

**Hypothesis H6: There exists a statistical and significant relationship between capital adequacy and bank profitability in Vietnam**

**Gross domestic product growth rate (GDP):** Gul, Irshad, and Zaman (2011) discovered that GDP had a direct and significant impact on ROE when researching factors affecting bank profitability in Pakistan. According to the study, rapid economic expansion boosts profitability in Pakistan's banking sector. In the same vein, Rachdi (2013) and Bhattarai (2017) discovered that the GDP growth coefficient is positively and strongly connected to ROE.

**Hypothesis H7: There exists a statistical and significant relationship between GDP and bank profitability in Vietnam**

**Inflation rate (INF):** According to Azam and Siddiqui (2012), Owoputi, Kayode, and Adeyefa (2014), and Rahman, Hamid, and Khan (2015), the inflation rate has a considerable and negative impact on ROE. This study implies that banks earn less during periods of excessive inflation.

**Hypothesis H8: There exists a statistical and significant relationship between inflation rate and bank profitability in Vietnam**

### 3. RESEARCH METHOD

#### 3.1. Data

The study employs a panel database containing 200 observations from the top 20 Vietnamese commercial banks in terms of capitalization from 2011 to 2020. All selected banks meet the criteria of having fully published their financial statements under the guarantee of independent auditing companies and having enough data to calculate the variables in the model during a 10-year period from 2011 to 2020. The financial inclusion factors and bank are gathered and calculated from the financial statements of the Vietnam Bank Card Association and the bank. Other control variables, such as GDP, inflation, and interest rates, are provided by the General Statistics Office (GSO) and the State Bank of Vietnam (SBV). Research data is secondary data that is organized and processed using Stata 15. To eliminate the impact of outliers, we winsorized all data except the number of branches, bank size, and liquidity at the 5th and 95th percentiles.

**Table 1: Measurement of variables and expected signs of impacts**

Variables	Description	Expected sign
ROAE	Net income/Average shareholders' equity	
ATM	Number of ATMs/100,000 adults	+
BRANCH	Number of bank branches/100,000 adults	+
POS	Number of POSs/100,000 adults	-
SIZE	ln(Total assets)	+
LIQUID	Totals loans/Total assets	+
CAP_AD	Total equity/Total asset	+
GDP	Yearly Vietnam GDP growth rate	+
INF	Yearly percentage change in CPI	-

Source: Synthesised by authors

#### Dependent variable:

Profitability is an important component in ensuring a bank's lucrative, appealing, and efficient development. Net interest margin (NIM), return on equity (ROE), and return on assets (ROA) are the most often utilized profitability indicators. In this study, return on average assets (ROAE) is employed as a measure of bank profitability from the standpoint of accessibility. ROAE is determined as a percentage by dividing net income by average shareholders' equity. ROAE is selected as an indication of bank profitability because it shows the potential to produce bank profits on all capital sources, regardless of which capital source has the same value.

Furthermore, using ROAE, it is possible to compare the performance of banks with the same risk because this index excludes changes in tax policy as well as financial leverage used by banks (Kupiec and Lee, 2012).

#### Independent variables:

**Financial inclusion variables:** From the annual available dataset, four financial inclusion variables were collected, including the number of ATMs per 100,000 adults, the number of bank branches per 100,000 people, the number of POSs per 100,000 adults, and the number of cards per 1,000 adults. In particular, the number of ATMs, POSs, and branches is indicated for a given number of adults' financial services approach.

#### Control variables:

In this analysis, both bank-specific and macroeconomic factors were collected. Liquidity, bank size, and capital adequacy ratio are bank-specific characteristics. The macroeconomic variables, on the other hand, are the GDP growth rate and the inflation rate.

The variables in the research model are explained as in Table 1.

### 3.2. Model specification

We estimated the following model:

$$ROAE_{it} = \beta_0 + \beta_1 ATM_{it} + \beta_2 BRANCH_{it} + \beta_4 POS_{it} + \beta_5 GDP_{it} + \beta_6 INF_{it} + \beta_7 SIZE_{it} + \beta_8 LIQUID_{it} + \beta_9 CAP\_AD_{it} + u_{it}$$

where the subscript  $i$  refers to the bank and  $t$  refers to the time period; ROAE is the dependent variable and refer to the profitability of the bank; ATM, BRANCH, and POS are the independent variables and refer to the financial inclusion of the country; SIZE, LIQUID, and CAP\_AD are bank-specific control variables; INF and GDP are country-specific macroeconomic control variables; and  $u_{it}$  is the error term.

### 3.3. Analysis techniques

The data analysis technique used in this research is the regression for panel data. Three types of panel regression models are commonly used, which are Pooled OLS (POLS) model, the Fixed Effects (FE) model and Random Effects (RE) model.

The Fixed-Effect technique tackles estimating concerns linked to unobserved heterogeneity (individual firm characteristics) across companies, and it is acceptable when the unobserved heterogeneity is stable throughout time for a given company (Schultz, Tan, & Walsh, 2010). Unlike the Fixed-Effect model, the Random-Effect model lowers variability within the sample by partly pooling the data and analyses the changes in error terms across particular businesses and periods. The Hausman test is a commonly employed econometrics test in panel data research for selecting between Fixed-Effect and Random-Effect frameworks. This test assesses the orthogonality of predicted effects and regressors, and was introduced by Hausman in 1978.

In order to choose whether Pooled OLS model or the Random-Effects model should be used, the Breusch-Pagan Lagrange Multiplier Test (LM), Trevor Breusch and Adrian Pagan (1979) is used to check for the significant difference across units (panel effect). The present study aims to examine the presence of a significant variation across units, also known as panel effect. The null hypothesis elucidates the rationale behind selecting the pooled regression, while the alternative hypothesis provides justification for the acceptance of the Random-Effect model.

Ordinary least squares (OLS) regression is a statistical technique for estimating the connection between one or more independent variables and a dependent variable. Studies apply ordinary least-square regression (OLS) analysis to identify the link between financial inclusion and bank profitability, Kumar et al. (2021).

The Newey-West is utilised to correct standard error when heteroskedasticity and autocorrelation happened and to compare the findings of OLS with the Newey West method on secondary and simulated data, which was first employed by Newey, W. K., and K. D. West. (1987). This strategy was utilised in the previous study in analysing the link between financial inclusion and banks in the finance sector, Adeola, O., and Evans, O. (2017) and is regarded as an acceptable estimation approach to study the dynamic nature of connections, Swamy, V. (2014).

## 4. RESULT AND DISCUSSION

### 4.1. Descriptive statistics

Table 2 includes descriptive statistics for each variable, such as mean, standard deviation, minimum and maximum values, and Skewness. ROAE is the dependent variable; the others are independent variables,

which are broadly classified as financial inclusion factors and macroeconomic variables. The ROAE of Vietnamese banks ranges from -27.1% to 28.1%.

ATM has a lower volatility rate of 1.006 per 100,000 adults. Similarly, with a standard deviation of 0.713, there are 0.576 bank branches per 100,000 people. POS has a range of 0 to 117.251 per 100,000 adults, with a standard deviation of 24.806.

**Table 2: Descriptive statistics**

Variable	Mean	Std.Dev.	Min	Max	Skewness
ROAE	0.111	0.076	-0.271	0.281	-0.109
ATM	1.006	1.095	0.007	0.013	1.212
BRANCH	0.576	0.713	0.044	3.377	2.608
POS	12.824	24.806	0	117.251	2.489
SIZE	18.963	1.119	16.502	21.173	-0.098
LIQUID	0.574	0.139	0.147	0.805	-0.748
CAP_AD	0.087	0.044	0.042	0.462	3.927
GDP	0.060	0.012	0.029	0.071	-1.561
INF	0.050	0.047	0.006	0.181	1.999

*Source: Results from Stata 15*

With a standard deviation of 0.044, the average capital adequacy ratio (CAP\_AD) is 8.7%. The SIZE, on the other hand, has an average of 18.963 and a standard deviation of 1.119. The average liquidity ratio is 57.4%, ranging from 14.7% to 80.5%. In terms of distribution, SIZE and LIQUID are considered very balanced.

Throughout the study period, the GDP fluctuated dramatically. Inflation varies widely, with a low of 0.6% and a high of 18.1%. With a standard deviation of 0.028, the average interest rate is 7.6%. INF has a positive skewness. A positive skewness suggests that the right-handed tail is greater in size than the left-handed tail. In the case of GDP, the opposite was true.

#### 4.2. Correlation matrix

Table 3 displays the correlation matrix between independent variables. The table shows that there are relatively low data correlations among the independent variables, indicating that there are no multicollinearity problems.

**Table 3: Correlation matrix**

Variables	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)
(1) ROAE	1.000								
(2) ATM	0.234 (0.001)	1.000							
(3) BRANCH	0.062 (0.386)	0.808 (0.000)	1.000						
(4) POS	0.201 (0.004)	0.758 (0.000)	0.456 (0.000)	1.000					
(5) GDP	-0.044 (0.534)	0.007 (0.916)	-0.004 (0.957)	0.051 (0.472)	1.000				
(6) INF	0.035 (0.626)	-0.069 (0.333)	-0.030 (0.668)	-0.123 (0.084)	0.017 (0.811)	1.000			

(7) SIZE	0.424 (0.000)	0.826 (0.000)	0.681 (0.000)	0.693 (0.000)	-0.036 (0.618)	-0.197 (0.005)	1.000		
(8) LIQUID	0.277 (0.000)	0.412 (0.000)	0.484 (0.000)	0.292 (0.000)	-0.006 (0.938)	-0.341 (0.000)	0.471 (0.000)	1.000	
(9) CAP_AD	-0.145 (0.041)	-0.344 (0.000)	-0.341 (0.000)	-0.257 (0.000)	-0.067 (0.344)	0.083 (0.245)	-0.543 (0.000)	-0.123 (0.083)	1.000

Source: Results from Stata 15

Table 3 shows a positive association between the dependent variable ROAE and the independent variables ATM, POS, SIZE, and LIQUID, with correlation values of 0.234, 0.201, 0.424, and 0.277 at the 5% significance level, respectively. The remaining independent variable is CAP\_AD which has a negative association, with a correlation coefficient of -0.145 at the 5% significance level. At the 5% significance level, variables BRANCH, GDP, and INF are not statistically significant.

### 4.3. Empirical Results

**Table 4: Regression results from Pooled OLS, REM and Newey-West models**

Variables	Pooled OLS	REM	Newey-West

Source: Results from Stata 15

The findings of the Hausman test suggest that the null hypothesis (H0) is supported, while the alternative hypothesis (Ha) is not, given that the computed p-value of 0.0947 surpasses the predetermined level of significance of 0.05. Based on the observed correlation between the ai findings of the Hausman

test and  $x_{it}$ , it is considered more appropriate to employ the Random Effect model. To investigate the relationship between the two models and derive accurate conclusions, the authors have presented the results of the Random Effects (RE) model and the Pooled Ordinary Least Squares (POLS) model in Table 4.

The impact of the ATM and GDP variables on the ROAE appears to differ from that observed in the POLS model, indicating a potential lack of consistency between the RE and POLS models. The findings indicate that the utilization of both the RE model and the POLS concurrently may result in incongruities in the examination and coherence of the research, particularly subsequent to conducting the Breusch-Pagan Lagrange Multiplier Test (LM). The statistical analysis resulted in a p-value of 0.811, which exceeds the predetermined significance level of 0.05. The acceptance of the null hypothesis occurs when the variance of the random effect is equal to zero, denoted as  $\text{Var}(u) = 0$ . In this scenario, the POLS model is preferred over the RE model.

Regarding to the POLS model, the results illustrate that the number of ATMs (ATM) has a positive impact on bank profitability with the coefficient of 0.003. The coefficient of the number of bank branches (BRANCH) and bank size are statistically significant for bank profitability. The number of POSs shows a negative but insignificant relationship with bank profitability with the coefficient of -0.0003, suggesting that this variable does not affect the profitability of banks in Vietnam.

This study also investigates the relationship between bank-specific variables and bank profitability. Liquidity has a positive relationship with ROAE and is statistically significant at a 1% significance level. With a correlation value of 0.153, we can affirm that banks with high profitability have high liquidity. The result examines the association between capital adequacy ratio and bank profitability. The coefficient of CAP\_AD is positive with the coefficient 0.191, in which we employed ROAE as a measure of profitability and applied the OLS estimation technique.

Turning to the country-level control variables, we observed the impact of gross domestic product growth rate (GDP) on ROAE. We also observed that the inflation rate (INF) increases bank profitability significantly at 1%. The coefficient of 0.411 indicates that every 1% rise in the inflation rate results in a 0.411% improvement in profitability.

#### 4.4. Robustness checks

**Table 5: Postestimation**

Breusch-Pagan test		Wooldridge test		Ramsay test	
Chi <sup>2</sup> test	Existence of heteroskedasticity	F-test	Existence of autocorrelation	F-test	Existence of omitted variables
0.06 (0.8116)	No	177.284 (0.0000)	Yes	0.47 (0.7057)	No

Tests were employed in the study to see if there is multicollinearity, autocorrelation, heteroskedasticity, or omitted variables. The variance inflation factor (VIF) is used throughout the paper to investigate multicollinearity. The test results reveal that the average VIF value is less than 5. Results in table 3, on the other hand, indicate no association coefficients more than 0.85. As a result, the authors conclude that the model does not suffer from multicollinearity.

The study used the Breusch-Pagan test to account for heteroskedasticity error. The results in Table 5 show that the model is unaffected by heteroskedasticity.

The Ramsey test is used in the examination for the omitted variable defect. The test results in Table 5 show that the model has no flaws in terms of missing variables.

The Wooldridge test is used to determine whether the model has an autocorrelation defect in terms of autocorrelation error. The results in Table 5 show that the model suffers autocorrelation defect.

After overcoming the autocorrelation defect using Newey-West regression, the results in Table 4 in Newey-West column indicate that the regression coefficients of the independent variables are unchanged. Among the independent variables, bank branches, POS and GDP are negatively related to bank profitability, but remaining variables like ATM, inflation, bank size, liquidity and capital adequacy have a positive correlation with bank profitability. In addition, the statistical significance of the Newey-West regression model is also consistent with the OLS model when it indicates that variables such as bank branches, inflation, bank size, liquidity are statistically significant in level 1%.

#### 4.5. Discussion

Regarding financial inclusion variables, the paper rejected Hypothesis H1 and Hypothesis H3 - which stated a statistically significant relationship between the number of ATMs and POSs toward bank profitability. Since banks equip many ATMs, they have to spend money on installing and sometimes fixing the equipment that can not be offset by the transaction fee at the ATM. This insignificant relationship is consistent with previous research, such as Kumar et al. (2021), when the authors could not find a significant relationship between bank profitability and the number of ATMs.

Our result related to POS is in line with (Itah and Ene,2014; Nwakoby et al.,2020), who also found no relationship between the number of POSs and return on equity for banks in Nigeria because most customers still prefer cash payment than use POS for all of such purposes. In Vietnam, the majority of adults still prefer cash transactions to other modern methods because people worry that they might not be able to carry the card all the time to withdraw money or pay at any time.

However, the paper accepted Hypothesis H3 since the regression result indicate that BRANCHES has a statistically significant impact on bank profitability. This result may come from the fact that the bank has spent a lot of money on expanding its network, investing in equipment and maintaining branches, but has not yet attracted the attention of customers. Bank branches in Vietnam often attract many customers and businesses in urban areas with diverse needs and large transactions. Consequently, banks will have to witness a decrease in profits since more new branches are open in many different places in Vietnam.

Moving onto bank-specific variables, the results illustrate that SIZE and LIQUID statistical and significant correlate with bank profitability. Hence, the paper accepted Hypothesis H4 and Hypothesis H5. This result is consistent with our expectations and the previous literature. Big banks in Vietnam frequently have a more substantial presence in the market and are constantly proactive in planning and monitoring market swings to respond swiftly; therefore, their profit growth rate is relatively high. The positive correlation between size and ROAE is consistent with previous studies by Alper and Anbar (2011) and Bhattarai (2017). Rachdi (2013) and Hirindu & Kushani (2017) stated that giant banks are more profitable because of economies of scale and scope. Profitability and liquidity are pragmatic markers of Vietnamese commercial banks' corporate health and performance and profit-oriented undertakings. A group of researchers states that higher liquidity has a positive effect associated with financial development (Rachdi, 2013; Hirindu & Kushani,2017). When it comes to banks in Vietnam, this is comparable to Rahman et al. (2015) and Ebenezer et al. (2017); here, this study reveals that liquidity and profitability are closely linked.

Since the coefficient of capital adequacy is not statistically significant, **Hypothesis H6** is rejected. It can be seen that, with the outstanding development and growth of the number of ATMs and bank branches along with other growth factors of banks in Vietnam, the bank's capital mobilisation sources have become more prosperous. Thereby leading to the capital adequacy ratio of banks at an acceptable level but still able to ensure stable cash flow and profits over the years.

GDP does not affect bank profitability since the coefficient of GDP is insignificant. Therefore, **Hypothesis H7** is rejected since no statistically significant relationship between GDP and bank profitability has been found. Our results are in line with the conclusions of the studies (Alper and Anbar, 2011; Samhan and Khatib, 2015), when no relationship between GDP and bank profitability was found. When GDP increases, it means that other industries and businesses are stepping up production and expanding their scale to meet the increasing social demand. Then, banks will have to keep interest rates stable to ensure a sustainable economy, so it will make it difficult for banks to achieve a breakthrough profit goal.

Inflation rate has a significant impact on bank profitability. This means that the paper accepted **Hypothesis H8**. It seems that banks in Vietnam can anticipate the inflation rate. Although banks recently endured an economic crisis in 2008, Vietnam's inflation level has climbed swiftly, yet this has not led banks to incur too many losses throughout the years. This association also corresponds with the findings of Vong & Chan (2009) and Guru et al. (2002) when assuming that there is a positive link between inflation rate and bank performance. This allows the banking sector in Vietnam more outstanding cash to engage in and combine lending operations.

## 5. CONCLUSION AND RECOMMENDATIONS

The central aim of the study is to examine whether financial inclusion from the accessibility aspect affects bank profitability (calculated by ROAE). The result indicates that the branch variable has a significantly negative impact on ROAE while the number of ATMs and POSs do not have a statistically significant relationship with ROAE. In terms of bank specific and macroeconomic variables, GDP and capital adequacy have insignificant impact on ROAE, however, inflation, bank size and liquidity have significant effect on bank profitability. The theoretical contributions of this research add to the existing knowledge and extends the understanding of financial inclusion, especially the accessibility aspect in the Vietnamese banking sector particularly and in emerging markets generally.

The findings of this study show important implications. Negative impact of the number of bank branches on profitability encourage banks to follow Circular No. 21/2013/TT-NHNN of the State Bank of Vietnam to limit of the number of branches and transaction offices. Higher intensity of financial inclusion than real participation in banking products and services will lead to higher inefficient cost, which then negatively affects bank profitability. Moreover, the negative result might be due to the lack of proper supervision so banks need to perform superior management practices in day-to-day operations while minimise input usage and weaknesses. Furthermore, concentrating only on the access dimension is not enough, banks should enhance all three aspects, especially the quality one, reduce fees and deploy incentive programs to stimulate use of formal financial services and products. According to Nguyen and Tran (2021), there are several backlogs in the enforcement of financial products and services in Vietnam. Besides, the positive correlation between liquidity and profitability demonstrates that each bank should maintain an appropriate liquidity level to balance risk and profitability preference. Liquidity will ensure the financial market's function, therefore, determine banking development.

Although this research paper has employed a handful of methodologies to offer robust results, limitations are undeniable. Very few research papers have been conducted on the influence of financial inclusion on

Vietnamese banks' profitability. This would result in some limitations in verifying the information and comparing between this research paper and other previous empirical studies in the same research field. Additionally, two other dimensions of financial inclusion (the usage and quality of financial inclusion) are not included in this paper because of the multicollinearity and deficient public information found in the Vietnamese banking sector. This lack of public information also resulted in limited observations as the study is focused on the panel of only 20 national banks in Vietnam during 10 years. Thus, future research studies should expand the observations and include all three dimensions of financial inclusion.

**ABSTRACT:** *This paper aims to analyze the impact of financial literacy, digital literacy and customer experience on customer choices toward digital banking services in Vietnam. We collected data randomly from 601 participants aged from 18 to above 40 years old who have experienced digital banking services and we applied both qualitative methods and quantitative methods on the collected information. The findings show that financial literacy and digital literacy significantly affect customer use of fintech products, proving our hypotheses. Moreover, the effect of other variables of customer experience (the propensity of technology adoption, customer value for privacy, customer trust, and customer loyalty to internet services) is proven to be strongly positive. These results will support banks, households, and the government on a wide scale.*

*Keywords: Financial literacy, Digital literacy, Digital banking services, Customer choice, Vietnam.*

### 1. INTRODUCTION

The last decade has witnessed dramatic changes in the financial industry with fast digitalization. We are now encountering the growth of the financial system and the introduction of new digital banking products and services, which introduce customers to a wide range of choices to better manage their personal finances, including saving and investing, payments, borrowing, and risk management. Rapid developments in financial technology also emphasize the importance of financial and digital literacy in order to use innovative digital banking products and services (Morgan and Trinh, 2023).

Recent literature in the world has shown that the use of digital payment tools and platforms is associated with higher digital literacy, at all levels of financial literacy (Prete, 2022). The usage of digital payments in the data is related with the capacity to utilize digital technologies at all levels of financial literacy, whereas personal finance decisions are associated with financial literacy at all degrees of digital literacy. However, the study focuses only on digital payment tools, while there are many other types of financial and digital services and products offered by banks.

The first and only study carried out in Vietnam by Peter J. Morgan (2020) discovered a link between financial literacy and awareness and use of fintech products. However, the research totally ignored the impact of digital literacy. Unfortunately, we are not aware of any other articles that explore the influence of both financial literacy and digital literacy on choices toward digital banking services, or any other similar-related issue, anywhere in the globe, much alone in Vietnam.

In addition, Vietnam is considered as a country with potential for digital banking development due to the great demand of the market. When it comes to digital payments, Vietnamese consumers are shifting from saving to buying first and paying later. This is also a motivator for banks to make efforts in the

<sup>1</sup> Foreign Trade University, Email: k59.2013380345@ftu.edu.vn.

<sup>2</sup> Foreign Trade University.

digital transformation process to improve the customer experience, as well as for regulatory authorities to implement regulations to stimulate the growth of digital banking (Luru, 2019).

This paper attempts to fill this gap. By using collected data in Vietnam, our research would study the impact of financial and digital literacy on customer choices toward digital banking services. Because there was no research study on this topic before, our contribution would be a breakthrough in the financial area, and our findings may be utilized in the real world.

The remainder of the paper is organized as follows. The next chapter reviews the relevant literature. Chapter 3 informally describes the data set and introduces the research methodology. Chapter 4 discusses the results from the descriptive statistics performed by SPSS statistical software employing the most recent methodologies linked to Cronbach's Alpha, and Exploratory Factor Analysis (EFA). In the same chapter, AMOS software is used to analyze Structural equation modeling (SEM). Chapter 5 concludes, reviews recommendations for bankers, and provides the researcher's directions for conducting future research.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Financial literacy**

#### **2.1.1. Definition**

In the context of this research, it can be said that financial literacy is an indicator of how well a person understands the basics of finance, its institutions, and how well that person can utilize the services available.

#### **2.1.2. Theoretical background and hypotheses development**

Financial literacy has been viewed as a key tool for improving financial inclusion and individuals' long-run financial security, among both researchers and practitioners alike. The key component of financial literacy is defined as having awareness and knowledge about available products and services and how to access and use them given available tools and modes of delivery.

Financial literacy is described as having the “*information, skills, and beliefs that affect attitudes and behavior to improve the quality of decision making and financial management in order to reach prosperity*” by OJK (2017). People require financial knowledge to make wise choices regarding their finances. Siregar (2018) said that financial literacy affected the use of internet banking services, meanwhile, according to Nurjannah (2017) knowledge of banking products did not affect the use of e-banking products. Therefore, we state our hypothesis as:

*H1: Financial literacy has a significant effect on the use of digital banking services.*

### **2.2. Digital literacy**

#### **2.2.1. Definition**

In its most common form, digital literacy can be characterized as one's ability to access and utilize digital platforms and services. Global organizations and institutions such as OECD, UNESCO, and the European Commission have also been working to create frameworks for defining and measuring digital literacy across a variety of digital contexts and mediums (Lyons and Kass-Hanna, 2020; Lyons *et al.*, 2019).

#### **2.2.2. Theoretical background and hypotheses development**

Digital literacy, according to Gilster (Kemendikbud, 2017), is the capacity to use information obtained through a computer or other electronic device. The idea of digital literacy is crucial for comprehending technology, information, and communication, according to UNESCO (Kemendikbud, 2017). Likewise,

according to Vainio (Yudha and Isgiyarta, 2015) the ability to learn information technology affects a person's Computer Self Efficacy (CSE) in various situations.

The primary individual demands for utilizing the internet, according to Korgaonkar and Wolin (1999), are social escapism, information, interactive control, socialization, and economic reasons. It's interesting to note that, contrary to popular belief, a large proportion of people in industrialized nations believe they do not require the internet (The Guardian, 2003). The "prospective gratification" theory (LaRose *et al.*, 2001) could be able to explain such disinterest. The decision to use the internet is influenced by a person's habit strength, deficient self-regulation, and self-efficacy (Bandura, 1997).

Kang *et al.*, (2015) provided a theoretical framework including concepts such as digital literacy, information literacy, performance expectancy, effort expectancy, hedonic motivation and habit. This was a model that had been adapted based on the unified theory of acceptance and use of technology 2 (UTAUT2) model, designed on the intention to apply digital technology in education practice. The results of this study show that digital literacy has a positive relationship with intention to use digital technology in learning.

Hoang *et al.*, (2022) suggests that digital literacy not only has a direct impact on behavioral intention to use technology in learning but also provide mediation effects by positively influencing self-efficacy, performance expectancy, effort expectancy, social influence, habits, and hedonic motivation. From the background above, the second hypothesis of the research is as follows:

*H2. Digital literacy positively impacts the use of digital banking services.*

### **2.3. Customer choices toward digital banking services**

#### **2.3.1. Definition**

A customer journey is a whole interaction a consumer has with a company. The four-stage of a customer journey are initial consideration of alternatives, evaluation, choice, and consumption (Court *et al.*, 2009). Consumer choice, refers to the decisions that consumers make with regard to products and services (Collins English Dictionary, n.d.). According to Davis (1993), customer choice is the third stage after the consumers consider and evaluate the products or services they want.

#### **2.3.2. Theoretical background**

Existing research explored Internet banking resistance and its relation to individual values and determined that both functional and psychological obstacles evolved from service, channel, customer, and communication (Kuisma *et al.*, 2007). Therefore, several theories and models have been developed to explain the relationship of user beliefs, attitudes, and intentions. Some of these theories and models include the innovation diffusion theory (IDT), theory of reasoned action (TRA), the theory of planned behavior (TPB), the technology acceptance model (TAM), the social cognitive theory (SCT), the motivational model (MM) and the model of PC Utilization (PCUM). The IDT measures why consumers don't adopt new products and services by identifying five characteristics of innovations: relative advantage, compatibility with current products/methods, complexity, limited trialability, and communicability of features that may affect online banking acceptance (Fain and Roberts, 1997). The TRA has been extensively questioned since it primarily focuses on conscious behaviors that have been thoroughly considered before being performed, neglecting illogical decisions, habitual acts, and those subconsciously performed by customers (Al-Qeisi, 2009). The TPB is an extension of the TRA, which was employed to solve the deficiencies of TRA. Attitudes toward the conduct, subjective norms about engaging in the behavior, and judgments about whether the individual will be able to successfully engage in the target behavior all influence intent (Marangunić and Granic, 2015).

According to Davis (1989), TAM is developed based on consumers' adoption of computer systems, especially on their behavioral intention to use these systems, which comprises two beliefs called perceived ease of use and perceived usefulness. The SCT examines the social dissemination of new patterns of behavior in terms of the psychological elements that influence their acquisition and adoption, as well as the social networks that spread and maintain them (Bandura, 2001). The MM theorizes that extrinsic and intrinsic motivation are the main drivers of an individual's intention to perform a given behavior, and the intention to conduct a behavior is a construct that is intimately tied to the actual behavior (Venkatesh and Speier, 1999). Thompson *et al.* (1991) developed a model to predict PCUM which included six factors of technology acceptance: job fit, complexity, long-term consequences, affect toward use, the social factor and the facilitating conditions.

The review and integration of these seven theories and models above developed the unified theory of acceptance and use of technology (UTAUT). The UTAUT indicates that four constructs—performance expectancy, effort expectancy, social influence, and facilitating conditions—are key drivers of behavioral intention and, ultimately, behavior (Venkatesh *et al.*, 2003). The UTAUT theory is used in the research of Salem *et al.* (2019), and then becoming the supporting theory of this study.

According to Salem *et al.* (2019), there are six factors including the propensity of technology adoption, customer value for privacy, customer trust, customer value for online personalization, technology and leadership, and customer loyalty to internet services affecting Palestinian customers' use of online banking services. However, when applied in the research environment of Vietnam, these six factors are changed and our research paper will focus on four exogenous latent indicators such as the propensity of technology adoption, customer value for privacy, customer trust, and customer loyalty to internet services.

### **2.3.3. Hypotheses development**

#### *2.3.3.1. The propensity of technology adoption*

Technical innovations that enhance performance in a specific context are typically influenced by customer predisposition to adopt them according to Chandio *et al.*, 2017. In 2020, a study by Santini *et al.* found a higher association between the TAM aspects and opinions regarding adopting electronic banking systems among Internet banking users. Similarly, the empirical study in Vietnam indicated a favorable association between client happiness and banks' capacity to stay on the cutting edge of technology (Wang and Pho, 2009). Therefore, we hypothesize that:

*H3. Customers' technology adoption propensity affects the use of digital banking services.*

#### *2.3.3.2. Customers' concern for privacy*

Most customers are concerned about their privacy when using online services (Sreejesh *et al.*, 2016). Chellappa (2001) offers scales for measuring consumer privacy perception. It was based on the recommendations of Smith *et al.* (1996) and the FTC (1996). These scales are intended to assess the subjective beliefs of customers. Previous study in Vietnam by Nguyen and Nguyen (2017) also supports that perceived risk was modeled and divided into privacy risk, which has a negative impact on online banking intention. Therefore, we hypothesize the following:

*H4. Customers' concern for privacy affects the use of digital banking services.*

#### *2.3.3.3. E-trust*

Trust is often conceived of as a relationship between one agent (the trustor) and another agent or object (the trustee). The trustors' ideas about the trustee's competence and the circumstances in which

the relationship happens are believed to underpin the relationship. This is a broadening of Gambetta’s (1998) concept of trust. E-trust arises when direct and physical contact is not feasible, moral and social influences are perceived differently, and interactions are mediated by digital technology. More importantly, the empirical study in Vietnam by Nguyen and Khoa (2019) indicated online trust has a significant role on customer electronic loyalty towards online business. Considering the recently identified relationship between e-trust and the usage of digital banking services, we present the following hypothesis:

*H5. E-trust affects the use of digital banking services.*

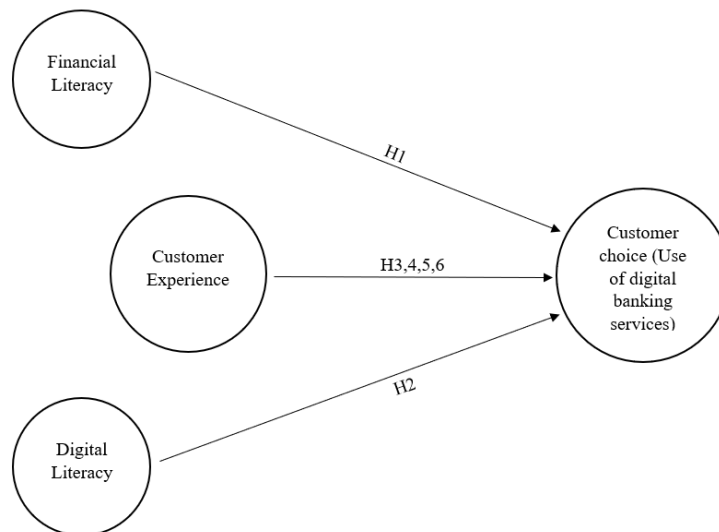

2.3.3.4. E-loyalty

E-loyalty is described by Flavián *et al.* (2006) as a preference that causes the website to be the most frequented and is selected for the purchase of a specific product category. In this study, e-loyalty is defined as customers’ perceived loyalty to digital services and their propensity to use these services again. In addition, Chen and Yang (2014), and Kassim and Abdullah (2008) claimed that providing services that are easily navigable and accessible allows online clients to create long-term connections with customers. In Vietnam, the study by Giao *et al.* (2020) showed a positive effect of website quality on e-loyalty regarding online shopping. As a result, loyalty might be viewed as an attempt to interact with consumers. This study proposes the following hypothesis:

*H6. E-loyalty affects the use of digital banking services.*

2.4. Expected Model

Based on the aforementioned theoretical basis, the expected model is built.

**Note:** Customer Experience includes four sub-variables such as technology propensity, customer’s concern for privacy, e-trust, and e-loyalty.

Figure 2.1. Expected model

3. RESEARCH METHODOLOGY AND DATA COLLECTION

3.1. Research methodology

The sample subjects were customers of commercial banks in Vietnam. The study’s main methodology was survey research. We gathered the questionnaires used in the previous studies (included in Table 3.1.)

to develop our own one. We translated the original questions into Vietnamese, and then they were reviewed by two separate and independent Vietnamese native speakers. The English version of the questionnaire was pilot tested for accuracy and content validity.

After that, the first version of the questionnaire was used to test with a small group of 20 people, then we collected the sheets back and analyzed the data to see whether or not these questions were suitable for the environment of Vietnam. As a result, the context of the financial literacy question set was changed to fit with Vietnamese bank customers and two questions of the digital literacy set were moved out because they have something similar to the other questions in the same set.

The results showed that when running the exploratory factor analysis, six sub-variables of customer choice only explained four dimensions of this big variable. Besides, 8 questions in the question set seemed to contribute weak exploratory power to the overall variable with loading factors all smaller than 0.5. Therefore, these 8 questions were canceled out and the remaining 24 questions were again divided into 4 categories which are e-loyalty, e-trust, customer concern for privacy, and technology propensity, respectively. The sub-variable “use of digital banking services” was used to measure the dependent variable, therefore, it remained the same. After that, the second version of the questionnaire was widely used. We used both printed and online versions when collecting samples. After three months of collecting data, we finally had 601 samples and decided to end this step here.

After classifying text data into categories giving each category a numerical code, the IBM SPSS Statistics software was used to test the validity and reliability of the questionnaire, ensuring that the questions in a dimension measure the same component and all the questions are in good correlation with each other. Afterward, the relationship between financial literacy, digital literacy and customer choice are tested by the SEM model using AMOS software. From the results generated, we can conclude whether or not the hypotheses are supported.

### 3.2. Research framework

The research design is described step by step in Figure 3.1.

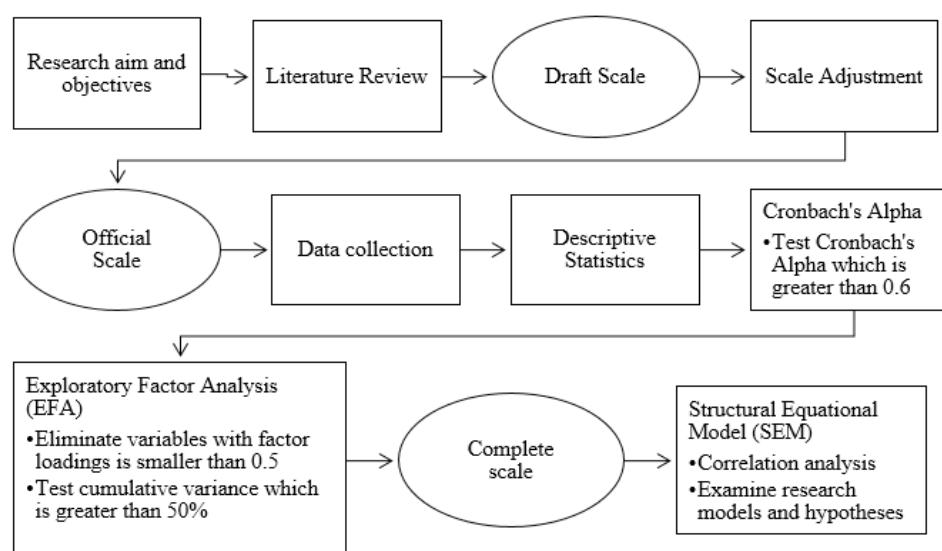

Figure 3.1. Research design

### 3.3. Measurement of variables

#### 3.3.1. Financial literacy

The measurement of financial literacy is summarized in Table 3.2.

**Table 3.1. Measurement of financial literacy**

Item	Content	Measure	Reference
FL1	Simple interest calculation	With one correct answer get one point, otherwise get zero point.	Author's own question
FL2	Compound interest calculation		OECD (2016)
FL3	Understanding the consequences of inflation		Lusardi and Mitchell (2011)
FL4	Benefits of risk diversification		Andreou and Anyfantaki (2020)
FL5	Understanding the composition of the annual percentage rate (APR)		

As having mentioned above, the financial literacy variable is calculated based on a set of 5 common questions. These consist of (i) one recommended question as per the OECD (2016) survey, and similar to that of Lusardi and Mitchell (2011), that relates to the concept of “compound interest calculation” (FL2); (ii) one questions from Lusardi and Mitchell (2011) that relate to the concepts of “understanding the consequences of inflation” (FL3) and “benefits of risk diversification” (FL4); (iii) one question from Andreou and Anyfantaki (2020) that relate to the concepts of “understanding the composition of the annual percentage rate” (FL5) and (iv) the authors’ own question that relate to “simple interest calculation” (FL1).

With one correct answer, the respondents get one point and get zero for a wrong answer or if they cannot answer the question properly. After marking each individual question, we calculate the total point for each respondent to measure their knowledge level of finance. A person who is regarded as having good understanding in finance needs to get at least 4 out of 5 points. Besides, the first 3 questions show the respondents’ understanding in daily financial activities, while the following 2 questions require the respondents to have knowledge about investment and banking.

#### 3.3.2. Digital literacy

**Table 3.2. Measurement of digital literacy**

Item	Content	Measure	Reference
DL1	Digital technology access and usage	For one device used, get one point.	Kass-Hana <i>et al.</i> (2021); Lyons and Fontes (2021)
DL2	Mobile phone proficiency	<ul style="list-style-type: none"> <li>- Choose one of the following options get one point: Gửi và nhận cuộc gọi, Gửi và nhận tin nhắn văn bản, Gửi và nhận hình ảnh</li> <li>- Choose one of the following options get two points: Lướt web trên thiết bị di động, Tải các phần mềm, Tham gia vào cuộc gọi video, Nghe nhạc, Quay video</li> <li>-Choose one of the following options get three points: Tải nhạc, video, hoặc game, Tìm đường và các gợi ý ăn uống, giải trí, sinh hoạt,..</li> <li>- Choose the following option and get 4 points: Thực hiện các giao dịch tài chính</li> </ul>	
DL3	Mobile money and other digital financial proficiencies	Answer “Yes” get one point, otherwise get zero point.	
DL4	Use of digital banking services	For one service used, get one point.	Author's own question

A set of 4 questions are put into the questionnaire to measure the digital literacy of respondents. The questions go from the very first level which is basic knowledge and skills to decision-making level, which reflects the ability to make appropriate digital decisions, reflective of attitudes and behaviors. The digital literacy framework is based on the results of Lyons and Kass-Hana (2021) and is already stated in Section 3.1. As shown in Table 3.3, with one digital device used, the respondents get one point. To measure digital proficiency, we divide the digital literacy into five dimensions namely basic knowledge and skills, awareness, practical know-how, decision-making, and self-protection, according to the study results of Lyons and Kass-Hana (2021). The answer options are divided into these five dimensions and the mark for each dimension increases in the same order with that of dimension. Then, the total score is calculated to measure the popularity of respondents with digital products and their ability to use digital services in daily life and in bank-related decisions.

### 3.3.3. Customer choices

Table 3.4 below summarizes the measurement of customer choice.

**Table 3.3. Measurement of customer choice**

Item	Indicator	Measure	Reference
TP	Technology propensity	Based on Likert-5 scale	Salem <i>et al.</i> (2019)
CCP	Customers' concern for privacy		
ET	E-trust		
EL	E-loyalty		
UDBS	Use of digital banking services		

Beside financial literacy and digital literacy, the customer experience toward digital banking services is measured through 4 dimensions, which are e-loyalty, e-trust, customer concern for privacy, and technology propensity. Table 3.1 above lists the questions in detail. The Likert 5 scale is used to measure the agreement of respondents with the above 4 dimensions, ranging from 1 (totally disagree) to 5 (totally agree) and the average score is calculated for each dimension. Besides, a set of 3 questions are used to calculate the choice of digital banking services, which is the dependent variable of this study.

## 3.4. Assessment model

### 3.4.1. Measurement model

#### 3.4.1.1. Cronbach's alpha

Alpha was developed by Lee Cronbach in 1951 to provide a measure of the internal consistency of a test or scale; it is expressed as a number between 0 and 1 (Cronbach, 1951). There are different reports about the acceptable values of alpha, ranging from 0.70 to 0.95 (Nunnally and Bernstein, 1994; Bland and Altman, 1997; DeVellis, 2003). According to Streiner (2003), a maximum alpha value of 0.90 has been recommended. A high value of alpha ( $> 0.90$ ) may suggest redundancies and show that the test length should be shortened (Tavakol and Dennick, 2011).

#### 3.4.1.2. Exploratory factor analysis (EFA)

According to Stapleton (1997), the purpose of exploratory factor analysis is to identify the factor structure or model for a set of variables. This often involves determining how many factors exist, as well as the pattern of the factor loadings (Stapleton, 1997). In other words, the EFA will test whether or not the sub-variables assumed to belong to one dimension are measuring the same component, and whether the sub-variables of this component are different from that of the other components.

The Kaiser-Meyer-Olkin (KMO) and Bartlett's test measure the strength of the relationship among variables. For the value of KMO, Kaiser (1974) recommends 0.5 as minimum (barely accepted), values between 0.7-0.8 are acceptable, and values above 0.9 are superb. For Bartlett's test, we want to reject the null hypothesis that the correlation matrix is an identity matrix at 95% confidence level. Therefore, the significance level of the Bartlett's test needs to be smaller than 0.05.

### **3.4.2. Structural equation model (SEM)**

SEM is a collection of statistical techniques that allow a set of relations between one or more independent variables (IVs), either continuous or discrete, and one or more dependent variables (DVs), either continuous or discrete, to be examined. SEM is also referred to as causal modeling, causal analysis, simultaneous equation modeling, analysis of covariance structures, path analysis, or CFA. The latter two are actually special types of SEM (Ullman, 2006).

This paper uses prior research and literature to form hypotheses and variables are tested using Cronbach's alpha and EFA. The latent variables include demography, measured by observed variables such as age, location, income, and gender; customer experience, measured by variables e-loyalty, e-trust, and more. These will be tested for the relationship with customer choice, itself a latent variable measured using Likert scale questions provided. More notable, however, is that in this research, observed variables of financial literacy, digital literacy, work and academic background are also directly tested for the relationship with the latent variable of customer choice. In the diagram created in the SPSS AMOS program, latent variables are conventionally denoted as ovals, observed variables as rectangles, and error terms as circles.

Model estimates for path coefficients and their standard errors are generated under the implicit assumption that the model fit is very good. If the model fit is very close, then the estimates and standard errors may be taken seriously, and individual significance tests on parameters (path coefficients, variances, and covariances) may be performed. There would be a test of the null hypothesis that there is no covariance between the two latent variables. This parameter estimate (covariance) is then evaluated with a z test (the parameter estimate divided by the estimated standard error). The null hypothesis is the same as in regression, the path coefficient equals zero. If the path coefficient is significantly larger than zero, statistical support exists for the hypothesized predictive relationship (Ullman, 2006).

## **4. RESEARCH RESULTS AND DISCUSSION**

### **4.1. Descriptive statistics**

Of the 1,000 questionnaires distributed among people who are living and working in different locations in Vietnam, 653 were returned, showing a response rate of 65.3 percent. Details of the participants show that a higher proportion of the sample was female, the majority of whom were between 31 and 40 years of age.

#### *Financial literacy*

The breakdown of the responses to financial literacy questions shows that a large number of the respondents (389 respondents or 64.73% of the entire sample) answered correctly to the question on the benefits of risk diversification (FL4) and the simple interest question (FL1) (383 respondents or 63.73% of the entire sample). This evidence provides the first indication of reliability in our instrument. Accordingly, the number of individuals who answered correctly to F1-F4 is quite close.

In this study, following Andreou and Philip, 2018, a proficiency in financial knowledge is attributed to those answering at least four out of five financial knowledge questions correctly.

### *Digital literacy*

Table 4.5 illustrates that most participants are aware of the available digital applications and have access to digital banking. However, their basic digital access and usage as well as awareness of available digital applications normally range from a low level to an average.

Considering this result, it can be mentioned that generally, the respondents have good knowledge of digital literacy and positive attitude towards digital banking service. The findings are in line with some previous empirical studies in different contexts (Nguyen and Habók, 2022, Hoang *et al.*, 2022). Rizal *et al.* (2021) stated that in general, digital literacy of males was better than that of females. However, in this study, we saw opposite results.

### *Customer experience*

The questionnaire results for customer experience reveals that the majority of the respondents agree on the 4 dimensions of customer experience toward digital banking services, including technology propensity, concern for privacy, e-trust and e-loyalty, regardless of their demography and background information. The study by Laforet and Li (2005) revealed evidence in favor of this.

The research results are also proved to be in line with the previous studies (Page and Luding, 2003). Stewart (2003) also stated that once clients have enough trust in a website or app, they find it to be more valuable. According to Fortes and Rita (2016); Glover and Benbasat (2010); Nguyen *et al.*, (2016) the risk of losing personal information or transactions creates a barrier to electronic services.

## **4.2. Testing indicators using Cronbach's alpha**

Cronbach's Alpha of the financial literacy index is 0.661 which is considered an acceptable degree of reliability. Furthermore, the digital literacy index has a Cronbach's Alpha value of 0.741 which means that digital literacy has a reasonable level of reliability. After all, Cronbach's Alpha of the customer choice index is acceptable at the number of 0.680.

Regarding the 4 dimensions of customer experience, e-loyalty (CCEL) has the highest Cronbach's alpha (0.911) which illustrates that the measurements for CCEL are the most reliable. Though Cronbach's alpha of propensity of technology is 0.513, it is appropriate because the number of these items is less than 10. Also, Cronbach's alpha of customers' concern for privacy and e-trust are both high values (0.842 and 0.845 respectively) indicating that the response values for these two dimensions across a set of questions are highly correlated.

## **4.3. Testing indicators using exploratory factor analysis**

In this study, the EFA is applied to test for three big variables: financial literacy, digital literacy and customer choice. In the case of financial literacy, the five sub-variables are moving into two components.

For financial literacy, the loading factors are all bigger than 0.5 with the total initial eigenvalues bigger than 1 (1.055) and the cumulative exceeds 50% (60.597%). The KMO and Barlett's test result of digital literacy shows that the data is adequate as the KMO measure equals 0.691 bigger than 0.5 and the Barlett's test significance equals 0.000 smaller than 0.05. This result is also true for the digital literacy.

For the customer choice, with the KMO measure of sampling adequacy bigger than 0.5 (0.938) and Barlett's test of significance smaller than 0.05 (0.000), the data collected to measure customer choice is proven to be adequate. With the loading factor bigger than 0.5, 21 sub-variables are divided into 4 components to measure 4 aforementioned dimensions, which are e-loyalty, customer concern for privacy, e-trust, and technology propensity, respectively.

**4.4. Structural model assessment**

This research used Structural Equation Modeling (SEM) to further examine the impact of various factors to customer choice toward digital banking services. Table 4.9 explains the variables used in the model.

**Table 4.9. Components of model**

Demography	Age
	Gender
	Location
	Salary
Working field/ Education major (FIN)	
Financial literacy (FL)	
Digital literacy (DL)	
Customer experience	E-Loyalty (EL)
	E-trust (ET)
	Customer Concern for Privacy (CCP)
	Technology Propensity (TP)

The research model will now be the “Customer choice” factor that will be reflected directly by three components: (1) Demography (4 items), (2) Background (3 items), (3) Customer experience (4 items).

**Table 4.10. Standardized coefficients**

	<b>Coefficients</b>	<b>p-value</b>
Demography	0.007	0.628
Financial literacy (FLtot)	0.31	***
Digital literacy (DLavg)	0.35	***
Working field	0.04	0.291
Customer experience	0.62	***

Financial literacy also has a positive relationship with customer decision to use digital banking services, with the standardized coefficient of 0.31. In other words, a one-standard deviation increase in the financial literacy score is associated with a 31% increase in the probability of the adoption of digital banking services. Individuals with a high level of financial education may have basic understanding and knowledge of the functionality of banks’ services and products, therefore, they would tend to use fintech products more than people with lower level of financial literacy. This result is quite consistent with the previous result of Morgan and Trinh in 2023. The study stated that there is a relationship between financial literacy and the adoption of fintech services in Vietnam.

On the other hand, our study results show a more significant relationship between financial background and customer choice toward digital banking services. While the previous result shows a small effect of financial education on customer adoption, only around 4%, our research result shows a very strong correlation with beta of 31%, nearly 10 times higher than expected. The spread may be explained by the difference in the digital banking services and fintech products. Digital banking services is a widely defined term, while fintech is just a subset of this term. In addition, during the Covid-19, digital banking products became more and more popular than ever as it emerged as an alternative for traditional banking services. Consequently, people who have financial literacy would prepare themselves with updated financial information, which means they would have higher probability of awareness of new financial products and use them for convenience during the Covid lockdown.

Digital literacy has the second highest influence on the customer choice of use with coefficients of 0.35. A standard deviation increase in digital literacy would increase the likelihood of using digital banking services by 35%. A previous study of Anna Lo Prete (2022) also indicated that digital literacy is associated

with higher likelihood of using digital banking services.

Customer experience has the largest impact on customer decisions. It has the highest coefficient of 0.62. The estimate is quite similar to the research of Salem *et al.* (2018), which present a positive relationship of customers' experience (including customer's propensity of technology adoption, customer's value for online personalization, customer's concern for privacy, e-trust, technology and leadership and e-loyalty) and their use of online banking services. This is understandable, as people always want to have the best experience for every service that they pay for.

In addition, our research findings show that the working field has the coefficient of 0.04, while the coefficient of demography is 0.07. However, both of them are not statistically significant with p-value greater than 0.1. Thus, we can not give any further conclusion.

## **5. CONCLUSIONS AND RECOMMENDATIONS**

### **5.1. Conclusions**

This paper presented an integrated understanding of the link among customers' decision to use digital banking services and their financial and digital background in Vietnam. More than 600 samples were collected from the population aged 18 to over 40 in Vietnam.

Our research findings show that customers' financial and digital backgrounds would significantly affect customer use of fintech products, proving our hypotheses. This result is similar to the findings of Morgan (2023) and Servon (2008), which prove the relationship between fintech and financial literacy. On the other hand, there have not been any papers studying the link between digital background and customer use of digital products, so our result can be considered a breakthrough point that practitioners and researchers should take into account.

Nevertheless, we can see that the impacts of the variables on customers' choices are not strong, even when they have a positive impact on customer choice. On the other hand, the customer experience has a strong positive impact on the way customers choose to use digital products of banks. We can also conclude from the model results that customers' demographic such as age, gender, etc. has no impact on their choice.

### **5.2. Recommendation**

While the primary goal of this research was to investigate the link between the usage of fintech products and customers' digital and financial literacy, it also has broad implications for the whole financial services sector. A positive relationship between customer decision to use digital banking services and financial and digital background indicates that clients who lack financial and digital skills may struggle the most with moving to digital platforms, executing basic digital transactions, and selecting and assessing among a more sophisticated collection of digital financial services. These clients should be given extra attention by financial institutions, who should provide information and training on how to use new digitalized platforms (Lyons and Kass-Hanna, 2021).

Increasing the financial literacy, as well as the digital literacy of Vietnamese people would be necessary. The government should encourage schools and educational institutions to provide fundamental technological and financial skills to children at a young age. When educating students about finance and digitization, practice is also essential. Schools should develop ways to make financial and digital information as practical and straightforward as feasible for their students.

On the other hand, being able to use digital banking services would probably benefit households in certain ways. Thus, each individual needs to realize the crucial role of financial technology products, and prepare themselves and be open-minded to adopt new technology in the financial and banking sectors

In addition, customer experience is regarded as one of the most essential aspects influencing client decisions. When leveraging their digital goods, financial institutions should be mindful of the client experience. Providing clients with valuable and high-quality products may not only entice them to use online banking solutions, but it may also increase their loyalty and frequency of usage toward the financial institutions.

### 5.3. Limitations and Future Research Directions

This study, like any others, has several limitations. Most importantly, the amount of responses is just over 600, which is still more than enough to ensure an acceptable 5% margin of error (Saunders et al, 2019), yet still leave significant room for improvement. In addition to expanding the size of the respondents pool, an increase in scope will also be needed in a future research to better understand the customers' choices in Vietnam, most notably, rural customers. While currently there is nothing in particular being biased against rural customers in this research, the data collection method of questionnaire and its distribution meant that the respondents pool inherently skewed towards more "accessible" respondents, those either with adequate internet access or within physical reach of the research team. In other words, it takes special effort and focus to get a truly balanced data pool and to better represent the less visible rural customers.

## ASSESSING THE PRICE AND OUTPUT EFFECTS OF MONETARY POLICY IN VIETNAM: EVIDENCE FROM A VAR ANALYSIS FROM 2018-2022

**Author: Nguyen Viet Anh<sup>1</sup>, Nguyen Thi Tam Anh<sup>2</sup>, Trieu Minh Dang<sup>2</sup>,  
Nguyen Thu Hoai<sup>2</sup>, Truong Duc Huy<sup>2</sup>  
Mentor: Pham Ngoc Anh<sup>2</sup>**

**ABSTRACT:** *This study uses the monthly data of fundamental macro indicators to conduct vector-autoregression analysis (VAR) and examine the impacts of monetary policy on the Vietnamese economy from 2018 to 2022. We concentrate on the period in which the COVID-19 pandemic outbreaks and the Vietnamese government has controlled the epidemic while preserving economic expansion, ensuring stable and streamlined money market operations. Our study found that tighter monetary policy helps stabilize prices, while an expansionary monetary policy can increase industrial production but also contribute to inflationary pressures from credit expansion.*

**Keywords:** *monetary policy, macroeconomic, Covid-19, vector-autoregressive analysis (VAR).*

### 1. INTRODUCTION

Monetary policy in Vietnam during 2018-2022 underwent significant changes, including multiple interest rate cuts by the State Bank of Vietnam (SBV) to facilitate credit institutions' access to capital at lower costs and support production and business activities. However, questions remain about the impact on price levels and production output. This study uses Vector Autoregression (VAR) analysis on monthly macroeconomic indicators to assess the effects of monetary policy on prices and production in Vietnam. The research aims to provide insights for policymakers, investors, and business leaders, especially given recent financial market turbulence and the COVID-19 pandemic's impact.

The study contributes by empirically evaluating the effects of contractionary and expansionary monetary policies on price stabilization and industrial production in Vietnam, aiding policy decisions during crisis periods. It serves as a guide for policymakers in formulating effective financial strategies for balanced economic expansion and inflation management.

The research is structured with Section 2 discussing international and domestic studies during the COVID-19 pandemic, identifying research gaps and outlining Vietnam's monetary policy framework. Section 3 explains data sources and the VAR model used for analysis. Section 4 presents the results analyzing the impact of monetary policy on output and prices, impulse response functions, and variance decomposition analysis. Section 5 concludes with essential findings supporting the need for country-specific monetary policy in Vietnam and provides recommendations for policymakers to achieve a balance between output and price objectives..

### 2. LITERATURE REVIEW AND HYPOTHESIS DEVELOPMENT

#### 2.1. Existing study results

Monetary policy's impact varies across countries and is influenced by factors such as the type, timing, and persistence of shocks. Developing nations with underdeveloped financial systems may face challenges

<sup>1</sup> Foreign Trade University, Email: [k59.2012380007@ftu.edu.vn](mailto:k59.2012380007@ftu.edu.vn),

<sup>2</sup> Foreign Trade University.

in transmitting monetary policy (Walsh, 2003; Grilli & Roubini, 1996). Studies suggest a positive relationship between increased broad money and inflation, but the effectiveness of monetary policy on industrial production and price levels may vary (Mojon & Peersman, 2001).

In Vietnam, empirical research on the effectiveness of monetary policy is limited. Some studies have shown limited effectiveness in influencing industrial production and price levels through certain transmission channels, but a positive effect through the cost channel has been observed (Hung & Pfau, 2009; Vo & Nguyen, 2017). Other research highlights the vulnerability of the Vietnamese economy to external disruptions (Anwar & Nguyen, 2018).

While several studies have explored the effects of monetary policy in Vietnam using VAR models, some did not align their variables or model identification with the country's practical implementation of monetary policy (Hai & Minh Trang, 2015; Phan, 2014; Nguyen, 2014a; Pham Anh, 2016). Previous assessments of monetary policy mechanisms in Vietnam have been considered preliminary research with limited time coverage (Camen, 2006; IMF, 2003, 2006).

## **2.2. Research gap**

Existing studies on the impact of monetary policy in Vietnam are limited and focus on specific transmission channels or inflation determinants. More comprehensive and up-to-date research is needed to examine the direct effects of monetary policy on industrial production and prices. The current studies have limitations in terms of variables, analysis period, and structural assumptions. Robust and flexible models that reflect the Central Bank's policy design are necessary, considering potential data distortions from external shocks and economic changes. There is a lack of academic papers specifically measuring the price and output effects of monetary policy in Vietnam from 2018 to 2022.

## **2.3. The monetary policy environment in Vietnam**

Since the late 1980s, Vietnam has undergone significant financial sector reforms, transitioning from a monobank to a multibank system. The State Bank of Vietnam (SBV) has played a crucial role in implementing monetary policy and ensuring the stability of the banking and credit institutions. The primary goal of monetary policy, as stated in the SBV Law, is to maintain price stability.

In response to the COVID-19 pandemic, the Vietnamese government and the SBV implemented various measures to support the economy. These included financial support packages, tax measures, and interest rate reductions. The SBV synchronized monetary, credit, and liquidity measures to maintain market stability and promote economic growth.

To facilitate access to bank loans and support priority sectors, the SBV directed credit institutions to increase credit effectively and efficiently. As of June 15, 2021, outstanding credit in the economy had increased compared to the previous year.

Circular 03/2021/TT-NHNN, issued by the SBV, provided guidelines for rescheduling debts, waiving or reducing bank interest and fees, and maintaining debt categories to assist clients affected by the pandemic. These measures aimed to alleviate the financial burdens faced by businesses and individuals.

Overall, the SBV has been proactive in implementing monetary policy and providing support to mitigate the adverse impacts of the COVID-19 pandemic on the Vietnamese economy (The State Bank of Vietnam, 2010; Mr. Pham Thanh Ha, Director General of the SBV Monetary Policy Department; Mr. Nguyen Tuan Anh, Director General of the SBV Department of Credit for Economic Sectors; Circular No. 03/2021/TT-NHNN).

## 2.4. Hypothesis development

Monetary policy's impact on economic growth varies across countries due to different factors. In Vietnam, monetary policy significantly influences output and prices, as shown in studies like Bui and Nguyen (2020). This supports the crucial role of monetary policy in driving economic growth, aligned with findings by other researchers (Bernanke & Gertler, 1995; Mishra et al., 2012; Österholm, 2005; Nguyen et al., 2016; Bui and Nguyen, 2020).

***H1. Monetary policy significantly impacts both output and prices in Vietnam and acts as a driver for the Vietnamese economy.***

Impulse response functions (IRFs) show that unexpected tightening of monetary policy leads to a temporary decline in output and delayed price increases in various countries, including the US (Christiano et al., 1999), the euro area (Peersman & Smets, 2001), and developing countries like Vietnam (Bui & Nguyen, 2020). Studies in Canada and the euro area indicate that prices respond with persistence due to nominal rigidities in prices and wages (Cushman & Zha, 1997; Galí et al., 2007).

Overall, consistent findings across different countries support the hypothesis that monetary policy has a substantial influence on the economy (Christiano et al., 1999; Peersman & Smets, 2001; Bui & Nguyen, 2020; Cushman & Zha, 1997; Galí et al., 2007).

***H2. The impulse response functions indicate a significant positive response of output and prices to monetary policy shocks, although the response tends to be more persistent for prices.***

Research on the causal relationships between money supply, output, and prices in Vietnam has shown mixed results. Some studies found bi-directional causality between money supply and prices, while others suggest uni-directional causality from money supply to output. These findings emphasize the significant impact of monetary policy on output and prices in the short run in Vietnam, as observed in Bui and Nguyen's study (2020) with contractionary policy effects.

***H3. There is bi-directional causality between money supply and prices, and uni-directional causality from money supply to output, indicating that monetary policy can affect both output and prices in the short run.***

Monetary policy impacts prices and output through interest and exchange rate channels, supported by research (Bernanke & Blinder, 1992; Christiano et al., 1996; Eichenbaum & Evans, 1995; Gali & Monacelli, 2005). In Vietnam, studies confirm the relevance of these channels (Nguyen, Nguyen, & Tran, 2018; Pham, 2016).

***H4. The effects of monetary policy on prices and output are transmitted through both the interest rate and the exchange rate channels.***

## 3. DATA AND METHODOLOGY

### 3.1. Model specification

This study uses the VAR model to analyze Vietnam's monetary policy transmission mechanism, considering both domestic and foreign variables. The research is based on established practices and focuses on the Vietnamese economy in 2018.

### 3.2. Variable measurement

#### ***Domestic Block:***

Key variables in analyzing the effects of monetary policy in Vietnam include the Consumer Price Index (CPI) for price changes and the Industrial Production Index (IPI) for industrial output. Broad money (M2) and interest rates are crucial indicators of the money supply and its influence on savings and

investments. Total credit and exchange rates also play significant roles in monetary policy’s impact on Vietnam’s economy.

**Foreign Block:**

Vietnam’s integration into the world economy exposes it to external shocks, making domestic prices and output growth more vulnerable (Anwar & Nguyen, 2018). Changes in oil prices, for example, can impact production costs and consumer prices (Trang et al., 2017). Considering that oil is a significant component of Vietnam’s exports, the world oil price is included as an exogenous variable.

The pass-through of policy rates to bank lending rates is crucial to monetary policy effectiveness. In the case of Vietnam, using data from neighbouring China is more appropriate than embedding the U.S Federal Fund Rate due to China’s economic significance and its status as Vietnam’s largest trading partner (Matemilola et al., 2015; General Department of Customs, 2023).

**Table 1. Variable selection**

Variable	Initial	Unit
Domestic block		
Industrial Production Index	IPI	Index
Consumer Price Index	CPI	Index
Broad money growth rate	M2	%
Central bank policy rate	Inte	%
Total domestic credit	Cred	Billion VND
Nominal exchange rate USD/VND change	EXC	%
Foreign block		
World oil price	OIL	U.S dollars per barrel
Chinese lending rate	Chirate	%

*Source: Authors’ compilation*

**3.3. Data analysis**

The first step was to examine the properties of the data to identify any seasonality. The time frame covered January 2018 to January 2022, and the data was plotted to assess seasonality. The industrial production index displayed clear seasonal patterns, while broad money, credit, and exchange rates exhibited partial seasonal patterns. A regression analysis was then conducted for each variable using seasonal dummy variables and a yearly time trend to detect seasonality.

To identify unanticipated shifts in time series that could lead to unreliable estimates, structural break tests were performed for industrial production and the price level, given the primary focus on output and price level responses to monetary policy shocks. The dependence of industrial production and price levels on all other included variables was estimated using OLS, followed by a test for unknown break dates. The analysis indicated a structural break in the time series, and two dummy variables were incorporated in the VAR models at the levels to account for them.

To examine the stationarity of all variables, unit root tests were conducted using the Augmented Dickey-Fuller statistic (ADF). A structural form of VAR was then employed to isolate purely exogenous policy shocks and measure their impact on the variables included in the VAR model, supported by Granger causality tests. Through conducting Granger causality tests using a VAR model with two lags at the levels,

we observed that economic target variables, specifically IPI and CPI, have a causal influence on policy variables such as M2, Inte, and EXC. Furthermore, our analysis revealed that M2 has a significant Granger-causal effect on Inte and EXC at a 10% significance level, and on Cred at a 1% significance level. Inte, on the other hand, Granger-causes Cred at a 1% significance level. Notably, EXC is influenced by almost all variables examined, including IPI, CPI, M2, and Cred.

**Table 2. Summary statistics**

Variable	Obs	Mean	Std.Dev	Min	Max
Domestic block					
IPI	60	106.25	13.06	98.46	145.09
CPI	60	100.24	0.49	98.46	101.52
M2	60	0.00	0.01	-0.01	0.04
Cred	60	0.00	0.01	-0.04	0.04
Inte	60	0.03	0.01	0.02	0.04
EXC	60	0.00	0.011	-0.04	0.04
Foreign block					
OIL	60	69.17	19.65	26.35	115.60
Chirate	60	0.04	0.00	0.036	0.04

*Source: Authors' compilation*

## 4. RESULTS AND DISCUSSION

### 4.1. Seasonality

We examine the characteristics of the data to identify any seasonality, covering the period from January 2018 to January 2022. To assess seasonality, we initially plotted the data, which revealed clear seasonal patterns in the industrial production index, while broad money, credit, and exchange rates exhibited partial seasonal patterns. No seasonal patterns were observed for the policy rate, world oil price, and Chinese lending rate. Subsequently, we detected seasonality by performing regression analysis for each variable using seasonal dummy variables and a yearly time trend. (see **Equation (1)**).

$$Y_t = c_0 + qYear_t + \varepsilon_t; (1)$$

where  $Y_t$  is the value of any variable Y at time t;  $c_0$  is the constant (corresponding to the mean value observed for month 12),  $q$  is the coefficient of the linear (yearly) time trend, and  $\varepsilon_t$  is the error term. The coefficients for the seasonal dummy variables are statistically significant for industrial production, broad money, total credit, and the exchange rate. As a third step, we generated seasonally-adjusted values using the X-12 ARIMA/TRAMO procedures (Franses, Paap, and Fok 2005). An alternative approach to addressing seasonality involves incorporating a full set of monthly dummy variables in the VAR models. The estimated impulse response functions, when employing seasonal dummy variables, closely resemble those obtained with seasonally-adjusted data.

### 4.2. Structural breaks

Structural breaks represent unanticipated shifts in time series, potentially resulting in unreliable estimates. We conducted structural break tests for industrial production and price level, as our primary focus is on the responses of output and price level to monetary policy shocks. Initially, we used OLS to estimate the dependence of industrial production and price levels on all other included variables. We then

applied a test for unknown break dates. The findings indicated a structural break in our time series. In the subsequent analysis, we incorporated two dummy variables to account for these structural breaks in our VAR models at levels. The two dummy variables selected are the first day of lockdown in Vietnam and the day when students nationwide returned to school. However, it is worth noting that the impulse response functions associated with the VAR models, both with and without structural breaks, are strikingly similar.

**4.3. Unit root tests**

We used the Augmented Dickey-Fuller statistic (ADF) to test for the stationarity of all variables. Table 3 presents the results.

**Table 3. ADF test for stationarity or unit root tests**

	Critical values				
	ADF Statistic	p-value	1%	5%	10%
IPI	-2.586353	0.095851	-3.546	-2.912	-2.594
CPI	-5.755844	0.000001	-3.548	-2.913	-2.594
M2	-0.424197	0.90598	-3.575	-2.924	-2.6
Cred	4.411826	1	-3.575	-2.924	-2.6
Inte	-1.379424	0.5921	-3.548	-2.913	-2.594
EXC	-6.027116	0	-3.548	-2.913	-2.594

**4.4. VAR identification for Vietnam**

A structural form of VAR is beneficial for isolating purely exogenous shocks from policy and assessing the impact of these shocks on the variables incorporated in a VAR model (Sims 1986). A structural form VAR can be expressed as follows:

$$A_0 Y_t = \alpha 0 + A_1 Y_{t-1} + A_2 Y_{t-2} p + \dots + A_p Y_{t-p} + u_i; \tag{2}$$

where Yt is an (m x 1) vector of the endogenous variable at time t; α0 is an (m x 1) vector of constants; Ai (i = 1,2, . . .,p) is an (m x m) vector of structural parameters, and ut is an (m x 1) vector of structural shocks. By multiplying Equation (2) by the inverse of matrix A0, we obtain a reduced-form VAR (**Equation (3)**), which can be directly estimated using ordinary least squares.

$$Y_t = g_0 + G_1 Y_{t-1} + G_2 Y_{t-2} + \dots + G_p Y_{t-p} + e_i; \tag{3}$$

where Yt (a vector of endogenous variables) depends on its own lag and the lag of other endogenous variables, along with the forecast error vector et; et = A0-1 \* ut is a linear combination of the structural shocks ut. The subsequent step involves recovering the structural parameters of Equation (2) from the estimated parameters of Equation (3), a process known as identification (Sims 1986). Since the number of unknown elements in a structural VAR exceeds the number of known elements from an estimated reduced-form VAR, the common approach is to impose restrictions on matrix A0 (i.e., the matrix of contemporaneous relationships among endogenous variables of the structural model) guided by economic intuition. If a VAR contains m endogenous variables, at least m(m-1)/2 restrictions must be imposed (Gujarati 2009). In this identification, the variable ordered first is assumed to have contemporaneous effects on all following variables, while the variable ordered last is assumed to affect other variables ordered before it with a lag.

An alternative identification is the structural decomposition (SVAR), in which the matrix A0 can have any structure, provided that it imposes sufficient restrictions (Kim and Roubini 2000)..

In our VAR model, the recursive identification of endogenous variables is represented by Equation (4):

$$\begin{array}{l}
 U_{IPI} \\
 U_{CPI} \\
 U_{M2} \\
 U_{INTE} \\
 U_{CRED} \\
 U_{EXC}
 \end{array}
 =
 \begin{array}{l}
 a_{11} \ a_{12} \ a_{13} \ a_{14} \ a_{15} \ a_{16} \ a_{21} \\
 a_{22} \ a_{23} \ a_{24} \ a_{25} \ a_{26} \\
 a_{31} \ a_{32} \ a_{33} \ a_{34} \ a_{35} \ a_{36} \\
 a_{41} \ a_{42} \ a_{43} \ a_{44} \ a_{45} \ a_{46} \\
 a_{51} \ a_{52} \ a_{53} \ a_{54} \ a_{55} \ a_{56} \\
 a_{61} \ a_{62} \ a_{63} \ a_{64} \ a_{65} \ a_{66}
 \end{array}
 \times
 \begin{array}{l}
 e_{IPI} \ e_{CPI} \\
 e_{M2} \\
 e_{INTE} \\
 e_{CRED} \\
 e_{EXC}
 \end{array}
 \quad (4)$$

The VAR model for Vietnam includes shocks uIPI, uCPI, uM2, uInte, uCred, and uEXC, representing industrial production, prices, monetary base, credit, and exchange rate, respectively. The ordering of output and price level aligns with the nominal rigidity theory, indicating persistence in output and inertia in prices after a monetary policy shock (Christiano, Eichenbaum, and Evans 2005). The policy variables adjust following the information on primary target variables (IPI and CPI): first, the broad money base, followed by interest rates and credit, with the exchange rate as the last variable adjusting based on the earlier values of the other variables in the VAR system.

Granger causality tests support this ordering, showing that economic target variables (IPI, CPI) Granger-cause policy variables (M2, Inte, EXC). M2 Granger-causes Inte and EXC at the 1% significance level, and Cred at the 1% significance level. Inte Granger-causes Cred at the 1% significant level. EXC is Granger-caused by almost all variables (IPI, CPI, M2, Cred).

Our VAR model's endogenous variable ordering (IPI, CPI, M2, Inte, Cred, EXC) for Vietnam is consistent with similar studies in Asian developing countries, supporting the order of economic target variables before policy variables (Raghavan, Silvapulle, and Athanasopoulos, 2012; Disyatat and Vongsinsirikul, 2003; Fung, 2002; Hung and Pfau, 2009).

Based on various criteria, the suggested lag length for the VAR model is four. However, we choose to include only two lags in our estimations, aligning with most selection criteria and the practice in the literature. This choice strikes a balance between capturing relevant dynamics in the data and keeping the model parsimonious for better interpretability (Sims, Stock, and Watson, 1990; Lütkepohl, 2005).

**Table 4. Lag length selection criteria.**

Lag	AIC	BIC	FPE	HQIC
0	-10.02	-9.689	4.462e-05	-9.890
1	-23.90	-20.62	4.308e-11	-22.63

#### 4.5. Impulse response functions

In this subsection, we compute impulse response functions (IRFs) to trace the dynamic response of endogenous variables to exogenous shocks emanating from other variables over a period of 30 months.

IRFs help to predict the sign, magnitude, and statistical significance of the responses to shocks from policy variables (Stock and Watson, 2001).

Below, we illustrates the impulse response functions of output and price levels to a shock (measured by a one standard deviation increase) in policy variables such as policy interest rate, exchange rate, broad money, and credit. We report the 95% confidence intervals for all graphs, represented by the grey-shaded area.

The IRFs offer insights into the impact of various policy shocks on the output and price levels in the economy. By analyzing the patterns, magnitudes, and confidence intervals of the impulse response functions, researchers and policymakers can understand how monetary policy actions might affect macroeconomic variables in the short to medium term, providing crucial information for designing effective monetary policy strategies.

**4.5.1. Shock from interest rate**

**Figure 1. Response of log of industrial production**

*Source: The author's own synthesis using Python*

The impact of the shock from interest rate changes can be observed to produce a notable response in industrial production price levels, as exemplified by the Consumer Price Index (CPI) illustrated in the graph provided. One of the most salient observations is that the industrial production, when expressed in logarithmic form, consistently remains greater than 0. This indicates that the value of industrial production is always above 1 during the time frame being analyzed. The logarithmic Industrial Production Index (log IPI) exhibits fluctuations around a level slightly above 0 before it starts to increase substantially when the interest rate experiences a growth of around 10%. This highlights the strong correlation between interest rate changes and the subsequent effects on industrial production price levels, emphasizing the importance of understanding and monitoring these economic indicators.

**Figure 2. Response of log of price level**

*Source: The author's own synthesis using Python*

The response of the price level to interest rate shocks is effectively illustrated in the graph above, taking into account a 95% confidence interval. In contrast to the log IPI index, it is evident that the log price level predominantly fluctuates below the baseline of 0 in most situations, with the exception of the initial minor increase in interest rates. The fluctuation becomes more pronounced following an observation of approximately a 15% increase in the standard deviation of interest rates. After this point, the log price level reaches its peak value of -0.002 towards the end of the period under analysis. This highlights the sensitivity of price levels to interest rate changes and the need for careful monitoring of these economic indicators to maintain stability in the market.

#### 4.5.2. Shock from exchange rate

**Figure 3. Response of log of industrial production**

*Source: The author's own synthesis using Python*

A more notable change in the interaction between the endogenous and exogenous variables is witnessed in the particular case of exchange rate and industrial production. It is now accepted practice, or at the very least acceptable practice, the use log-transformed data has become a crucial step in identifying impulse functions within the research studies using the VAR model. The normality assumption of traditional econometric methods serves as the foundation for the use of log-transformed data in time series regressions and macroeconomic predictions. It seeks to reduce the negative effects that heteroscedasticity and skewness in the level data have on the results of estimation and testing. Several in-sample statistical tests based on the Box-Cox-transformation have been created and used to choose between using data in levels and log-transformed data. Particularly, the log of industrial production fluctuates midway between 0 and be greater when the increase in standard deviation of exchange rate index gets smaller.

**Figure 4. Response of log of price level**

*Source: The author's own synthesis using Python*

A similar pattern can be observed in the relationship between the log price level and shocks from exchange rate changes. However, when the increase in the standard deviation of the exchange rate is relatively small, the log price level displays a stark contrast to the expected peak at approximately 0.01. Instead, it reaches an all-time low of -0.01, highlighting a certain degree of asymmetry in the interactions between these variables. This asymmetric behavior may lead to several thought-provoking discussions within the context of this research paper and could potentially serve as a basis for future research in the field. The exploration of these nuanced relationships can contribute to a more comprehensive understanding of the dynamics between exchange rate fluctuations, price levels, and their interconnected impact on the overall economy.

4.5.3. Shock from broad money

Figure 5. Response of log of industrial production

Source: The author's own synthesis using Python

With regard to broad money, the response of industrial production appears to be divided into two distinct patterns. A larger fluctuation is observed when the standard deviation of broad money increases up to 15%. Following this, a period of temporary stability ensues before the index experiences a considerable drop to nearly -0.01. Subsequently, it demonstrates a significant increase, recovering to reach its original peak value of 0.01.

This dual-pattern behavior suggests that the relationship between broad money fluctuations and industrial production is complex, with different responses depending on the magnitude of changes in broad money. Understanding the intricacies of this relationship is crucial for policymakers and economists, as it can help them develop appropriate strategies to manage the potential impact of broad money changes on industrial production and, by extension, the overall economy.

Figure 6. Response of log of price level

Source: The author's own synthesis using Python

A contrasting outcome is presented in the results of the Vector Autoregression (VAR) model examining the response of the log price level to changes in log broad money. Similar to the previous case, the fluctuations can be divided into two distinct phases, with sharper ups and downs occurring when the standard deviation of broad money increases up to 15%. However, there is no period of stability at 0 for this particular scenario. Instead, the log price level rises to around 0.001 before experiencing a sharp decline towards the end of the period under study. This is in contrast to the continuous increase observed in the previous result.

This difference may suggest crucial insights regarding the characteristics of the variables analyzed in this paper and their potential implications for future research. Understanding these disparities could help elucidate the unique dynamics between broad money fluctuations, price levels, and industrial production. This information, in turn, can inform more effective policy decisions and economic strategies that account for the complex relationships among these factors.

**4.5.4. Shock from credit**

*Figure 7. Response of log of industrial production*

*Source: The author’s own synthesis using Python*

The aforementioned graph provides a clear depiction of a wide fluctuation in the response of the log of industrial production. The results obtained from our analysis reveal that the response initially experiences an upward trend, gradually rising until it reaches a peak at a value of 10000. However, it subsequently undergoes a moderate drop, declining to approximately 5000 before continuing to fluctuate. Eventually, the response hits its lowest point at a negative value of under 0. These findings are of significant academic interest and highlight the dynamic nature of industrial production, which is subject to various external and internal factors. Further research could be conducted to explore the potential drivers behind these fluctuations and their potential implications for economic and policy-making decisions.

**Figure 8. Response of log of price level**

*Source: The author's own synthesis using Python*

The results reveal a prominent trend of negative values persisting throughout the analyzed period. The log price level initially underwent a significant decline before displaying signs of recovery, ultimately attaining a value of approximately -10,000. Beyond this point, the data demonstrated a moderate level of fluctuation, with oscillations observed until the log price level reached its lowest point at -150,000. Nevertheless, the log price level eventually rebounded, achieving its peak at over 10,000 towards the end of the period.

These observations underscore the dynamic nature of the economic landscape, which is influenced by a multitude of internal and external factors. Recognizing and understanding these fluctuations is crucial for policymakers, economists, and market participants in order to make informed decisions and devise effective strategies for navigating the ever-changing economic environment. Additionally, these findings can serve as a foundation for further research, enabling a more comprehensive comprehension of the complex interplay between various economic indicators and their impact on the overall economy.

## 5. CONCLUSION

This study investigated the impact of monetary policy on the real economy in Vietnam during the period of 2018-2022. The key findings can be summarized as follows:

A tighter monetary policy, as evidenced by an increase in interest rates, effectively stabilizes prices in Vietnam. This suggests that when the central bank raises interest rates, it can control inflation and maintain price stability.

Expansionary monetary policy, as indicated by an increase in broad money, has a significant positive effect on industrial production in the country. This implies that when the central bank increases the money supply, it can stimulate economic activity and boost industrial production.

The study also supports the notion that credit expansion in Vietnam can lead to inflationary pressures. This finding highlights the importance of closely monitoring credit growth and implementing appropriate macroprudential measures to prevent excessive credit expansion from causing inflationary problems.

These results offer valuable insights for policymakers in Vietnam and contribute to the existing literature on monetary policy transmission mechanisms in developing economies. By understanding the effects of different monetary policy tools on the real economy, authorities can better design and implement effective policy measures to achieve their macroeconomic objectives, such as price stability and sustainable economic growth.

Our study reveals that a tighter monetary policy, indicated by increased interest rates, effectively stabilizes prices in Vietnam. This aligns with conventional wisdom, as central banks use interest rate adjustments to influence inflation and maintain price stability. Policymakers in Vietnam can utilize interest rate changes as an effective tool to control inflation and achieve macroeconomic objectives.

Our research addresses a gap in the literature by uncovering a negative relationship between interest rates and the consumer price index in the Vietnam market. We also highlight the inflationary pressures associated with credit growth in Vietnam. Policymakers must monitor and manage credit expansion to maintain price stability.

While our findings are valuable, we acknowledge limitations such as potential endogeneity concerns and omitted variable biases. Future research should explore additional monetary policy channels beyond interest rates and credit expansion to gain a comprehensive understanding of their impact on the economy during different business cycle phases in Vietnam. This knowledge can guide policymakers in formulating effective and sustainable monetary policies that promote economic growth, price stability, and overall financial resilience.

## DEMOGRAPHIC FACTORS AND FINANCIAL LITERACY OF WOMEN IN NEW RURAL AREAS IN HANOI: AN EMPIRICAL RESEARCH

**Author: Phan Thanh Dieu Linh<sup>1</sup>, Bui Hai An<sup>2</sup>, Do Huyen Vy<sup>2</sup>, Nguyen Duc Tam<sup>2</sup>**

**Mentor: Nguyen Do Quyen, PhD<sup>2</sup>**

**ABSTRACT:** *The study investigates the influence of demographic factors on women's financial literacy in new rural Vietnam; more specifically, it focuses on factors reflecting financial knowledge, including financial knowledge, financial behavior, and financial attitudes. Utilizing descriptive analysis, we have a complete picture of the demographic characteristics of 303 samples of women in the new rural area of Hanoi. Of the six demographic factors, 4 subgroups, including age, income, education, and marital status significantly correlate with financial literacy. In addition, all demographic variables and financial knowledge maintain their positive relationship with financial literacy. Thus, in the new rural Vietnam, financial knowledge is one of the positive factors reflecting financial literacy. The significant contributions of the research paper in improving financial literacy in new rural areas of Vietnam are focusing on building financial literacy concepts for individuals, families, and communities; and making recommendations for organizations involved in research, policy formulation, and implementation.*

**Keywords:** *demographic factors, financial literacy, Hanoi city, new rural areas, women*

### 1. INTRODUCTION

Nowadays understanding personal finance is crucial for both the stability and growth of the economy in general as well as the balance and success of each individual. High financial literacy among the populace can help emerging economies' financial sectors efficiently contribute to genuine economic development and the eradication of poverty (Faboyede et al., 2015). And Vietnam is an emerging economy with high economic growth and integration. However, Vietnam's financial system is still far behind many other countries in terms of size, service diversification, and professionalism (Tran et al., 2017). This finding demonstrates a direct connection between Vietnamese people's low financial literacy and their difficulty accessing modern financial services and instruments, which is a barrier to the growth of modern banking and financial services in Vietnam. Even individuals with a strong background in finance can have poor financial literacy. It is therefore crucial to measure financial literacy in Vietnam. From there, it helps determine the best adjustment to satisfy the financial system's needs while also assisting financial policymakers in understanding people's financial literacy and providing solutions.

However, according to Phung Quang and Anh Khuc (2019), the assessment of OECD countries is still used to test financial literacy, which is inappropriate given that Vietnam is an economy in transition. There hasn't been much in-depth research on financial literacy in Vietnam. Previous studies only evaluated how a professional's financial sector competence affected the caliber of financial performance without considering other subjects who were also involved in financial activity. Specifically, previous research has primarily focused on urban areas (Ngo, Le, 2016; Tran, 2017; Nguyen, 2015; Marszaek-Kawa, 2012), and there has also been researching (Atkinson and Messy, 2012; OECD, 2013, 2015) indicating that financial literacy has a positive impact on poverty reduction by increasing income, however, there is little to no evidence for this in rural areas of developing countries like Vietnam.

<sup>1</sup> Foreign Trade University, Email: k59.201280021@ftu.edu.vn

<sup>2</sup> Foreign Trade University

In addition, gender is a significant aspect that influences a person's financial literacy. Numerous studies have indicated that financially independent women can be a valuable resource for economic development because they have a significant potential to contribute to the expansion of the economy (Chetna Singh and Raj. Kumar, 2017). The degree of financial literacy of female business owners determines their performance in the development of rural businesses (Atahau et al., 2021). National and global prosperity will increase if women have equal access to education, work opportunities, and financial resources, as well as if they are represented in economic and political decision-making processes. there (Allgood and Walstad, 2016; Marini et al., 2018; Linddahl and Mokvist, 2022).

More specifically, the economic situation and people's lives have improved as a result of Vietnam's rural areas being transformed and upgraded into new rural areas. The rapid urbanization of Vietnam is a significant phenomenon. Urbanization has positively accelerated the process of economic restructuring, moving faster in the structure of industry, commerce, and service, which reflects its impact on poverty reduction. The growth in income and per capita spending is a result of the numerous employment and incomes that this migratory trend has generated in the cities themselves (Ministry of Planning and Investment, 2021). This is a chance for household growth in general and for women in particular. However, this is a significant difficulty because it calls for women in new rural areas to have more sophisticated financial knowledge and abilities.

Based on the aforementioned points of view, the research team believes that studying the demographic characteristics that have an impact on the financial literacy of women in rural areas is crucial for improving the financial literacy of women in new rural areas. Making recommendations and establishing new rural regions in Hanoi are required.

The study consists of 5 main parts. Chapter 1 is a general introduction to the research topic; Next, Chapter 2 is an overview of research on the influence of demographic factors on women's financial literacy in new rural areas. Chapter 3 is the presentation and explanation of the research methods used and data collection. After synthesizing theory, research theory, and survey data, in Chapter 4, the research team will conduct data analysis, thereby giving research results and explaining the influence of variables on the financial literacy of women in new rural areas in Hanoi. And finally, in Chapter 5, based on the research results as well as the influence of the variables on the research subjects, the research team reaffirms the factors that significantly affect the financial literacy of women. women in new rural areas, from which several policy options can be considered, which can help identify actions to improve the financial literacy of new rural women in the region.

## **2. THEORETICAL BACKGROUND**

### **2.1. An Overview of Financial Literacy**

#### **2.1.1. Definition of Financial Literacy**

The concept of financial literacy lacks a clear and agreed-upon definition. Researchers and authors have proposed various definitions, leading to a diverse range of interpretations (Remund, 2010). Some studies have focused on financial knowledge acquired through education programs, while others have explored the relationship between financial literacy and financial decision-making (Bernheim, 1998; Hilgert et al., 2003). The President's Advisory Council on Financial Literacy (PACFL) emphasized the importance of financial decision-making skills (Lusardi and Mitchell, 2014). The OECD provided a comprehensive definition that combines skills, behavior, awareness, attitude, and knowledge, aiming to improve financial well-being and enable participation in economic life (OECD, 2013; French and Mckillop, 2016).

Financial literacy is an important breakthrough in education, and various terms such as knowledge, skills, and behavior are used to describe it (Hung et al., 2009). The diversity of these terms highlights the varied definitions and their potential influence on the data used in research (Allgood and Walstad, 2016; Kimiyaghalam and Safari, 2015). The most comprehensive definition of financial literacy provided by the OECD encompasses financial knowledge, behavior, and attitude, emphasizing the ability to make informed financial decisions for improved financial well-being (OECD, 2013).

In conclusion, synthesizing the definitions from published articles and research terminology, the research group agrees with the most comprehensive definition of financial literacy provided by the OECD (2013). Financial literacy is defined as the knowledge and understanding of financial concepts, and risks, and the skills, motivation, and confidence to apply that knowledge and understanding of financial concepts, knowledge, and understanding in making effective decisions in various financial contexts, aiming to enhance individual and societal financial well-being and enable participation in economic life.

### **2.1.2. The importance of Financial Literacy**

Numerous benefits of financial literacy have been identified, demonstrating its positive impact on individuals and families (Danes and Hira, 1987; Grable and Joo, 1998; Kerkmann et al., 2000; Blalock et al., 2004). Increased financial knowledge encourages greater confidence, self-control, independence, and marital satisfaction (Conger et al., 1999; Allen et al., 2007; Cleek and Pearson, 1985; Kerkmann et al., 2000; Oggins, 2003). Financial literacy also plays a crucial role in household finance by helping families organize their spending efficiently.

In the case of women, the COVID-19 pandemic has had negative consequences that extend beyond their financial recovery capacity (Bucher-Koenen et al., 2021). The financial literacy needs of women in using payment products, savings, credit, and risk management are significant (Demircuc-Kunt et al., 2015).

The success of female entrepreneurs in rural business development depends on their level of financial knowledge (Atahau et al., 2021). If women have equal access to education, employment opportunities, financial resources, and representation in economic and political decision-making processes, domestic and international prosperity will follow (Lindahl and Mokvist, 2022; Marini et al., 2018; Allgood and Walstad, 2016).

## **2.2. An Overview of Financial Literacy of Women in New Rural Areas**

### **2.2.1. Definition of Rural Areas**

According to Decree No. 41/2010/NĐ-CP (2010) issued by the Government of Vietnam, rural areas are defined as territories outside the urban areas, cities, and towns, and managed by the local administration at the commune level. These areas have distinct natural environmental characteristics, socioeconomic conditions, and agricultural activities.

### **2.2.2. Definition of New Rural Areas**

The concept of new rural areas was first mentioned in Resolution No. 26-NQ/TW of the Central Party Committee on Agriculture, Farmers, and Rural Areas (2008). New rural areas are defined as progressive rural areas with synchronized infrastructure and rich cultural life. They preserve the traditional values and characteristics of each region and ethnic group while improving the living standards of the residents.

### **2.2.3. Characteristics of Financial Literacy of New Rural Areas**

The financial literacy of farmers, particularly women, in new rural areas has gained importance as they are the key contributors to the socioeconomic development of these regions. However, there is a lack of comprehen-

sive research or articles on measuring the financial literacy of farmers, specifically women, in new rural areas. The article “Financial Literacy in Vietnamese Rural Areas” (Vietnam State Bank Journal, 2018) surveyed over 400 participants across Vietnam. The results showed that women, especially in the northern region, had higher financial behavior and attitudes scores compared to men, due to their role in managing household finances and borrowing for family economic development. The survey also found regional variations, with higher savings rates in the northern region compared to other regions, while the central region had the lowest. In terms of income, those with higher incomes tended to have better financial attitudes and behavior, particularly in the aspects of financial behavior and attitudes. This suggests that financial knowledge may not necessarily have a direct impact on income, but financial attitudes and behavior can have positive effects.

Currently, financial education is being provided by various institutions in Vietnam, such as credit organizations and individuals participating in microfinance services (Ngo et al., 2017). However, the focus on financial attitudes and behavior in training programs is still inadequate. Therefore, it is necessary to develop more appropriate policies to address this issue.

### **2.3. An Overview of demographic factors**

#### **2.3.1. Reflective factors affecting Financial Literacy in New Rural Areas**

##### **a) Financial knowledge**

Lack of financial literacy is one of the main causes of low financial literacy (Collins, 2012; Huston, 2010; Nicolini et al., 2013). Zhan et al., (2006) show that improving financial literacy can improve financial literacy (see also Taft et al., 2013; Scheresberg, 2013).

*H1: Financial knowledge and financial literacy have a positive relationship*

##### **b) Financial attitude**

Atkinson and Messy (2012) show that attitude is a vital factor in reflecting financial literacy. Financial attitudes are included in the regression of financial literacy as an independent variable in many studies, such as Godwin and Carroll (1986), Godwin and Koonce (1992), and Godwin (1994). Specifically, Godwin (1994) measured the influence of variables on personal financial management and concluded that financial attitude is an important factor to predict an individual’s cash flow. People with a positive financial attitude tend to manage their money better (Atkinson and Messy, 2012; OECD, 2013).

*H2: Financial attitude and financial literacy have a positive relationship*

##### **c) Financial behavior**

Atkinson and Messy (2012) believe that individuals with positive financial behaviors such as prudent budgeting and concern for financial stability have a higher level of financial literacy, while those with negative effects, such as a high reliance on credit loans, have a lower level of financial inclusion. The more positive the financial behavior, the higher the financial literacy. Furthermore, Hilgert et al. (2003), Robb and Wodyard (2011), and Taft et al (2013) demonstrate that this relationship is statistically significant. According to research by Banerjee, Kumar, and Philip (2017), financial literacy has a positive impact on financial awareness, leading to an increase in financial access behavior.

*H3: Financial behavior and financial literacy have a positive relationship*

#### **2.3.2. Demographic factors affecting the financial literacy of women in new rural areas**

##### **a) Age**

Agarwal et al. (2009) said that the group of people between the ages of 18 and 24 have the lowest financial literacy while the group with the highest financial performance is between the age of 53 - 55 years old. Bhushan and Medury (2013) conducted a study in the developing country of India, with a sample of

individuals with paid work in Himachal Pradesh. Looking at the survey results, it can be seen that the older the age, the higher the level of physical education also increases.

*H4: Age and financial literacy are related*

#### **b) Academic level**

Research by Bhushan and Medury (2013) shows that an individual with a higher education level will have a higher financial literacy level. Similarly, individuals with lower EMs are more likely to be in the group whose educational attainment stops at the primary or secondary level, according to Alessie (2011). This result is consistent with the study of Brown et al. (2013), the group that has undergone a university program has a significantly higher rate of correct answers than the group that only stops at the elementary level. Trinh (2017) indicates that higher educational attainment has a strong and positive correlation with financial literacy in Vietnam. The results of the above studies have shown that the level of education is a factor that positively affects an individual's financial position; The higher the educational attainment of the target group, the higher the rate of correct answers to financial questions and vice versa.

*H5: There is a positive relationship between education level and financial literacy*

#### **c) Occupation**

The statement is that those who are more consistent in their career path tend to have higher financial literacy scores. Nanziri and Leibbrandt (2018) pointed out that labor force participants have higher financial literacy scores than those who do not join the labor market. The Vietnamese setting provided another view regarding the relationship between occupation and financial literacy. Those who have jobs whose characteristics are stable show better performance when tested for financial literacy, according to Trinh (2017).

*H6: The fields of profession and financial literacy have a positive correlation.*

#### **d) Marital status**

Brown and Graf (2013) proved that there is a relationship between marital status and financial literacy. Dummy variables were used to test the effect of marriage on the level of financial literacy. The result showed that married contestants outperformed. Calamanto (2011) explained that individuals who are deficient in financial knowledge and practice are more susceptible to wrongful financial decisions. Credit debts overall can threaten the sustainability of a relationship, and therefore, couples have more motivation to increase their financial efficiency. This explanation is consistent with the one provided by Dew (2008), that married individuals enhance their financial proficiency for the sustainability of their marriage. However, when surveying settings with developing economies, mixed results were attained. In defense, Dewanty, N., and Isbanah, Y. (2018) argue that married women carried other household responsibilities other than economic management. Therefore, they are less inclined to enhance their literacy. Sundjaja (2015) stated that the lower average living expenses discourage couples from improving their financial practices as they now have surplus income.

*H7: Marital status and financial literacy have a positive correlation*

#### **e) Number of dependencies**

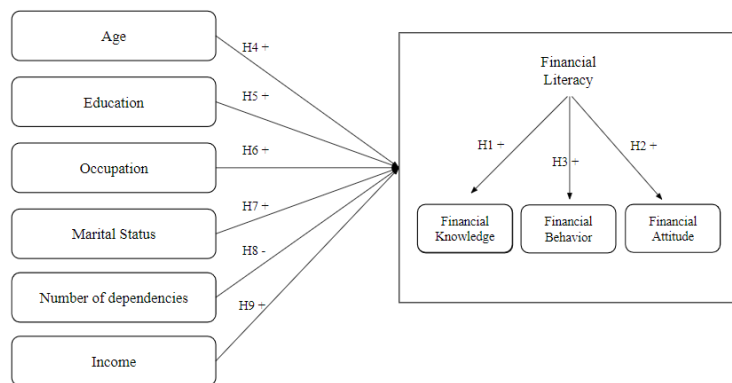

Servon and Kaestner (2008) showed that women with one child performed better in financial knowledge testing than those with two or three children. Those with larger families tend to have lower financial literacy levels, according to Mottola (2013). The explanation behind this is that those who have lower financial literacy tend to be less concerned about family planning. The new rural area with mixed characteristics called for examination to be certain of which side the effect took.

**H8:** *The number of dependents and financial literacy have a negative correlation.*

**f) Income**

Most research on financial literacy considers the effect of income level. Alwee and Salleh (2015), ANZ (2008), Monticone (2010), and Atkinson and Messy (2012) all proved that this is a significant positive relationship. The results showed that income level and financial literacy scores share the same pattern of movements. Members of households with lower income also show a weaker result in testing for financial literacy. Vietnam’s developing economic setting did not exclude itself from this pattern. The income variables showed significant status at a 1% degree of confidence.

**H9:** *Income and financial literacy have a positive correlation.*

**Figure 2.1. Theoretical Framework**

**3. DATA AND METHODOLOGY**

**3.1. Methods**

The research team developed a questionnaire adapted from the OECD (2018) and the Banking Science Research Institute (2022) to suit the new rural women. After adjusting the questionnaire twice, the research team continued to collect data through questionnaires and direct and online surveys. The research team modified the questionnaire to make it more feasible and effective after testing its viability on a small sample of 27 people. Few inquiries with duplicate objectives were eliminated. The authors integrate qualitative and quantitative research within the parameters of the study. The team then went on to create a more appropriate theoretical foundation for the new rural district women in Hanoi after gathering information and eliminating irrelevant samples. The picked studies presented relevance to the developing economy of Vietnam. At the same time, low-income women in less developed areas are the target demographic. The research team believes that the trend among people who meet the criteria is more accurate.

The authors have specifically qualitatively investigated factors impacting the financial literacy of people in rural areas based on combining and developing theories from prior studies as well as theories of financial literacy utilizing data obtained from interviews and surveys. Age, marital status, the number of financially reliant family members, occupation, and income were considered. Combining quantitative methodologies, the study quantified survey data to learn about the financial situation of researched participants.

**3.2. Data collection**

The data was collected through online surveys and direct interviews. The respondent must fit into the age range of 16 and above. Also, the answer is only accepted if the respondent is a resident of the restricted area; temporary guests’ answers would be excluded from the final set of data input. Respondents were

chosen from various locations within each district to ensure coverage. The survey location includes local markets and apartment complexes at different price ranges.

Out of the 250 handout questionnaires, the number of valid responses was 197, while the online survey reached 106 samples. Each interview took 10 to 25 minutes. In total, 303 samples were used for conducting measurements. Older interviewees usually take longer to be interviewed because they are less open about their financial situation.

### 3.3. Descriptive statistics

#### 3.3.1. Demographic factors

**Table 3.1. Demographic factors: Age, Education, Occupation**

	Number	%
<b>Age</b>		
16 - 22	112	36.96%
23 - 35	146	48.18%
36 - 55	26	8.58%
> 56	19	6.27%
<b>Total</b>	<b>303</b>	<b>100%</b>
<b>Education</b>		
College	219	73.60%
Higher education	11	3.63%
High school	35	11.55%
Secondary school	19	6.27%
Elementary school	8	2.64%
None	11	3.63%
<b>Total</b>	<b>303</b>	<b>100%</b>
<b>Occupation</b>		
Family attending	11	3.63%
Searching/Unemployed	21	6.93%
Vocational Training	5	1.65%
Students	6	1.98%
Not working	9	2.97%
Unable to work	9	2.97%
Currently not searching	6	1.98%
Paid jobs	192	63.37%
Retired	3	0.99%
Self-employed	41	13.53%
<b>Total</b>	<b>303</b>	<b>100%</b>

**Table 3.2. Demographic factors: Marital Status, Number of independent family members, Income**

	Number	%
<b>Marital Status</b>		
Single	161	53.14%
Married	133	43.89%
Divorced	3	0.99%
Separated	3	0.99%
Widowed	3	0.99%
<b>Total</b>	<b>303</b>	<b>100%</b>

<b>Number of independent family members</b>		
0	99	31.67%
1	83	27.39%
2	65	21.45%
3	32	7.92%
> 4	24	10.56%
<b>Total</b>	<b>303</b>	<b>100%</b>

<b>Income (million VND)</b>		
< 03	45	14.85%
03 – 05	26	8.58%
05 – 07	76	25.08%
07 – 10	62	20.46%
10 – 12	21	6.93%
12 – 15	26	8.58%
> 15	47	15.51%
<b>Total</b>	<b>303</b>	<b>100%</b>

Most respondents fell between ages 16 and 35, with 6.27% above 56. About two-thirds had or were pursuing a college education, showing a willingness to acknowledge financial limitations in the survey. 63.67% had paid jobs, and 13.53% ran their businesses. The majority earned just under 10 million VND monthly, with the 5-7 million VND group comprising 25.08%. Marital status had two categories: single and married, while the remaining categories accounted for 3%. Family size mainly consisted of 2 financially dependent members.

### 3.3.2. Financial literacy

Each financial knowledge question gave the respondent three options: “true,” “false,” and “unable to answer or understand the question.” Each correct answer will receive a point. The final score will be the percentage of total correct answers out of all. The distribution of scores skewed to the left, with the heaviest-concentrated score range being from 0.33 to 0.44. In general, the whole sample score is quite low. The lower tiers had more respondents than the upper classes.

The questions with the highest right answers dealt with inflation, interest, and calculating simple interest. The inflation question asked about the event leading to price change due to currency depreciation. Interest questions requested identifying interest-bearing loans with details on principal and repayment. Two questions covered calculating simple and compound interest, with over 75% handling basic interest, but under 50% correctly answering the compound interest question. Investment and credit safety questions had a significant percentage of misunderstandings, covering specialized concepts like securities, risk, and return. These questions reflect the low need for such information in financial or investment matters, evident in the scores.

The majority of respondents oversaw choosing their own or their family’s budgets. This shows the need for better financial records to enhance financial decisions. Overall, more than half of the women who participated in the poll used at least one budgeting technique, and keeping track of expenses using handwritten notes is still quite common. Technology and digital tools are still mostly underutilized. Due to its superiority in time, effort, and efficiency savings, this is another technique that must be made more widely known.

The two most typical methods of reserving income were storing it at home and putting it in a savings account at a bank or doing both at once. However, looking at the predominant proportion of cash reserves

at home, we could see a situation that does not optimize income and savings. Due to the higher risk nature, the weights are even lower for the other two choices. Furthermore, financial institutions are not a common choice in newly developed rural communities. In addition to the increased risk, inhabitants of these locations have fewer options when it comes to saving since they lack financial awareness.

Answer	Number	Percent
Deposit withdrawals	59	25.76%
Delay/removed planned expense	171	74.67%
Sell assets	49	21.40%
Overtime/Extra job	153	66.81%
Demand Government's support	68	29.69%
Demand family/friends' support	133	58.08%
Family/friends' loan	131	57.21%
Advance salary	51	22.27%
Pawn shop	41	17.90%
Non-depository institutions' loan	42	18.34%
Overdraft	67	29.26%
Credit card	59	25.76%
Banking institutions' loan	45	19.65%
Personal/Non-official institutions loan	54	23.58%
Peer-to-peer lending (P2P)	41	17.90%
Delay or avoid paying bills	74	32.31%
Other	4	1.75%

Table 4.7 questions were aimed at those who experienced difficulties covering their living expenses in the last 12 months. Many are currently struggling financially because of the epidemic, and it is predicted that the situation will get worse and last longer in places where there are still constraints on the degree of economic development. 229 of the 303 survey samples revealed financial challenges within the designated time limit.

Answer	Number	Percent
I considered several options before deciding	180	59.41%
I considered many different options from a single financial institution	64	21.12%
I did not consider any option	31	10.23%
I did consider some options but was unable to reach the final decision	38	12.54%
I did not have the need to look for any financial instruments recently	39	12.87%
Price comparing websites	104	44.64%
Hired financial consultant	54	23.18%
Advertisement	65	27.90%
Family/friends reference	205	87.98%
Influential individuals' reference	69	29.61%
Financial Institution consultancy	111	47.64%
Other	43	18.45%

Of the 303 survey samples, 223 had considered financial products with an investment element. The questionnaire is designed to examine behavior when participating in investing. More than 60% of the survey sample had considered multiple options, but up to 21.2% only considered options from a single financial in-

stitution. This demonstrates that women in rural areas who are new to investing are still not very engaged in doing so. Although the number of considerations is not small, the effect is not high when, among the products considered, up to a fifth still could not find a suitable option, accounting for 12.54% of the total sample.

The study considers the source of information for the procedure to provide a clearer picture of how effective women are at looking for and selecting investment goods in new rural areas. By deducting the number of responses from the sum of “I did not consider any options” and “I did not need to look for any financial instruments recently”, the weight is computed based on the number of women who have thought about utilizing investment products and selected financial items recently. The results show that 223 samples are eligible to make statistics for the information source aspect. It is clear from them that most customers base their assessment of product quality on their friend’s and family’s views. This method’s advantage is that it allows the user to learn from the first-hand knowledge of other investors. As we consistently offer competitive prices on everything we carry, however, the prices on our website are subject to change.

**4. RESULTS**

**4.1. Descriptive statistics**

As for the result, the authors first start with Cronbach’s Alpha, then EFA and CFA to analyze the accuracy and reliability of data before running SEM.

In the first step - Cronbach’s Alpha, the authors used SPSS (Statistical Package for Social Sciences) to measure the removal of variables using the reliability test. Thus, we performed the selection of Cronbach’s Alpha if Item Deleted. Then, we compared each group of variables’ Financial Behaviors, Financial Attitudes, and Financial Knowledge, and if a variable had Cronbach’s Alpha if the Item Deleted > Cronbach’s Alpha of the group of variables and/or Corrected Item-Total Correlation < 0.3, that variable would be eliminated to increase Cronbach’s Alpha - the strong correlation between variables. After removing the variables that met the above conditions, the remaining variables had the following Cronbach’s Alpha values. In the second step - EFA, the authors established the following criteria for conducting EFA analysis:

**Table 4.5. Reliability Testing**

	<b>Cronbach's Alpha</b>	<b>Explained variables</b>	<b>Variable's name</b>	<b>Correlation</b>	<b>Cronbach's Alpha if deleted</b>
<b>Financial Attitude (ATT)</b>	0.669	4	A22	0.451	0.603
			A23	0.618	0.483
			A24	0.372	0.654
			A25	0.379	0.651
<b>Financial Knowledge (KNOW)</b>	0.758	5	K13	0.364	0.742
			K151	0.529	0.697
			K152	0.595	0.677
			K153	0.639	0.661
			K154	0.5	0.705

<b>Financial Behavior (BE)</b>	0.697	5	B331	0.369	0.685
			B332	0.566	0.595
			B333	0.544	0.607
			B37	0.53	0.613
			B344	0.299	0.694

First, the Kaiser-Meyer-Olkin (KMO) coefficient must be equal to or greater than 0.5 ( $0.5 \leq KMO \leq 1$ ). If this value is less than 0.5, factor analysis may not be suitable for the research data. The first EFA results were as follows:  $KMO = 0.718 > 0.5$ , sig Bartlett’s Test =  $0.000 < 0.05$ , thus confirming that the exploratory EFA analysis is appropriate.

The factor loading was set at 0.3. After conducting the second EFA analysis, the authors could proceed to use 10 convergent observed variables and differentiate them into 3-factor groups.

In this case, the 3 factors include Financial Knowledge, Financial Behavior, and Financial Attitude. Specifically, Financial Knowledge consists of 2 observed variables, including understanding investment and understanding credit safety. Financial Behavior includes 4 observed variables related to budgeting, saving, and financial shock preparedness.

In the third step – CFA, the structure of the Financial Attitude domain consists of questions related to subjective financial perception. The research team used various indices to evaluate the model fit according to Hu and Bentler (1999). The Chi-square/df ratio has a value of  $2.11 < 3$ , indicating a good model fit. The CFI index has a value of  $0.936 > 0.9$ ,  $GFI = 0.958 > 0$ .

Figure 4.2 SEM Result

From the SEM model (Figure 4.5), the authors observed that the attitudes towards finance (ATT), financial behaviors (BE), and financial knowledge (KNOW) all have a positive impact on financial literacy (FL). Age (AGE), education level (EDU), and income (SAL) also have a positive relationship with financial literacy (FL). However, the number of dependents (SIZE) currently has a negative coefficient on financial literacy. Therefore, the relationships between the observed variables and the reflected variable have an impact on financial literacy according to the constructed hypothesis.

#### **4.2. Internal Factors' Impact on Financial Literacy**

Regarding financial knowledge, the SEM model shows that there is a positive relationship between financial knowledge and financial literacy. This result is consistent with the results from the studies of Collins (2012), Huston (2010), and Zhan (2006). For new rural women in Hanoi, equipping them with this knowledge helps them improve their investment skills as well as their use of credit products.

Regarding financial attitudes, individuals with higher financial attitudes will lead to higher financial literacy scores. This result corresponds to the one studied by Le (2015) and Nguyen and Le (2016).

It has been demonstrated that there is a positive and significant association between financial behavior and financial literacy. Studies by Atkinson and Messy (2012), Hilgert (2003), and Banerjee, Kumar, and Philip (2017) lend credence to this conclusion. Financial Literacy scores will be greatly raised by improvements in the standard and quantity of active financial behavior practice. Higher levels of financial literacy are associated with desirable financial behaviors like cautious budgeting and concern for financial stability, whereas lower levels of financial literacy are associated with negative behaviors like being overly reliant on credit and loans.

#### **4.3. Demographic Factors' Impact on Financial Literacy**

Financial literacy's demographic factor is influenced by various factors, including age, education, family structure, income, marital status, and occupation. Research suggests a positive correlation between age and financial literacy, with older individuals exhibiting higher levels of financial literacy (Bhushan and Medury, 2013; Brown, 2013). This can be attributed to their greater engagement with financial products and behaviors. Older age groups, particularly those over 23, also demonstrate better comprehension of complex financial information. Education level is another important factor, as higher education is associated with higher financial literacy scores (Bhushan and Medury, 2013; Trinh, 2017). Higher education equips individuals with the ability to access and assimilate complex financial knowledge effectively.

The study reveals a negative link between financial literacy and the number of dependent family members (Mottola, 2013). Women with more family members, especially dependent children or elderly relatives, tend to have lower financial literacy scores. This is likely due to the additional responsibilities and roles that women take on, which may divert their attention from financial matters. Moreover, households with poor financial literacy are often less engaged in family planning.

Income and marital status also play a role in financial literacy. Higher-income individuals tend to have lower financial literacy scores (Morgan and Long Q. Trinh, 2017), possibly because they have more financial options and complexities to navigate. Married women, particularly newlyweds in rural areas, tend to have lower financial literacy compared to single or unmarried women (Dewanty and Isbanah, 2018). This can be attributed to the additional responsibilities they assume within the family, leaving them with less time and inclination to actively manage their finances.

Occupation is another factor influencing financial literacy, with individuals who work for a salary or are self-employed exhibiting higher financial literacy scores (Nanziri and Leibbrandt, 2018; Banks and Oldfield, 2007; Bhushan and Medury, 2013). This suggests that the nature of one's occupation may provide exposure and experience in managing personal finances. Understanding these factors can inform targeted efforts to improve financial literacy among different demographic groups.

### **5. CONCLUSIONS AND RECOMMENDATIONS**

#### **5.1. Research Conclusion**

Looking at the results provided for demographics, we discovered some interesting findings. First, out of 6 demographic subgroups, only four subgroups, including Age, Income, Education, and Marital

Status, significantly correlate with financial literacy. The results show that in the new rural areas when the economic situation is innovating and developing, Age status, Marital status, and Income have a positive relationship with financial literacy, however, Education is negatively related. More specifically, Age is the main factor contributing to the decision on the financial literacy level of new rural women. Older women will often make investment decisions based on experience and safety, while young people today are more adaptable to recent changes such as digital finance.

Turning to the results from the reflection factors, we find several other important implications. First, all demographic variables and financial literacy maintain a positive relationship with financial literacy. Thus, in rural Vietnam, financial knowledge is one of the positive factors reflecting financial literacy. Specifically, individuals with good knowledge about investing or lending will have better investment and saving skills. Next, we find that a positive financial attitude leads to higher financial literacy. Specifically, if the subject accurately and positively evaluates changes in the economy, or invests and saves, then he or she will be more accurate and positive. This view is also supported by Le (2015), Nguyen and Le (2016). Therefore, improving financial attitudes through different methods can help people improve their financial literacy. Finally, the results showed that financial behavior positively reflects financial literacy; For that reason, hypothesis H3 is accepted. Specifically, if people invest, save, and spend correctly; one's understanding and attitude toward the economy, in general, will be more accurate and positive. Therefore, it is necessary to develop a good savings and investment portfolio.

Financial literacy is still new in Vietnam, and there has yet to be a specific implementation program to improve financial literacy for the people, especially women in the new rural areas of Vietnam who still have difficulty orienting. Based on the above contents, financial literacy programs should focus on curriculum and news channels, television programs on investment and savings planning, financial literacy, and financial attitudes. Policies should encourage those with low incomes and education levels to consolidate and improve financial literacy to improve living standards and economic development.

## **5.2. Proposing and recommending policies to improve the financial literacy of new rural women in the region**

### **5.2.1. Recommendations to the Government and Specialized Agencies**

New rural women are a significant demographic group in the Vietnam region, and their level of financial literacy is relatively low. An increasing number of National Strategies for Financial Education in Vietnam are now coordinating stakeholder initiatives, which is also a vital objective of the currently developing strategies.

*Firstly*, actively facilitate women to simplify terms and conditions and provide more accessible financial services, such as the aging system, insurance, pensions, healthcare and social security (care), education, and employment in order to raise women's awareness of investment.

*Second*, monitor developments in these areas to identify potential collaborative work with relevant partner organizations. Coordinating institutions and policymakers may consider combining financial education with financial inclusion and more inclusive government action to address geographic, demographic, infrastructure, financial service delivery, and other challenges.

*Third*, rely on a holistic and strategic approach to addressing uncertainties and vulnerabilities, which is especially important for new rural women.

*Fourth*, use evidence-based approaches – standards, for example, the organization of national surveys and participation in regional and international data collection activities, monitoring, evaluation, and other

activities. Taking action to address their insights in further financial education initiatives can have a tangible impact on the financial literacy levels of rural people in the region.

### **5.2.2. Cooperation and synergies of stakeholders enhancement**

New rural women are only sometimes considered the financial education target group of the National Strategy on Financial Education. They have specific needs as a socio-demographic group (and also from different segments) and often live in hard-to-reach areas where they benefit less from many financial institutions. Hence, stakeholders need to address the issue of trust in financial institutions and address problems of rural population availability and readiness.

*Firstly*, stakeholders can collaborate with credible, relevant public sector organizations, including international organizations, bilateral donors, non-profit organizations, financial industry representatives, and microfinance institutions.

*Second*, stakeholders can establish and develop a women-only group to assist women in locations where they cannot leave their homes for any kind of information so that they can learn skills in money management basics, their importance, and how these skills can help them in managing financial and family conditions.

*Third*, when compared to spending, the ratio of saving to family income is meager. Women manage family spending by reducing unexpected expenses and starting to save money in banks/financial services institutions. Banks can increase the awareness of rural people's savings.

### **5.2.3. Effective programs development and implementation and successful initiatives replication**

Some programs in Vietnam have already developed or refined a strategic approach to financial education; however, further improvement in the quality and effectiveness of financial education initiatives needs to be considered. This will provide a well-informed basis for scaling up successful programs to increase impact and behavior change that can lead to greater financial resilience and well-being.

*Firstly*, financial education initiatives can cooperate with stakeholders and especially with community organizations and intermediaries. In doing this, it is essential to understand the local context of the region and village, as there are many cultural and social differences between regions and even between towns within the same area.

*Second*, financial education initiatives work with local community leaders, cooperatives, and business organizations. For example, farming families are key components of rural society, embracing values as they must cooperate and work together to maintain a successful farm. Or build their financial advisory organizations in rural areas to oversee financial literacy services.

*Third*, financial education initiatives build on synergy and focus on cost-effective methods with lasting impact. When warranted and to exploit synergies and cost-effective approaches, trainer training and financial education courses for rural people can also be part of the programs. Working with chambers of commerce and industry associations with existing training facilities and faculty/participant accommodation may be worth exploring.

*Fourth*, financial education initiatives design programs include a combination of innovative delivery methods, including behavioral science and digitization (Internet, social media), with traditional methods (traditional) regional radio, rural radio) to reach large numbers of the rural population and build trust. Focus on changing behavior by promoting budgeting tools, interest tables, and more. And use simple, informative, and straightforward content, and integrate the provision of financial education into the local social and cultural context.

## THE IMPACT OF DEBT OVERHANG ON THE INVESTMENT EFFICIENCY AT THE FIRM-LEVEL IN VIETNAM

**Author: Do Nguyen Hanh Dung<sup>1</sup>, Ly Khanh Linh<sup>2</sup>, Nguyen Thi Thu Nhi<sup>2</sup>, Su Van Hoai Linh<sup>2</sup>**

**Mentor: Nguyen Ngoc Thuy Vy<sup>2</sup>**

*ABSTRACT: This paper is about the impact of debt overhang on the investment efficiency at the firm-level in Vietnam. The authors used data from 508 financial and non-financial corporations operating in 10 industries in Vietnam. The results of the study shows that debt overhang has a negative impact on the investment efficiency of companies. This paper also shows that there is a nonlinear relationship between debt overhang and investment efficiency. Moreover, the authors indicate that growth opportunities can mitigate the negative impact of debt overhang on investment efficiency. Under the effect of growth opportunities, debt overhang has a positive impact on investment efficiency.*

*Key words: debt overhang, investment efficiency, non-linear effect, growth opportunity.*

### 1. INTRODUCTION

During business operations, companies face various risks and challenges that can greatly affect their performance, such as: the coronavirus pandemic, supply chain disruptions, inventory shortages, and declining customer demand. Addressing these issues requires strategic decision-making and capital allocation to minimize risks and maximize outcomes. However, in Vietnam, many companies have experienced low investment efficiency, leading to significant losses and even bankruptcies due to suboptimal project implementation and inefficient capital use.

Researches show that excessive debt, or debt overhang, significantly affects the investment efficiency of companies. Companies burdened with debt overhang may face capital depletion, debt defaults, and hindered investments, impacting the investment climate. Global financial institutions have reported a rise in capital markets in developing and emerging economies (EMDEs) due to economic growth policies, leading to increased debt levels. For instance, in China, corporate debt exceeded 160% of GDP in 2017. Similar trends have been seen in Vietnam. Given the consequences of debt overhang, there's a growing need to study and explore potential solutions for effective debt management. This issue has gained attention from various stakeholders, including company managers, shareholders, investors, credit institutions, and government agencies.

Though several studies exist on this subject in countries like China and Nigeria, there's a noticeable absence of research in Vietnam, specifically on debt overhang's impact on investment efficiency. This study aims to analyze how debt overhang affects investment efficiency at the firm-level in Vietnam. It explores the relationship between investment efficiency and debt overhang, considering development opportunities' influence. The research will offer valuable insights for future studies and businesses operating in Vietnam. Based on findings, practical solutions will be proposed to help Vietnamese companies access relevant reference materials, make informed financial decisions, and improve investment outcomes.

## 2. THEORETICAL FRAMEWORK

### 2.1. Theory 1 - The impact of debt overhang on the investment efficiency at the firm-level

Currently, Vietnam is named among the fastest growing economies in the region and the world. However, the Vietnamese economy is facing challenges in maintaining stability, especially regarding managing the debts of businesses. Increasing debt overhang can lead to insufficient resources for debt repayment and other business activities; decreasing the effectiveness of investment activities, and affecting the overall economic development. Therefore, close management of debts and evaluation of investment efficiency is crucial. Investment efficiency increases labor productivity, contributes to economic growth, and improves people's quality of life, while minimizing risks and improving market competitiveness.

In this context, understanding the relationship between debt overhang and investment efficiency will help businesses make informed investment decisions and achieve optimal effectiveness. The following compiled experimental studies serve as the basis for proposing the research methodology in this study.

This research is based on Myers' (1977) theory: "The determinants of corporate borrowing" regarding the factors influencing corporate borrowing. Myers demonstrated that outstanding debt is the primary cause of debt overhang, reducing investment incentives of businesses. Short-term debt is suggested as a solution to improve investment efficiency since investing maturing debts before opportunities arise allows the company to make investment decisions as if fully equity-owned, reducing the debt overhang burden on businesses.

Aligned with this perspective, several studies agree that corporate debt overhang significantly affects investment decisions and efficiency of businesses. In Eduardo Borensztein's study (2020), the authors highlighted the rising corporate debt in EMDEs (Emerging Market and Developing Economies), negatively affecting business investments, with varying effects among different scales of businesses. Higher existing leverage correlates with a higher marginal rate of investment. Besides, the research conducted by Serhan Cevik and Fedor Miryugin (2020) also suggests that high corporate debt can become a burden for non-financial firms, particularly during severe economic downturns, and companies with high leverage tend to have lower investment levels.

From these studies, it is evident that businesses with high short-term debt ratios benefit greatly. Businesses gain financial management flexibility by using short-term debt to finance investment projects and meet short-term financial needs. Additionally, short-term debt minimizes financial risks and improves profitability with lower interest rates. It also enhances access to lower-cost capital and improves credit ratings. Increasing the use of short-term debt can address overinvestment and underinvestment situations for companies.

In the paper "Debt overhang, rollover risk, and corporate investment: evidence from the European crisis" i.e (Kalemli-Özcan, 2022), the authors used a large sample of firms before and after 2008 - the global financial crisis to measure the interaction between corporate leverage, debt maturity, and investment activities. They found that debt overhang and rollover risk significantly hindered corporate investment during the European debt crisis. Specifically, companies with higher leverage ratios will reduce their investment more, while those relying more on short-term debt faced higher rollover risk and reduced their investment; contrary to normal times when companies that borrow more short-term debt tend to invest more. This highlights the risks of excessive reliance on short-term debt to finance investment during good times.

In the paper "Debt overhang and investment efficiency" i.e (Alexander Popov, Francesca Barbiero, and Marcin Wolski, 2018), the authors used data from 8.5 million companies in 22 countries, utilizing

comprehensive information on firm investment and debt. The authors (2018, p.31) stated that “while debt overhang reduces firm investment, this effect is less pronounced for firms operating in sectors facing good global growth opportunities”. This result aligns with the disciplining role and contradicts the underinvestment problem proposed by Myers (1977). Additionally, debt overhang, especially dominated by short-term debt, positively impacts reduced investment allocation. In the context of a banking crisis, debt overhang can be reversed, having a negative effect on investment allocation.

## **2.2. Theory 2 - The nonlinear impact of debt overhang on the investment efficiency at the firm-level**

In addition to finding that debt overhang has a negative impact on firm investment efficiency, the study “Debt overhang and investment efficiency” i.e (Alexander Popov, Francesca Barbiero, Marcin Wolski, 2018) also found a nonlinear effect of debt overhang on firm investment efficiency. The paper “Theory of the firm: Managerial behavior, agency costs and ownership structure” i.e (Jensen and Meckling, 1976) provided a theoretical basis, suggesting that moderate debt levels discipline firm investment. Meanwhile, debt overhang can negatively impact investment efficiency, particularly for companies near bankruptcy. The combination of these arguments indicates a concave relationship (i.e nonlinear relationship) between debt overhang and investment efficiency.

The study “Corporate Debt Overhang and Investment: Firm-Level Evidence” i.e (Eduardo Borensztein and Lei Sandy Ye, 2020) also demonstrated the nonlinear relationship between these two variables. The authors found that debt overhang is a complex and non-linear concept that is difficult to capture in a linear form. Specifically, at low levels of debt overhang risk, the level of debt may not be related to investment decisions. However, when the debt overhang risk exceeds a certain threshold, investment begins to respond to the level of debt. Various factors, such as future profit volatility and growth prospects, which may interact with the level of debt in affecting firm investment. The effect of debt overhang is more severe for companies with high debt levels compared to those with low debt levels, demonstrating the sensitivity of investment to debt overhang and the nonlinear relationship between debt overhang and investment efficiency.

## **2.3. Theory 3 - The impact of debt overhang on the investment efficiency under the influence of growth opportunities at the firm-level**

Apart from the negative impact of debt overhang on investment efficiency, we want to explore other effects of debt overhang on investment efficiency under different growth opportunities. In the study “Debt overhang and investment efficiency” i.e (Alexander Popov, Francesca Barbiero, and Marcin Wolski, 2018), the authors showed that in normal conditions, debt overhang reduces investment efficiency. However, for firms operating in industries with good global growth opportunities, those with higher levels of debt overhang actually have higher investment efficiency than those with lower levels of debt overhang. However, the positive impact of debt on investment efficiency may be limited in three situations: when debt is too high, when there is a higher proportion of short-term debt, and during global financial crises. These effects suggest possible misallocation of investment due to bad credit market conditions during economic crises.

## **3. RESEARCH METHOD**

### **3.1. Data sampling**

The study analyzes data from 381 business firms covering the period 2008-2021, classified into 10 industry sectors based on GICS (Table 2). The data is collected from Refinitiv Eikon. Using panel data, the study explores the connection between debt overhang and investment efficiency. The study employs three regression methods, namely Pooled Ordinary Least Squares (Pooled-OLS), Fixed Effects (FEM), and

Random Effects (REM). After conducting F-Test and Hausman test, the study utilizes the FEM regression method with Stata 17.0 software.

### 3.2. The measure of the dependent variables

As previously mentioned, the dependent variable in this study is the firm's investment efficiency. To align with the research objectives, the study will adopt the method proposed by McNichols and Stubben (2008), Biddle et al. (2009), Goodman (2014), and Edwin Lok (2021). These studies suggest measuring unexpected investments by the absolute value of the residual from the regression model with fixed effects by industry and year using the following equation:

$$CE_{i,t} = \beta_0 + \beta_1 SG_{i,t-1} + \beta_2 Q_{i,t-1} + \beta_3 CFO_{i,t} + \beta_4 Inv_{i,t-1} + \varepsilon_{i,t} \quad (4)$$

Where:

- $CE_{i,t}$ : represents the firm's capital expenditure, which refers to the money invested in purchasing, maintaining, or enhancing fixed assets like buildings, vehicles, equipment, or land for the company's business operations.

- $SG_{i,t-1}$ : represents the variable indicating the firm's revenue growth rate in the previous year, measured as follows:

$$SG_{i,t-1} = \frac{\text{revenue}(t-1) - \text{revenue}(t-2)}{\text{revenue}(t-2)}$$

- $Q_{i,t-1}$ : represents the firm's Tobin's Q ratio in the previous year, which is a measure of the company's value and investment efficiency, calculated as:

$$Q = \frac{\text{Market value of debt} + \text{Market value of equity}}{\text{Book value}}$$

- $CFO_{i,t}$ : represents the cash flow from the firm's operating activities, such as supplying goods or services to customers.

- $Inv_{i,t-1}$ : represents the total amount of investment made by the firm in the previous year, calculated as:

$$Inv = \text{Long-term investment} + \text{Short-term investment}$$

- $\hat{\varepsilon}_{i,t}$ : represents the residual of model (4). This residual is used as a measure of unexpected investments. In Goodman's (2014), the author argues that good investment choices are often indicated by smaller deviations from expectations. Therefore, to ensure consistency in the sign, the investment efficiency of the company will be the absolute value of the model's residual multiplied by -1.

$$IE = -|\hat{\varepsilon}_{i,t}|$$

### 3.3. Model 1: The impact of debt overhang on the investment efficiency at the firm-level

To investigate the relationship between debt overhang and investment efficiency, we employed a fixed effects model with industry and year fixed effects. The model aims to examine the impact of debt overhang on investment efficiency, and the following econometric model are as follow:

$$IE_{i,t} = \beta_0 + \beta_1 DO_{i,t-1} + \beta_2 Control_{i,t-1} + \varepsilon_{i,t} \quad (1)$$

**3.4. Model 2: The nonlinear impact of debt overhang on the investment efficiency at the firm-level**

In model (2), the squared debt overhang variable (DOsq) was included in model (1) to examine any changes in the relationship between debt overhang and investment efficiency. This addition enables a more thorough examination of the nonlinear relationship between debt overhang and investment efficiency, as follows:

$$IE_{i,t} = \beta_0 + \beta_1 DO_{i,t-1} + \beta_2 DOsq_{i,t-1} + \beta_3 Control_{i,t-1} + \varepsilon_{i,t} \quad (2)$$

**3.5. Model 3: The impact of debt overhang on the investment efficiency under the influence of growth opportunities at the firm-level**

After estimating model (2), we conducted a more in-depth analysis to evaluate the impact of debt overhang on investment efficiency under different growth opportunities. We decided to include the control variable PE (price-to-earnings ratio) in the main model to assess the financial situation and reflect the true value of a company, as well as to represent growth opportunities.

$$IE_{i,t} = \beta_0 + \beta_1 DO_{i,t-1} + \beta_2 PE_{i,t-1} + \beta_3 DOxPE_{i,t-1} + \beta_4 Control_{i,t-1} + \varepsilon_{i,t} \quad (3)$$

Where:

$IE_{i,t}$  represents the dependent variable, indicating the investment efficiency of company  $i$  in year  $t$ .

$DO_{i,t-1}$  represents the independent variable, denoting the debt overhang of company  $i$  in the previous year,  $t-1$ .

$Control_{i,t-1}$  represents control variables included in the model to enhance the robustness of the relationship between the independent variable and the dependent variable. The control variables include:

- $Q_{i,t-1}$ : Lag of Tobin’s Q, measuring the effect of Tobin’s Q of company  $i$ , year  $t-1$ .
- $CF_{i,t-1}$ : Cash Flow of company  $i$  in the previous year,  $t-1$ .
- $STD_{i,t-1}$ : Short-term Debt ratio of company  $i$  in the previous year,  $t-1$ .
- $SIZE_{i,t-1}$ : Firm size of company  $i$  in the previous year,  $t-1$ .
- $SG_{i,t-1}$ : Sales growth of company  $i$ , representing the ability to improve revenue, in the previous year,  $t-1$ .

$DOsq_{i,t-1}$  represents the squared debt overhang, enabling an assessment of the nonlinear relationship between company debt overhang and investment efficiency.

$PE_{i,t-1}$  represents the price-to-earnings variable, which measures the price-to-earnings ratio of a stock.

$DOxPE_{i,t-1}$  is the interaction variable between debt overhang and the price-to-earnings ratio.

**4. RESULTS AND DISCUSSION**

**4.1. Data description**

Source: Summarized by Stata 17.0

The descriptive statistics provide insights into the characteristics of business firms that used debt financing from 2008 to 2021. They present the means and standard deviations of each analyzed variable, illustrating their movement patterns. The table shows that the sample’s investment efficiency has an average value of -0.0926, suggesting relatively high investment efficiency among Vietnamese companies. The debt overhang variable has an average value of -0.3105, which is relatively high, indicating that these companies carry significant financial risks. This value suggests that their debt levels are considerable compared to their income. Furthermore, the firm’s size has an average value of 27.2019, indicating that most of the 508 companies in the sample from 10 industries in Vietnam (at the company level) between 2008 and 2021 have a considerable scale. Regarding short-term debt, the STD variable has an average value of 0.3423, suggesting that companies in Vietnam have a relatively low ratio of short-term debt, preferring not to borrow long-term debt. As for business growth rate, the SG variable has an average value of 0.1839, showing that the growth rate of companies in Vietnam is currently relatively low. The Tobin’s Q ratio, with an average value of 0.9302, indicates that the average value of companies in the group is priced lower than their actual market value, which could pose challenges in raising capital. Lastly, the average value of the leverage ratio for this variable is 0.4286, a relatively high value indicating that companies face significant risks in their investments.

Table 4.2 presents a correlation matrix examining the relationships between the studied variables in the model. The correlation coefficients show the mutual impact among them.

Firstly, the correlation coefficient between Debt Overhang (DO) and Investment Efficiency (IE) is -0.0799, indicating a weak inverse relationship. Similarly, Sale Growth ratio (SG), Tobin’s Q ratio (Q), and Cash Flow ratio (CF) have correlation coefficients with Investment Efficiency (IE) of -0.0048, -0.0987, and -0.0502, respectively. These coefficients are also weak, but negative, suggesting that as Sale Growth Rate, Tobin’s Q Ratio, and Cash Flow Ratio increase, the Investment Efficiency decreases.

Regarding the variables Debt Maturity (STD) and Company Size (SIZE), their correlation coefficients with Investment Efficiency (IE) are 0.1686 and 0.0839, respectively, indicating a positive relationship. In other words, as Debt Maturity and Company Size increase, the Investment Efficiency also increases.

#### 4.2. Multiple Regression results & Discussion

Based on the results presented in Chapter and quick review regarding previous research, the authors have gained several findings to support the stated prior research, along with some of the evidence that may counter the previous discoveries found in this field.

1. Regression results between investment efficiency and debt overhang, along with other control variables.
2. Regression results between investment efficiency and the square of debt overhang, along with other control variables.
3. Regression results between investment efficiency and debt overhang, along with other control variables, under the influence of business growth opportunities

We employed three different econometric methods, namely Pooled-OLS, Fixed Effect, and Random Effect, to determine the most optimal regression approach. The results indicate that Fixed Effect Model (FEM) is the most suitable method for model regressions.

We employ industry and year fixed effects to eliminate differences across industries and years. This helps ensure the accuracy of data comparison and analysis. By doing so, we can focus on determining the relationship between the independent variable ( debt overhang) and the dependent variable (investment efficiency) without being influenced by these factors' variations. In this research study, we only present the results based on the optimal method's findings.

##### 4.2.1 The impact of Debt Overhang on Investment Efficiency of firms in Vietnam

$$IE_{i,t} = \beta_0 + \beta_1 DO_{i,t-1} + \beta_2 Control_{i,t-1} + \varepsilon_{i,t} \quad (1)$$

The regression results of this model are presented in column (1) of Table 4.3.

Debt Overhang (DO) shows statistically significant negative association with investment efficiency, with a coefficient of -0.0213. This implies that Debt Overhang has a negative impact on the investment efficiency of companies. When the level of debt overhang increases by one unit, the investment efficiency decreases by 0.0213 units. This result is consistent with economic theories and aligns with previous empirical studies conducted by Myers (1977), Kalemli-Özcan (2022), Alexander Popov (2018), and others, as well as the original expectations of this paper.

Previous studies have also highlighted that debt overhang occurs when a company has borrowed too much debt, which can lead to various issues for the company and affect its investment efficiency. Specifically, debt overhang impairs the growth prospects of the company due to debt and interest repayment obligations at the present. Therefore, debt overhang has a significant negative impact on investment efficiency and can affect various aspects of a company's operations. One of the most notable impacts is the increase in borrowing costs. When a company raises capital for investment by debt, the borrowing costs can exceed the potential profits from investment, resulting in a loss of profitability.

In addition, debt overhang also reduces the ability to invest in new projects or expand company operations. When a company is heavily indebted, it lacks necessary resources to pursue new investment opportunities because a significant portion of its cash flow needs to be allocated to servicing current debt, leading to underinvestment.

Another impact of debt overhang is the financial pressure that exerts on a company. If a company is unable to meet its debt obligations, it may face penalties and fees, further damaging its financial situation. In extreme cases, a company may default on its debt, leading to bankruptcy and loss of capital for investors.

This not only harms the company but also the investors and creditors. Therefore, debt overhang can also diminish the reputation and credibility of the company in the views of investors, banks, and customers. In summary, it can be seen that debt overhang has a significantly negative impact on the investment efficiency of the company, highlighting the crucial importance of debt management.

Control variables also have an impact on the investment efficiency of businesses.

The research findings indicate that short-term debt (SDT) positively impacts business investment efficiency with a high level of statistical significance. An increase of 1 unit in short-term debt maturity leads to a 0.0344 unit increase in investment efficiency. Businesses benefit from short-term loans with lower interest costs compared to long-term loans. Utilizing tax shields helps reduce debt repayment pressure. Additionally, businesses can improve their credit rating with credit institutions, accessing low-cost capital for investment projects. Short-term debt offers flexibility, aiding businesses in addressing urgent situations and enhancing negotiation capabilities with stakeholders. Using short-term debt ensures timely payments to stakeholders, strengthening trust and important relationships for business operations. It supports short-term business activities, especially for businesses with clear investment plans and debt control capabilities. Consequently, short-term debt has a positive impact on business investment efficiency.

For the Tobin's Q variable (Q), the results from Table 4.3 show an inverse relationship with the investment efficiency of the company, with a regression coefficient of -0.0094. This means that when Tobin's Q increases by 1 unit, the investment efficiency decreases by 0.0094 units. According to the research of Nguyen Thi Loan, Le Thi Tuyet Hoa, Nguyen Viet Hong Anh (2021), it is also demonstrated that Tobin's Q has a negative impact on the investment efficiency of businesses, especially in situations when investments are below par. This result aligns with the author's study.

However, there are many studies suggesting that a company with a high Tobin's Q ratio is often seen as the market's positive evaluation of the investment opportunities and growth potential of the company, indicating efficient investment. But according to our research findings, this is not always true. A high Tobin's Q does not guarantee that a company is making efficient investments. When Tobin's Q is high, it means that the market value of the company is higher than its actual asset value, which may indicate that the company has invested too much in assets and lacks the necessary capital to optimize the efficiency of those assets. This can lead to suboptimal utilization of assets and a decrease in investment performance. Additionally, sometimes a high Tobin's Q is a result of market speculation. In such cases, companies may focus on increasing their market value through dividend payments, share repurchases, or investing in riskier projects rather than optimizing the use of their existing assets. This can have a negative impact on the investment efficiency of the company. In conclusion, there exists a negative relationship between Tobin's Q and investment efficiency.

Regarding the Firm Size (SIZE), the regression results show a positive impact with a coefficient of 0.0065 on the investment efficiency of businesses with a significance level of 1%. However, these findings are inconsistent with previous studies. The research by Eduardo Borensztein and Lei Sandy Ye (2020) suggests that firm size has a negative impact on the investment activities of businesses. Large companies tend to have wider access to credit markets, including bank loans and bonds, which can lead to excessive borrowing or debt overhang. This, in turn, reduces the investment efficiency of the company. However, this perspective may not be entirely applicable to the conditions of the Vietnamese economy. Specifically, Vietnam is a young and developing economy with numerous opportunities for growth and scale expansion. Therefore, a large firm size can ensure the necessary resources to carry out large investment projects and develop business operations, while also enhancing competitiveness in the market. Thus, in this context, firm size has a positive impact on investment efficiency in Vietnam.

To investigate the impact of scale factors on investment efficiency, we conducted separate regressions for large firms and medium/ small firms. Columns (2) and (3) of Table 4.3 display the relationship between debt overhang and investment efficiency for each group. The scale of firms is determined by the average value of their assets. The results in Table 4.3 indicate that the effect of debt overhang exists in both large firms and medium/small firms. Notably, medium/ small firms show greater sensitivity to debt overhang compared to larger ones. This could be due to asymmetric information between the two groups. Large firms typically possess more comprehensive information about their business, enabling better investment decisions and less impact from debt overhang. On the other hand, medium and small firms may lack resources and reputation to weather economic shocks, making them more affected by debt overhang. These findings underscore the positive impact of the scale factor on investment efficiency in firms.

**Table 4.3. The impact of Debt Overhang on Investment Efficiency at firm-level in Vietnam**

Dependent variable: **Investment Efficiency**

#### 4.2.2. Nonlinear relationship between Debt Overhang and Investment Efficiency

$$IE_{i,t} = \beta_0 + \beta_1 DO_{i,t-1} + \beta_2 DOsq_{i,t-1} + \beta_3 Control_{i,t-1} + \varepsilon_{i,t} \quad (2)$$

The regression results for a deeper analysis of the nonlinear relationship between debt overhang and investment efficiency are presented in Table 4.4 below. To further examine this issue, we included in Model (2) the variable DO square, which represents the squared Debt Overhang variable (DOsq). The use of DOsq allows us to assess the impact of debt overhang on investment efficiency at different levels. The results in Table 4.4 reveal a nonlinear relationship between debt overhang and investment efficiency of enterprises. Specifically:

For the squared variable DOsq, according to Table 4.4, the regression coefficient for this variable is -0.0292 at a significance level of 5%. Based on this, we can observe that the relationship between the level of debt overhang and investment efficiency is nonlinear, meaning that the impact of debt overhang on investment efficiency is not uniform across all levels. Additionally, under this nonlinear model, we find that the influence of debt overhang on investment efficiency significantly increases as the regression coefficient for DO is -0.0596 at a significance level of 1%. Therefore, it can be seen that after surpassing a certain threshold, the impact of debt overhang on investment becomes substantial. Consequently, in this case, enterprises need to carefully consider and control the issue of debt overhang in order to limit the negative effects on investment efficiency.

To explain this nonlinear relationship, we can refer to Myers' theory (1977) that states as debt levels increase, the conflicts of interest between debtors and creditors become more prominent, as the firm allocates a significant portion of its profits from a project to repay its creditors. This situation creates tighter debt repayment constraints and potential for higher investment reduction.

Based on these results, we conclude that the relationship between debt overhang and investment efficiency is nonlinear. Therefore, it can be inferred that reducing debt overhang may benefit the investment efficiency for the firm, but this impact will not be uniform across all levels of debt overhang and may diminish at a slower rate as debt overhang decreases.

#### ***4.2.3. The impact of Investment Efficiency and Debt Overhang, along with other control variables, under the influence of business growth opportunities***

The investment decision depends heavily on the available investment opportunities of a business. Typically, investment opportunities are not observed by economists or in empirical research. They usually rely on a few indicators to represent growth opportunities such as Tobin's Q ratio (Allayannis et al., 2003). However, most representations like Tobin's Q are endogenous or influenced by the local economic conditions or only available for a limited number of listed companies. Therefore, to study the impact of debt overhang and investment efficiency under growth opportunities, this study will rely on an empirical representation - the Price-to-Earnings ratio (PE). In this ratio, a higher PE indicates higher growth opportunities for the business (Bekaert et al., 2007). At the same time, a high PE ratio is an indication that the company continues to invest with expectations of future growth.

Additionally, to control the impact of debt overhang under the influence of growth opportunities, the leverage ratio is an important factor which affects the PE ratio. For example, a company with a high leverage ratio tends to have lower growth opportunities compared to companies with lower leverage ratios. When a company uses high leverage, meaning it utilizes more borrowed assets to invest and expand its business, the company will have to pay more interest and other costs related. This leads to a decrease in the company's profitability and, consequently, a potential decrease in its growth opportunities.

To further investigate the impact of debt overhang on investment efficiency under growth opportunities, the regression results are presented in Table 4.5:

Regarding the impact of Debt Overhang under the influence of Growth Opportunities (DOxPE), the regression results show that the debt overhang has a positive effect on investment efficiency, with a significance level of 10%. Under the influence of growth opportunities, when debt overhang increases by 1 unit, investment efficiency increases by 0.0014 units. This result is consistent with the study of Alexander Popov, Francesca Barbiero, Marcin Wolski (2018). In previous models, without the influence of growth opportunities, the impact of debt overhang on investment efficiency is reversed, meaning that as overinvestment increases, investment efficiency decreases. This contrast can be explained by the profitability of investment opportunities under the influence of growth opportunities. When a company has high growth opportunities, the profitability from investment projects also becomes higher. In this case, if the company borrows a large amount of capital to invest, it can generate significant profits for the company and still have the ability to bear the risks associated with a large amount of debt, such as interest payments and debt repayment. However, this is only true when debt overhang is used to invest in projects that yield high returns. Increasing debt overhang under the influence of growth opportunities can be seen as a form of financial leverage, and using this leverage can benefit the company when investing in projects with higher profitability. However, using leverage can also pose risks to the company, especially when debt overhang is not used to invest in projects that generate high returns, but only to pay off existing debts.

Regarding the Leverage ratio (Lev), the results in Table 4.5 show that the regression coefficient is -0.0851. This indicates that when a company's leverage ratio increases by 1 unit, its investment efficiency decreases by 0.0851 units. In other words, using leverage to invest and expand the business reduces the efficiency of investment projects at a specific rate. This finding aligns with Eduardo Borensztein's study (2020). The explanation lies in the additional costs incurred when a company employs leverage for investment, such as interest payments, financiers' fees, management costs, monitoring expenses, and risks. These costs diminish the profits from investment projects, resulting in decreased investment efficiency. This research finding has implications for investors and asset managers. If the leverage ratio is high, investment projects may not yield high efficiency, and vice versa. Therefore, careful consideration is crucial when deciding to use leverage for investments in a company.

**Table 4.5. The impact of Investment Efficiency and Debt Overhang under the influence of business growth opportunities****Dependent variable: Investment Efficiency**

All independent variables are lagged by 1 year.

\*  $p < 0.10$ , \*\*  $p < 0.05$ , \*\*\*  $p < 0.01$

*Note:* DOxPE represents Debt Overhang under the influence of growth opportunities, calculated as the product of DO and PE. DO stands for Debt Overhang. PE is the Price-to-Earnings ratio. STD = Short-term Debt/Total Debt. SG is the revenue growth rate. CF represents cash flow. Lev is the leverage ratio, calculated as total debt over total revenue. The regression model is Fixed Effects Model, controlling for industry and year. The t-statistic values are shown in parentheses.

*Source: Synthesized by authors*

From these results, we can conclude that the impact of growth opportunities mitigates the negative influence of debt overhang on the investment efficiency of the company, which aligns perfectly with the hypothesis of the research. Based on this, we will provide recommendations for businesses in Vietnam to control debt overhang in order to achieve optimal efficiency.

## 5. CONCLUSION

The results of the study shows that Debt Overhang has a negative impact on the investment efficiency of companies. The regression results showed that high levels of debt lead to increased borrowing costs, limiting profitability and the ability to invest in new projects or expand operations. Debt overhang can also create financial pressure and damage the company's reputation and credibility. Hypothesis 2 showed that there is a nonlinear relationship between debt overhang and investment efficiency. While moderate levels of debt may have an insignificant effect, surpassing a critical threshold leads to a significant negative impact on investment efficiency. Therefore, companies should carefully control debt overhang to mitigate its adverse effects. For hypothesis 3, growth opportunities can mitigate the negative impact of debt overhang on investment efficiency. Under the effect of growth opportunities, debt overhang positively affects investment efficiency. Companies

use debt overhang to invest in high-profit projects, leveraging financial resources for greater returns. However, if debt overhang is not used for profitable investments but only for debt repayment, it can pose risks. Besides, control variables including Debt Maturity (STD), Firm Size (SIZE), and Tobin’s Q ratio (Q) also influence investment efficiency. The results from the model revealed that the use of short-term debt has a significant positive impact on the investment efficiency of companies. Firm size also positively influences investment efficiency. However, there exists a negative relationship between the Tobin’s Q ratio and investment efficiency. In summary, besides the independent variables, the control variables also have a relatively significant impact on the dependent variable, investment efficiency, at different levels of statistical significance.

The research findings indicate that controlling and managing debt levels is crucial for enhancing investment efficiency and sustainable growth in Vietnamese companies. Regular debt control allows companies to balance borrowing costs and investment returns, while also enabling them to allocate resources towards potential investment opportunities instead of debt repayment. Moreover, using short-term borrowing intelligently can increase investment funding capacity and improve investment efficiency. Short-term debt provides access to low-cost borrowing, offers tax advantages, and helps mitigate risks. However, it’s essential to avoid overreliance on short-term debt to prevent financial strain and hinder business expansion. Additionally, when companies have high-growth prospects, leveraging debt overhang can lead to significant profits and still maintain the ability to manage associated risks. However, careful evaluation and management of debt overhang are necessary to ensure financial stability and enhance investment efficiency. Overall, implementing these recommendations can assist Vietnamese companies in improving investment efficiency, seizing growth opportunities, and achieving sustainable financial performance.

## THE IMPACT OF CORPORATE SOCIAL RESPONSIBILITY ON CORPORATE FINANCIAL PERFORMANCE: EVIDENCE FROM LISTED FIRMS ON VIETNAM STOCK MARKET.

**Authors:** Tuong Bao Ngoc<sup>1</sup>, Hoang Thien Trang<sup>2</sup>, Nguyen Phuong Quynh Anh<sup>2</sup>,  
Nguyen Thao Nguyen<sup>2</sup>, Duong Khanh Van<sup>2</sup>  
**Mentors:** Le Thi Thu, Nguyen Thu Hang<sup>2</sup>

**ABSTRACT:** *This research provides quantitative evidence of the relationship between social responsibility (CSR) and corporate financial performance of listed corporations in Vietnamese stock markets. Despite the overarching CSR impact on firm performance, CSR is not widely popular and taken into thorough consideration in Vietnam. With a view to providing a deeper insight into this issue, especially CSR in the Vietnamese context, this research uses panel data of 1025 observations, which were collected from 205 companies listed on the Vietnamese stock market between 2016 and 2020. By applying OLS robust regression to examine the relationship between corporate performance and CSR proxies, we came to the conclusion that companies that disclose and practice more CSR activities experience a contradictory reduction in revenue and profitability, which may go against most studies relating to this topic.*

**Keywords:** *Corporate social responsibility (CSR), corporate financial performance, corporate performance, Vietnamese stock market*

### 1. INTRODUCTION

Since there have been little attention to this topic in the Vietnamese economic context, along with the desire to gain a deeper understanding and contribute to a clearer depiction of the relationship between CSR and CFP in the world in general and the Vietnamese market in particular, we decided to study the topic “Effect of corporate responsibility on the financial performance of enterprises listed on the Vietnamese stock market”.

With the outstanding development of science and technology, and the digital transformation of the global economy, social responsibility has gradually become one of the hot topics that businesses are most concerned about today. 20 years ago, when talking about CSR, in general, there were not many businesses in the world that really cared about this aspect. The reason may be that they were not really aware of the benefits that CSR brings. However, in recent years, in the midst of industrialization - modernization, when corporate social responsibility has gradually asserted its value and position, many global corporations and companies, including Vietnam, has implemented innovation and development in the direction of being friendly with nature - society, contributing to portraying the concept of CSR more clearly.

In Vietnam, activities showing social responsibility are not really popular and are often carried out by large companies and corporations, mainly revolving around the volunteer aspect. Two typical enterprises can be mentioned are the Vietnamese dairy company Vinamilk and Vingroup. Their campaigns fund towards the goals of culture - education, community health care, economic support and social security with many charity programs. The publication of information about the above activities has contributed to improving the reputation of the company as well.

## 2. LITERATURE REVIEW

### 2.1. Literature review

Research on the concept of Corporate Social Responsibility has been known and debated since the 1950s. The ISO 26000 international standard (2010) states that the social responsibility standard includes seven important factors: corporate governance, responsibility to workers, the environment, human rights, transparent organizational management, consumer issues, and contribution to the community. According to Moon and Matten (2004), CSR encompasses the concepts of business ethics, corporate philanthropy, corporate citizenship, sustainability, and environmental responsibility. Companies must perform social responsibilities at four priority levels: economic, legal, ethical, and philanthropic.

In the past, many global studies have been conducted and produced inconsistent results with the following 3 groups of results:

The first group of results shows a positive relationship between CSR and CFP, that is, CSR has a positive impact on CFP, or in other words, when businesses increase declaration and implementation of CSR activities, financial efficiency is increased. business will increase. Research by Okafor et al (2021) has shown that increasing costs for CSR-related activities improves corporate financial performance.

The second group of results shows the negative relationship between CSR and CFP, that is, CSR has a negative impact on CFP, or in other words, when enterprises increase declaration and implementation of CSR activities, financial efficiency is better. This result implies that when businesses implement social responsibility, they will create many additional costs, leading to low operational efficiency. This result is supported by a study by Rhou et al (2016) when this group of authors argued that focusing too much on social responsibility activities can be avoided or should be the responsibility of another party (e.g. government) and can lead to a loss of a company's competitive advantage.

The final group of results shows that there is no relationship between CSR and CFP. This result occurs when researchers cannot conclude whether the relationship is positive or negative, which is found in the study of Moore (2011).

Regarding the impact of CSR information disclosure on business performance in the Vietnamese market, Tién and Anh (2017) showed that CSR information disclosure has a positive impact on the financial performance of enterprises. However, no studies have yet examined the reverse relationship between business performance and CSR in Vietnam. Domestic studies mainly focus on community and environmental aspects of production enterprises. Experimental studies mostly involve case studies of specific companies such as Nguyen Phuong Mai's (2013) study on Dap Cau Company. Nevertheless, there are certain limitations since they are carried out in a specific context of a limited company and do not provide specific solutions.

According to Hồ Thị Vân Anh (2018), there is still a lack of consistency in the empirical research on the relationship between CSR and CFP in the world. Therefore, research on the relationship between CSR and CFP is still necessary and needs to be further expanded to understand the true meaning of CSR, especially in developing countries like Vietnam. This study will examine whether the CSR disclosure index has an impact on the financial performance of companies listed on the Vietnamese stock market, and if so, whether this is a positive or negative relationship. From there, the research will support and provide more grounds for businesses in deciding the level of CSR implementation, helping businesses deal better with the risks of financial performance caused by the level of participation in community supporting activities.

From the research results, the authors expect to provide more bases for economists and business managers in making decisions about the level of CSR disclosure. In addition, the authors also hope that this information can support businesses to identify and deal better with risks related to CFP caused by the level of and disclosure of communal activities participation.

## 2.2. Theoretical background

Stakeholder theory states that a business can only survive if it is able to satisfy the needs of its stakeholders, which significantly affect the well-being of the business. Stakeholders provide resources such as capital, labor, and revenue, thus, they are both potential beneficiaries and bearers of high risk to the corporation (Yoon and Chung, 2018). This theory provides a theoretical basis for research supporting the view that the implementation of CSR can promote corporate development. A donor enterprise that actively carries out community development and social welfare activities will attract the attention of the public, thereby helping to promote the image of the enterprise, build its brand and reputation, and promote long-term development. Furthermore, stakeholder theory also helps to explain competitive interests and the influence of stakeholders on management decisions, henceforth, it has been used to assess the impact on financial performance and strategic planning in business. Financial statements also need to become more reliable, as this is the most accurate tool to report the business situation to shareholders. To ensure the quality of financial statements in widespread use today, GAAP or IFRS should be applied with the aim of improving the completeness, clarity, consistency, and comparability of financial information disclosure.

## 2.2. Hypothesis

A number of studies have found a positive relationship between social responsibility and financial performance, which means that when businesses invest more in CSR, financial performance will increase. To explain this argument, stakeholder theory suggests that the implementation of CSR can promote corporate development. A number of other studies have also confirmed the positive impact of social responsibility on financial performance, such as that of Qiu et al (2020), which tested the role of CSR in terms of protecting the company during the spread of the COVID-19 pandemic. His study provides evidence that CSR engagement is beneficial for improving stock returns as well as increasing stakeholder attention during the pandemic. Based on the above arguments, the authors propose the following research hypothesis:

***H1A: Implementation of social responsibility increases the financial efficiency of the enterprise.***

On the contrary, some studies suggest that disclosure of social responsibility information can increase costs and reduce financial efficiency. Price and Sun (2017) found that companies with a good record of employee welfare have lower leverage. The main reason for this is that CSR activities require financial resources, which can reduce profits and negatively impact CFP in the short term. Some businesses believe that the implementation of CSR is due to pressure from national policies, laws, regulations, and social organizations.

Companies that invest heavily in CSR may overlook other important aspects of their business, such as innovation and cost-cutting, which can negatively affect CFP. Additionally, consumers may not consider CSR activities important enough to justify their costs, leading to lower revenues and profits. However, the negative association between CSR and CFP does not mean businesses completely abandon socially responsible actions. Many managers believe it is important to be an exemplary employee of the company, even if doing so would result in damage to shareholders. Besides, shareholders may require the company to make CSR disclosures even at the cost of poor financial performance. Based on the above arguments, the authors propose the following research hypothesis:

***H1B: Implementation of social responsibility decreases the financial efficiency of the enterprise.***

## 3. METHODOLOGY

### 3.1. Data

Both primary and secondary data were used to analyze the impact of CSR on financial performance. The panel data were established by collecting information from annual reports and financial statements of 205 manufacturing enterprises listed on the Ho Chi Minh Stock Exchange (HOSE) from 2016 to 2020 provided by Vietstock and secondary data from Fiiipro. At the same time, based on market changes and the

appearance of Circular 155/TT-BTC/2015, the authors decided to focus on studying the impact of social responsibility on financial performance in the period 2016 to 2020 to bring more accurate and relevant results to the trend of the times.

**List of information indicators on corporate social responsibility**

Type		Index	Indicators
Environment	Management of raw material	1	Total amount of materials used to manufacture and package the organization's key products and services during the year
		2	Report the percentage of recycled materials used to produce the organization's key products and services
	Energy consumption	3	Direct and indirect energy consumption
		4	Energy saving initiative
	Water consumption	5	Water supply and water usage
		6	Percentage and total amount of recycled and reused water
	Compliance with law on environmental protection	7	Number of times of being fined for not complying with environmental laws and regulations
		8	Total amount due to fines for non-compliance with environmental laws and regulations
Labor	Policies related to employee	9	Total amount due to fines for non-compliance with environmental laws and regulations
		10	Average salary for employees
		11	Labor policy to ensure the health, safety and welfare of employees
		12	Average training hours per year
		13	Continuous learning and skills development programs to support workers with job security and career development. Continuous learning and skills development programs to support workers with job security and career development
Society	Responsibility for local community	14	Community investments and other community development activities, including financial support to serve the community

**3.2. Measurement of corporate social responsibility**

In order to ensure the objectivity of the selection process criteria, the data collection and survey were conducted by the authors in two steps:

Step 1: Collect data from 205 largest listed companies in Vietnam stock market and survey 2016. After the survey, the authors adjust the indicators in accordance with the characteristics and situation. of Vietnam;

Step 2: Based on the agreed criteria, the author group actually surveyed 205 companies with a total of 1025 observation samples within 5 years.

Principle of data collection: The author first reads the financial statements and finds information related to the criteria in the evaluation list. If the enterprise does not disclose the i-th indicator, it shall label it as "0", if the i-th indicator has been published in the general presentation or only with a quantitative presentation, the label shall be "1". After data collection is completed, CSRALL is measured according to the following formula:

$$CSRALL_j = \frac{\sum_i^n X_{ij}}{14}$$

CSRALL is CSR disclosure score for j<sup>th</sup> company

X<sub>ij</sub> = 1 if i<sup>th</sup> activity is not disclosed in the general presentation or only with a quantitative presentation;

X<sub>ij</sub> = 0 if i<sup>th</sup> activity is not disclosed.

### 3.3. Control variables

After referring to previous studies, the authors have controlled for fixed effects by industry and year by using 2 dummy variables year, industry to compare the difference between industries and the past years. Besides, the group also uses some other control variables in the model as follows: Board independence (*Baysinger and Butler, 1985*); Board ownership (*Short and Keasey, 1998 & Cui and Mark, 2003*); Manager ownership (*Duc Hong Vo and Tri Minh Nguyen, 2014*); CEO duality (*Richer and Dalton, 1991; Boyd, 1995*), Board size (*B. Xie et al, 2003*); Firm size (*Glaum et al, 2004; Kim et al 1976; Pham Nguyen Dinh Tuan, 2020*); Leverage (*Pham Nguyen Dinh Tuan, 2020*); Asset turn (*Duc Hong Vo and Tri Minh Nguyen, 2014*).

### 3.4. Research model

Based on the above theoretical bases, the aim of this study is to explore the impact of CSR and CFP, and to examine the moderating effect of ownership structure between both variables to understand how firms control the relationship between CSR and CFP through their ownership structure. The study also focuses on aspects of corporate social responsibility, including the level of interest, declaration and implementation of activities related to social responsibility. Therefore, the research team offers a quantitative model to clarify the relationship between CSR and CFP as follows:

$$ROA_{i,t} = \alpha_0 + \alpha_1 CSRALL_{i,t} + \alpha_2 CONTROL_{i,t} + \epsilon_{i,t}$$

$$ROE_{i,t} = \alpha_0 + \alpha_1 CSRALL_{i,t} + \alpha_2 CONTROL_{i,t} + \epsilon_{i,t}$$

#### *Bảng giải thích biến trong mô hình*

Variables	Definition	Measurement	Expectation	Studie
<b>DEPENDENT VARIABLES</b>				
ROA	Return on assets	Ratio of net income to total assets		Okafor et al. (2021)
ROE	Return on equity	Ratio of net income to total shareholders' equity		Okafor et al. (2021)
<b>INDEPENDENT VARIABLES</b>				
CSRALL	Disclosure of social responsibility	Select "1" if there is a declaration of social responsibility and "0" for other cases	+	Rui Ang et al., (2021)
<b>CONTROL VARIABLES</b>				
BOARD_IND	Proportion of independent members of the Board of Directors	Number of independent member/ Total member of Board of Directors	-	Baysinger và Butler (1985)
OWN BOARD	Ownership of the Board of Directors	Percentage of shares owned by the Board of Directors/ Total number of shares outstanding	+	Short and Keasey (1998), Cui and Mark (2003)
OWN MNG	Ownership of the Manager	Percentage of shares owned by the Manager /Total number of shares outstanding	+	Duc Hong Vo & Tri Minh Nguyen (2014)
DUAL	The duality of the CEO	Select "1" if the CEO is also the chairman and "0" for other cases	-	Richer and Dalton (1991), Baliga, Moyer and Rao (1996)
BOARD SIZE	Board size	Natural logarithm of the total number of board members	+	Essa et al., (2016), Huy (2016).
FIRM SIZE	Firm size	Natural logarithm of the total assets of the firm	+	Glaumet al., (2004), Pham Nguyen Dinh Tuan (2020)
LEV	Financial leverage	Total debt/Total assets of the business	-	Pham Nguyen Dinh Tuan (2020)
ASSET TURN	Asset turn	Total net revenue/Total assets of the business	+	Duc Hong Vo & Tri Minh Nguyen (2014)

## 4. RESULTS

### 4.1. Descriptive statistics

With 935 observations obtained in the period of 2016 - 2020, Table 1 illustrates the descriptive statistics of independent and dependent variables. Nine independent variables are CSRALL (CSR score), BOARD\_SIZE (board size), BOARD\_IND (board independence), DUAL (CEO duality), OWN\_MNG (ownership of manager), OWN\_BOARD (board ownership), ASSET\_TURN (asset turnover), LEV (leverage) and FIRM\_SIZE (firm size) while dependent variables are ROA (return on asset) and ROE (Return on equity). CSR has the mean score of 0.492 with a standard deviation of 0.275. In the selected time period, the mean of return on asset is 0.063 with the range running from -0.094 to 0.377. Similarly, the mean value of return on equity is 0.121 along with the minimum and maximum values of -0.251 and 0.505 respectively for the sample obtained.

**Table 1: Summary of descriptive statistics**

Variable	Obs	Mean	Std.Dev	Min	Max
ROA	1025	0.063	0.071	-0.094	0.377
ROE	1025	0.121	0.11	-0.251	0.505
CSRALL	1025	0.492	0.275	0	1
BOARD_IND	935	0.549	0.247	0	1
DUAL	935	0.193	0.394	0	1
OWN_MNG	935	0.071	0.116	0	0.765
OWN_BOARD	935	0.093	0.144	0	0.81
BOARD_SIZE	935	5.448	1.231	3	11
LEV	1025	0.484	0.233	0.031	0.942
ASSET_TURN	1025	0.832	0.823	0	4.712
FIRM_SIZE	1025	28.482	1.78	23.95	34.955

*Note: ROA: Return on asset; ROE: Return on equity, CSRALL: CSR score, BOARD\_IND: board independent; DUAL: CEO duality; OWN\_MNG: Ownership of manager; OWN\_BOARD: board ownership, BOARD\_SIZE: board size; LEV: leverage; ASSET\_TURN: asset turnover; FIRM\_SIZE: firm size.*

### 4.2. Correlation analysis

Table 2 shows the two-tailed test correlation including the correlation coefficients and the statistical significance of various variables. The Pearson correlation test is conducted with a total of 11 variables.

**Table 2: Correlation analysis**

VARIABLES	(1)	(2)	(3)	(4)	(5)	(6)	(7)	(8)	(9)	(10)	(11)

(11) FIRM_SIZE	-0.010	-0.247***	0.029	-0.062*	-0.001	0.015	0.078**	0.004	-0.307***	0.539***	1.000

Note: ROA: Return on asset; ROE: Return on equity, CSRALL: CSR score, BOARD\_IND: board independent; DUAL: CEO duality; OWN\_MNG: Ownership of manager; OWN\_BOARD: board ownership, BOARD\_SIZE: board size; LEV: leverage; ASSET\_TURN: asset turnover; FIRM\_SIZE: firm size.

Gujarati et al. (1995) noted that regression analysis can be inefficient due to two major issues: multicollinearity and homoscedasticity. To address these problems, the Variance Inflation Factor (VIF) and the Breusch-Pagan-Godfrey test were conducted, respectively. The results presented in Table 3 indicate that most independent variables have a VIF of under 2.0, with the exception of board independence and board ownership. Although these two variables have VIF values of 2.233 and 2.016, respectively, the difference between their values and the accepted level of 2.0 is not significant and can be considered acceptable. Therefore, multicollinearity does not appear to be a serious issue in the two models.

**Table 3: Testing for multicollinearity by using the variance inflation factor (VIF)**

VARIABLE	VIF-ROA	VIF-ROE
CSRALL	1.115	1.115
BOARD_IND	2.233	2.233
DUAL	1.241	1.241
OWN_MNG	1.971	1.971

The variable CSRALL represents the level of concern, disclosure, and implementation of corporate social responsibility. With a significant negative regression coefficient at the 5% significance level, the obtained result contradicts the initial expectation of the authors under hypothesis **H1A: Implementation of social responsibility increases the financial efficiency of the enterprise**. In a study on the relationship between CSR and financial performance in China, Rui Ang et al. (2021) found a positive correlation between social responsibility and the financial efficiency of companies. Similarly, in the United States, Okafor et al. (2021) demonstrated that CSR has a positive correlation with ROA and ROE, meaning that the higher a company’s level of concern, publicity, and application of social responsibility, the more efficient its operations. However, the results regarding the inverse relationship between CSR and financial indicators also revealed many surprising and interesting points. Accordingly, this research findings are reinforced by studies conducted by Sekhon et al. (2019) and Buallay et al. (2019), which both show a negative correlation between CSR and ROA, ROE. Sekhon et al. (2019) believe that companies that implement social

responsibility will bear direct costs, resulting in many disadvantages compared to competing companies in the same industry. This seriously affects the value provided to company shareholders. Meanwhile, Buallay et al. (2019) affirm that publicly disclosing social responsibility has a negative impact on operational and market performance but does not affect financial performance. In their study, Buallay et al. (2019) point out that investors evaluate the ability to implement social responsibility based on whether or not companies declare relevant actions. Specifically, issuing any related reports not only increases the effectiveness of social responsibility but also improves the expected value of related activities. Therefore, they consider this to be an important result as it explains the complexity of previous studies on the issue.

Many control variables, such as board independence (BOARD\_IND), CEO duality (DUAL), and leverage (LEV), have a significant negative impact on corporate financial performance, meeting the initial expectations with a significance level of at least 5%. On the other hand, asset turnover (ASSET\_TURN) and firm size (FIRM\_SIZE) are significant, indicating a strong relationship between them and ROA and ROE. These findings are consistent with previous research conducted by Sekhon et al. (2019). However, board size (BOARD\_SIZE), ownership of manager (OWN\_MNG), and board ownership (OWN\_BOARD) are either insignificant or significant at a low level of 10%, suggesting that their effects on corporate performance are minor or non-existent.

## 5. CONCLUSION

From the theoretical bases mentioned, including agent theory, shareholder theory, stakeholder theory, to analyze the relationship between the level of enforcement and disclosure of social responsibility to the effectiveness of Financial results, the study has measured and tested: the degree of social responsibility disclosure, the ratio of the number of independent members of the Board of Directors, the ownership of the Board of Directors, the ownership of the Management, the duality CEO, and finally asset turnover. Applying the above theories and using a processed data set consisting of 1025 observations from 205 non-financial listed companies published through the annual report for the period 2016-2020, it resulted in a negative relationship between CSR disclosure and financial performance. With their research results, the team has identified variables that have an impact and some are not significant on financial performance.

In this study, the overall level of CSR disclosure has been shown to have a negative impact on financial performance, i.e. the more CSR is enforced and disclosed, the lower the financial performance. Accordingly, the research results of the authors were reinforced by the study of Sekhon et al. (2019), the study of Buallay et al (2019) when both showed a negative correlation between CSR and ROA, ROE. This can be explained that the performance and business results of enterprises are greatly influenced by the behavior of profit management. Therefore, enterprises need to try to improve and enhance the quality of their internal management to ensure the correctness of the managers' influence on the financial performance of the company. Regarding individual investors, the group whose majority lack in-depth knowledge of the market, it is advisable that they learn more about the internals of businesses through various information channels such as publications, newspapers with guaranteed quality and reputation in the financial field, or articles from reputable market analysts. For shareholders of enterprises - large investors who aim for long-term investment, this group of investors should closely monitor and control the structure and quality of the Board of Directors to minimize the risks of representatives-related issues.

## 6. LIMITATIONS

Despite important theoretical and experimental contributions, the study still has some limitations in three aspects: time and information quality, space and data analysis method. Firstly, the data set is collected

and processed by the research team from annual reports and financial statements of 205 enterprises from 2016 to 2020. This is a limited time period and the quality of information remains. The shortage leads to the existence of quite a lot of blank data, reducing the number of research samples of the topic. Secondly, in terms of space, the study was conducted with only 1025 observations, all of which are listed on the Ho Chi Minh Stock Exchange (HOSE). Third, in terms of data analysis methods, the study only uses performance indicators based on accounting measures to measure the relationship between CSR and CFP. Hence, future research is recommended to overcome these shortcomings to present a better picture of this phenomenon.

## DOES CSP MATTER FOR FIRM'S STOCK LIQUIDITY IN EMERGING COUNTRIES?

Academic advisor: Dr. Ho Thi Hai Ly<sup>1</sup>

Student: Lam Binh Chi<sup>1</sup>

**ABSTRACT:** *The objective of this study is to investigate the influence of Corporate Social Performance (CSP) activities on the stock liquidity of firms in emerging nations. Utilizing a panel analysis of data collected from six emerging nations from the year 2002 to 2016, I demonstrate the main research hypothesis that CSP initiatives have a negative effect on the stock liquidity implying that CSP investment could place a significant financial strain on businesses in these countries. Furthermore, the empirical results also indicate that different elements of CSP have varying levels of effect on firm financial performance. For instance, while governance activities have the greatest impact, the result of environmental scores is irrelevant. These primary findings are supported by numerous robustness tests. Interestingly, the adverse association between CSP and stock liquidity is mitigated in countries with strong institutional environments.*

**Keywords:** *Corporate Social Performance (CSP); stock liquidity; ESG score; emerging countries, institutional environments.*

### 1. INTRODUCTION

Recent years have witnessed the emergence of CSP investment as a global economic trend, particularly in wealthy nations. The firm must take into account a variety of other aspects, consisting of expenses, resources, and other considerations, meaning this is not a simple decision for them to make. In developing nations, where industrialization tends to be associated with environmental destruction, implementing CSP activities into their business processes creates even more hurdles and difficulties. They must determine whether investing in CSP initiatives will have the desired impact on the company's financial performance because the sustainability issues may occasionally be costly for businesses but beneficial for society as a whole (Nguyen et al., 2021). For these reasons, I suppose that it is important to investigate the influence of CSP practices on stock liquidity particularly in the developing markets for the purpose of offering a theoretical basis for firms in making investment decisions.

While the nexus between CSP and corporate performance has been the subject of much discussion over the years, there is limited evidence to investigate either the processes or the impact of sustainable activities on stock liquidity of firms in the developing countries (Zhang & Zhang, 2021; Egginton & McBrayer, 2018). As a result, I conduct a global study across emerging economies that permit me to explore the bottom line which is the association between CSP and firms' stock liquidity.

I expect that CSP will have an intensive influence on a firm's stock liquidity by investigating both the positive and negative aspects of this association in order to find out which is more relevant in developing nations. At the country-level, I have found external control mechanisms influencing this correlation, called institutional environments, and I anticipate that the negative impact of CSP on liquidity can be reduced thanks to the strength of the institutional settings.

Using a cross-country panel dataset of publicly listed companies from 06 emerging countries between 2002 and 2016 obtained from Datastream to test the hypotheses, the study suggests that, due to the increase

---

<sup>1</sup> University of Economics - The University of Danang.

in firm costs and challenges regarding emerging markets, CSP initiatives have a significant and adverse impact on the firm stock liquidity. Furthermore, powerful institutional environments, characterized by the presence of six macro-level institutional indexes, have the tendency to alleviate the negative correlation between CSP and stock liquidity.

This study implies three key contributions including academic and practical impacts to literature. First and foremost, this one enriches the financial literature on whether it is worthwhile for firms with demand to invest in CSP by determining the influence of them through a niche approach, stock liquidity, rather than the overall approach, firm financial performance, like most of previous studies. In addition, instead of using samples in developed countries, I decided to conduct the research in emerging countries where CSP initiatives investment is still a mystery. More intriguing, this research also emphasizes the critical role of institutional environments in the correlation of CSP and stock liquidity.

The remaining of my research is organized as follows. Section 2 reviews the relevant literature followed by outlining two primary hypotheses. The variable construction, data, and sample are described in section 3. Section 4 explains the methodology while section 5 reports the results. Section 6 concludes the study.

## **2. LITERATURE REVIEWS AND HYPOTHESIS DEVELOPMENT**

### **2.1. CSP and stock liquidity**

Previous studies argue that an essential component in affecting a firm's equity liquidity is its information environment (Healy & Palepu, 2001; Ravi & Hong, 2014). In detail, enterprises whose corporate announcements are better disclosure and transparency might minimize the problem caused by asymmetric information and accordingly experience a higher level of stock liquidity, and vice versa (Kurlat, 2018). This result holds true for both required and voluntary CSP disclosure as long as the disclosure is valuable (Dhaliwal et al., 2011).

Moreover, reputation plays an important role in helping increase the liquidity in a firm's stock by reducing adverse selection and moral hazard issues (Battalio et al., 2007) as well as strengthening the trust and admiration of stakeholders to firms (Bai & Ho, 2022). A variety of works (Fombrun & Shanley, 1990; Karl V. Lins, 2017) examine how investing in social and sustainability activities may increase social capital as well as firms' reputation in the public and the community in which they function, which is consistent with Sacconi & Antoni, 2011's conclusions. In line with all of these research, I propose the following hypothesis:

***H1a: CSP engagement is positively related to the stock liquidity of firms in the emerging countries.***

When investing in CSP initiatives, huge costs are needed to cut emissions or improve the use of natural resources (Rassier and Earnhart, 2010). Some businesses have to convert from their own outdated technologies into environmentally friendly ones in their production processes (Bansal & Clelland, 2004), leading to a quite high investment in their expenses. If these practices dramatically raise the costs without yielding desired outcomes, it will degrade the company's financial performance and increase the stock illiquidity of the firm accordingly. Furthermore, because costs associated with strengthening CSP are not frequently reflected exactly in the financial performance of a firm (Duque-Grisales & Aguilera-Caracuel, 2019), CSP is also consider as a sign of managerial agency issues that worsen information asymmetry and reduce firm's stock liquidity, as a consequence (Bénabou & Tirole, 2010).

Besides, CSP investment is not highly concerned in the emerging market. Therefore, the businesses have not yet won over their stakeholders' and society's overall trust and loyalty despite initiatives on social issues being developed (Marquis & Raynard, 2015). In comparison with developed markets which already have a strong CSP foundation, emerging market firms confront more uncertainties and difficulties

in pursuing extensive CSP initiatives. The existence of institutional voids (eg. Marquis & Raynard, 2015; Rottig, 2016), instability in politics, corruption, working conditions, the effects of climate change (Clark et al., 2015) as well as limited corporate transparency in organizational cultures and business rules are some of primary reasons leading to risks when opting to invest in CSP, and is a key factor deciding the illiquidity in their stock. These reasons led me to an alternative hypothesis to H1a as follow:

*H1b: CSP engagement is negatively related to the stock liquidity of firms in the emerging countries.*

## **2.2. The impact of institutional environments**

Institutional contexts are seen as an external method to resolve agency issues (Bai & Ho, 2022), which are frequently positioned beyond the supervision of enterprises and are much cheaper control measures than internal ones. The relationship between CSP and stock liquidity might be strengthened or weakened by institutional environments.

According to previous study results (eg., Porta et al., 2006; Roy et al., 2022), the powerful institutional environments can improve financial market efficiency, offer more effective enforcement mechanisms and more transparent data, as well as safeguard creditors and investors; firms operating in these countries can benefit from lower transaction costs, less asymmetric information, and a greater level of liquidity. Consequently, I highly expect that institutional context might mitigate the negative correlation between CSP and liquidity:

*H2: The negative impacts of CSP to stock liquidity of firms is less pronounced in nations which have strong institutional environments.*

## **3. VARIABLES AND DATA SAMPLE**

### **3.1. Variable construction**

In this study, I employ Turnover as the primary proxy to measure LIQ, followed by Amihud illiquidity to test the robustness of my findings. Stock turnover (Turny) is defined as the annual average number of shares traded on a day divided by the entire number of shares outstanding (eg. Berkman & Nguyen, 2010; Datar et al., 1998). Turnover ought to be negatively correlated with spread and positively correlated with liquidity. Amihud (2002) illiquidity indicator is defined as the annual average ratio of the daily absolute stock return divided by the dollar value of volume, reflecting the price impact of order flow or the price change linked to trading volume. To provide a liquidity proxy in order to make the results simpler to interpret, I multiply the Amihud illiquidity measure by (-1) in the regression model.

Next, I make use of ESG performance assessments from the Thomson Reuters ESG database to quantify CSP. Thomson Reuters creates ESG scores from this pool of data that reflect a company's ESG performance in three categories (environment (E), social (S), and governance (G) and ten fields.

I implemented a set of control variables at firm-level in this research, which are firm size (SIZE), profitability (PROF), depreciation (DEP), market-to-book value (MTB), research and development expenses (RD), research and development expenses dummy (RDDUM), tangibility (TANG) and leverage ratio (LEV).

### **3.2. Data and samples**

I gathered information from a variety of sources through four stages in total. Firstly, I used the Datastream database to obtain annual firm-level accounting data from Worldscope. Secondly, I gathered daily data from Worldscope like share prices, stock returns, and trading volumes. Thirdly, ESG factor information from the Thomson Reuters ESG database is obtained. Lastly, I relied on the works of Djankov et al. (2003); Porta et al. (2006), Djankov et al. (2008), Porta et al. (1998) and Gao & Zhu (2015) to

obtain six macro-level institutional index. After using some filters, the final sample included 757 firm-year observations from 06 different countries including China, Indonesia, Malaysia, Philippines, South Korea, and Turkey, from 2002 to 2016. I also winsorized both the dependent and independent variables at the 1st and 99th percentiles to eliminate the outliers.

#### 4. METHODOLOGY

The subsequent baseline regression to investigate the relationship between CSP and stock liquidity (LIQ) is:

$$LIQ_{i,j,t} = \alpha_0 + \beta CSP_{i,j,t} + Control\ variables_{i,j,t} + y_{t,j} + \mu_{i,j,t}$$

Beyond the basic link, I additionally design another equation below to find evidence for the debated question of how institutional settings (INSENV) affect the association between CSP and the stock liquidity (LIQ):

$$LIQ_{i,j,t} = \alpha_0 + \beta_1 CSP_{i,j,t} + \beta_2 INSENV_{j,t} + \beta_3 (CSP_{i,j,t}) * (INSENV_{j,t}) + Control\ variables_{i,j,t} + y_{t,j} + \mu_{i,j,t}$$

#### 5. EMPIRICAL RESULTS

##### 5.1. Descriptive statistics

We report the descriptive statistics in Table 1. The mean of ESG score is 50.1212 and ENV score witnesses the highest mean score in three pillars of ESG, at 59.0919. Besides, the mean scores of Turny and Amihudy which are employed in the sample to proxy for LIQ are 4.9582 and 0.0008 respectively. They are consistent with previous studies in the same stream of research (e.g., Duque-Grisales & Aguilera-Caracuel, 2019; Bai & Ho, 2022).

**Table 1. Summary statistics**

The summary statistics for the full sample are reported in Table 5.1. The variable definitions are in Appendix A.

	Mean	Median	SD	Min	Max
ESG score	50.1212	51.4700	20.2066	9.3800	90.0900
ENV score	59.0919	67.1100	31.4237	9.4800	96.9700
CGV score	21.2280	14.7600	20.4152	1.3500	93.6800
SOC score	56.2174	61.6700	32.1961	4.3500	98.6900
TURNY	4.9582	3.5397	5.1957	0.0617	50.6842
AMIHUDY	0.0008	0.0000	0.0115	0.0000	0.3139
SIZE	15.9317	15.9188	1.2850	12.7851	19.7941
PROF	0.1263	0.1098	0.0963	-0.2693	0.8701
DEP	0.0407	0.0307	0.0351	0.0015	0.3313
MTB	2.2928	1.6000	2.9000	-4.8200	29.2100
TANG	0.3748	0.3710	0.1823	0.0361	0.8493
RD	0.0129	0.0043	0.0244	0.0000	0.3235
RDDUM	0.9406	1.0000	0.2366	0.0000	1.0000
LEV	0.2450	0.2420	0.1530	0.0000	0.8322

Table 2 reports the correlation coefficient. It shows that most correlation coefficients are quite low with the exception of the strong connection of the ESG, ENV, SOC, and CGV scores with each other. Multicollinearity is therefore unlikely to be an important limitation in my regression study.

**Table 2. Correlation coefficients**

This table provides the Pearson correlation coefficients between the primary analyses’ explanatory variables. Stars imply significance at the 5% level. The variable definitions are in Appendix A.

**5.2. CSP initiatives and firm’s stock liquidity**

Based on Table 3 that shows the baseline result, I note that except the environment performance which does not lead to any correlation between CSP and the stock liquidity, all remaining significant and negative coefficients of ESG on Turny lead to the conclusion that there is an adverse correlation of CSP investment on the firm’s stock liquidity. These findings prove that the ESG index as a whole has particular negative implications on the liquidity of a firm’s stock, which are consistent with my hypothesis H1b regarding the presence of a negative correlation between the CSP and firm’s stock liquidity.

**Table 3. CSP and stock liquidity – baseline regression results.**

The baseline regression findings regarding the effect of CSP on stock market liquidity are presented in this table. Turny serves as the proxy for LIQ. ESG and E, S, G scores are the proxies for CSP. Firm characteristics are included in control variables. The values \*\*\*, \*\*, and \*, respectively, show significance at 1%, 5%, and 10% levels, in turns. T-statistics are provided in parenthesis. The variable definitions are in Appendix A.

### 5.3. Robustness tests

#### 5.3.1. Alternative proxy of liquidity

I check the robustness of the baseline results using an alternative proxy of liquidity, named Amihud illiquidity indicator. As shown in Table 4, the coefficient on CSP is negative and significant at 1 % level, indicating that there is a negative relationship between CSP and stock liquidity. This supports my main finding.

**Table 4. The robustness check – alternative proxy of liquidity**

The table shows the regression findings for equation (4). Stock liquidity (LIQ), also known as the dependent variable, represented by Amihudy. ESG and E, S, G scores are the proxies for CSP. Firm characteristics are included in control variables. The values \*\*\*, \*\*, and \*, in turn, show significance at 1%, 5%, and 10% levels. T-statistics are provided in parenthesis. The variable definitions are in Appendix A.

### 5.3.2. Alternative methodology

I employ an alternative methodology that is the two-step system GMM to deal with endogeneity issues. In this model, the lags of the dependent variables are used as explanatory variables, which means that lagged values of CSP are used as instruments for managing this endogenous association. Indeed, it may not be the CSP practices used this year that are having an impact on stock liquidity, but rather the choices made the year before. The results are reported in Table 5. I find that the coefficients of CSP proxies are significant and negative, supporting the baseline results.

**Table 5. The robustness check: an alternative methodology**

The table illustrates the influence of CSP on the firm’s stock liquidity using two-step system GMM as an alternative econometric method. Turny serves as the proxy for LIQ. ESG and E, S, G scores are the proxies for CSP. Firm characteristics are included in control variables. The values \*\*\*, \*\*, and \*, respectively, show significance at 1%, 5%, and 10% levels, in turns. T-statistics are provided in parenthesis. The variable definitions are in Appendix A.

#### 5.4. The role of institutional environments in remodeling CSP – Liquidity association

Table 6 reports the result. As expected, the correlation coefficients of the interaction terms, , used as the variables explaining the way institutional environments influence the CSP – Liquidity association, are statistically significant and positive, indicating that institutional environments can weaken the undesirable correlation between CSP and the stock liquidity of firms. This result supports the hypothesis H2.

**Table 6. Institutional environments and CSP – LIQ relationship.**

The table following shows the regression findings. Stock liquidity (LIQ), represented by Turny, is the dependent variable. There are a total of six elements of institutional environments, which are: Eliabs, formalism, bankrp, antidir, edisclose and cifar. ESG scores are the only proxy for CSP. Firm characteristics are included in control variables. The values \*\*\*, \*\*, and \*, in turn, show significance at 1%, 5%, and 10% levels. T-statistics are provided in parenthesis. The variable definitions are in Appendix A.

## 6. CONCLUSIONS

This study explores the implications of CSP initiative investments on the firm's stock liquidity in emerging countries. Based on an analysis of 06 emerging countries data from the year 2002 to 2016, I conclude that there is a negative correlation between CSP and the stock liquidity, implying that CSP investment could place a significant financial strain on businesses in these nations. Each component of ESG has a different negative impact on stock liquidity at different levels, except for environmental scores. The results remained unchanged through various robustness tests. Furthermore, I find that the adverse impact of CSP on the stock liquidity is significantly improved in countries with extremely strong institutional frameworks.

The study has various implications. At firm-level, the findings may encourage managers to enhance governance and administration practices, in an effort to promote long-lasting CSP initiatives and a rise in stock liquidity. At the national level, policymakers initially can develop a complete legal framework to strengthen their institutional contexts in order to establish favorable conditions for businesses to uphold their social obligations, and lessen the negative effects of CSP issues on their companies. Public and regulatory authorities should have some campaigns granting for the CSP activities of firms as well as glorifying the firms that have effective CSP initiatives and responsibility in terms of social concerns. In this way, CSP projects will be considered an opportunity rather than a cost

## THE ROLE OF AGILE LEADERSHIP AND STRATEGIC FLEXIBILITY TO SMES' DIGITAL TRANSFORMATION IN THE CENTRAL AND CENTRAL HIGHLANDS REGIONS OF VIETNAM

**Academic advisor: Truong Duy Nhat Phuong, MSc<sup>1</sup>**

**Students: Phan Thi Thanh Hoai, Pham Hoang Phuc<sup>1</sup>**

**ABSTRACT:** *This research aims to examine the role of agile leadership and strategic flexibility in the digital transformation of SMEs in Central and Central Highlands regions in Vietnam. This work applied structural equation modeling (SEM-PLS) and a multi-group analysis to test four hypotheses, with data from 97 SMEs in Central and Central Highlands regions, Vietnam. Empirical results showed that: Strategic flexibility becomes the key to success in implementing digital transformation of SMEs in the Central and Central Highlands regions. Moreover, the transformation of the workforce and dynamic capability of the enterprise is also decisive factor in creating digital transformation in SMEs.*

**Keywords:** *agile leadership, strategic flexibility, digital transformation, SMEs*

### 1. INTRODUCTION

In recent years, digital transformation has become a significant trend across the world as businesses seek to embrace new technologies and innovative business models. In Vietnam, the government has also identified digital transformation as a key priority, to create a digital economy and improve the competitiveness of Vietnamese businesses. Digital transformation is rapidly spreading across all types of organizations including SMEs and has a significant impact on them and their business environment. The digital transformation of SMEs has been investigated in various countries. However, there is a lack of research on this topic in Vietnam, especially in the Central Highlands, where SMEs have unique characteristics such as a collectivistic society, low risk tolerance, and a rapidly changing political and legal environment. Therefore, studying the digital transformation of SMEs in this region is necessary for achieving the national digital transformation goal and enhancing economic development. As a means to achieve this purpose, the following research questions were formulated:

*“What are the roles of agile leadership and strategic flexibility in improving SMEs digital transformation in Central and Central Highlands regions of Vietnam?”*

In order to answer that question, the authors have conducted a study with the following objectives:

Reviewing the literature regarding agile leadership, strategic flexibility, and digital transformation.

Establishing scales to measure agile leadership, strategic flexibility, and digital transformation of SMEs in Central and Central Highlands regions of Vietnam.

Conducting a survey on SMEs in Central and Central Highlands regions of Vietnam upon their leadership, strategic flexibility, and digital transformation.

Analysing the data collected from the SMEs in Central and Central Highlands regions of Vietnam.

Drawing conclusion and recommendation from the data analysis.

## **2. LITERATURE REVIEW**

### **2.1. Digital Transformation for SMEs**

The authors approach digital transformation by definition digital transformation is a business process that facilitates the relationship between a company and its customers by simplifying various processes through the use of recent technology. This change is not only restricted to technology implementation, but also affects the company's structure and strategy to align with the new business model resulting from the new technology. The dimensions for measuring Digital Transformation include: navigating the innovation ecosystem, redesigning internal structures, and enhancing digital maturity, (Warner & Wäger, 2019).

### **2.2. Workforce Transformation and Strategic Flexibility**

Workforce transformation is the process of adapting the workforce to changing business needs, strategies, and technologies. According to a report by Deloitte (2021), it involves identifying the skills and capabilities needed for the future, developing and upskilling employees to meet those needs, and creating a culture of continuous learning and improvement. From dimensions to measure workforce transformation of Shaughnessy (2018) and Stevens (2018), this research will measure workforce transformation using the dimensions of skills and qualities required from the workforce, adoption of new social values, flexible and fluid work, and faster and more adaptive work on a daily basis.

According to (Warner & Wäger, 2019), Strategic flexibility is a company's ability to respond to changes in the dynamic business environment in order to achieve the objectives, with the support of knowledge and superior capabilities. The strategic capabilities are comprised of an integrated workforce, process, product, and system. Adopted from (Warner & Wäger, 2019) we measure strategic flexibility through four items, which are sensitivity, strategy, leadership unity, and resource fluidity.

A study in agrifood nanotechnology (Yawson & Greiman, 2017), found that workforce transformation through human resource development can identify future skill needs, provide skills training and development, identify opportunities and challenges, and increase coordination and consultation among stakeholders, thereby creating strategic flexibility for the company. So hypothesis can be concluded as follows:

H1. There is a positive relationship between workforce transformation and strategic flexibility.

### **2.3. Dynamic Capability and Strategic Flexibility**

The authors approach dynamic capability is an organization's ability to adapt to changing environments by reconfiguring resources and processes and disseminating knowledge to all members of the organization persistently. From the dimensions to measure the Dynamic capability of Gnizy et al. (2014); Oliva et al. (2018); (Park et al., 2018); (Tallott & Hilliard, 2016), we conclude that the dimensions for measuring dynamic capabilities include sensing, adaptive, innovation, networking, learning, integrating, and coordinating capabilities.

Based on previous research, companies need to build strong dynamic capabilities to quickly create, deploy, and transform business models to remain relevant in the current digital economies (Teece, 2018; Teece & Linden, 2017; Velu, 2017). And according to (Schneider & Spieth, 2014), the utilization of information technology by SMEs is an example of high dynamic capability, which enables them to achieve objectives more efficiently, develop strategic flexibility, and adapt to competitive positions. As such, we hypothesize the following:

H2. There is a positive relationship between dynamic capability and strategic flexibility

## 2.4. Strategic Flexibility and Digital Transformation

Warner (2013) proved that strategic flexibility has the potential to give positive impacts of technological capabilities. In the digital era, companies are encouraged to transition from traditional to digital methods. Achieving this change requires strategic flexibility to enable companies to respond to uncertainty and achieve their objectives. Based on this, hypothesis 3 can be stated as follows:

H3. There is a positive relationship between strategic flexibility and digital transformation.

## 2.5. The Moderating Role of Agile Leadership:

The authors argue that successful strategic flexibility and digital transformation is determined with the existence of agile leadership. Agile leadership is an agile leader who can guide his team and continually influence the team behaviour by defining, spreading, and maintaining organizational vision (Perker et al., 2015). From the dimensions of previous studies, we use dimensions to measure agile leadership are: shares responsibility, effective in recognizing problems and making decisions, adaptive systems, and flexible structure.

According to previous research results, an organization will have greater agility capability, if a leader uses a far-ahead and strategic perspective. Agile leadership allows congruence in the implementation of strategies, and quickly articulates and creates a strategy into the choice of business logic, as well as infrastructure. The skills, system infrastructure, functions, and processes are required in articulating and prototyping essential strategies in preparing SMEs to quickly respond to the changing environments (Li et al., 2018). Thus, Hypothesis 4 is as follows:

H4. Agile leadership strengthens the relationship between strategic flexibility and digital transformation.

## 2.6. Conceptual framework

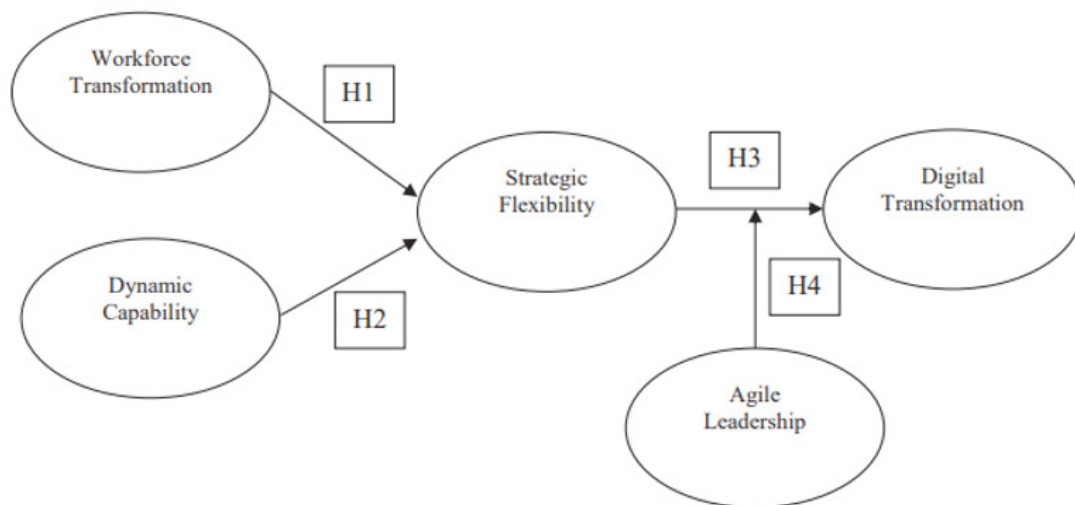

Figure 1: Conceptual framework- Olivia Fachrunnisa et al., (2020)

This model fits a strategic approach since it adheres to the idea of strategic alignment, which is a crucial element of strategic management. The process of matching an organization's actions and resources with its strategic goals and objectives is known as strategic alignment (Hussein et al., 2020). The model indicates that a strategic approach is required to guarantee that an organization's workforce, strategy, and digital capabilities that are aligned with the goals and objectives of the organisation in question by tying workforce transformation to strategic flexibility and digital transformation.

### **3. METHODOLOGY**

#### **3.1. Population, Sample and Data Collection**

In this research, a survey methodology was employed to gather primary data for empirical analysis. The study population consisted of SMEs that extensively utilize basic digital technologies such as social media for marketing and client partnership purposes and these enterprises in the Central and Central Highlands regions of Vietnam. The sample for this study comprises SMEs with fewer than 200 employees, and the sampling technique used was non-random with a purposive sampling method. The criteria of SMEs selected as samples in this study are based on Article 6, Decree No. 39/2018/ND-CP dated 11/03/2018 of the Government of Vietnam. And after nearly 2 months, a total of 97 usable surveys were collected.

#### **3.2. Measures**

The questionnaire includes multiple-choice questions built on a 5-level likert scale from 1 (Strongly disagree) to 5 (Strongly agree) and consists of 27 items.

The questionnaire form was developed into two main parts. In the first part of the questionnaire, 7 questions determining demographic characteristics such as type of enterprise; annual sale; employee staff;... In the second part, there were 20 questions belonging to five earlier-mentioned factors. And the respondents of these questionnaires are Managers or Owners of SMEs.

With “Workforce Transformation” construct, we used 4 items which were developed by combining insights from previous studies by Kucukusta et al. (2015), Liu (2014), Shaugnessy (2018), and Stevens (2018). In addition, the authors found that Vietnam has a high collectivist culture, so they added 1 observed variable related to Vietnam’s collectivist culture to examine the Workforce Transformation.

“Dynamic Capability” construct, we used 2 items, adapted from previous studies by Bamel and Bamel (2018), Gnizy et al. (2014), and Schilke et al. (2018). Furthermore, Vietnam’s state institutions are not yet complete, leading to a rapidly changing political and legal environment, hence the authors have added 1 observed variable about the ability of SMEs to adapt to regulatory changes of the government.

“Strategic Flexibility”, to measure this construct, we adopted multi-items from Warner and Wäger’s (2019) research and used three items.

“Agile Leadership” construct we used four items adapted from Perker et al. (2015) and added 2 observed variables about leadership’s awareness of digital transformation.

“Digital Transformation” construct, we used three items developed by Warner and Wäger (2019).

### **4. DATA ANALYSIS RESULTS**

#### **4.1. Description of the characteristics of respondents**

##### **4.1.1. The characteristics of demographic**

In terms of position in SMEs, 58.8% were managers and 41.2% were owners. In this survey, the majority of respondents (81.4%) were SMEs respondents working in the commerce and services sector, while 18.6% were from other business sectors. The majority of SMEs in Central Vietnam (58.8%) employ between 11 and 50 people. SMEs with less than 10 employees and those with 51 to 100 workers come in second with 39.2% and 2.1%, respectively. Considering the prospect of annual sales, the annual sales of most SMEs in Central Vietnam have a production capability of >3 (75.3%), and the other have a production capability between 3 and 50 (24.7%).

#### 4.1.2. T test: Test for differences for qualitative subjects

Sig F-test is equal to  $0.798 > 0.05$ , there is no difference in variance between the business fields and the digital transformation.

#### 4.2. Evaluation of the measurement model

The proposed variance model's latent variables were evaluated for tightness, unidimensionality, validity, and reliability using a modeling technique adapted from Garver and Mentzer (1999). PLS-SEM 4 software was used for statistical analysis and model development, beginning with initial techniques for quality assessment, reliability, convergence, and discriminability of observed variables. More rigorous approaches using the confirmatory factor analysis module of SEM were subsequently applied, as introduced by Anderson and Gerbing (1982) and Gerbing and Anderson (1988).

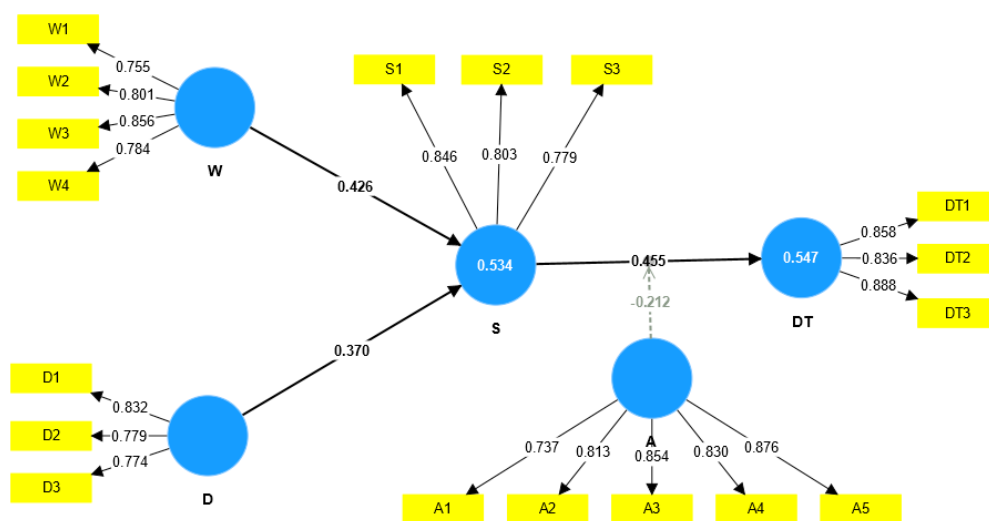

Figure 1: Structural proposal model

#### 4.1.1. Assess the quality of observed variables (Indicators)

The use of SMART-PLS software for model analysis yielded results identical to those presented in Table 11. All observed variables were found to have Outer loading coefficients exceeding 0.7, in line with the theoretical framework. This finding indicates that the indicators are meaningful and can be used to interpret the outcomes of the model. Furthermore, these indicators show that the relationship between the observed variables and the corresponding latent variables is strong.

#### 4.1.2. Assess Construct Reliability

According to the processing results, the reliability metrics of the scale were evaluated using both Cronbach's Alpha and Composite Reliability. It was found that both indices exceeded the desired threshold of 0.7, indicating that the observed variables of the scale were highly reliable and represented a high degree of representativeness of the variable. This indicates that the proposed model is suitable for evaluating the relationship between the variables under investigation.

#### 4.1.3. Assess Convergent Validity

After examining the a-priori model, none of the observed variables violated the convergence. All observed variables have convergent values above 0.6. This shows that the scale has done its job well. All indicators have

a strong positive correlation with each other. Therefore, the results suggest that the scale used in this study has a high level of convergence and can be considered appropriate for further statistical analysis.

#### **4.1.4. Assess Discriminant Validity**

The exact threshold level of the HTMT is a debatable situation. Clark & Watson (2016) and Kline (2015) suggest a threshold of 0.85, whereas others propose that if this value is below 0.9, discrimination will be guaranteed (Gold et al., 2001; Henseler et al., 2013). In this study, we use the threshold of the HTMT index is less than 0.9. The analysis shows that the HTMT indexes are all less than 0.9, ensuring the discriminant for the observed variables in the model.

#### **4.2. Structural Model Evaluation and hypotheses testing**

In this study, the authors employ the Bootstrapping technique to carry out hypothesis testing and evaluate the structural model.

##### **4.2.1. Path coefficients 4.3.2**

The results show that the P Values of the effects are all less than 0.05. The remaining effects are statistically significant. In addition, the Original Sample coefficients of these variables (W, D) are 0.426 and 0.37 respectively, which indicates that Digital Transformation has a stronger impact on Strategic Flexibility than Dynamic Capability. And based on table 15, it can be seen that Strategic Flexibility has a stronger impact on Digital Transformation than Agile Leadership has. In addition, the Original Sample of the effect of the interaction variable AxS on DT has the sign (-), which means that when the moderator variable A increases, the independent variable S will have a weaker effect on the dependent variable DT.

##### **4.2.2. Collinearity Evaluation:**

VIF Values of the independent variables are all less than 3, which is unlikely to have multicollinearity between the independent variables in this model.

##### **4.2.3. R-squared and R-squared adjusted**

The analysis results show that the independent variables W, D explains 52.4% of the variation of the dependent variable S. The independent variables S, A explains 53.2% of the variation of the dependent variable DT.

##### **4.2.4. The f-squared values:**

The results show that the relationship between the independent variables and the dependent variable in turn is as shown in the table above. In which, variable D and variable W are suggested to have a medium impact on variable S. However, the results show that moderate variable A can only affect variable DT with a small degree. The variable S is also suggested to have a positive effect in correlation with DT, f-squared value = 0.215, which indicates the mean influence.

##### **4.2.5. Total Indirect Effects**

P values of these effects are all less than 0.05 in the 95% statistical reliability. Hence, there is an indirect relationship between D-DT and W-DT with statistical significance.

##### **4.2.6. Specific Indirect Effects:**

The results in the table above show that the P Values of the effects are all less than 0.05, so these indirect effects are statistically significant. In which, the indirect effect from W to DT through the intermediate variable S is stronger than the indirect effect of D on DT through the mediated variable S.

**4.2.7. Summary of Hypotheses Tests:**

	Original sample (O)	Sample mean (M)	Standard deviation (STDEV)	T statistics ( O/STDEV )	P values
A → DT	0.263	0.264	0.105	2.494	0.013
D → S	0.370	0.386	0.122	3.035	0.002
S → DT	0.455	0.460	0.095	4.781	0.000
W → S	0.426	0.422	0.099	4.322	0.000
A x S → DT	-0.212	-0.213	0.070	3.015	0.003

**Table 1: Path coefficients**

After measurement model refinement and validation, the hypotheses presented in Chapter 2 were tested. The structural model results are presented in Figure 1 and Path coefficients in Table 1, The following hypotheses were tested:

***H1. There is a positive relationship between workforce transformation and strategic flexibility.***

The path from W to S was significant ( $p < 0.001$ ), in the direction hypothesized, and strong (0.426). The data supported the hypothesis.

***H2. There is a positive relationship between dynamic capability and strategic flexibility.***

The path from D to S was significant ( $p = 0.002$ ), in the direction hypothesized, and medium (0.37). The data supported the hypothesis.

***H3. There is a positive relationship between strategic flexibility and digital transformation.***

The path from S to DT was significant ( $p < 0.001$ ), in the direction hypothesized, and strong (0.455). The data supported the hypothesis.

***H4. Agile leadership strengthens the relationship between strategic flexibility and digital transformation.***

The path from AxS to DT was significant ( $p = 0.003$ ), in the direction hypothesized, and medium (-0.212) but it moderates in the opposite direction. This hypothesis was not supported by the data.

**5. CONCLUSION****5.1. Discussion**

Workforce transformation establishes a strong, positive, significant effect on strategic flexibility (the Original Sample coefficients(O)= 0.426,  $\rho$ -value < 0.001). The results indicate that frequent transformation of the workforce can enhance the likelihood of achieving strategic flexibility. This study confirms that the existence of workforce transformation, which combines knowledge, skills, and attitude of workers, is a precondition for achieving strategic flexibility. The study also shows that higher levels of workforce transformation in small and medium-sized enterprises (SMEs) can increase their ability to design strategic flexibility.

H2 is supported by the data. The findings demonstrate that dynamic capability has a positive effect on strategic flexibility (the Original Sample coefficients(O)= 0.37;  $\rho$ -value = 0.002). Dynamic capability, such as sensing, adaptiveness, innovation, networking, learning, and their integration, are important in developing strategic flexibility. Therefore, firms that focus on workforce transformation and dynamic capability are likely to invest resources in developing and supporting strategic capabilities, including strategic sensitivity, leadership unity, and resources fluidity.

In this study, it was found that there is a significant and positive relationship between strategic flexibility and digital transformation (the Original Sample coefficients (O) = 0.418;  $\rho$ -value < 0.001), which

is supported by the result of H3. Strategic flexibility has a strong impact on digital transformation, and this impact is enhanced by the combination of strategic planning, leadership, and resources.

According to the analysis, agile leadership has a negative moderation effect (the Original Sample coefficients(O) = -0.212;  $\rho$ -value= 0.013) on the interaction between strategic flexibility and digital transformation. This suggests that Agile leadership has a negative moderating effect on the relationship between strategic flexibility and digital transformation. This would suggest that the fast response of the leader followed by strategy flexibility may not be effective in achieving success in digital transformation implementation.

### **5.2. Contributions of the study:**

This research contributes to society and the scientific research world by examining the role of strategic flexibility and agile leadership in improving digital transformation in SMEs in the Central and Central Highlands regions of Vietnam. The findings of this research can help SMEs to take advantage of information technology advancements in their business processes, which can lead to improved competitiveness and economic growth. By understanding the importance of strategic flexibility, SMEs can respond quickly to changes and advances in information technology, and build dynamic capabilities to adapt to rapidly changing environments. This can help SMEs in Vietnam to improve their performance and contribute to the economic growth of the country. Additionally, the research highlights the importance of dynamic capabilities and workforce transformation in creating digital transformation in SMEs. because they enable firms to integrate, build, and reconfigure internal and external competencies to address rapidly changing environments. Dynamic capabilities refer to a firm's ability to adapt to changing circumstances, while workforce transformation involves developing the skills and knowledge of employees to meet the demands of digital transformation. By building dynamic capabilities and transforming their workforce, SMEs can respond quickly to changes and advances in information technology, and build the flexibility and agility needed to succeed in the digital economy. Overall, this research paper provides valuable insights into the factors that contribute to successful digital transformation in SMEs in the context of the Central and Central Highlands regions of Vietnam.

### **5.3. Limitations and Recommendations**

Similar to many studies, the study is not without certain limitations. First of all, in order to draw an accurate result upon the roles of agile leadership and strategic flexibility in improving SMEs digital transformation in Central and Central Highlands regions of Vietnam, the study needs an abundance of samples. However, this research is limited by its sample. Though the study is expected with a large sample size to reduce bias, data gathering is limited for the student authors due to tight budget and time constraints.

An additional important consideration is that the sampling process is fairly difficult. Because the survey respondents for this study are owners and managers at enterprises. With the group of authors who are students, the relationship, as well as understanding of this survey respondents, is still limited. So the data collection process takes a lot of time and effort.

As the authors mentioned above in the report, in the data processing process, the authors removed 2 items from the questionnaire because they did not have enough impact on the latent variable. And these 2 items are in the original scale of the research paper on the same topic in Malaysia that the authors refer to. This implies that SMEs in Vietnam are different and special compared to other countries. Therefore, it enhances that there should be studies dedicated to SMEs in the Central Highlands region as well as to all SMEs in Vietnam.

In addition, the sample size for this study is limited. Hence, if this research paper is to be developed, the author should collect more samples and on a larger scale to explore other interesting analyzes and results.

Finally, this research examines the concept of strategic flexibility in terms of strategy changes, leadership unity and resources fluidity. Besides, agile leadership is evaluated based on leader competencies in sharing responsibility, recognizing problem and decisions making, adaptive system and flexible structure. However, it is important to consider context-specific approaches to fully leverage these two processes and achieve distinct outcomes in different situations such as varying environments and stages of development (Rosing et al., 2011). Therefore, when SMEs require innovative and experimental approaches to navigate fast-paced changes, alternative measures for strategic flexibility and agile leadership should be considered. Future studies can explore different types of strategic flexibility and agile leadership within diverse environmental and temporal contexts.

## FACTORS AFFECTING THE DIGITAL STRATEGY AT SMALL AND MEDIUM ENTERPRISES IN DA NANG CITY

**Academic advisor: MSc. Hoang Ha<sup>1</sup>**

**Students: Nguyen Thi Viet Bac<sup>1</sup>, Nguyen Ngoc Nhi<sup>1</sup>, Pham Thi Yen Nhi<sup>1</sup>,  
Phung Khanh Linh<sup>1</sup>, Tran Thi Huu Tri<sup>1</sup>**

**ABSTRACT:** *This study uses the Research Framework Technology - Organization - Environment (TOE) to analyze the factors affecting the decision to apply digital strategy in small and medium-sized enterprises in Da Nang city. The study uses a quantitative method with 175 samples including a system of questions referring to three TOE contexts collected from employees and managers at small and medium enterprises in Da Nang. Research results show that technology contexts offer comparative advantages that support profitable growth for businesses, while at the same time there are risks that limit digital readiness. The study also encourages managers to increase employee support and facilitation in technology adoption, as well as encouraging government to enact promotional policies and finance digital transformation in business. This research provides useful and theoretical insights that enhance the knowledge of how firms adapt to technology adoption and advise managers and policymakers on how to optimize their efforts to promote technology in business.*

**Keywords:** *SME(s), TOE, digital transformation, digital strategy, technology, financial performance organisation, environment, enterprises, business, Da Nang.*

### 1. INTRODUCTION

#### 1.1. Overview of research in the subject area

Technology enables SMEs in emerging economies to improve their competitiveness and make better decisions. By applying digital technologies, SMEs can increase their information flow, reduce their operational costs, and enhance their quality to gain a competitive edge. However, digital transformation is not without its difficulties and disadvantages. It can also result in negative outcomes due to gaps in knowledge, misconceptions about technology applications, and low ability to expand resources and align them with business objectives.

#### 1.2. Reasons for doing this research

The need for innovation and development in all aspects where digital technology plays the role of an effective support tool. Therefore, the application of digital technology to businesses has attracted much attention from researchers, practitioners, and policymakers in this field. Although the application of digital technology is very important and urgent, SMEs in Da Nang City are considered to have a slower rate of access. This research has proceeded to find out the motivations and factors that limit the access and application of digital technology in these organizations and it also helps SMEs and local authorities to come up with specific solutions.

#### 1.3. Objectives of the study

- General objective: Assessing the factors affecting the digital strategy in SMEs in Da Nang City.

---

1 University of Economics – The University of Danang.

- The detailed goal is to find out the relationship between:
- + TOE factors and the strategy of applying digital technology in SMEs in Da Nang city.
- + The strategy of applying digital technology to financial performance in SMEs in Da Nang City.

#### **1.4. Research object, research scope**

##### **1.4.1. Research object**

Small and medium enterprises.

##### **1.4.2. Research scope**

Da Nang City, Vietnam.

#### **1.5. Methodology**

##### **1.5.1. Reasons for taking survey samples on employees and managers**

The decision to include both employees and managers in the research samples, rather than solely focusing on business owners, is supported by several academic justifications.

- Holistic Perspective:
- Employee Involvement:
- Managerial Decision-making:
- Organizational Culture and Structure:
- Stakeholder Alignment:

##### **1.5.2. Research methods**

###### **a) Data collection**

- The quantitative method was mainly used in the research

A questionnaire was used to collect data.

The number of valid surveys for analysis was 175 surveys.

- Sampling method:

The business matches the research topic and sends the survey to its employees and managers.

###### **b) Scale building**

The total of 8 independent groups of variables including Comparative advantages from digital transformation (as LTSS), Risks of applying digital technology (as RRUD), Support from top management (as UHQL), Organizational barriers (as RCTC), Effects of competitive pressure (as ALCT), Influence of government regulation (as QDCP), Digital Strategy (as CLKS), Financial performance of the company (as HQTC).

###### **c) Data analysis methods**

SPSS 20 and SmartPLS 4

###### **d) Data source:**

1. Primary data source

Source: The answers from 175 survey participants are employees of SMEs in Da Nang City.

2. Secondary data source

Source: From the Internet, magazines, books, newspapers, and related research papers

## **2. LITERATURE REVIEW AND THEORETICAL FRAMEWORK**

### **2.1. SMEs**

SMEs are businesses that have a certain size limit in terms of employees, revenues, or assets. Different countries and industries have different criteria for defining SMEs. SMEs are essential for the economy because they create many jobs, especially in developing countries. They also help with innovation and entrepreneurship. SMEs are the majority of the businesses and employment around the world and are a high priority for many governments.

### **2.2. Digital transformation**

Digital transformation is the process of using technology to change tasks or processes that are not digital into digital form, so that computers can help with information management and communication. It also means using digitized products or systems to create new ways of doing business, such as new organizational processes, business models or services.

### **2.3. Digital strategy**

A digital strategy is a company's plan to use technology to grow the brand. It can help employees reach customers, increase sales and showcase their brand effectively. A company's leadership team may create and change its strategy based on market needs, popular technology or platforms and business performance.

### **2.4. Financial performance**

Financial performance is a measure of a company's financial health in terms of assets, liabilities, equity, expenses, revenue, and profitability. It is determined by using various formulas that relate to business activities and show how efficient a company is. Financial performance is important for internal and external users to evaluate the company's health, status, and investment potential.

### **2.5. The impact of digital transformation on digital strategy**

Digital transformation is the process of using technology to reach business objectives. It provides a framework for digital strategy. Digital transformation can help enterprises enhance their customer experience by offering more customized and good service, and by knowing customers better.

### **2.6. TOE Research Framework**

The TOE framework is a model that explains the factors affecting technology application and innovation in a firm. It considers three contexts: technology, organization, and environment. Technology refers to the attributes of technology inside and outside the firm that can affect its suitability, innovation, and usefulness. Organization refers to the attributes, characteristics, and resources of the firm that can affect its size, structure, management, human resources, and linkages. Environment refers to the attributes of the business environment that can affect its industry, competition, customers, regulations, and macroeconomics. These three factors can create barriers or opportunities for technological innovation in a firm.

### **2.7. Studies in Vietnam have applied the TOE model**

- Application of TOE model to analyze intention to accept and continue to use information and communication technology in tourism in Da Nang
- Incorporating TAM and TOE models into the study of social network acceptance in retail business in Vietnam

- The determinants of innovation in Vietnamese manufacturing firms: an empirical analysis using a technology–organization–environment framework
- An extended Technology-Organization-Environment (TOE) framework for online retailing utilization in Digital Transformation: Empirical evidence from Vietnam
- Protecting organizational information security at home during the COVID-19 pandemic in Vietnam: Exploratory findings from Technology - Organization - Environment Framework

#### **2.7.1. Studies in other countries have applied the TOE model**

- Using TOE theoretical framework to study the application of ERP solution
- Social commerce application using TOE framework: An empirical investigation of Saudi Arabian SMEs
- A Conceptual Framework of RFID Application in Retail Using TOE Framework
- Factors Influencing SMEs' Application of Cloud Computing Services in Lebanon: An Empirical Analysis Using TOE and Contextual Theory
- Exploring Risks in the Application of Business Intelligence in SMEs Using the TOE Framework

#### **2.7.2. Overall assessments**

The TOE framework is different from other theories of technology adoption because it includes both internal and external factors in one model. However, the TOE framework has some problems, such as ignoring the interplay between the three factors, missing important constructs and variables, and being vague and changing from context to context.

#### **2.7.3. Analysis of TOE factors affecting the application of digital technology in businesses**

##### **2.7.4. Technological factors**

###### **e) Comparative advantage**

Digital transformation brings many long-term benefits, such as better use of data, process improvement, innovation enhancement, smarter outsourcing, and customer-centricity. It can also help businesses save time and money, increase income and efficiency, reach more markets and customers, share more information, persuade more customers, perform better, work better, make better products and services, track and measure performance and productivity, and decide and plan well.

H1. Comparative advantage has a positive influence on digital strategy in SMEs

###### **a) Risks**

Although digital transformation brings various advantages for business, it also comes with many risks, such as cyber-attacks, information insecurity, loss of important data, dependence on technology, legal compliance issues, and human factors that affect the quality, accuracy, security, and performance of the business.

H2: Application risks influences the decision on digital strategy in SMEs

##### **2.7.5. Organizational factors**

###### **b) Support from senior management**

Top management support is the availability of resources and policies that support managers in the organization's strategic vision. It influences organizational decisions, behaviors, and strategies, as well as the knowledge and expectations of technology benefits.

H3: Support from top management positively affects the strategy of digital technology in SMEs

### c) Organizational barriers

There are barriers that businesses encounter in the process of digital transformation, such as high investment costs, difficulty in changing habits and practices, lack of human resources, lack of digital infrastructure, lack of information, difficulty in integrating solutions, lack of commitment and understanding of leaders and employees, and fear of data leakage.

H4: Organizational barriers limiting the application of a digital strategy in SMEs

### 2.7.6. Environment factor

#### d) Competition

Competitive pressure is a factor driving the application of technology by enterprises. When businesses have to meet the requirements and expectations of stakeholders such as customers, legal entities, governments, commercial partners, and others, they tend to apply technology faster.

H5: Competitive pressure positively affects digital strategy in SMEs

#### e) Government regulations:

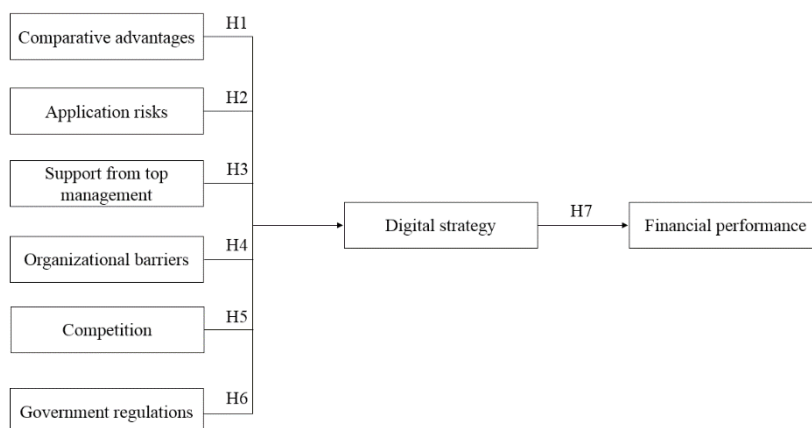

Government support is considered the most influential factor for digital technology application, especially in developing countries..

H6: Government regulations have a positive influence on the digital strategy in SMEs

H7. The digital strategy positively affects the financial performance in SMEs

The technology of digital transformation enhances business processes, even increases business revenue and income. It can increase satisfaction, better customer relegation, improve profitability and decrease minimum expenses.

Therefore, digital transformation application solutions bring more productive financial results.

## 3. RESEARCH RESULTS

### 3.1. General data

### 3.2. Data analysis

#### f) Outer loading

	ALCT	CLKS	HQTC	LTSS	QDCP	RCTC	RRUD	UHQL
ALCT1	0.770							
ALCT2	0.827							
ALCT3	0.812							
ALCT4	0.767							
CLKS1		0.733						
CLKS2		0.782						
CLKS3		0.802						
CLKS4		0.803						
CLKS5		0.726						
HQTC1			0.759					
HQTC2			0.851					
HQTC3			0.809					
HQTC4			0.700					
LTSS1				0.762				
LTSS2				0.775				
LTSS3				0.772				
LTSS4				0.790				
LTSS5				0.779				
QDCP1					0.804			
QDCP2					0.872			
QDCP3					0.784			
QDCP4					0.820			
RCTC1						0.780		
RCTC2						0.885		
RCTC3						0.881		
RCTC4						0.837		
RRUD1							0.775	
RRUD2							0.867	
RRUD3							0.792	
RRUD4							0.806	
UHQL1								0.845
UHQL2								0.850
UHQL3								0.829
UHQL4								0.780

- The Outer Loadings coefficient of the first-order variables are all greater than 0.7, so the first-order variables are significant in the model

**g) Construct Reliability and validity**

	Cronbach's alpha	Composite reliability (rho_a)	Composite reliability (rho_c)	Average variance extracted (AVE)
ALCT	0.805	0.806	0.872	0.631
CLKS	0.828	0.833	0.879	0.593
HQTC	0.786	0.788	0.862	0.611
LTSS	0.835	0.837	0.883	0.602
QDCP	0.839	0.851	0.892	0.674
RCTC	0.868	0.880	0.910	0.717
RRUD	0.826	0.834	0.885	0.657
UHQL	0.845	0.846	0.896	0.683

- The alpha coefficient of all items is mostly higher than 0.8, showing that the degree to which the scale is consistent and stable is good, only the alpha coefficient of the variable Financial Efficiency (0.788) is lower but still usable.

**h) Convergence**

- The AVE index of all variables is greater than 0.5, the scale achieves good convergent validity

**i) Discriminant validity**

	ALCT	CLKS	HQTC	LTSS	QDCP	RCTC	RRUD	UHQL
ALCT								
CLKS	0.579							
HQTC	0.585	0.712						
LTSS	0.548	0.658	0.518					
QDCP	0.718	0.519	0.468	0.447				
RCTC	0.744	0.443	0.311	0.387	0.590			
RRUD	0.368	0.275	0.264	0.304	0.331	0.501		
UHQL	0.511	0.571	0.540	0.577	0.467	0.416	0.387	

- Through the HTMT index, all HTMT index pairs of the latent variables are less than 0.85. Therefore, all pairs of variables ensure differentiation from each other.

**j) Collinearity statistics (VIF)**

	ALCT1	ALCT2	ALCT3	ALCT4	CLKS1	CLKS2	CLKS3	CLKS4	CLKS5
VIF	1.641	1.930	1.757	1.478	1.605	1.617	1.824	1.889	1.514
	HQTC1	HQTC2	HQTC3	HQTC4	LTSS1	LTSS2	LTSS3	LTSS4	LTSS5
VIF	1.943	2.283	1.738	1.321	1.924	2.013	1.679	1.763	1.733
	QDCP1	QDCP2	QDCP3	QDCP4	RCTC1	RCTC2	RCTC3	RCTC4	
VIF	1.903	2.213	1.804	1.970	1.780	2.480	2.507	2.252	
	RRUD1	RRUD2	RRUD3	RRUD4	UHQL1	UHQL2	UHQL3	UHQL4	
VIF	1.747	2.213	1.796	1.769	2.151	2.215	1.917	1.640	

In the Outer model - List section, we see that most of the VIF coefficients are less than 3, indicating that the independent variables are weakly correlated with each other. The Inner Model - List section has all VIF indices below 3. Conclusion, the model does not occur collinearity.

**k) Assessment of Impacts (PATH COEFFICIENTS of Bootstrap analysis) (P values , R-square )**

	Original sample (O)	Sample mean (M)	Standard deviation (STDEV)	T statistics (O/STDEV)	P values
ALCT → CLKS	0.134	0.134	0.086	1.556	0.120
CLKS → HQTC	0.583	0.586	0.057	10.213	0.000
LTSS → CLKS	0.333	0.325	0.076	4.405	0.000
QDCP → CLKS	0.133	0.140	0.079	1.685	0.092
RCTC → CLKS	0.057	0.052	0.081	0.703	0.482
RRUD → CLKS	-0.023	-0.010	0.079	0.294	0.769
UHQL → CLKS	0.199	0.199	0.086	2.301	0.021

- The hypotheses between Competitive Pressure, Organizational Barriers, Application Risk and Digital Strategy have P values > 0.1. This proves that the hypothesis about them in the above statistics is ineffective. That means, the factors of Competitive Pressure, Organizational Barriers, Application Risk do not affect the use of Digital Strategies.

	R-square	R-square adjusted
CLKS	0.418	0.397
HQTC	0.340	0.336

- The adjusted R squared of Digital Strategy is 0.336, so the independent variable Digital Strategy explains 33.6% of the variation of Financial Efficiency.

**l) Correlation**

	ALCT	CLKS	HQTC	LTSS	QDCP	RCTC	RRUD	UHQL
ALCT	1.000	0.476	0.468	0.454	0.594	0.619	0.301	0.424
CLKS	0.476	1.000	0.583	0.553	0.439	0.378	0.228	0.481
HQTC	0.468	0.583	1.000	0.431	0.382	0.260	0.213	0.440
LTSS	0.454	0.553	0.431	1.000	0.379	0.332	0.255	0.483
QDCP	0.594	0.439	0.382	0.379	1.000	0.506	0.283	0.392
RCTC	0.619	0.378	0.260	0.332	0.506	1.000	0.425	0.354
RRUD	0.301	0.228	0.213	0.255	0.283	0.425	1.000	0.325
UHQL	0.424	0.481	0.440	0.483	0.392	0.354	0.325	1.000

- Organizational barriers have the greatest impact on competitive pressures, and conversely, application risks have the least impact of the rest of the factors. Financial performance has the most impact on digital strategy, but not significantly. Comparative advantage has the strongest correlation with digital strategy. Government regulation affects competitive pressures more than factors such as application risk or financial performance, etc. Support from management has a weakly correlated relationship with most of the rest of the factors.

**3.3. Discussion**

**3.3.1. Discussion**

	Original sample (O)	Sample mean (M)	Standard deviation (STDEV)	T statistics ( O/STDEV )	P values
ALCT -> CLKS	0.134	0.134	0.086	1.556	0.120
CLKS -> HQTC	0.583	0.586	0.057	10.213	0.000
LTSS -> CLKS	0.333	0.325	0.076	4.405	0.000
QDCP -> CLKS	0.133	0.140	0.079	1.685	0.092
RCTC -> CLKS	0.057	0.052	0.081	0.703	0.482
RRUD -> CLKS	-0.023	-0.010	0.079	0.294	0.769
UHQL -> CLKS	0.199	0.199	0.086	2.301	0.021

There are 3 out of 6 variables that affect digital strategy. Firstly, top management is the main decision maker and an indispensable factor to build an ecosystem for business to apply technology. Digital transformation helps SMEs to observe the environment, make better decisions, and provide accurate and comprehensive data and information... Moreover, some studies have found that digital transformation creates financial performance for businesses and enhances their capabilities.

On the other hand, competitive advantage in smaller firms often arises accidentally because of operating circumstances surrounding the enterprise. This shows that within the same tier as SMEs, if some of them achieve a positive transformation on digital, it will create a competitive advantage over their competitors in the same area. Then, government regulations have less influence on digital application strategies. Most regulations are beneficial to process application of digital, but it is also limited to intellectual property rights. According to other studies the application of digital transformation is a challenge for SMEs due to the lack of expertise and the manager’s lack of confidence in their abilities. Apart from that, the loss of control over confidential data and the risk of disclosure and leakage of information to competitors negatively affects them to the application of digital transformation.

**3.3.2. Policy implications**

In practical terms, the results can be used to develop business strategies and support decision-making for managers. Theoretically, the research has contributed to enriching information related to the factors affecting the organizational decisions and confirmed the empirical evidence on the usefulness of digital transformation.

In the technology aspect, the above hypotheses suggest businesses should be more daring in approaching changes in technology and have measures to prevent technology risks and information.

In the organizational aspect, in Da Nang, the majority of enterprises are small in scale and lack knowledge of management and technology. Therefore, the creation of affiliate programs between enterprises and technology organizations is essential.

In the environmental aspect, SMEs in Da Nang need to get out of their comfort zone, set innovation, and compete in a world dominated by advanced technology. Digital transformation not only helps SMEs transform themselves, thereby receiving more new business opportunities.

Digital strategy helps to reduce the waste of budget and money without achieving efficiency and increasing corporate profits. Because after each campaign, measuring and adjusting the strategy will help businesses achieve their goals faster.

### **3.3.3. Limitations and directions for further research**

First, the survey sample was limited to SMEs, which differ in resources and structural flexibility compared with large enterprises.

Second, the study only focuses on Da Nang city. Therefore, in the following studies, these limitations can be overcome by expanding the scope of the study - not only in one city but also in the whole destination of Vietnam.

Third, the data collection method should be combined with the direct interview method to answer the questions arising from the interviewees thoroughly.

## **4. CONCLUSION**

The study used the TOE model to study the factors affecting the digital transformation of SMEs in Da Nang. This demonstrates that technological, organizational, and environmental contexts have a dramatic impact on decisions related to digital technology usage.

According to technology context, empirical research has proven that digital transformation will bring positive results by enhancing working quality and efficiency, influencing decisions to apply technology in organizations. SMEs should apply digital transformation to gain comparative advantage even if it challenges their businesses.

According to organizational context, top manager support has been proven to have a positive effect on applying digital technology strategy. The findings highlight the importance of top management support in driving the application of digital transformation in organizations. However organizational barriers, lack of capital/ financial resources does not affect the maximum exploitation of digital technology.

According to the environmental context, digital strategy in SMEs is not strongly influenced by government regulations. Local governments have not had many solutions to reduce cost, establish technology infrastructure and regulatory frameworks still lack the agility. In the era of digital transformation technology 4.0, the application of that by businesses is an advantage for SMEs to gain competitive advantages, survive and develop.

## THE IMPACT OF RISK – TAKING BEHAVIOR ON CREDIT RISK: EVIDENCE FROM VIETNAM

**Author: Nguyen Thanh Duy<sup>1</sup>, Dang Khanh Van<sup>1</sup>, Nguyen Minh Tan<sup>1</sup>, Tran Huong Ly<sup>1</sup>, Do Viet Tu<sup>1</sup>**

**Mentor: Pham Thi Hoang Anh<sup>1</sup>**

*ABSTRACT: After the crises, the complexity of the monetary transmission mechanism is becoming more evident when they not only affect money supply, credit, and interest rates but also can affect the tendency to accept risks of subjects in the economy, especially financial intermediaries. This study aims to evaluate the impact of this behavior on the loss loan reserve ratio of commercial banks in Vietnam based on panel data regression model. Some implications and policies have been recommended to State Bank of Vietnam to operate monetary policy flexibly and cautiously so that the effectiveness of the risk-taking channel is maximized. Keywords: low – interest rate; risk – taking behavior; credit risk; State Bank of Vietnam.*

### 1. INTRODUCTION

Since the Global Financial Crisis of 2008 and economic shocks of the COVID-19 crisis, the question of whether low interest rates encourage bank risk-taking has been extensively debated, especially in the context of advanced economies (Altunbas, Gambacorta, & Marques-Ibanez, 2014; Delis, Hasan, & Mylonidis, 2012; Jiménez, Ongena, Peydró, & Saurina, 2014). Because poor risk management practices, including excessive risk-taking behaviors by commercial banks, have been identified as one of the key contributing factors to the outbreak of the Global Financial Crisis.

Recent studies show that “too low for too long” interest rates result in higher risk-taking by banks through a “risk-taking channel”. Low-interest rates maintained over a prolonged period through monetary policy may incentivize banks to lend more (Maddaloni and Peydro, 2011) and accept a higher level of risk (Altunbas et al., 2014; Jimenez et al., 2014) in order to generate returns on their investments for four reasons: (i) low-interest rates promote risk-taking through the effect of interest rates on valuation, earnings and cash flow; (ii) low-interest rates create incentives for bank managers and businesses to seek profits; (iii) low-interest rates increase equity value and encourage credit institutions to accept more risks; (iv) The increased level of information transparency and policy commitment of the Central Bank reduces instability, causing market participants to underestimate risks, thereby increasing the desire to accept risks. bank risk. If banks are incentivized to take on excessive risks by low-interest rates and other factors, and this behavior is not well controlled, it could lead to an imbalance between the banks’ ability to manage risks and the level of risks they are taking on. This could potentially pose risks to the stability and functioning of the financial system. The collapse of major financial institutions and financial systems around the world such as in the US, Spain, Turkey, and Ireland,... since 2008 has shown the seriousness of risk-taking behavior of financial institutions.

In Vietnam, during the period 2015-2019, the effectiveness of the transmission mechanism of the monetary policies has been increasingly improved. However, the COVID-19 pandemic has posed significant challenges for businesses and people which made the State Bank of Vietnam implement a loosening

---

<sup>1</sup> Banking Academy.

monetary policy with relatively low-interest rates to support capital for production and contribute to the implementation of social security policies. Credit growth has always exceeded the target set by the State Bank of Vietnam and the ratio of credit to GDP reached 124% at the end of 2021, which was one of the highest in the world. The increased financial leverage of the business system, and speculative markets such as stocks, real estate, and foreign currencies have caused many consequences, indicating the development of this risk-taking channel. Our paper aims at obtaining to find the impact of risk-taking behavior on credit risk through loan loss provision in Vietnam. In Vietnam, there have not been any reports or scientific studies indicating the impact of the risk-taking channel. Previous studies only determined the overview of the risk-taking channel. Therefore, based on preliminary content from previous studies, our paper focuses on assessing the impact of risk-taking behavior on the credit risk of commercial banks.

The remainder of this paper is structured as follows. Section 2 provides a literature review about the impact of risk-taking behavior. Section 3 introduces the data set and the empirical methodology. Section 4 presents the results of risk-taking behavior on bank risk. Section 5 concludes with some policy implications.

## 2. LITERATURE REVIEW

Low interest rates maintained over a long period of time through loosening monetary policies not only encourage banks to lend to customers as described in the traditional credit channel but also encourage banks to accept higher levels of risk (Altunbas et al, 2010). This is the main cause leading to the emergence of the risk-taking channel, a new channel in the transmission of monetary policies. Unlike traditional transmission channels, the risk-taking channel began to be studied from the beginning of the 21st century and received special attention after the outbreak of the financial crisis.

Using a VAR regression model, data from 140 banks in Europe and from the European Central Bank (ECB) from 2003 to 2016, Matthias Neuenkirch and Matthias Nockel (2018) evaluated the impact of the ECB's interest rate cut on the behavior of banks in the euro area. The authors pointed out that during the period of low-interest rates, banks were willing to lower credit standards to provide more credit. Although banks knew they had to maintain stable credit operations during this period, they were unsuccessful in stabilizing credit supply, causing instability in the financial system in the euro area as well as the global financial system.

Nimrod Segev (2020) presented the impact of the monetary policy transmission mechanism through the risk-taking channel in the United States. The United States is one of the countries most affected by the 2008 financial crisis. In a short period from May 2001 to December 2002, the FED reduced the interbank lending rate 11 times from 6.5% to 1.75%. In an easy credit environment, US banks tended to lend recklessly to stimulate the development of the real estate sector and construction industry as a driving force for economic growth. The real estate bubble gradually formed and developed to an extreme level and burst, leading to non-performing loans which many banks could not recover from, causing significant losses and the collapse of many financial institutions. Nimrod Segev's research also showed that the monetary policy transmission mechanism affects the scale and risk acceptance level of banks. When the transmission mechanism is maintained over a long period of time, banks will loosen their risk sensitivity to seek more profits, leading them to accept more risk to provide unsecured loans.

In addition, Paligorova and Jimenez's study (2012) evaluates the effectiveness of the risk-taking channel from the perspective of the lending behavior of banks. The article was based on data on the information of loans combined with the balance sheet data of banks in Canada from 1993 to 2010. The research results showed that the trend of reckless lending by banks was clearly shown during the period of low interest rates through an increase in the number of risky loans that were illiquid.

In Viet Nam, Nguyen Thi Kieu Nga (2021) pointed out the evidence of a positive relationship between interbank interest rates and risk-taking level. The 3-month and 6-month term deposit rates have a positive impact on the risk acceptance level, reflecting the high information asymmetry in Vietnamese banks. The real estate bubble bursting at the end of 2011 and the beginning of 2012 caused adverse effects on real estate businesses and banks involved in financing these businesses. After this period, banks continued to increase mobilized capital to invest in real estate, causing interbank interest rates to continuously increase from about 9% in 2009 to nearly 11% in 2010, reaching a peak of almost 14% in 2011. This reflects the instability of the interbank lending system due to the overuse of mobilized capital to finance the real estate market. The “put all eggs in one basket “ behavior of many banks led to the 2012 non-performing loan crisis.

Furthermore, the study of Ha Thi Sau et al. (2013) provided evidence of the existence of the risk-taking channel in the transmission of monetary policy. The authors found that in the years 2006-2007 and 2009-2010, monetary policy was loosened, increasing the risk acceptance level of the banking system, which was reflected in the pursuit of high profit and growth targets, and contributed to the expansion of the scale of the banking system.

In general, domestic studies currently only provide an overview of the risk-taking channel. Therefore, based on the preliminary content from previous studies, the research group’s study has two new contributions to the topic. First, our paper focuses on in-depth evaluation of the effectiveness of the risk-taking channel from the perspective of its impact on credit risk. Second, the study is particularly relevant in the context of the COVID-19 pandemic where the central bank has lowered interest rates, making the risk-taking behavior of banks more evident.

### 3. METHODOLOGY AND MODEL SPECIFICATIONS

#### 3.1. Model

The research team uses a simple linear regression model based on previous research models to analyze and evaluate the impact of the risk-taking channel of monetary policy on the loss loan provision - loss loan reserve of listed commercial banks in Vietnam from 2011 to the end of 2022. Based on the research of Mite Mitesk et al (2018), Neuenkirch, M., and Nöckel, M. (2018), V.D.Dang and V.C.Dang (2020) the research team builds a model to assess the impact of behavior Risk tolerance to the size of banks in Vietnam with the variables shown in Table 1:

Moreover, to check the consistency of the model, we alternately use the Rate variables (Lrate, Prate, and ONrate) to represent the monetary policy variable to clearly see the risk-taking behavior of commercial banks in Vietnam.

**Table 1: Variables**

Variable	Variable name	Expected impact
RATE	Lrate	+
	Prate	+
	ONrate	+
ROE	Return on equity	-
SIZE	Bank's size	+
GDP	Economic growth	-
INF	Inflation	-
COVID	COVID-19 period	+

### 3.3. Data

#### 3.3.1. Dependent variable

**Loss loan reserve ratio (LLR):** Loss loan reserve is an amount set aside to provide for possible losses due to the credit institution's customers' failure to fulfill their obligations. commitment service. Provisions for risks are calculated according to the principal outstanding balance and accounted into operating expenses of credit institutions. The setting up of provisions for credit risks is based on the classification of debts at the bank. Credit institutions and banks base on qualitative and quantitative standards to assess the risk level of loans and off-balance sheet commitments, on that basis, classify debts into debt groups. fit. LLR represents each bank's provision for its loans, mainly belonging to the credit group classified as Bad debt - or Non-performing loan.

#### 3.3.2. Independent variable

- Group of macro variables

**Economic growth (GDP):** Measured by the national economic growth indicator, to show the development potential of a business in the economy. In a state of stability and growth, the economy will open up to new investment opportunities, introducing new rigorous conditions for businesses to find the right investors with the right capital to invest. for new projects, leading to an impact on the use of debt for new investment activities. This indicator has a positive effect on the performance of enterprises. An increase in GDP causes businesses to attract investors, increases business output and consumer income, leading to increased spending and boosting markets, increasing corporate profits.

**Inflation Rate (INF):** Along with economic growth (GDP) is the inflation rate. Fofack (2005) and Klein, N. (2013), macro factors including economic growth rate, inflation rate also affect the micro factors of the bank.

**Interest Rate Variables (Rate):** In fact, there is still no consensus on the best interest rates to reflect the monetary policy stance in the existing literature (Altunbas et al. et al., 2010; Chen et al., 2017; de Moraes et al., 2016; Ehrmann, 2003; Khan et al., 2016; Olivero et al., 2011; Sáiz et al., 2018; Yang & Shao, 2016) Therefore, the authors have used 3 alternately 3 different interest rate variables, namely average lending rate of commercial banks - or lending rate (Lrate), policy interest rate (Prate) and interbank interest rate - or overnight rate (ONrate). The research team selected lending interest rates due to available data and suitable for Vietnam. In addition, with the above discussion on monetary policy, lending interest rate becomes the most appropriate indicator of monetary policy in Vietnam, where the SBV regularly makes adjustments and interventions to regulate monetary policy. the borrower's cost of capital. Next, the research team approaches the operating interest rate that the SBV uses to charge commercial banks for short-term credit transactions as lenders of last resort. The operating interest rate can be raised or lowered to stabilize or regulate a country's economic activity. The interbank rate - or overnight rate, is the interest rate used by banks in transacting with each other. The overnight interest rate is generally lower than other interest rates and is seen as the base rate of the economy, as well as an important indicator to be watched in the monetary policy of several countries.

- Group of micro variables (characteristics of commercial banks)

Besides, the research team also takes into account a number of bank-specific factors, including:

**Bank Size (SIZE):** First, larger banks can benefit from portfolio diversification and economies of scale, which will reduce their exposure to risk. them (Abedifar et al., 2013; Tan and Floros, 2013). Second, the relationship between bank capital and bank risk could be negative, as higher capital buffers make bank owners more careful with their investments.

**Return on Equity (ROE):** Using the relationship between profit after tax and the capital of the business owner to determine profitability, we use the formula:

$$\text{Return on Equity} = \text{Net income Shareholder's equity} \times 100\%$$

This index most clearly reflects the production and business efficiency of enterprises from owners' equity. The larger this coefficient, the higher the return to the owner's equity, the owner's investment capital is also managed and used properly. Profit margin shows us how much profit a business will make when they spend 1 dollar of equity.

- Dummy

In addition, the group also used a dummy variable COVID, representing the time when the Covid-19 epidemic appeared in Vietnam. Elnahass et al (2021) assert that the COVID-19 crisis has devastated many banks worldwide. Every country has had to implement certain policies to minimize the spread of the disease. The most prominent is implementing de-globalization by closing the border between

### 3.4. Descriptive Statistics

We collect 2 groups of data including: (i) Micro data of 19 banks for the period 2011 - 2022 from financial statements (ii) Macro data from the World Monetary Fund and the World Bank. world, the S&P Global dataset. Descriptive statistics of the variables in the model are shown in Table 2.

**Table 2: Summary statistics**

Variable	Obs	Mead	Std. Dev.	Min	Max
LLR	228	1.387719	0.472655	0.19	3.12
SIZE	228	19.11645	0.9900092	16.53	21.47
ROE	228	12.44	9.086617	-56.33	30.64
GDP	228	5.845	1.567093	2.56	7.98

Lrate	228	9.0775	2.972528	6.96	16.95
Prate	228	6.916667	2.74146	4	15
ONrate	228	4.11	3.413069	0.18	14.12
COVID	228	0.25	0.4339654	0	1

Source: Author's calculation from STATA

The study was checked the defects of the model including: (i) Multicollinearity test by VIF coefficient and shows that the model does not have multicollinearity phenomenon (ii) Hausman test shows that  $Pro > \chi^2 > 0.05$  thus accepting the random effects regression model as optimal; (iii) The variable variance test results in  $p\_value < 0.05$ , thus rejecting the hypothesis that the variance across entities is constant. (iv) Autocorrelation test results  $Prob > F < 0.05$ , thereby showing that the model has autocorrelation. Therefore, the research team used additional correction Cluster Robust SE to overcome defects.

### 4. FINDINGS AND COMMENTS

We use the Hausman test along with Cluster Robust SE calibration to handle the model's defects and shows that the optimal model for 3 data series about 3 different interest rates with (1) (2) (3) Lrate, Prate and ONrate are the fixed effect model, respectively.

*First, the panel data regression results indicate that the coefficient of the lending rate, policy rate, overnight rate variable is positive with respect to loan loss provision and statistically significant at the 1 percent level.* This finding is also in line with Khemraj and Pasha (2009), Farhan et al. (2012), Borio and Zhu (2012) who showed that when the lending rate increases, default risk on the balance sheets of banks rises. In particular, Borio and Zhu (2012) found that expansionary monetary policy in the long term will cause inflation which forces

central banks to raise interest rates to control inflation. Higher rates make loan repayment harder by increasing the interest burden of borrowers, which in turn, lead to higher loan default rates. An increase in NPLs can have a negative impact on credit institutions, particularly in terms of their ability to collect liquidity. Furthermore, if the increase in NPLs occurs within a particular economic sector or industry, it could pose a heightened risk to banks that are particularly exposed in that area. In such cases, the losses from NPLs could spill over to other banks and have broader implications for the entire financial system in the country. In the early years of the 21st century, many central banks around the world lowered interest rates in an attempt to stimulate economic growth. This led to an increase in lending by credit institutions and a corresponding increase in borrowing by consumers and businesses. However, when interest rates suddenly reversed and began to rise again, it put pressure on borrowers to repay their loans, which led to an increase in NPLs and bad debts. This, in turn, contributed to the financial crisis of 2007-2008, which had far-reaching effects on the global economy. Recently, due to COVID-19 pandemic interest rates were lowered by central banks encouraging credit institutions to increase lending until inflation starts to rise again, potentially leading to an increase in NPLs.

**Table 3: The impact of risk-taking behavior on LLRs**

	(1) LLR		(2) LLR		(3) LLR	
Lrate	0.192 [5.58]	***

The table reports the estimated results using the Fixed Regression Model. The dependent variable is GDP economic growth. The standard error is in parentheses. ***, ** and * at the 1%, 5% and 10% significance levels, respectively.						

Source: Author's calculation from STATA

**Second, we find that the coefficient of the interaction bank size with LLR variable is positive at the 1 per cent level.** Lower interest rates can encourage banks to expand their lending activities and take on more risks, potentially leading to an increase in scale as well as NPLs. This is consistent with the findings of Astrini et al. (2014) and Barus and Erick (2016) that larger banks might have a higher bad debt ratio.

Larger banks often have broader lending capabilities and can lend with more significant amounts. However, they may also face higher financial risks and may need to make appropriate credit risk provisions to deal with potential risks, including NPLs. In Vietnam, the three big banks BIDV, VPBank, and VietinBank have always led the list of the largest bad debts among listed banks. Specifically, in 2022, VP Bank is the bank with the most bad debt with nearly VND 25,100 billion of bad debt. In which, most of them come from consumer finance company FE Credit, the bad debt of the parent bank in 2022 is just over 10,000 billion dong. Second is BIDV with the size of bad debt at 17,622 billion dong, up 30% compared to the end of last year. Another big bank, VietinBank, also ranked right after that in third place with the number of bad debts increasing by 10% compared to the end of 2021, to 15,726 billion dong.

**Another interesting result is the positive relation found between GDP growth and bank risk.** However, this result contradicts the findings of Salas and Saurina (2002), Fofack (2005), Jimenez and Saurina (2006), Khemraj and Pasha (2009), Mwegu (2015) who showed that growth economy has a negative impact on bad debt and loan loss provision ratio. Specifically, the authors argue that a strong economy with low unemployment and steady growth can help borrowers improve their financial situation, making it easier for them to repay their debt and limit the amount of bad debt. However, we found that banks and other lending institutions can be overly optimistic in their lending practices during strong economic times, leading them to extend credit to borrowers who may not be able to afford it. This optimism can lead to an increase in bad debt accumulation when economic conditions deteriorate or when borrowers face financial difficulties. Meanwhile, according to data from the SBV, credit balances of credit institutions increased from 121% of GDP in 2012 to about 142% of GDP in 2018, the strongest credit growth in 2016 with 18.2%. To ensure stability and reduce risks for credit institutions, with the goal of quickly and completely handling bad debts of credit institutions in the 2016-2020 period, the State Bank has developed and submitted to the National Assembly for approval Resolution No. 42. /2017/QH14 dated June 21, 2017 on piloting bad debt settlement of financial institutions (NQ 42) in order to quickly and completely handle bad debts of credit institutions and Decision No. 1058/QĐ-TTg approving the basic scheme restructuring credit institutions associated with bad debt settlement in the 2016-2020 period has helped the industry's bad debt ratio decrease from 10.58% in 2016 to 3.81% in 2020.

**In the case of inflation, we find that inflation has negatively impact on credit risk of banks.** This implies that high inflation can lead to currency depreciation, which may result in a decrease in the value of loan loss provisions. Moreover, when inflation is high, central banks may raise interest rates to control it. This could increase the cost of borrowing for banks, including the cost of the short-term loans. As a result, banks may find it more difficult to meet their liabilities and may face additional credit risk, as they could experience an increase in defaults on loans. The evidence is also in line with the findings of Hai and Duong (2021), Shao et al (2017) who argue that inflation has a negative impact on the risk provision ratio of credit institutions.

**Finally, the model also shows that the COVID variable has a positive effect on credit risk at the 1 per cent and 5 per cent levels.** This conclusion is consistent with the results of previous studies: Ratnovski and Lev (2020), Ahmed and Abedin (2021), Lawrence Kryzanowski (2023). COVID-19 has had a negative impact on many economic sectors, including credit risk. The COVID-19 pandemic has indeed led to a slowdown in the global economy and caused financial strains, resulting in increased risks to financial institutions and systems. The pandemic has disrupted economic activity across many sectors and caused widespread job losses, which has led to a rise in credit risk for banks and other financial institutions. According to the General Statistics Office, in 2020, Vietnam had 32.1 million people aged 15 and higher nationwide negatively affected by COVID-19. Those with income decreased to account for 69.2 percent, those with staggered working hours or

layoffs and rotating leave at 39.9 percent, and those having to quit working or stop their economic activity at 14 percent. Vietnam's working age unemployment rate for the whole year of 2020 is 2.48%, 0.31 percentage points higher than in 2019 and the highest in the past 10 years. By 2021, only in the second quarter of 2021, the whole country had 557 thousand workers lost their jobs; 4.1 million people had to suspend production and business; 4.3 million people have their working hours cut or forced to take time off from work or rotational leave; and 8.5 million workers lost income. During the outbreak of the COVID-19 pandemic, the labor market in Vietnam faced difficulties leading to an increase in unemployment and a decrease in income, so people and businesses may have difficulty in paying debts. The increase in the level of bad debt also means an increase in credit risk for financial institutions and banks. The labor market in Vietnam faced difficulties during the COVID-19 pandemic, with increases in unemployment and reductions in income for many individuals and businesses. Furthermore, the increase in bad debt due to difficulty paying debts may have led to an increase in credit risk for financial institutions and banks.

## 5. CONCLUSION

Based on quantitative modeling, research shows that credit institutions exhibit risk-taking behavior, and the pressure of non-performing loans is becoming increasingly prevalent. The non-performing loan ratio is trending upwards, which affects the effectiveness of credit institution operations and disrupts the achievements of restructuring phases for credit institutions in the 2016-2020 period. Therefore, the SBV needs to be flexible in using tools and measures to manage the risk-taking behavior of credit institutions as well as addressing non-performing loans.

To minimize risk and non-performing loans, the SBV needs to promote credit institutions to enhance supervision and risk management by utilizing risk prevention tools. This includes monitoring, assessing, and tracking changes in relevant risk indicators associated with loan portfolios. Thus, the intervention of the SBV is essential, including the use of economic tools such as: (1) Minimum capital adequacy ratio (CAR) tool: By applying this tool, credit institutions can ensure that they have sufficient capital to cope with potential risks and meet customer needs. It assesses and monitors the risk levels of credit institutions; (2) Tight control of minimum capital safety: This tool helps ensure that credit institutions maintain a minimum level of equity to cope with potential risks; (3) Short-term funding ratio and medium to long-term lending ratio: These economic tools are crucial for minimizing risk and maintaining the stability of the financial system. The short-term funding ratio ensures that credit institutions do not overly rely on short-term funding, enhancing their flexibility. The medium to long-term lending ratio helps ensure that credit institutions do not depend on short-term debt and reduce risks associated with short-term lending to customers. Other tools, such as risk threshold tools, interest rate adjustments, and managing liquidity, can also be utilized.

Secondly, the SBV should actively inspect and supervise banks, forecast risks, and ensure timely safety measures to prevent risks from occurring during an economic recession caused by the impact of the COVID-19 pandemic. To prevent risks during an economic recession, banks should implement effective risk management measures, monitor changes in market interest rates, and adjust lending rates accordingly. The SBV should also encourage banks to conduct comprehensive assessments of loan portfolios to identify and classify non-performing loans and implement measures to address them. Strengthening monitoring and inspection activities related to lending operations will help detect and address risks in a timely manner when crises occur, reducing the burden of dealing with potential risks.

To enhance supervision, it is recommended that the SBV use credit monitoring tools as an important means to monitor the credit situation and evaluate risks associated with approved loans. This tool ensures

that approved loans meet credit safety standards and enables the early detection of potential risks. Credit monitoring tools may include identifying indicators to assess credit risk (such as indicators related to borrowers' debt repayment ability, interest payment capability, and financial status), monitoring loan portfolios and borrowers, and analyzing credit trends. The credit monitoring system will support the SBV in early detection of high-risk loans, enabling preventive and timely actions. This tool is crucial in ensuring credit safety and financial stability in the face of shocks. Additionally, utilizing risk management tools for lending, such as COSO ERM (Committee of Sponsoring Organizations of the Treadway Commission Enterprise Risk Management) or ISO 31000 (International Organization for Standardization Risk Management), can assist the SBV in evaluating and managing credit risks and non-performing loans in the banking system in the post-COVID-19 period. Both frameworks provide systematic processes to identify and evaluate credit risks, and establish risk management measures to minimize their impact.

## IMPACT OF ATTENTION INVESTORS ON FLUCTUATIONS IN THE VIETNAMESE STOCK MARKET

**Author: Phan Thi Hang Ngan<sup>1</sup>, Ngo Thi Thanh Truc<sup>1</sup>, Vu Thi Kim Anh<sup>1</sup>, Trinh Tuyet Nhi<sup>1</sup>**

**Mentor: Le Hai Trung<sup>1</sup>**

**ABSTRACT:** *This research paper studies the impact of investors' attention on the operation and volatility of Vietnam's stock market in the period of 2018 to the present. More specific, we built a research model of investor interest on the basis of investors' online Google search behavior. Since then, we found that the SVI - index reflects the search volume on Google as a reliable representative of investor interest in stocks in particular and the whole stock market in Vietnam in general. Specifically, we also have shown that investor interest is strongly correlated with trading volume and is a significant determinant of liquidity, profitability and stock market volatility. Most importantly, this paper was conducted during a sample period even before, during, and after the financial crisis caused by the outbreak of the Covid-19 pandemic worldwide.*

**Keywords:** *Google search volume, SVI, investor attention, Vietnam stock market, liquidity of stocks, profitability.*

### 1. INTRODUCTION

Investor behavior is a combination of behavioral psychology effects and the perception and understanding of economics from which to make investment decisions. That behavior does not always follow the principles available but is subject to the influence of emotions, experience and practice. Therefore, in each case, each investor may have different levels of reaction to market fluctuations. From there, the attention of investors can affect volatility in the stock market. Specifically, the interest of investors is closely related to the total trading volume on the stock market. Empirical studies such as Barber (2007); Amal Aouadi et al. (2013); Yu Yuan (2015)... have shown that increased investor attention will increase the total volume of transactions. Besides, investor attention is often directly proportional to trading volume, specifically when a stock receives little investor attention, the trading volume of that stock decreases. In addition, changes in investor interest can affect the liquidity of each stock in the market (Seasholes et al., 2007); or the investment in advertising can also affect the liquidity and profitability of company shares (Chemmanur and Yan (2019)). Therefore, the attention of investors has certain impacts on the change of price and profitability in the market. With each level of stock and the state of the market, it leads to the increase or decrease of the price and the rate of profit. In addition, there are also many articles by experts who have conducted research on the above issue.

Since its establishment, Vietnam's stock market has always played the role of medium and long-term capital mobilization channel for businesses, with the number of individual investors accounting for a large proportion. In general, Vietnam's stock market in the last 5 years has a lot of fluctuations due to the impact of epidemics, wars... In 2020, the stock market declined sharply in the first phase of the year, but then thanks to the efforts of the Government and the state, the stock market indexes have grown again. Continuing after the upward momentum of the market in 2020, 2021 continues to be a sublimation year of Vietnam's stock market. However, this stock market has potential risks due to slightly hot and out of phase growth compared

<sup>1</sup> Banking Academy.

to the real economy, in the market, crowd psychology appears to go in a bad direction (Dr. Can Van Luc, 2021). 2022-2023 is a period full of expectations that the stock market will grow strongly again. Hence, it can be said that the Vietnamese stock market is subject to strong fluctuations by the psychology and behavior of investors. With limited time and effort, investors can only pay attention to such a limited amount of information that value-related information can sometimes be overlooked and temporary mispricing may occur. The lack of information has a great impact on the psychological development of individual investors with overreactions when unstable information appears, causing the stock market to face high instability factors. This is also the reason for the strong fluctuations of Vietnam's stock market in recent years with the overreaction of investors, especially individual investors to the uncertainties and less positive prospects in the world economy - politics in the post-Covid-19 period. In particular, at present, in Vietnam, there is relatively little research on the impact of investor interest on fluctuations in the Vietnamese stock market. It is easy to see that this is a new topic in Vietnam.

With the important role of the stock market as well as the characteristics of the Vietnamese market, the research team selected the topic *“Impact of attention investors on fluctuations in the Vietnamese stock market”*. In particular, we conducted an assessment of the impact of investor interest related to the level of liquidity and volatility of Vietnam's stock market. Specifically, the level of investor interest in the stock market and with each stock is assessed through the level of search information on Google of investors related to the stock market with each stock through the Google Trend index.

## **2. LITERATURE REVIEW**

### **2.1. Behavioral finance on attention investors**

In the face of the strong development of the stock market, more and more people are interested in the knowledge and scientific research in this field. Currently, most investors are more professional, know how to apply knowledge and analyze information to make the right investment decisions. Nonetheless, in the stock market, there are still many investors who make decisions based on emotions, based on the influence of external factors, so they make wrong investment decisions, thereby leading to losses and unintentionally creating negative effects on the market.

One of the most important theories of emotional investor behavior is the behavioral finance theory developed by Kahneman and Tversky (1979), De Bondt and Thaler (1990) and Shiller (2003). In particular, behavioral finance is a field of finance that offers theories based on psychological analyses to explain unusual movements in the stock market. Behavioral finance explains the collection and use of information and problem solving by individual investors, whereby individual decisions and market outcomes are influenced by the information structure and characteristics of market participants (Bakar and Yi, 2016).

Merton (1987) was one of the first studies to assess the impact of investor attention on stock market performance. Merton theorized that if investors avoided stocks they were unfamiliar with, the market for those stocks would be greatly diminished. Thus, the investor's attention has a significant impact on the liquidity and valuation of the stock. Research by Barber and Odean (2008) shows that stocks that attract investors' attention in relation to news, irregularities and fluctuations in profits, prices, trading in the market more will be traded relatively more than stocks that receive less attention.

Based on these studies, more and more recent limited attention hypotheses are developed in theoretical models such as those of Andrei and Hasler (2014), Hirshleifer et al. (2009). Specifically, Hirshleifer et al. (2009) point out that investors' reaction to information about the price and volume of stocks will be

weaker when investors are distracted, with low levels of attention, where distraction is measured by the number of simultaneous announcements. Similarly, Della Vigna and Pollet (2009) observed and compared the responses obtained by investors during and after the news releases on Friday with those observed when the announcements were made on weekends. The upshot is that investors' reactions to announcements and news on other days are weaker than they are on Fridays, as investors are often more distracted on the last working days of the week. More recently, Jank and Dimpfl (2011), Vlastakis and Markellos (2012), Kita and Wang (2012)... argue that investors' online search behavior has a significant impact on the volatility of stocks in developed markets.

In summary, over time, people have come up with the most general concept for behavioral finance theory, specifically, behavioral finance is a combination of psychology, economics and sociology. The theory of behavioral finance can be used to evaluate and explain the behavior of individuals and organizations investing in the stock market, in which, can giups learn and explain market anomalies based on concepts and theories related to sociology, psychology and economics such as susceptibility and misperceptions, different attitudes to risk, regret, overreaction to investor information. Investor behavior is a combination of behavioral psychology effects and the perception and understanding of economics from which to make investment decisions.

Investor behavior is a combination of behavioral psychology effects and the perception and understanding of economics from which to make investment decisions. Thus, in each case, each investor may have different levels of reaction to market fluctuations. To this day, the most studied important factors that influence investor decisions and stock market volatility are:

The first, representativeness and conservatism. Representativeness refers to making a judgment about a phenomenon based on a similar or similar phenomenon in the past when investors showed great interest in their previous beliefs. The reluctance to update beliefs stems from conservative tendencies. That's how conservatism was born. The evidence is that investors who are psychologically stuck with their data analysis in the past, react poorly to recent market news.

Second, self-assertiveness and overconfidence. Overconfidence refers to the fact that investors are very confident in their own judgment, analysis and stock valuation more effectively than relying on external information sources. Investors assume that any profitable win is the result of their own proper process of analysis and investment. On the contrary, when the investment is on the path to loss or not as they expected, they will blame external factors that have affected their investment. Self-assertion will make investors become overconfident and forget to evaluate the event in the most accurate and objective way. The tendency to self-assertion and overconfidence is correlated and the tendency to self-assertion is also a factor in forming and forecasting overconfidence. Self-assertive overconfidence leads to poor response to information in the market and overreaction to personal analysis. The confidence of investors increases, maintaining overreaction because they tend to blame all the mistakes on objective factors and believe absolutely in their success.

Third, adjustment and mooring. Anchor which determines whether the investment is accurate and reliable or not. On the other hand, choosing the correct anchor is based on the investor's own calculations and inferences. The initial anchor can be from a calculation, a present value, or some historical level. Anchors must be chosen correctly and appropriately for decisions and judgments to go in the right direction and be successful. Investors need to constantly make judgments about the value or purchase of a stock in the future.

Fourth, the confirmation trend. Investors tend to collect information that confirms their previous hypotheses rather than contradictory or unconfirmable hypotheses, more so when they deliberately misinterpret the available theories to support the confirmation of the hypothesis itself.

## **2.2. Measuring attention investors**

One of the biggest difficulties in measuring investor interest is the absence of an accurate measure of investor interest. Previous studies have suggested assessing investor interest indirectly through investor behavior when seeking information related to his or her investment decision-making. One of the proposed methods is the appearance of investment information in the media.

Antweiler and Frank (2004) use the volume of posts on Yahoo to represent the attention of investors and say that higher posting levels lead to greater volatility of stocks listed on the US market. Grullon et al. (2004) found that advertising costs have a positive relationship with the number of investors. Similarly, Boyd and Schonfeld (1977) showed that financial news ads can positively influence the value of securities by reducing the cost of seeking information or investor search behavior, changing investor preferences, or providing new information. Fang and Peress (2009) show a negative relationship between media coverage and stock market returns.

Another method proposed and used in recent studies is through internet search queries conducted through internet browsers such as Baidu, Yahoo and Google search volume. Da, Engelberg and Gao (2011) suggest that investor interest can be determined by seeking action because investors actively seek information to make investment decisions. As a result, the search volume index through Google Trend can be used as a direct measure of investor attention. Similarly, Drake, Roulstone and Thornock (2012) and Bijl, Kringhaug, Molnar and Sandvik (2016) all argue that Google search volume is an avowedly evidence for attention because investors are certainly paying attention to a stock that leads to informational behavior about that stock search.

## **2.3. The impact of attention investor on stock market volatility**

Drake et al. (2012) analyzed the Google search behavior of investors around the stock market and found that online search affects market valuation and facilitates price discovery. Similarly, Andrei and Hasler (2014) point out that the volatility of the stock market and the level of investor search through the Google Trend index have a simultaneous relationship with each other. Besides, Chen et al. (2021) pointed out that the interest of retail investors, as measured by Baidu search volume, has a significant positive impact in the short-term on the liquidity of future stocks. However, as the time period expands, this positive effect tends to weaken and eventually reverse after four weeks. More importantly, the short-term improvement in stock liquidity is mainly caused by the net buying activity of retail investors.

Tang and Zhu (2017) measured the increase in investor attention via Google search volume and found evidence that the level of investor search for information in a day is related to positive abnormal returns on the same day. By contrast, such a positive association between investor attention and stock returns quickly reverses after the first day. Adachi, Masuda and Takeda (2017) investigate the relationship between investor attention and stock price movements at Japan's startup stock exchanges, Mothers and JASDAQ. Research shows a positive relationship between search intensity and profitability and stock liquidity, especially in startups with a high percentage of individual shareholders. Colaco, Cesari, and Hegde (2017) also used Google search volume to represent retail investor attention and found that the increase in retailer attention after the initial filing but before the initial valuation was positively related to the initial valuation. A study conducted by Kim et al (2019) of the Norwegian stock market, found that Google searches did not correlate, nor could they predict, abnormal returns. Nevertheless, they found that increased Google search could predict increased trading volume and volatility. For developing markets, research by Shen et al. (2017) indicates that Baidu's search frequency can predict the next day's price change: stock prices rise when individual investors pay less attention to stocks, and fall when individual investors pay more attention

to stocks. Additionally, Lee A. Smales (2021) wanted to assess whether investor interest could account for stock returns across different sectors during the Covid-19 period. Research has shown that investors' interest in Covid-19 is increasing and has a negative impact on US stock profits. Relatively speaking, however, some sectors such as media, consumption, health and information technology may have benefited from this increased interest. Most recently, another study by Zhou and Lou (2023) on Chinese markets as investors are interested in the Russian-Ukrainian conflict and pointed out that investors' interest in this conflict contains more valuable information to predict the volatility of the Chinese stock market than some common predictors such as economic leverage, leapfrogging economic policies or political risks. Based on the research of Killian and Park (2009), Bampinas, Theodore and Georgios (2023) expanded further in the case of investors subjected to oil shocks and concluded that changes in investor interest can have a lasting and significant impact on stock market returns and oil prices, while investors often react strongly to shocks in oil prices and stock market returns of various intensities. These studies have confirmed Internet search activities as a direct representation of investor attention.

Consequently, it can be seen that investors' interest, trading volume of stocks and the level of stock volatility are proportional to each other and there is a strong correlation that helps investors make investment choices. According to the research team, so far, in Vietnam, there is very little research to analyze the interest of investors in the fluctuations of the stock market. This is the research gap that the team carried out in this study.

### 3. RESEARCH METHOD

#### 3.1. Research models

In this study, the research team assesses the level of investor interest towards two key factors when investors invest in the stock market, namely the liquidity of stocks and the volatility of stock returns. votes.

The model to evaluate the impact of investors' interest on the liquidity of stocks is shown as follows:

$$\begin{aligned} \text{ILLIQ}_{it} = & \alpha + \beta_1 \cdot \text{Ln}(\text{SVI}_{t,i-1}) + \beta_2 \cdot \text{Ln}(\text{SVI})_{M,t-1} + \beta_3 \cdot \text{Volatility}_{i,t-1} \\ & + \beta_4 \cdot \text{Return}_{i,t-1} + \beta_5 \cdot \text{Ln}(\text{Market Value}_{i,t-1} \\ & + \beta_6 \cdot \text{Tradding Volume}_{i,t-1} + \beta_7 \cdot [\text{Ln}(\text{Market Value}_{i,t-1} \\ & * \text{Ln}(\text{SVI}_{t,i-1}))] + \beta_8 \cdot \text{ILLIQ}_{i,t-1} + \varepsilon_t \end{aligned}$$

In which, similar to Goyenko et al. (2009) and Xiong et al. (2013), the research team measures the liquidity of the illiquid ratio of Amihud (2002)  $\text{ILLIQ}_{it} = \frac{|\text{Rit}|}{\text{TV}_{it}}$  where Rit is the rate of return of stock i in time t, TVit is the trading volume of stock i in time t.

The first explanatory variable chosen is the level of investor interest in the stock under consideration SVI<sub>i,t-1</sub>, and the investor's interest in the stock market in general SVI<sub>M,t-1</sub>. The next explanatory variable is Volatility<sub>i,t-1</sub>, which represents the volatility of stock returns. Next, the research team chooses Return<sub>i,t-1</sub> stock return. Return<sub>i,t-1</sub> stock return is calculated by dividing the natural base logarithm of the stock price at time t by the stock price at time t-1. Trading Volume is the number of units of a stock traded in a given period of time. Finally, the research team selected the explanatory variable as market capitalization Market Value. Market capitalization is the value of the total number of shares outstanding on the stock exchange of a listed company.

The model for assessing the impact of investors' interest on stock market volatility is shown as follows:

$$\text{VOL}_{i,t} = \alpha + \gamma_1 \cdot \text{Ln}(\text{SVI}_{t,i}) + \gamma_2 \cdot \text{Ln}(\text{SVI}_{M,i}) + \gamma_3 \cdot \text{Ln}(\text{Tradding Volume}_{i,t}) \\ + \gamma_4 \cdot \text{Ln}(\text{Return}_{i,t}) + \gamma_5 \cdot \text{VOL}_{i,t} + \varepsilon_{i,t}$$

Besides liquidity, volatility in profitability (VOL) is believed to have an impact on stock market performance. Volatility in earnings is a measure that shows the trend of changes in security prices over a period of time (Khositkulporn, 2013).

### 3.2. Research data

#### 3.2.1. Research data

The research team assesses the impact of investors' interest on the stock market in general, as shown by the VN-Index and the volatility of 15 stocks with the largest market capitalization on the stock market. Vietnam stock market as of the end of the first quarter of 2023. The data period is taken from January 5, 2018 to February 19, 2023 with a weekly frequency. . To ensure results are less biased, the team excluded stocks with less than 20 weekly search volume data. What's more, the team also eliminated stocks where SVI for eight consecutive weeks or more was zero. Additionally, Google insights allows the team to filter search volume so that only queries submitted within Vietnam are available. On the basis of these limitations, we end up with a sample consisting of 10 of the original 15 stocks.

**Table 1: List of stocks in the sample and search query**

COMPANY'S NAME		STOCK	SEARCH
Full company name	Abbreviated company name		
Stock exchange for shares of public companies listed by Ho Chi Minh Stock Exchange	VN Index	VNI	"VNI"

### 3.2. Descriptive statistics of data sets

Table 2 shows descriptive statistics for SVI, where:

Mean is the mean of the distribution.

Skew is the kurtosis value to see if the distribution of the SVI variable is standard deviation.

The KURT value is the kurtosis value of the distribution. If SKEW is not 0 and KURT is not 3, then the distribution of SVI is non-normal.

In addition, Table 2 also reports the normality test statistics of Jarque–Berra (J–B).

**Table 2: Descriptive statistics report for SVI**

#### 4.2. Discuss the results

The group's research results are consistent with the results of previous research papers. Amal Aoaudi, Mohamed Aroui, Frederic Teulon (2013) indicate that it is concluded that the level of investor attention has a negative impact on the illiquidity of stocks in the French market. In the research of Rimada Diamanta Putri, Pardomuan Sihombing (2020) also showed that trading volume has a negative impact on the liquidity of stocks, increasing trading volume will increase the liquidity of stocks in different markets. companies listed on the IDX Stock Exchange (Indonesia) for the period 2015 - 2019. However, contrary to the research of Jonathan Batten and Vo Xuan Vinh (2019), the research team believes that the market capitalization value has a negative relationship with the illiquidity of the stock, or with the larger the company, the higher the liquidity of the stock.

Overall, the team's findings confirm a key finding in the group's analysis based on the standard deviation of returns: that investor attention as measured by SVI is significantly associated with volatility in most returns. all cases. This confirms that the team's findings are accurate and consistent with the results of previous research papers. Malgorzata Just and Krzysztof Echaust (2020) show that there is a positive relationship between returns and volatility of stock returns, the higher the return, the lower the volatility of returns and opposite. Similarly, Yousaf and Yarovaya (2022) show that trading volume has a strong and positive relationship. Increased trading volume will increase the volatility of the stock's rate of return. Brochado A, 2020 believes that the level of investor interest has a close relationship with the volatility of stock returns, especially in times of economic crisis.

#### 5. CONCLUSION

Through the above study on the level of investor interest and activities on the Vietnamese stock market, the group can draw some conclusions, specifically as follows:

Firstly, the larger the companies, the more liquid the stock will be and vice versa.

Second, the higher frequency of searching for information related to the online market is due to increased uncertainty among investors, increasing liquidity.

Third, stocks that receive more attention will be prioritized to trade in relatively larger numbers than stocks with less attention.

Fourth, online search volume is strongly correlated, reflecting investor interest.

Fifth, past returns can reflect market interest and volatility through Google search volume.

Through the research paper, the research team has contributed to the existing literature that confirms that investor attention is a determinant of stock market performance and volatility. Although previous studies have mainly focused on stock markets of developed countries such as the United States, the European Union (EU), China... but the first group chose to use the data of Google and the Vietnamese stock market.

## THE IMPACT OF TRANSACTION ACCOUNT'S ZERO FEE POLICY ON THE PERFORMANCE OF COMMERCIAL BANKS IN VIETNAM

**Author: Nguyen Hong Van<sup>1</sup>, Trieu Hong Nguyen<sup>1</sup>**

**Mentor: Pham Thu Thuy<sup>1</sup>**

*ABSTRACT: Transaction accounts are one of the most popular services to satisfy the customers' need for cash transactions, money transferring and other financial transactions. These used to be the banks' main source of fee income, including account opening fees, maintenance fees, transaction fees. . . . Recently, competition in digital banking services led to a trend in waving fees on transaction accounts in order to attract new customers. The zero free policies can be in form of un-conditional free transaction accounts applied for all types of users and conditional free transaction accounts applied for customers satisfied certain conditions. It is undeniable that the waives of transaction account fees have brought some losses to the banks' fee income. However, the banks may benefit by attracting new customers, reducing cost of funds (cause the balances on transaction accounts are consider as low cost of funds), increasing cross-selling. . . . To this point, there's no research findings on the impact of zero fee policy to the overall banks' performance. The study focuses on assessing the impact of the free payment account policy on the financial and operational results of commercial banks in Viet Nam in the period of 2011 - 2021. Using combined qualitative and quantitative method, the study estimates the impacts of free payment accounts to banks' ROA and ROE using balanced panel data from 18 Vietnamese commercial banks with regression model like OLS, fixed-effects and random effects regression model, adjusted with FGLS method. The results show that the application of both unconditional and conditional free policy of transaction accounts have positive impacts on the bank's financial performance. The impacts of free transaction accounts on non-financial performance with interview methods have found considerable effects in increasing brand reputation, expanding customers and increasing competitiveness. The study suggests an effective fee policy for payment accounts of commercial banks.*

**Keywords:** zero fee policy; transaction account; banks' performance; commercial banks.

### 1. INTRODUCTION

In the 21st century, the development of 4.0 industry revolution has affected all aspects of human life, especially the way financial transactions are performed. Transaction accounts have also changed drastically, from electronic identification technology (eKYC), security technology, new payment methods (QR code), contactless card to the features of ordering, paying and performing financial transactions...to bring outstanding experiences to customers. row. Banks also waive all fees (accounts opening fees, accounts maintenance fees, fees for performing transactions on accounts ...) to attract clients. In Vietnam, the trend of zero fee, which was started by Vietnam Technological and Commercial Joint Stock Bank (Techcombank) in 2016, has made an important contribution to making the transaction accounts products more popular and promoting non-cash payments in the economy. The benefits and losses of banks' transaction accounts' zero fee policy are still the matter of debate. Obviously, transaction accounts' zero fee (including unconditional and conditional free policy) will reduce fee income of commercial banks. On the other hand, this can be offset by opportunities to attracting low-cost sources of fund, cross-selling products, attracting and retaining customers. The previous studies show that the problem of the benefits and losses of fee income has not yet been clearly solved. Therefore, this study focuses on solving the question of how transaction accounts' zero fee policy affects the financial and non-financial results of commercial banks? Using quantitative method

<sup>1</sup> Banking Academy.

through regression models, using panel data collected from financial statements of 18 commercial banks with the largest capital scale in the market in the period 2011-2021, combined with qualitative methods through interviews with bank experts in 2021, the results found that the transaction accounts' zero fee policy has a positive impact on financial results and some non-financial results of commercial banks.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Fees and transaction accounts**

Studies have shown that service fees are one of the important factors in attracting customers. Fee income is a stable source of income, contributing significantly to commercial banks' profits. Nowadays, fee per transaction can be drastically reduced thanks to automation and modern technology adoption. Related previous studies give the following results.

DeYoung & Rice (2004) suggested that when customers make transactions, banks will receive fees, and increase their non-interest income. Recently, advances in technology have allowed banks to provide their financial services more efficiently, reflecting in the reduction in cost per transaction, increasing convenience for customers, and also total fee income for banks. More specifically, due to the introduction of new distribution channels, such as ATMs and online banks, customers are willing to pay service fees, in exchange for their convenience. As a result, the fee revenue of banks increases (DeYoung and Rice, 2004). Mateus Feld et al. (2021) also showed that as electronic banking services develop, the cost of banks can decrease. In addition to the benefits of efficiency and practicality, technology also contributes to reducing the costs that customers pay to the bank.

Kashian.R & Drago.R (2016) studied non interest checking accounts (NICs) of banks from 2008 to 2012 and stated that customers with NICs need a minimum balance to avoid fees. Compared to large banks, NICs holders at small banks have more privileges. Large banks often do not waive fees and impose high minimum balances on customers' accounts, while small banks are more likely to offer free NIC accounts. The words 'free account' can create an aura of goodness (Nisbett and Wilson, 1977), resulting in a positive review of banking from the customer's side. Tyler Spaid & Mike Branton (2013) researched free payment accounts based on the relationship between customer and bank and suggested that customers would be free of payment accounts if guaranteed specific conditions such as a large account balance, being a regular bank debit card or other service users. Teplý (2015), Giordani et al. (2009) reviewed the online banking services of Greek commercial banks. The authors also present the related costs and fees that customers pay when using these services. The findings show that there is a disparity in the fees that Greek commercial banks impose on their customers for conducting internet banking transactions. However, banks cannot reduce the cost of providing online services because they have to invest in facilities to support customers. Thus, these costs are transferred to the customer in the form of fees for using the services (Keeton, 2001). Bergendahl and Lindblom (2007) report that Swedish banks do not charge paper and electronic payments. However, they charge a fixed annual fee for customers using paper banking and electronic banking services. The more transactions are made using the online method, the lower the fee.

Nguyen Van Chien, Pham Thi Minh Thuy (2021) indicated that the number of transaction accounts has an impact on performance of banks. The increase in both quantity and quality of transaction account has positive impact on bank's performance. Transaction accounts are one of the services of electronic banking Sullivan (2000). At the same time, it helps banking operations become more professional, helps reduce operating costs, saves human resources, thereby increasing profits. In addition, the development of

electronic banking services (including transaction accounts products) helps increase customer satisfaction and retention in the retail banking sector. Similar research by Angelakopoulos & Mihiotis (2011) showed that e-banking services and technologies provide the banking industry with several opportunities to attract new potential clients.

## **2.2. Results/performance of commercial banks**

There are a number of studies on commercial bank's operational effectiveness, among which some are highlighted: Dawood's (2014) studied on the effects of micro-factors on the operational efficiency of 23 commercial banks in Pakistan (2009 – 2012). ROA is the only dependent variable, while Equity Rate on Total Assets, Total Asset Scale, Rate of Recovery on Total assets, Liquidity Capacity and Cost-to-Income Rate are independent variables. The percentage of capital raised on total assets, the total asset scale and the share of equity on total assets all affect the ROA in the same direction. The other two variables have an inverse effect on ROA. Ramadan Kilani and Kaido Mi (2011) studied the factors affecting the performance of the banking system in Jordan in the period 2001-2020. The author uses two dependent variables: ROA and ROE, while dividing into three groups for independent variables bank specific variables (Scale, Loan outstanding, Total Credit Risk, Equity capital on Total asset, and Cost to Income ratio), industry environment variables (Total banks'assets to GDP, level of concentration of the three largest banks) and macro-environment variables (GDP growth rate and CPI inflation rate). Nguyen Viet Hung (2008) study of the operational efficiency of Vietnam's commercial banks in the period 2001-2005 showed that the variables Deposit Rate on Loans, Level of Market Concentration, Equity ratio to total assets and variables on changes in the macro environment, banking technology have the same impact as the results of the bank's operations. Meanwhile, the remaining variables of interest income on total income, borrowing on total assets have the opposite effect.

From related studies, it can be noted that transaction accounts are one of the "must - have" products of commercial banks and transaction account fees used to be one of banks' important sources of income. However, there are not many studies directly assessing the impact of free transaction accounts on the performance of commercial banks. These studies mainly examine the role of transaction accounts on several aspects such as customers attraction and satisfatiton, costs reduction. There is no study that comprehensively assessed the impact of free transaction account on both the financial and non-financial outcomes of commercial banking, especially in the context of post Covid-19 period.

## **3. RESEARCH METHOD**

### **3.1. Quantitative methods**

To assess the impact of free transaction accounts on financial results, the study used a quantitative research methodology based on 02 models:

Model 1: Study the impact of transaction account's zero fee on the bank's financial results (unconditionally free policy, applicable to all customers with transaction accounts).

Model 2: Study the impact of transaction account's zero fee on the bank's financial results (conditionally free policy, only applicable to clients who satisfy certain criteria).

Inheriting the results of preliminary research and filtration in accordance with the conditions of the figures as well as characteristics of Vietnamese commercial banks, the author proposed to build a model for assessing the impact of free transaction accounts on the performance of commercial banks, as follows:

$$Y = \beta_1 + \beta_2 \times MP\_TK_{it} + \beta_3 \times Size_{it} + \beta_4 \times TyleTGKH/TTS_{it} + \beta_5 \times LDR_{it} + \beta_6 \times TyleCasa_{it} + \beta_7 \times CI_{it} + \beta_8 \times Equity_{it} + \beta_9 \times GDP_{it} + \beta_{10} \times CPI_{it} + e_{it} \quad (1)$$

$$Y = \beta_1 + \beta_2 \times MP\_DK_{it} + \beta_3 \times Size_{it} + \beta_4 \times TyleTGKH/TTS_{it} + \beta_5 \times LDR_{it} + \beta_6 \times TyleCasa_{it} + \beta_7 \times CI_{it} + \beta_8 \times Equity_{it} + \beta_9 \times GDP_{it} + \beta_{10} \times CPI_{it} + e_{it} \quad (2)$$

Y is a measure of the performance of commercial banks, including the dependent variables ROA, ROE

In the independent variables in the model, the variables are divided into 3 groups: bank specific factor, macro factors and free transaction account factor. Bank specific factors include: Bank size (SIZE), Customer deposit/Total asset ratio (TyleTGKH/TTS), Casa/Total assets ratio (CASA/TTS), Loan to deposit (LDR), Cost/Income (CI), Total equity/Total assets (VCSH/TTS). Macro-factors includes GDP growth rate (GDP) and inflation rate (CPI). The free transaction accounts variables are dummy variables, which are included to assess the impact of free transaction accounts on the bank's financial index, including the unconditional fee transaction account variables (MPTK) applicable to Model 1 and the conditional free transaction account variable (MPDK) applied to Model 2.  $E_{it}$  is called the model error.

The study used POOL OLS models, Fixed Effects Model (FEM), Random Effects Model (REM) to quantify the impact of free transaction accounts variables on bank profits, using Stata software for balance sheet data with 190 observations of 18 banks over 11 periods of time (years). The data collected from the financial statements of 18 commercial banks with the largest capital scale in the Vietnamese. To select the most suitable model, the study used Hausman accreditation. The subsequent model selected will be tested theories, including multi-common line verification, variability verification (Breusch and Pagan Lagrangian verification) and self-correlation (Wooldridge verification), and the shortcomings of the model will be corrected by Atiken's general minimum equal estimate (FGLS) (1936).

**Table 1. Variables in the model**

Symbol	Variables	Expect	References
Dependent variable			
LAGROA	Net income/Total assets ratio (Lag variable)		Dawood (2014), Ramadan Kilani & Kaido Mi (2011)

### 3.2. Qualitative method

The study used an interview method to evaluate the impact of transaction account’s zero fee policy on non-financial result. The survey was conducted with 141 bank experts who had at least one year of work experience. This method is used to explain the results of quantitative models, identify the benefits of commercial banks, evaluate factors affect to free transaction account. The results obtained from expert interviews help to more comprehensively. Analytical studies based on two indicators are the average score and the standard deviation. The average score is calculated according to the per capita of rights, also known as the common average of rights - is the average value plus reflecting reliability, the quantity is only the frequency of repetition. Standard deviation is an indicator used to measure the extent to which a data set is spread around an average value.

## 4. RESULTS AND DISCUSSION

### 4.1. Results

#### 4.1.1. The impact of transaction account’s zero fee policy on the financial performance of commercial banks.

Hausman test showed that p value < 0.05, the fixed effects model (FEM) is suitable. The FEM model has all VIF coefficients smaller than 3, showing the model has no multicollinearity (Nguyen Quang Dong and Nguyen Thi Minh, 2013). The results of the Breusch and Pagan Lagrangian tests and the Wooldridge tests show that the model has heteroskedasticity and autocorrelation. To remedy the shortcomings of the model, the study used Feasible generalized least squares (FGLS) (Aiken, 1936) to restructure the FEM models.

**Table 2. Results after correction using the FGLS method**

	LAGROE	LAGROA	LAGROE	LAGROA
MPTK	3,009*** [2,70]	0,388*** [4,08]		
MPDK			2,639** [2,29]	0,364*** [3,72]
SIZE	1,437 [0,80]	0,295* [1,95]	1,417 [0,79]	0,296** [1,98]
VCSH/TTS	-52,45*** [-2,85]	5,330*** [3,41]	-49,71*** [-2,70]	5,748*** [3,69]

Note: \* p < 10% \*\* p < 5% \*\*\* p < 1%

The results showed that factors have a strong impact on ROA and ROE include the MPTK: The LDR ratio (which has the same directional impact on the ROA as well as the ROE with the significance of 1%);, the VCSH/TTS ratio (with the opposite significance to the ROA but the same significance with ROE at the same meaning of 1%), the CI (with a reverse effect to the ROA and the ROE at the significant level of 1%). The CASA/TTS ratio affects both ROA and ROE in the same direction with a significance of 5%.

The impact model of free conditional transaction account to ROA, ROE, the MPDK has the same directional impact to both ROA and ROE but has a stronger degree of significance to the ROA. The LDR ratio, VCSH/TTS ratio, CI ratio, CASA/TTS have an impact on ROA and ROE with dimensions and significance levels similar to the above model. This may explain that both the free unconditional transaction account and free conditional transaction accounts have a more positive impact on the profitability of commercial banks. The act of entirely free helped attract customers to use services, increase cross-sales of products and increase cheap capital from non-term deposits (CASA)...Therefore, banks can compensate for the profits that had to be sacrificed for reducing the source of service fees.

Some banks have free conditions for VIP customers, customers need to have a large minimum balance or a level of regular transaction execution. As we can see, attracting new customers is not the main goal of free. Besides, these banks want to use fees as an additional incentive for client care, thereby increasing the loyalty of VIP customers. It can be seen that free services are an inevitable trend in the process of competition and development of the modern financial system. The results of the study were similar to those of Russell Kashian & Robert Drago (2016), Mateus Feld and colleagues (2021) and Nguyen Van Chien, Pham Thi Minh Thuy (2021).

#### 4.1.2. The impact of transaction account's zero fee policy on the non-financial performance of commercial banks.

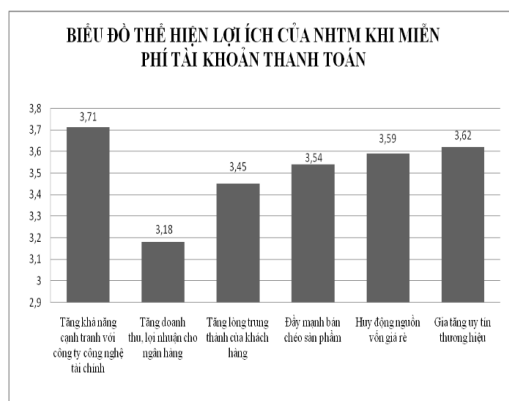

Chart 1a: Benefits of commercial banks when free transaction account

Chart 1b: The biggest factors affect free transaction account

Source: Survey results of the research team in April 2022

The results of the survey showed that the majority of bank experts interviewed believe that free transaction accounts have a positive impact on the performance of commercial banks in Vietnam. The free transaction accounts increase the bank's competitiveness with financial technology companies (3.71 points), improves the image and increases bank's brand reputation (3.62 points), helps bank mobilize cheap capital sources (3.59 points), boosts cross-selling products (3.54 points), increases customer loyalty (3.45 points). However, the benefits increased revenue and profit are the least agreed with bank officials with an average of 3.18.

The majority of bank officials chose attracting customers to open a transaction account as the biggest motivator, with 35.1% of respondents agreeing. Competitive pressure is the second-largest driver (with 29.6% of opinions in agreement). Social expectations (16.9%) and opportunities from the adoption of new technologies (12.7%). The government's obligation in the request for exemption, the reduction of transaction accounts fees to support the people is the weakest motive (5.7%). Because, before there was this requirement of the government, there were several banks that pioneered the free account (Techcombank is started free from 2016, while TPBank started free from 2019 and until the time since the pandemic there are 17 banks have also started free).

#### 4.2. Discussion

It can be seen that the transaction accounts' zero fee policy at commercial banks is still effective at the present time. However, it is necessary to look objectively as the number of free banking accounts increases. The benefits of having free transaction accounts will decrease as clients will see that free is no longer the different factor that helps attract customers to choose a transaction account. Trending free transaction accounts in the near future is only really effective if the bank has a proper pricing and fee policy. In order to be able to further improve the efficiency of banks when free transaction accounts and meet the increasing needs of customers, banks should pay attention to the following solutions: develop a reasonable non-term interest rate policy for customers; carefully calculate the overall benefits from customers; promote cross-sales of products; improve comprehensive client care services; modernize technology and processes to minimize transaction costs, manage operating costs effectively.

#### 5. CONCLUSION

The research set out to investigate the impact of transaction account's zero fee policy on the performance of commercial banks in Vietnam. This study show that free transaction account has been a popular trend in commercial banks over the years. Research indicate that free transaction accounts have brought both financial and non-financial benefits to commercial banks. Although there are some limitations due to the size of the new study sample limited to the 18 commercial banks. However, the research team also hopes the paper may suggest commercial banks fee policy for further research.

## THE IMPLICATION OF MACHINE LEARNING TECHNIQUES FOR FINANCIAL SOLVENCY PREDICTION AN EMPIRICAL ANALYSIS ON VIETNAMESE LISTED ENTERPRISES

**Author: Bui Huyen Anh<sup>1</sup>, Quach Thuy Dung<sup>1</sup>, Le Huyen Dieu<sup>1</sup>, Pham Thi Hai Yen<sup>1</sup>**

**Mentor: Duong Ngan Ha<sup>1</sup>**

**ABSTRACT:** *The study aims to predict short-term and long-term solvency of Vietnamese listed enterprises. The authors use a standard model with Linear Regression method and 3 supervised learning techniques: KNN (K-nearest Neighbor), Decision Tree and Random Forest. Through the analysis and evaluation, KNN is the best forecasting technique and has improved over the linear regression model. The research results indicate that KNN and Random Forest are good at predicting solvency, but they do not have improvement over the regression model. Additionally, almost techniques have good scores when forecasting Cash ratio and TD\_TA. After that, the authors proceed to split the data set into 8 separate industries. It can be seen that Information Technology (IT) has the highest accuracy when predicting solvency. By way, conclusions can be drawn that can be applied to understand the application of machine learning models to predict solvency for enterprises.*

*Keywords: solvency, machine learning, micro and macro factors, Viet Nam*

### 1. INTRODUCTION

In finance or business, liquidity is defined as the amount by which an individual's or organization's current assets exceed its current obligations. Solvency is one of the indicators used to analyze an enterprise's financial capacity, indicating its ability to satisfy its liabilities at any moment. Strong financial capacity indicates great solvency; the company always has adequate funds to pay its debts on time. When a company's financial capacity is limited, it faces numerous obstacles, including the inability to pay its debts. There are numerous dangers that could lead to insolvency in the future, influencing the enterprise's reputation, scale, character, and current operational position. A protracted challenging position without a remedy will lead to the company's demise.

As a result, anticipating company solvency is a critical task in identifying the financial risks that firms confront. At the same time, it serves as the foundation for quickly addressing problems when solvency is low. Furthermore, the solvency forecast is used by businesses to analyze their current position in the commercial market. Assisting investors, suppliers, and banks in determining a company's ability to pay its payments on time. To reduce risks, make investment, collaboration, and loan decisions. Currently, research on forecasting enterprise solvency is sparse and not frequently used. It is critical to undertake research on the factors influencing enterprise solvency using relevant and practical approaches. The study intends to forecast the solvency of Vietnam's listed enterprises. It is clear that firms can self-assess their financial capacity and credit risk management, as well as decide the best business strategy. Simultaneously, it serves as a source of information to assist investors, credit institutions, and partners in making sound investment and lending decisions.

Based on domestic and international research on the impact of several factors on the solvency of publicly traded companies. Solvency is influenced by both internal corporate characteristics and economic

---

<sup>1</sup> Banking Academy.

factors, which are classified as micro factors and macro ones. Micro factors include return on asset, debt ratio, assets and so on. Macro factors include inflation rate, gross domestic product and interest rate.

The research employs both qualitative and quantitative methodologies. The authors employ synthesis, analysis, and comparison methodologies to determine the current solvency of listed firms. Furthermore, the authors employ machine learning to forecast the solvency of organizations. It is a branch of artificial intelligence (AI) and computer science concerned with the development of strategies that enable systems to learn automatically from data in order to tackle specific issues.

## **2. THEORETICAL FRAMEWORK**

The solvency of enterprises can be highly evaluated based on influencing factors. Through domestic and foreign research, the authors synthesize and classify the influencing factors into two main groups: micro factors and macro factors. The specifics are as follows:

### **2.1. Micro factors**

A micro factor is a group of factors belonging to the enterprise; studies often focus on financial indicators such as firm size, return on assets, return on equity, net profit margin, return on sales, asset growth, revenue growth, and some other factors.

#### **Return on asset (ROA)**

In their studies, Bruinshoofd and Kool (2004), Waqas Bin Khidmat Mobeen Ur Rehman (2014), Dang Thu Hang (2020), Truong Thanh Hang et al. (2020), and others discovered a negative correlation between company solvency and many factors. In order to evaluate the variables impacting solvency, Bruinshoofd & Kool (2004) used data from more than 450 businesses operating in the Netherlands between 1986 and 1997 as the basis for their research sample. The return on assets has a detrimental effect on the viability of the company, as the authors have demonstrated. A similar study has been done in Vietnam by author Dang Thu Hang on 6,700 observations, which are data gathered from companies registered on the Vietnamese stock exchange between 2008 and 2019. The results indicate a negative relationship between solvency and ROA. On the contrary, Tran Manh Dung and Nguyen Nam Tai's (2018) research came to a different conclusion. The authors' analysis of data from 31 food processing companies registered in Vietnam between 2012 and 2016 revealed that the rate of return on total assets has a positive impact on the business's short-term viability. When the study is based on businesses in Ghana, the results of Issaq and Bokpin (2009) are comparable.

#### **Return on equity (ROE)**

Author Waqas Bin Khidmat Mobeen Ur Rehman (2014) conducted an empirical analysis on data gathered from 10 chemical businesses registered in Pakistan over the course of the previous year for return on equity (ROE). According to research, there is a negative relationship between ROE and an organization's solvency. In addition, researchers in Vietnam led by authors Tran Manh Dung and Nguyen Nam Tai (2018) reached the identical conclusion that return on equity has a negative impact on an enterprise's ability to pay down short-term debt. In order to identify the key elements influencing the solvency of joint stock commercial banks in Vietnam, authors Dang Thi Quynh Anh and Tran Le Mai Anh (2022) gathered information from the financial statements of 15 banks for the years 2009 to 2020. Similar to the results of the author Dang Thu Hang's previous studies, it is determined that profitability, equity, and solvency have a favorable link.

#### **Debt ratio**

Regarding the debt ratio, a number of studies conducted abroad suggest that this element has the opposite impact on a company's solvency. In a 1999 study, Opler and colleagues examined the variables

that affected 1,048 U.S. banks' solvency between 1971 and 1994. They discovered that the rate of debt had a detrimental effect on solvency. In addition, from 1987 to 2000, the researchers for Ferreira & Vilela (2004) examined data from 400 enterprises in 12 member nations of the European Economic and Monetary Union (EMU). The findings demonstrated an adverse relationship between a company's ability to pay and its pace of debt accumulation. Other authors have reached the same conclusions as Afza and Adnan (2007), Chen and Mahajan (2010), and Gill and Mathur (2011). Additionally, several researchers around the nation who did their own studies also pointed to similar results. Chen Van Hai (2021) collected data on 48 listed securities companies in Vietnam from 2012 to 2019 and analyzed it, finding a negative correlation between the debt ratio and short-term payability, similar to the authors Tran Manh Dung and Nguyen Nam Tai (2018), who studied food processing firms in Vietnam.

### **Assets**

The solvency of the company is impacted by a number of variables, including asset size, asset growth, revenue growth, and more. This is a factor that is frequently mentioned in study articles when it comes to business scale. The size of the firm had a positive effect on solvency, according to research conducted by Afza and Adnan (2007) on 205 firms in Karachi, Pakistan, from 1998 to 2005. Other research groups such as Isshaq and Bokpin (2009), Haan and Kakes (2010), Filippo Ippolito and Ander Perez (2011), Joo (2013), Ambarwati and Hasib (2018), Tran Manh Dung and Nguyen Nam Tai (2018), Zhong Thanh Hang and colleagues (2020), Tran Van Hai (2021) when conducting research on different datasets, also concluded that the size of the enterprise and the ability to pay have a correlation in the same direction.

Meanwhile, the size of the firm has a negative impact on solvency, according to the research team of writers Dang Thi Quynh Anh and Tran Le Mai Anh (2022), who used data from 15 Vietnamese commercial banks with significant scale and market dominance between 2009 and 2020. The conclusions of several other investigations, including those by Opler and colleagues (1999), Ferreira and Vilela (2004), Verma (2014), Kumar (2016), Siti Rahayu Ningsih and colleagues (2021), V Th Snow Russia (2019), and Pham Ngoc Van (2021), are consistent with this one. In order to evaluate the solvency of businesses through impact variables, two writers, Chen and Mahajan (2010), studied 45 nations between the years of 1994 and 2005 for the ratio of capital circulation and found that the debt ratio has a reverse correlation. Similar to this, Gill & Mathur (2011) found that a number of factors, including the rate of liquidity, had a detrimental impact on the solvency of 164 companies listed on the Toronto Stock Exchange between 2008 and 2010. Isshaq & Bokpin (2009) analyzed data in Ghana from 1991 to 2007 to examine the relationship between solvency and impact variables, contradicting the previously mentioned conclusion. When the study was based on data collected from 23,000 U.S. corporations over a seven-year period, starting in 2002, the research results supported the observation of Filippo Ippolito and Ander Perez (2011) that the rate of movable assets had a positive association with solvency.

### **Other factors**

Other aspects of an enterprise's assets, such as investment capital, as determined by studies by Bruins Hoofd and Kool (2004), Gill and Mathur (2011), and the structure of assets by Zhang Qing Heng et al. 2020, demonstrate an inverse relationship with solvency. Additionally, Baum et al. 2008 established a correlation between asset growth determinants and the company's solvency. Also, a number of studies have drawn conclusions concerning factors that positively affect an enterprise's ability to pay its debts, including those on fast payment rates by Zhong Qing Hui et al. 2020, Tran Van Hai (2021), and capital security rates by Eissa A. Al-Homaidi and Associates (2019) and Faruque Ahamed (2021).

## **2.2. Macro factors**

Besides micro factors, some studies use variables belonging to the group of macro factors, such as interest rates, inflation, and GDP growth, as control variables.

### **Inflation rate and Gross domestic product**

Two factors, the inflation rate and the GDP growth rate, are mentioned in the study of Tran Van Hai (2021). The author has collected data on 48 securities companies listed in Vietnam in the period from 2012 to 2019 and analyzed it; however, in the process of data processing and model building, the author has These variables were excluded due to concerns about autocorrelation. The same thing happens in the study of Tran Manh Dung and Nguyen Nam Tai (2018), who argue that GDP growth and inflation have no impact on the solvency of enterprises. On the other hand, some studies have shown that GDP growth and inflation have an impact on solvency. Author Dang Thu Hang (2020) has conducted empirical research on listed companies in Vietnam and shows that GDP growth has a positive correlation with solvency, but the inflation rate has no relationship. The relationship to the research variable is similar to the two studies on Faruque Ahamed (2021), which also suggest that GDP growth has a positive effect while inflation negatively affects the payment risk of banks. trade in Bangladesh. On the other hand, the authors, Eissa A. Al-Homaidi et al. 2019, came to the opposite conclusion when the study was based on data from commercial banks in India through fixed-effects models. Both determined and random factors have determined that the GDP growth rate has a negative effect on bank solvency, while the inflation rate has a positive correlation.

### **Interest rate**

The interest rate factor is also mentioned in a number of foreign and domestic studies. Pavla Vodová (2011) conducted an empirical study to determine the macro and internal factors affecting the solvency of commercial banks in the Czech Republic. When collecting and analyzing the data of the above banks in the period from 2009 to 2011, the author has shown that interbank interest rates have a positive correlation with the solvency of commercial banks. However, the authors, Eissa A. Al-Homaidi et al. 2019, when conducting research on the data of 37 commercial banks listed in India between 2008 and 2017, came up with the opposite conclusion. When considering macroeconomic factors, the study suggests that interest rates have a negative relationship and have a significant impact on the solvency of commercial banks. Some domestic studies, such as Truong Quang Thong et al. 2013, Dang Thi Quynh Anh and Tran Le Mai Anh (2022), did not find a correlation between interest rates and the solvency of enterprises.

## **2.3. Research gap**

The solvency of an enterprise is the financial capacity with which the enterprise can make payments at the time the obligation arises, a factor that is of great interest to managers and investors. Because of a good assessment of the solvency, it is possible to make a management policy or an investment plan suitable for each stage of the business in order to achieve the ultimate goal of maximizing the company's profits. businesses. There are many measures of the solvency of a business, such as short-term solvency, quick solvency, and instant solvency. Besides, there are indicators of long-term solvency. Solvency is influenced by both internal factors of the business and external factors of the economy, which are divided into micro and macro factors. Micro Factors include profitability ratio, debt ratio, assets, business size, and some other factors. Macro factors include inflation rate, growth rate, interest rate, and other factors. Each factor has a distinct impact on solvency.

### 3. RESEARCH METHOD

#### 3.1. Data

The authors have collected data of 420 enterprises listed on HOSE at the end of 2021. The study focuses mainly on factors affecting the solvency of listed companies in Vietnam. South in the period 2010-2021. Because the group of businesses in the Finance - Banking industry has certain differences with other industries, the authors remove from the sample the enterprises belonging to these two industry groups. The remaining data is 305, for 11 years, the total number of observations is 3014. Enterprise data is primary data, collected from fully audited annual financial statements as well as aggregated from non-publicly published figures on the Fiinpro platform. Table 1 displays the definition of each variable.

#### 3.2. Method

##### Linear regression

Linear Regression is a basic and most popular algorithm of Supervised Learning, where the forecast output is continuous. The authors based on multivariable linear regression model (Şirin Özlem & Omer Faruk Tan – 2022), has the following general formula:

$$Y = \alpha_0 + \alpha_1 X_1 + \alpha_2 X_2 + \dots + \alpha_k X_k + e \quad (1)$$

Y is the dependent variable,  $X_1, X_2, \dots, X_k$  is independent variable,  $\alpha_0$  is a constant,  $\alpha_1, \alpha_2, \dots, \alpha_k$  is the coefficient angle of independent variable, e is the error term of the model.

**Table 1. Definition of variables and dterminants of solvency**

Variables	Formula	Studies
Outcomes		
Cash_ratio	$\frac{\text{Cash and cash equivalents}}{\text{Current Liabilities}}$	Nguyen Thi Xuan hong (2019), Tran Manh Dung & Nguyen Nam Tai (2018)
Quick_ratio	$\frac{\text{Short – term assets – Inventories}}{\text{Current Liabilities}}$	
Current_ratio	$\frac{\text{Short – term assets}}{\text{Current Liabilities}}$	Nguyen Thi Xuan hong (2019), Tran Manh Dung & Nguyen Nam Tai (2018), Dang Thu Hang (2020), Truong Thanh Hang et al. 2020, Tran Van Hai (2021), Anirbid Sircar et al. 2021
DE	$\frac{\text{Liabilities}}{\text{Equity}}$	The authors rely on the characteristics of listed companies to include variables in the model
TD_TA	$\frac{\text{Liabilities}}{\text{Total assets}}$

### K-nearest Neighbor (KNN)

K-nearest neighbor (or KNN) is the most basic supervised learning technique in Machine learning. This algorithm solves classification and prediction problems. Here it is considered as one of the top 10 algorithms in data mining because of its efficiency and simplicity simple (Wu et al. 2008), can handle both regression and classification problems. KNN algorithm starts by determining the distance between each value observed data and new data values with unknown target. Distance metric is Euclidean or Manhattan distance function (Zhang 2016), where the Euclidean distance is The simplest and most commonly used. In n-dimensional space, the distance Euclidean between two points  $p(p_1, \dots, p_n)$  and  $q(q_1, \dots, q_n)$  is calculated by the formula:

$$d(p, q) = \sqrt{(p_1 - q_1)^2 + \dots + (p_n - q_n)^2} \tag{2}$$

In addition, the Manhattan distance is calculated based on the absolute difference between points, with the formula:

$$d(p, q) = \sum_{i=1}^n |p_i - q_i| \tag{3}$$

### Decision Tree

Decision Tree is a supervised learning algorithm, applied to judge physical regression and classification problems. Simply, it has the form of a tree with branch represents a feature. This method cuts the data set into parts smaller while growing an associated decision tree. For this technique, it is necessary to clearly define the important terms: Entropy, Information Gain, Gain Ratio and Gini Coefficient. In which, Entropy is a theoretical measure information measuring impurity or uncertainty in a group of (Şirin Özlem & Omer Faruk Tan – 2022). It determines how a decision tree chooses to split the data, is represented by the following formula:

$$H(p) = H(p_1 \dots p_n) = - \sum_{i=1}^n p_i * \log_2 p_i \quad (4)$$

so that the entropy function has the minimum value.

Meanwhile, Information gain (IG) is a metric describing the decrease (improvement) in entropy in X after dividing the dataset on feature (variable) Y. It is calculated as follows:

$$IG(X; Y) = H(X) - H(X|Y) \quad (5)$$

To construct a decision tree, we must perform a search for all valid attributes Information highest gain.

### Random Forest

Random Forest is a commonly used technique for forecasting purposes ability to perform both regression and classification problems. This algorithm works by building multiple decision trees when working with training datasets (Liaw et al.2002; Kumar et al.2006), each tree will perform classification or regression tasks and its own results. The final output is the most voted predictor value through voting rather than relying solely on the conclusions of individual trees, purpose in order to reduce errors in the forecasting model (Mehtar Vijha et al. 2020). This is considered a strong and reliable method. as the number of trees increases, accuracy will be improved. An essential hyperparameter in this algorithm is the number estimated number, representing the number of trees in the forest. Grid Search Cross Validation is often applied to find the number of best estimates. Therefore, this technique has advantages more points than Decision Tree and less problem of overfitting.

### 3.3. Statistical measurements

#### Coefficient of determination

R squared shows how well the model fits the data. Some studies have shown that, with R squared > 50%, a model is considered appropriate. In particular, the higher the R2 value, the stronger the relationship between the independent variable and the dependent variable. That is why R squared is also known as the correlated number system.

$$R^2 = \frac{MSS}{TSS} = 1 - \frac{ESS}{TSS} = \frac{\sum(f_i - \bar{y})^2}{\sum(y_i - \bar{y})^2} = 1 - \frac{\sum(y_i - f_i)^2}{\sum(y_i - \bar{y})^2} \quad (6)$$

#### Mean absolute error (MAE)

Mean Absolute Error (MAE) measures the average magnitude of errors in a set forecasts without considering their direction. That is the mean value on the sample test of the absolute error between the forecast and the actual observation, where all differences individual has the same weight.

$$MAE = \frac{\sum_{i=1}^n |y_i - x_i|}{n} \quad (7)$$

n is the number of data points,  $x_i$  is the actual value and  $y_i$  is the predicted value.

#### Mean squared error (MSE)

Mean Squared Error (MSE) is the most commonly used metric for regression problems. Basically, perform a mean squared error between the predicted and actual values. MSE is a measure of the quality of an estimator and values as close to zero as possible.

$$MSE = \frac{1}{n} \sum_{i=1}^n (Y_i - \widehat{Y}_i)^2 \tag{8}$$

n is the number of data points,  $y_i$  is the observed value  $\hat{y}_i$  is the predicted value.

In regression analysis, plotting is a more natural way to see the overall trend of the data as a whole. Simply MSE indicates how close the regression line is to a set of points. To minimize the MSE, the model can be more accurate, which means the model is closer to the actual data. An example of linear regression using this method is - the OLS method evaluates the fit of a linear regression model to a two-variable data set, but its limitation is related to the distribution of the data.

#### 4. RESULTS AND DISCUSSION

##### 4.1. Results

The data in the paper are one-year lag data for the independent variable. When running the model, the number of observations of the sample decreasing from 3132 observations to 3014 observations after removing the missing data. The results of the descriptive data of the research are showed in Table 2.

Dependent variables on short-term solvency include cash ratio, quick ratio and current ratio with mean value of 0.374, 1.423 and 2.003 respectively. The current ratio fluctuates in the range of [0.097; 6.094]; quick ratio has the smallest value of 0.054 and maximum value of 5.093. The minimum and maximum value of cash ratio are 0.000 and 1.627 respectively. Dependent variables to predict long-term solvency include debt-to-equity ratio and debt-to-total asset ratio with average values of 1,307 and 0.479, respectively. The values of them fluctuate in [0.126;4.079] and [0.001; 1.294] respectively.

Micro-independent variables, the firm size has an average value of 27,881 and fluctuates in [22,939;32510]. The mean value of ROA is 0.078, its minimum value is negative (-0.625) and its maximum value is 0.743. The average asset structure is 0.574 and fluctuates between [0.000;1,000]. The coefficients of revenue growth, asset growth and profit growth have an average value of 0.105, 0.113 and -0.034 respectively. The fluctuations of the 3 variables are [-2.617; 4.029]; [-1.347; 4.422] and [-6.348; 5.489]. The mean value of the mean fixed asset coefficient variable is 0.281, while the minimum value is 0.000 and the maximum value is 0.970. Finally, the variable cash\_assets has an average value of 0.098 and the minimum and maximum values of 0.000 and 0.491 respectively.

For macro-independent variables such as inflation and GDP growth, the mean values of the variables are 0.054 and 0.060 respectively. Inflation has a minimum value of 0.006 and a maximum value of 0.186, while the maximum and minimum values of GDP growth are 0.029 and 0.071 respectively.

**Table 2. Data description**

Features	Obs	Mean	Median	Std. dev	Min	Max
Cashratio	3014	0.374	0.198	0.433	0.000	1.627
Quickratio	3014	1.423	0.982	1.248	0.054	5.093
Currentratio	3014	2.003	1.478	1.390	0.097	6.094
DE	3014	1.307	0.985	1.074	0.126	4.079
TD_TA	3014	0.479	0.494	0.213	0.001	1.294
Size	3014	27.881	27.689	1.380	22.939	32.510

ROA	3014	0.078	0.058	0.088	-0.625	0.743
Assets_structure	3014	0.574	0.604	0.232	0.000	1.000
Sales_growth	3014	0.105	0.089	0.385	-2.617	4.029
Assets_growth	3014	0.113	0.070	0.275	-1.347	4.422

Source: Google Colab

Figure 1 shows the correlation between the variables. It can be seen that the independent variables all have correlation coefficients with the dependent variables all below 0.8. That proves that when running the models, there will be no multicollinearity phenomenon. In addition, most of the correlation between the independent variable and the dependent variable on short-term solvency and long-term solvency is opposite. Variables such as industry, ROA, profit growth, GDP growth and cash\_asset have a positive correlation with short-term solvency and a negative correlation with long-term solvency. Besides, the industry variable has a negative correlation with the quick ratio and the GDP variable has a negative correlation with the cash ratio. The other variables such as size, asset structure, revenue growth, asset growth, fixed asset ratio, and CPI have a negative correlation with current ratio and a positive correlation with long-term debt ratio. In addition, revenue growth, fixed asset ratio, and CPI are negatively correlated with cash ratio.

Figure1. Correlation between features and solvency ratios.

Source:Google Colab

In this study, the authors use supervised learning techniques to predict the short-term and long-term solvency of listed companies, respectively. Besides that, estimating the R2\_score, MAE and MSE indexes to evaluate the accuracy of the model. A higher R2\_score would be expected because it reflects how much the variable is likely to explain the model, while a lower MAE and MSE will be better because it shows the difference between the predicted value and the observed value is not great.

Linear Regression is the first technique used as a measure for comparison with other algorithms. The results are presented in Table 3. It can be seen that Cash ratio and TD\_TA are the two models with the best R2 value, about 42.5% and low mean error. However, the other model has bad results due to very high level error.

**Table 3. Performance metrics with Linear Regression**

Linear Regression	Short-term solvency ratios			Long-term solvency ratios	
	Cash ratio	Quick ratio	Current ratio	DE	TD_TA
R square	0.425	0.292	0.282	0.349	0.426
MAE	0.239	0.778	0.853	0.663	0.130
MSE	0.118	1.143	1.408	0.732	0.026

Source: Google Colab

KNN is the second algorithm used. The short-term and long-term solvency models have not improved, even somewhat less effectively. Table 4 shows that MAE and MSE remain high, however R2\_score significant decrease in Cash ratio and other models have no significant change.

Decision Tree is the next algorithm used by the authors and its result is shown at Table 5. This is the technique with the worst predictive results, in which two models, Quick ratio and Current ratio, are not significant due to the inability of variables to explain the model. The R2\_score values of most models are very low, and the MAE and MSE show that the difference between the observed and predicted values is very high.

**Table 4. Performance metrics with KNN**

KNN	Short-term solvency ratios			Long-term solvency ratios	
	Cash ratio	Quick ratio	Current ratio	DE	TD_TA
R square	0.237	0.292	0.304	0.373	0.424
MAE	0.251	0.681	0.742	0.592	0.121
MSE	0.157	1.143	1.364	0.706	0.026

Source: Google Colab

**Table 5. Performance metrics with Decision Tree**

Decision Tree	Short-term solvency ratios			Long-term solvency ratios	
	Cash ratio	Quick ratio	Current ratio	DE	TD_TA
R square	0.018	-0.087	-0.124	0.130	0.238
MAE	0.289	0.849	0.935	0.675	0.139
MSE	0.202	1.753	2.203	0.980	0.035

Source: Google Colab

The last technique used was the Random Forest. Table 6 gives quite good estimation results but has similarities with previous algorithms. In general, the two models Cash ratio and TD\_TA predict solvency effectively.

**Table 6. Performance metrics with Random Forest**

Random Forest	Short-term solvency ratios			Long-term solvency ratios	
	Cash ratio	Quick ratio	Current ratio	DE	TD_TA
R square	0.344	0.224	0.236	0.298	0.353
MAE	0.263	0.809	0.873	0.679	0.139
MSE	0.135	1.251	1.497	0.791	0.030

Source: Google Colab

We split the data set into 8 parts based on industry hierarchy, corresponding to 8 models to predict the solvency of listed companies in the industry. Supervised learning techniques continued to be used, and the authors found that Information Technology industry had the best predictive results. Table 8 shows that most of the solvency models of both industries have a high fit, except for Quick ratio.

**Table 8. Performance metrics of solvency ratios for Information Technology**

	Linear Regression	KNN	Decision Tree	Random Forest
Cash ratio				
R2_score	0.505	0.504	0.404	0.611
MAE	0.285	0.336	0.337	0.289
MSE	0.159	0.159	0.192	0.125
Quick ratio				
R2_score	0.145	0.194	0.409	0.354
MAE	0.539	0.505	0.416	0.488
MSE	0.424	0.400	0.293	0.321
Current ratio				
R2_score	0.546	0.477	0.444	0.533
MAE	0.599	0.662	0.641	0.624
MSE	0.616	0.709	0.753	0.633
DE				
R2_score	0.457	0.367	0.307	0.338
MAE	0.506	0.561	0.588	0.606
MSE	0.484	0.565	0.618	0.591
TD_TA				
R2_score	0.647	0.492	0.443	0.485
MAE	0.104	0.127	0.117	0.128
MSE	0.017	0.024	0.027	0.025

## 4.2. Discussion

Solvency is an important measure to assess the financial capacity of the business, showing the ability to meet debts when they come due. The study uses data of 305 enterprises (except companies in the Banking and Finance sector) listed on HOSE in the period 2010 - 2021, the total number of observations is 3014. The authors use 4 supervised learning techniques: Linear Regression, KNN, Decision Tree and Random Forest to predict short-term and long-term solvency of firms.

When evaluating the accuracy of the predictive model on testing data, we found that besides the regression model, KNN and Random Forest have good predictive ability. In which the model TD\_TA has the highest fit, followed by Cash ratio but the difference in accuracy between the techniques is quite large. The remaining models are not highly effective because the average error is at a very high level, making the reliability of the prediction results unsatisfactory. In general, when building a machine learning model and testing it on testing data, it does not bring the expected results due to the large error, which is shown by the two indicators MAE and MSE while the explanatory power of the model is poor (low R2\_score). Compared with the regression model (Linear Regression), three techniques KNN, Decision Tree and Random Forest have not had a clear improvement, even for some predictive models there is no meaning.

The authors, when retesting the predictive ability of the model on training data, found that the results had a positive trend. It is noteworthy that Decision Tree technique when giving absolute efficiency with R2\_score in all models is 100%, but before working with testing data, this algorithm did not have good results. This shows that Decision Tree is having an overfitting problem, that is, when working on training data that performs well but is less effective on testing data. On the other hand, KNN shows a good ability to operate and work with the model because both bring positive results for the two data sets.

## 0. Conclusion

A lot of significant data may be evaluated and produced through the application of machine learning to the administration of businesses. By accurately accounting for the impacts of several influencing factors, this approach performs an analysis of large-scale and complicated research samples, something that previous methods have not been able to do. Due to the fact that each technique will have a different approach to data analysis and processing, there are still a lot of issues with machine learning accuracy that need to be resolved. According to the outcomes of the research, each algorithm's anticipated value and the actual value diverge by a sizable amount, even after accounting for the influence of macro and micro factors on solvency. The research project is limited in part by the size of the data set and the close relationships between the variables, which render the standard supervised learning techniques ineffective. The authors propose utilizing deep learning techniques (Deep Learning) and Neural networks to resolve this issue because these methods function more intricately and create neural networks to analyze the input vastly and interconnectedly.

## FACTORS AFFECTING THE SUSTAINABLE DEVELOPMENT OF VIETNAM COMMERCIAL BANKS

**Author: Ngo Yen Nhi<sup>1</sup>, Nguyen Hong Hanh<sup>1</sup>, Hoang Thi Phuong Anh<sup>1</sup>,  
Pham Minh Tu<sup>1</sup>, Than Thi Thu Hoai<sup>1</sup>  
Mentor: Nguyen Minh Phuong<sup>1</sup>**

**ABSTRACT:** Sustainable development is emerging as a global trend among commercial banks. In Vietnam, this issue has garnered attention from the government, as well as economic and social management agencies, initiating a promotion process. However, the lack of sustainable development standards in Vietnamese commercial banks poses several challenges to this process. This study aims to examine and analyze the significant factors that influence the sustainable development of commercial banks in Vietnam. The research sample consists of 112 bank officials and employees who possess knowledge of sustainable development issues. They participated in an online questionnaire survey. The authors conducted theoretical research based on domestic and international literature regarding the factors influencing the sustainable development of commercial banks. They employed linear regression analysis to analyze the current situation based on the questionnaire responses. By utilizing online surveys and multiple regression models, the study aims to identify and conclude the factors that influence sustainable development in commercial banks in Vietnam. A total of 112 participants took part in the survey, and the collected data was quantitatively analyzed using SPSS 20.0 software. The research results identified three influencing factors in the sustainable development process of commercial banks in Vietnam: Environmental factors, Social factors, and Governance factors. Therefore, the study proposes recommendations to assist commercial banks in effectively achieving the government's sustainable development goals.

**Keywords:** Affecting Factors; Sustainable Development; Commercial Banks.

### 1. INTRODUCTION

#### 1.1. International studies

##### Assessing Sustainability through Operational Efficiency

In recent years, the concept of “sustainable development” has been extensively discussed in articles and research papers. It is evident that the notion of sustainable development has gained recognition globally. In order to effectively implement sustainable development processes in banks, researchers both internationally and in Vietnam have conducted numerous studies to identify factors that influence the stability, efficiency, and sustainability of commercial banks.

Tom (2012) utilized the CAMEL model, developed by the US Office of the Comptroller of the Currency to monitor the status of credit institutions in the United States, to determine the operational efficiency of commercial banks in Kenya. By analyzing linear regression using tabular data, the author discovered that Capital adequacy, Income, and Liquidity had a negative impact on bank operational efficiency. Consequently, banks should strive to strike an optimal balance in terms of capital adequacy and liquidity ratios. In the same year, Vijayakumar also employed the CAMEL model to assess the operational efficiency of commercial banks in India. Based on the average of the following ratio groups: C - Capital adequacy, A - Asset quality, M - Management capability, E - Earnings capacity, and L - Liquidity capacity, the author ranked the commercial banks. The computed figures demonstrated that commercial banks in India succeeded in maintaining a higher capital adequacy ratio than the prescribed requirement (>9%).

<sup>1</sup> Banking Academy Vietnam.

In contrast to the assessment of the operational efficiency of commercial banks based on the CAMEL model, Michael Adusei (2015) examined the impact of bank size and loan risk on bank stability. This study collected data from rural banks in Ghana from the first quarter of 2009 to the fourth quarter of 2013. The research incorporated diversification, credit risk, liquidity risk, profitability, inflation, and GDP as control variables. The findings revealed that an increase in the scale of rural banks enhances bank stability, and loan risk also positively affects bank stability.

Evaluating the Sustainability of Commercial Banks through Environmental and Social Commitments:

Contrary to previous studies, the research team consisting of Guang-Wen Zheng, Abu Bakkar Siddik, Mohammad Masukujjaman, and Nazneen Fatema (2021) has demonstrated the validity of the hypothesis that the environmental aspect of Green Finance plays a crucial role in enhancing the sustainable operations of banks through investments in environmentally beneficial projects. The study utilized secondary data obtained from the annual reports of the Bangladesh Bank, as well as surveys conducted among employees in 35 out of 47 operational banks. However, it is important to note that the study solely focused on the opinions of bank executives regarding the aspects of Green Finance, which represents only a fraction of the bank's sustainability efforts. Therefore, the resulting findings may not be generalized beyond the scope of the study. Based on a comprehensive review of research conducted worldwide, it is evident that there has been a lack of comprehensive studies analyzing the factors influencing the sustainable development model of the commercial banking system and their direct impact on it.

Assessing the level of sustainable development according to the Global Reporting Initiative (GRI) standards:

The Global Reporting Initiative (GRI) is a widely utilized framework for voluntary reporting on environmental and social activities by businesses and organizations worldwide. GRI offers comprehensive guidance and standards for reporting information regarding an organization's environmental, social, and governance issues. The GRI performance indicators encompass a range of core indicators and supplementary indicators that encompass the three fundamental dimensions of sustainability: economic, environmental, and social indicators. The following are the performance indicators as outlined by GRI:

**Table 1: GRI performance indicators**

Performance indicators	Core indicators	Additional indicators	Total number
Economic	10	3	13
Society	16	19	35
Environment	24	25	49
Total number	50	47	97

*Source: Moneva and collaborators (2006)*

GRI has been widely adopted by banks worldwide to assess their level of sustainable development. Standard Chartered Bank, for instance, has implemented GRI in reporting and evaluating its financial, environmental, and social performance. They have incorporated GRI into their sustainability reports, providing detailed information about the bank's impact on the community and the environment. Similarly, ABN AMRO, a multinational bank headquartered in the Netherlands, has utilized GRI to develop its sustainability strategy and assess its effectiveness in promoting sustainability. They have employed GRI to select appropriate indicators and report in accordance with international standards. Another bank, Santander, a multinational bank based in Spain, has utilized GRI to report on its sustainable activities and approach

to social finance. GRI has played a pivotal role in helping Santander identify key indicators and reporting standards, ensuring transparency, and facilitating comparisons with other banks.

A comprehensive analysis of existing global studies reveals that, thus far, no research project has thoroughly examined all the influencing factors and their direct impact on the sustainable development model of the banking system. Therefore, this research aims to enhance our understanding of the factors that influence the awareness of sustainable development in banking institutions.

## **1.2. Domestic studies**

In Vietnam, sustainable development in commercial banks has also been addressed in several studies as follows:

Nguyen Thanh Phuong (2014) argued that two main factors influence the sustainable development of commercial banks, including internal and external factors. The external factor is the macro environment, which includes elements such as the economy, politics and law, government, culture and society, population, nature, and the microenvironment, which includes factors like existing and potential competitors, customers, and alternative financial markets. The author focused on studying the internal factors: human resources, managerial capabilities, product portfolios, services, and banking technology. However, since the research aimed to explore the requirements and standards of sustainable activities and the development model of the commercial banking system, the article did not delve deep into the impact of the influencing factors on sustainable development.

To analyze the impact of macro factors more clearly, Leng Thi Lan and colleagues (2021) established a model and presented their findings. The study showed that the growth rate of GDP, interest rates, and risk-free interest rates have a greater impact on the market risk of banks. Therefore, the State Bank of Vietnam and relevant government agencies need to control GDP growth and reduce lending and treasury bond interest rates.

Nguyen Hong Son and colleagues (2015) synthesized perspectives and evaluation criteria for sustainable banking development. Through an assessment of the current state of development of the commercial banking system in Vietnam and its restructuring following international practices, the authors proposed solutions for sustainable development of the commercial banking system in Vietnam. However, the study mainly focused on assessing the current state of development and restructuring of the commercial banking system based on criteria for evaluating stability and soundness. It did not extensively evaluate the current state of sustainable development of the commercial banking system in terms of environmental and social aspects in banking operations, following international practices.

In the above studies, the authors identified factors influencing sustainable development, but most of them had a limited scope, focusing on one or a few commercial banks without comprehensive coverage. Furthermore, the studies did not extensively examine the impact of each factor on the sustainable development model of commercial banks.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Theoretical basis**

#### **2.1.1. *Characteristics of sustainable development in commercial banks***

Based on previous research, the authors have identified the characteristics of sustainable development in banks as follows:

(1) Sustainable banks have strong and efficient financial capabilities. They employ medium and long-term strategies to maintain a sufficiently robust financial capacity, enabling them to sustain and recover from risks arising from external impacts or business losses.

(2) Sustainable banks have policies that support and provide financing for companies or projects that are responsible for the environment and society, aiming to foster sustainable economic development. Additionally, sustainable banks implement solutions to monitor, limit, and address adverse impacts on the environment and society.

(3) The activities of sustainable banks bring benefits not only to shareholders but also to customers, regulatory authorities, and employees. The strategies of sustainable banks aim to meet the needs of both the bank and the community while considering short-term and long-term value.

### ***2.1.2. The role of sustainable development in commercial banks***

Firstly, sustainable development enhances the profitability of commercial banks and creates favorable conditions for the overall sustainable development of the economy.

Secondly, it ensures the resilience, safety, survival, and development of commercial banks against environmental impacts.

Thirdly, the sustainable development of commercial banks plays a role not only in the sustainable development of the economy but also in the stability of the environment and society.

Fourthly, from a social perspective, sustainable banks prioritize not only profitability for shareholders but also ensure benefits for customers and the rights of bank employees. Sustainable banks focus on social and political aspects, including employee welfare, issues of equality, human rights, and policies supporting lending to the poor and rural areas to improve the quality of life and achieve social and political sustainability.

### ***2.1.3. Indicators for assessing the sustainable development of commercial banks***

The Global Reporting Initiative (GRI) Sustainable Development Report is the first widely applied global standard for sustainable development reporting. It supports large and small public and private companies in protecting the environment, community development, and economic development by improving governance and stakeholder relationships, enhancing reputation, and building trust. Currently, Vietnamese commercial banks are preparing reports based on the standards provided by the Global Reporting Initiative (GRI) Sustainability Reporting Guidelines. The GRI standard provides a common language for banks and stakeholders to understand the economic, environmental, and social impacts of the banks.

According to GRI (2016), a sustainable development report is defined as “measuring, disclosing, explaining, and being accountable to internal and external stakeholders for an organization’s performance toward sustainable development goals.” The issues related to the 17 Sustainable Development Goals and the National Action Plan for implementing the 2030 Agenda for Sustainable Development have been simplified and integrated into the 2020 Corporate Sustainability Index (CSI) on social responsibility and environmental responsibility (VCCI, 2020). In 2020, the CSI program evaluated companies based on 119 indicators in four areas: Sustainable Development Performance Indicators, Governance Indicators, Environmental Indicators, and Labor-Social Indicators (VCCI, 2020). Therefore, sustainable development indicators include profitability, profitability capacity, import-export turnover, average income of workers, contributions to the budget and society, wastewater ratio, waste collection and recycling, and energy efficiency in production and business processes. Environmental indicators are also emphasized, including compliance with laws, efficient use of natural resources, environmental protection, pollution prevention,

incident response, environmental improvement, and environmental education and communication within companies. Thus, it can be seen that the CSI indicators align with the GRI standards, serving as a basis for listed companies in Vietnam to comply with and fulfill their obligations regarding sustainable development reporting.

Based on the GRI report, it is possible to compare the performance of banks in achieving sustainable development goals. When a bank successfully fulfills these goals and discloses them comprehensively, the market will react positively to the bank. This increases the bank's reputation and long-term profitability.

## **2.2. Research hypothesis**

Sustainability in the environment means that while utilizing natural resources, the quality of the human living environment must be ensured. This includes ensuring the purity of air, water, land, geographic space, and landscapes. The quality of these elements must be consistently valued and evaluated according to national and international standards. We need to efficiently utilize natural resources to improve the environment and enhance the quality of the living environment. According to Associate Professor Dr. Pham Thi Thanh Binh from the Institute of World Economy and Politics (2020), sustainable environmental development includes the following main contents: efficient use of resources, particularly non-renewable resources; development within the carrying capacity of ecosystems; biodiversity protection and ozone layer preservation; greenhouse gas emissions reduction; strict monitoring of sensitive ecosystems; waste reduction, pollution improvement (water, air, soil, food), and environmental improvement and restoration in polluted areas.

Hypothesis 1: The Environmental Factor has a positive impact on the sustainable development of commercial banks.

Long-term and ever-changing issues such as consumer habits, saving habits, religion, ethnicity, etc., are factors that banks need to understand in order to create demand for people to use banking products and services and develop products that align with their habits and needs. According to Tran Thi Hoang Yen (2016): "The social responsibility of a bank is a commitment to effectively address issues of corporate governance, human rights, labor practices, environment, fairness in operations, customers, and communities, based on compliance with national laws, international customs, and ensuring a harmonious balance of interests while contributing to the sustainable socio-economic development of the country." In practice, the social responsibility of banks, in particular, and businesses in general, is a broad concept that can be understood and expressed in various ways based on the perspective of each author. Regarding the responsibility towards stakeholders, Hopkins (2003) points out that Corporate Social Responsibility (CSR) concerns dealing with both internal and external stakeholders of a business in a socially responsible manner. In other words, the broader goal of CSR is to create an increasingly high standard of living while maintaining the profitability of the business for its relevant parties.

*Hypothesis 2: The Social Factor has a positive impact on the sustainable development of commercial banks.*

Governance in banking refers to a system of arrangements, policies, and regulations that guide, operate, and control the bank. Governance focuses on the structures and processes of the company to ensure fairness, transparency, and accountability. Therefore, governance is always an important aspect of effective bank management and serving the interests of shareholders. Sustainable development of banks in terms of governance includes the following aspects: the rate of total asset growth of commercial banks, which reflects the scale, structure, and quality of assets and indicates the bank's level of development; the rate of loan growth, which is a criterion that clearly reflects the bank's management capability; the rate of

net income growth, which indicates the business efficiency of commercial banks through criteria such as net interest income, income from service activities, income from foreign exchange trading, income from securities trading, etc.

*Hypothesis 3: The Governance Factor has a positive impact on the sustainable development of commercial banks.*

**Figure 1. Proposed research model**

### 3. RESEARCH METHOD

After synthesizing theories, models, and inheriting from domestic and international research studies, the research team has filtered and selected appropriate factors to construct a research model (Figure 1) on the influential factors of sustainable development consciousness among SMEs in Vietnam.

The research team chose to conduct the investigation through a questionnaire distributed to employees and staff members of banks throughout Hanoi city. The data collection for this study took place from January 2022 to March 2022, resulting in a total of 115 responses. However, upon further examination, three responses were found to be erroneous and inconsistent, leaving a final sample of 112 valid responses for the research. The sample size met the required standards of Bollen (1998) and Hair et al. (1998), which stipulate that it should be at least five times the number of observed variables (minimum of 75).

To measure the sustainable development consciousness of SMEs, the observed variables were assessed using a Likert scale with five response options: (1) Strongly Disagree; (2) Disagree; (3) Neutral; (4) Agree; (5) Strongly Agree. All valid samples were processed using SPSS software to perform the steps of reliability analysis, correlation analysis, factor analysis, regression analysis, and hypothesis testing based on the constructed questionnaire. The questionnaire consisted of three independent variables (Management, Environment, and Society).

### 4. RESULTS AND DISCUSSION

#### 4.1. Results

##### 4.1.1. Survey sample characteristics.

Through the survey, the author collected 115 responses, out of which 112 valid responses (accounting for 97.39%) were used as research data.

**Table 2. Descriptive statistics of the sample by individual characteristics**

Personal Characteristics	Detail	Quantity	Percent (%)
Gender	Male	48	43%
	Female	64	57%
Age	20 - under 40 year olds	46	41%
	40 - under 60 year olds	39	35%
	Above 60 year olds	27	24%
Academic qualification	Bachelor	75	67%
	Master	27	24%
	Doctorate	10	9%
Job position	Specialist	81	72%
	Manager	31	28%
Experience duration	Under 5 years	12	11%
	5 - under 10 years	30	27%
	10 - under 20 years	45	40%
	Above 20 years	25	22%

**4.1.2. Reliability testing of the measurement scale.**

The results in Table X indicate that all variables have Cronbach’s alpha coefficients  $> 0.7$ , and the variable-total correlations are  $> 0.3$ , demonstrating that the variables meet the requirements for reliability and can be used for further exploratory factor analysis (EFA).

**Table 3. Reliability testing of the measurement scale**

Observed variable	Number of observed variable	Cronbach’s Alpha	Minimum total variable correlation coefficient
Governance (GOV)	4	0,757	0,585
Environment (ENV)	5	0,858	0,439
Social (SOC)	6	0,837	0,484

**4.1.3. Exploratory factor analysis:**

The EFA analysis results for 15 independent observed variables represent 3 independent factors with a Kaiser-Meyer-Olkin (KMO) coefficient of 0.771 and a significance level (Sig. = .000) of Bartlett’s test at 5%. This confirms that the data used in this study is suitable. The total variance extracted coefficient is  $61.056\% > 50\%$ , and all factors have Eigenvalues  $> 1$ , indicating that the 3 factors used in the model explain 61.056% of the data variation.

The factor analysis of the dependent variable on the sustainable development of the organizations achieves a score of 0.683 and a significance level (Sig. = .000) of Bartlett’s test at 5%, indicating that these variables are correlated with each other and entirely appropriate for factor analysis. The total variance extracted coefficient is 81.226%, and the Eigenvalue index reaches 2.208, indicating that the 3 observed variables of the dependent variable have formed 1 factor with a total variance extracted of 81.226%.

**Table 4. Results of Exploratory Factor Analysis (EFA)**

Factor	KMO measure	Sig	Total extracted variance
1. Independent variables	.771	0.000	61.056
2. Dependent variables	.738	0.000	81.226

**Table 5. Results of Exploratory Factor Analysis (EFA)**

Biến quan sát	Factor		
	1	2	3
SOC4	.875		
SOC3	.802		
SOC2	.760		
SOC1	.748		
SOC6	.616		
SOC5	.514		
ENV2		.805	
ENV5		.825	
ENV4		.806	
ENV3		.766	
ENV1		.728	
GOV4			.856
GOV2			.745
GOV3			.708
GOV1			.653

**4.1.4. Correlation coefficient matrix**

To examine the correlation between the independent variables GOV, SOC, ENV, and the dependent variable BV, we employed Pearson's correlation test in a scientific research style. The analysis results revealed that all Sig. values were less than 0.05, indicating a linear relationship between the dependent variable and the independent variables.

**Table 6. Analysis of the correlation between factors**

Correlations					
		BV	GOV	SOC	ENV
BV	Pearson Correlation	1	.637**	.476**	.302*
	Sig. (2-tailed)	.000	.000	.000	.002
	N	112	112	112	112
GOV	Pearson Correlation	.637**	1	.593**	.655*
	Sig. (2-tailed)	.000		.000	.000
	N	112	112	112	112
SOC	Pearson Correlation	.476**	.593**	1	.393**
	Sig. (2-tailed)	.000	.000		.001
	N	112	112	112	112
ENV	Pearson Correlation	.302*	.655*	.393**	1
	Sig. (2-tailed)	.002	.000	.000	
	N	112	112	112	112

The adjusted coefficient of determination ( $R^2$ ) is 54.3%, which is considered appropriate as it exceeds the threshold of 50%. Additionally, the Durbin-Watson (DW) statistic of 2.088 falls within the

range of [1, 3], indicating the absence of first-order autocorrelation among the error terms, suggesting good data integrity.

The regression results also reveal that 3 out of 6 variables exhibit statistically significant relationships at the 5% level (Sig.  $\leq 0.05$ ), indicating that the theoretical model is well-aligned with the research data. Furthermore, the variance inflation factor (VIF) for all variables is  $< 2$ , suggesting no issues of multicollinearity in the model.

Regression model:  $BV = 0.940 + 0.402GOV + 0.223SOC + 0.098ENV$

In exploring violations of linear regression assumptions, the Scatterplot (Figure 3) illustrates that the standardized residuals are concentrated around the zero axis, indicating that the assumption of the linear relationship is not violated.

The Histogram (Figure 2) displays a bell-shaped curve, which aligns with the graph’s form of a normal distribution. The standard deviation of 0.986 is close to 1, suggesting that the residual distribution approximates normality and is not violated.

The P-P Plot (Figure 4) represents the observed data points closely clustered around the diagonal line of expected values, indicating that the residual data follows a normal distribution

**Table 7. Regression model results**

Model	B	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
		Std. Error	Beta				Tolerance	VIF
1	(Constant)	.940	.460		2.043	.043		
	GOV	.452	.100	.402	4.546	.000	.833	1.200
	SOC	.229	.091	.223	2.523	.013	.834	1.199
	ENV	.081	.067	.098	1.197	.000	.979	1.022

Adjusted R = 54,3%  
 Durbin – Watson = 2,088  
 Sig. of ANOVA test = .000

**Figure 2. Histogram chart**

**Figure 3. Scatterlot**

**Figure 4. P-Plot**

## 4.2. Discussion

### 4.2.1. Discussion

After the analysis, the research results show that 3 factors are used to include in the model including “Governance”, “Society” and “Environment” all have significant impact on the dependent variable “sustainable development consciousness of commercial banks”. The Governance factor is considered to have the strongest impact on the sustainable development of the Bank, followed by the Environmental factor with the second strongest impact after the Governance factor, and finally the social factor.

According to the research team, this result is quite accurate and appropriate compared to the present time, in the context that Vietnamese commercial banks are increasingly interested in sustainable banking development. According to the ESG model, activities that have a positive impact on society are a part of affecting the sustainable development of Commercial Banks. income is linked to the bank’s business results, salary is paid according to requirements and work efficiency, there are reward regimes to encourage employees to stick with the bank. Commercial banks have training policies to improve the quality of human resources and promotion policies to motivate employees to promote their own capabilities.

### 4.2.2. Solutions and Recommendations

#### For Commercial Banks

##### About Environment and Society

Firstly, Commercial Banks need to establish and improve their ESMS (Environment and Social Risk Management System) based on the environmental and social risk management policy framework established by the State Bank. Establishing an ESMS to assess, manage environment and social in the customer management process will enable banks to facilitate the approval of loan projects.

Secondly, Commercial Banks need to focus on training and developing the quality of human resources towards sustainable development. Specifically, this includes presenting a positive and professional image to candidates at the early stage of recruitment; implementing specific career development paths for officers and staff; providing appropriate incentives for each job position.

##### About the Governance

Firstly, Commercial Banks need to effectively manage and tightly control non-performing loans to improve the quality of assets and financial capacity. This includes regularly assessing and classifying

the debt recovery ability of customers, undertaking debt restructuring to support struggling businesses, especially in the aftermath of the Covid-19 pandemic.

Secondly, Commercial Banks need to enhance their management capacity and operate according to international standards. Quality management is a crucial factor for sustainable development and the banking governance model must ensure independence in terms of authority and responsibility.

Thirdly, Commercial Banks need to develop and leverage capital sources, increasing equity capital through various measures, including issuing bonds, medium and long-term deposit certificates; studying capital costs in urban areas to formulate appreciate mobilization policies; utilizing capital sources from financial institutions as they provide long-term funding with low fundraising costs.

#### **For regulatory agencies**

To achieve sustainable development goals in Vietnam Commercial Banks, regulatory agencies such as the government and the State Bank of Vietnam play a crucial role in issuing and overseeing regulations. Specifically:

Firstly, the government needs to establish a national legal framework for sustainable development and enforce it mandatorily for banks, businesses, and other organizations. This framework should align with national sustainability policies and require businesses to adhere to sustainable practices.

Secondly, the State Bank of Vietnam should introduce incentive mechanisms and tax advantages to promote green and sustainable financial activities in commercial banks. This can include providing preferential interest rates for loans or supporting investment capital for projects that have positive impacts on the environment and society.

Thirdly, the State Bank of Vietnam needs to invest in training and raising awareness about sustainable development within the banking industry. This can be achieved through developing training programs, organizing seminars and discussions, and collaborating with educational institutions to create research programs and address issues related to sustainable development.

Fourthly, the State Bank of Vietnam should implement programs to promote and disseminate information about sustainable development in commercial banks. The content should include reports, guidelines, and educational materials aimed at explaining fundamental concepts, benefits, and standards related to sustainable development. Additionally, the State Bank of Vietnam can collaborate with environmental and social organizations, institutions, and relevant stakeholders to enhance promotion through campaigns, events, and community activities. This can also involve partnerships with universities, research institutes, and participation in international forums and discussions.

#### **For customers**

Firstly, customers should research and choose sustainable commercial banks by considering their criteria and regulations regarding the environment, society, and governance. They should explore the sustainable financial products and services offered by banks.

Secondly, customers should use sustainable financial products and services provided by commercial banks, including green loans, social savings and investments, green investment funds, and green insurance.

Thirdly, customers can request and provide feedback to commercial banks regarding the promotion of sustainable development. They can send feedback, suggestions, and proposals to banks regarding policies, standards, and products related to sustainable development. Customer participation and proactivity can exert pressure on banks to enhance awareness and implement positive changes.

## 5. CONCLUSION

The research study evaluated the factors influencing the sustainable development of commercial banks, including Environment - Society - Governance. The study surveyed management executives from several Commercial Banks, and the results showed that the surveyed banks are all concerned and actively implementing sustainable banking development. From this, it can be seen that the majority of Commercial Banks in Vietnam have been and are pursuing sustainable development goals. However, there are still many barriers to overcome in the implementation process. These barriers need to be addressed promptly to successfully execute a safe, effective, and sustainable development strategy for the commercial banking system, such as: enhancing the legal framework for sustainable development, improving the quality of human resources and capital capacity, and refining the environmental and social risk management system. Based on the analysis of the current situation of the influencing factors and their impact on the sustainable development process of Vietnamese Commercial Banks, the research project has proposed sustainable solutions for the sustainable development of Vietnam Commercial Banks in line with international integration trends.

Mentor: Le Thu Ha<sup>1</sup>**

**ABSTRACT:** *This study uses a number of regression models and data from several registered Vietnamese commercial banks to examine the impact of the policy rate on the profitability of commercial banks in Vietnam over the course of ten years, from 2013 to 2022. Differently from most of the previous related studies that concentrated on advanced economies, this study offers empirical evidence on the relationship between the policy rate and commercial bank profitability in Vietnam. The refinancing rate is used to measure the policy rate, while the Return over Equity ratio serves as an index for bank profitability. The estimations reveal a significant negative impact of the refinancing rate on the Return over Equity ratio of Vietnamese commercial banks, although this negative effect was found to be increased over time. Moreover, the results show that the Return over Equity ratio of Vietnamese commercial banks is significantly affected by it lags, from the first to fourth lags.*

**Keywords:** *bank profitability, policy rate, monetary policy*

### 1. INTRODUCTION

The COVID-19 pandemic caused a 3.1% reduction in the global economy in 2020, with advanced economies experiencing a 4.5% decline and emerging and developing nations experiencing a 2.1% decline. Many countries aggressively launched a loosening monetary policy together with multiple stimulus packages to address the challenge of the pandemic. As a result, aggregate demand suddenly increased in 2021. In the US and other developed economies, this has led to excessive inflation along with supply chain disruptions. Inflation was further fueled by the energy crisis as Russia, one of the largest fossil fuel exporters, was isolated from Western markets.

In 2022, inflation issues continued to intensify in several countries. To control and bring inflation close to the target inflation rate, the US Federal Reserve has increased the FED fund rate six times since March 2022, specifically the federal funds rate has been raised to 3.75% - 4%, the highest level since January 2008. Many central banks around the world have applied tightening monetary policies and raised their policy rates. By the end of the third quarter of 2022, nearly 90 economies around the world have conducted 257 interest rate hikes. In response to interest rate adjustments made by more than 90 central banks around the world, on October 24, 2022, the State Bank of Vietnam also issued Decision No. 1809/QĐ-NHNN to raise the policy rate by 1% to control inflation, stabilize the macro-economy, and simultaneously securitize crucial economic indicators.

It is clear that the State Bank of Vietnam's interest rate policy is essential for keeping inflation under control and stabilizing the macroeconomy. This policy has an impact on how commercial banks operate, which has an impact on their profitability. A number of studies have shown how the policy rate affects the profitability of commercial banks (Borio et al, 2017; Gambarcota, 2009, etc). However, these studies were frequently carried out in developed and advanced economies. In developing nations, particularly Vietnam, the

literature and empirical evidence are found to be rather inefficient. Therefore, the authors decided to conduct this research to determine the impact of the policy rate on the profitability of commercial banks in Vietnam, which contributes to both the literature and the monetary policy conduction of the State Bank of Vietnam.

This study includes five sections. Apart from the first section of introduction, literature review will be presented in section 2. Section 3 describes data and methodology which are applied in this study. Section 4 shows results of regression models and related discussion, while some conclusions and policy implications will be provided in section 5.

## 2. LITERATURE REVIEW

Monetary policy has been used by central banks around the world as a mean to regulate a country's economy and achieve its macroeconomic goals. The policy rate (also known as the central bank rate) is a key monetary policy instrument set by the central banks as a basis for all interest rates in an economy. Due to the crucial role of the policy rate and its impact on the financial system, a number of studies on the topic have been conducted.

In the context of advanced economies, the body of literature often focuses on how banks react in a condition that interest rates are purposefully kept low for an extended period. Using data from 109 international banks based in developed economies for the 1995-2012 period, Borio et al (2017) examined the impact of changes in the level of short-term rate and the slope of the yield curve on the different components of a bank's income statement. The study suggests that the positive impact of the interest rate structure on net interest income dominates the negative one on loan loss provisions and on non-interest income, and that an extended period of unusually low-interest-rate environment erodes bank profitability. Elaborating on bank activities in a low-interest-rate environment, a study by Brei et al (2020), in which Borio was also a contributor, found that low-interest rates induce banks to shift their activities from interest-generating to fee-related and trading activities. Based on this shift in the main income source of banks, an inference of a corresponding change in bank profitability can be made, which needs further study.

Gambacorta (2009) found a trend of increased risk-taking in banks when interest rates are low for an extended period. In particular, an average bank's probability of default increases by 3.3% after 10 consecutive quarters of interest rates being maintained below the benchmark. This growth in bank risks implies a decrease in the bank's profitability and stability. This finding is further supported by another study also by Gambacorta et al (2014) which was conducted on 643 listed banks in the European Union and the United States.

On the other hand, Hancock (1985) with data from the Federal Reserve System showed a positive relationship between raising interest rates and bank performance. This is due to the income generated by higher loan interest rates being higher than the cost generated by higher deposit rates.

From the aforementioned research, it can be seen that an expanded time of low-interest-rate environment tends to have a damaging effect on bank income; on the other hand, a rising interest rate in some cases will support the improvement in bank profitability. However, there are also a number of studies that have established a negative relationship between a higher policy rate and the performance of commercial banks. Gerlach et al (2018) studied how banks' funding costs will change when interest rates are raised. The study implies that a 1% increase in the Federal Funds rate would increase overall deposit funding costs by about \$40 billion, which is roughly equal to 25% of aggregate annual net income for commercial banks and savings institutions. This means that banks' interest income and subsequently bank profitability will be damaged by an increase in the FED rate.

Altavilla et al (2017) examined the impact of monetary policy on banks' profitability in the context of a low-interest-rate environment with ROA as the indicator for bank profitability. The study focused on the period from 2000 to 2016 with quarterly data collected from banks in Europe and found that a loose monetary easing policy is relatively more beneficial for banking activities. Specifically, low interest rates will promote economic activities, and have a positive impact on bank profits. However, keeping interest rates low for an extended period also harms the profitability of banks.

Lehmann and Manz (2006) concluded a significant impact of macroeconomic factors, which include interest rates, on the profitability of Swiss banks. In particular, rising interest rates, among other changes in the macroeconomic environment including financial crisis and the crash of the stock market, will lead to a remarkable loss in the Swiss banking system.

Kumar et al (2020) studied the relationship between monetary policy and bank profitability in New Zealand using a generalized method of moments model on data for 19 commercial banks in New Zealand from 2006 to 2018. The result shows that short-term rates have a positive impact on bank profitability, while long-term rates affect bank performance negatively. Paula (2020) also found that a loose monetary policy has a negative impact on net profit margin, thereby affecting bank profitability.

In the context of developing economies, there are different conclusions in the body of literature. Examining the effect of monetary policy on bank profitability in India, Rao et al (2006) included the bank rate of RBI (Reserve Bank of India) as one of the independent variables in their regression model. The study was conducted on data from both the public and private banking sectors. The result showed that the central bank rate contributes negatively to both sectors' profitability, with the public banks being subjected to more significant influence. On the other hand, Uchendu (1995) used data from 44 commercial banks and data provided by the Central Bank of Nigeria and concluded a positive influence of a rising interest rate on bank profitability.

Mbabazize et al (2020) used data covering nine years from 2010 to 2018 from all registered commercial banks at the time in Uganda and found a positive relationship between the policy rates and bank profitability.

The impact of the policy rate on bank profitability has also been studied from an unconventional banking perspective. Minny and Görmüş (2017) used a FMOLS model with quarterly data from three Islamic banks in Turkey (Kuveyt Turk, Al Baraka Turk, and Turkiye Finance) for the 2008-2016 period to investigate the impact of interest rates on Islamic banks' profitability. The empirical study suggests that a rising interest rate induces a slight increase in an Islamic bank's profitability. Noreen et al (2018) studied the relationship between changes in interest rates and the profitability of four Pakistani banks and found a direct and positive influence of interest rates on bank performance.

As same as in other countries, in Vietnam, the policy rate and its impact are often examined as a part of the monetary policy. To investigate how monetary policy affects bank profitability, Nguyen et al (2016) used annual data for the period 2007-2014 from 20 commercial banks operating in Vietnam. The study then constructed a regression model in which the bank's profit was implemented as the dependent variable, together with three independent variables representing different proxies of the monetary policy, including the money base, the discount rate, and the required reserve ratio. Aside from that, they also included some internal and external determinants of bank performance as other independent variables including the bank's credit growth, loan-to-deposit ratio, liquidity ratio, and the economic growth of the country. The study concludes a significant negative relationship between the discount rate and banking profit.

Do (2017) evaluated how interest rates and yield curves affect the profitability of Vietnamese commercial banks. The study used a research sample of 24 commercial banks in Vietnam with the annual data from 2006 to 2016. The research results show a nonlinear relationship between the interest rate structure and bank income. More specifically, how short-term interest rates and the slope of the yield curve affect the ratio of banks' ROA and NIM can be illustrated by an inverted U-shaped parabola. This means that in the short term, an increase in interest rates helps increase bank profitability but in the long term, the impact is reversed and becomes damaging. Meanwhile, the relationship between interest rates and NIM is U-shaped, which means that at first, an increase in interest rates reduces non-interest income, then at a certain point, as interest rates keep rising, non-interest income increases. In another study, Nguyen (2017) with data for the 2006-2015 period in Vietnam found that the impact policy rates have on banks' interest rate spread is inconclusive, which is different from previous studies.

According to the literature, bank profitability can be significantly impacted by changes in policy interest rates. However, there are some differences in the findings of the earlier studies, and the specific impacts depend on various factors. Therefore, more research is required.

### 3. DATA AND METHODOLOGY

#### 3.1. Data

Data were collected from quarterly reports of 11 Vietnamese commercial banks over the period from the first quarter of 2013 to the fourth quarter of 2022. The total number of observations is 440. Bank profitability is indexed by return on equity (ROE) and the policy rate is indexed by the refinance rate issued by the State Bank of Vietnam (PR). A number of bank-specific independent variables are also added to the model, including non-performing loans ratio (NPL) which indexes the credit quality of the bank, loans to deposit ratio (LDR) which represents the liquidity availability of the bank, and the leverage ratio (LEV) which measures the insolvency risk of the bank.

**Table 1. Data Sources and Measurement**

Variables	Acronym	Source	Measurement	A Priori Expectation
Bank Profitability	ROE	Reports of banks	Profit after taxes over equity	
Policy Rate	PR	State Bank of Vietnam	Refinance rate	-
Non-performing loans ratio	NPL	Reports of banks	Non-performing loans over total loans	-
Loan-to-deposit ratio	LDR	Reports of banks	Total loans over total deposit	+
Leverage ratio	LEV	Reports of banks	Total liabilities over total	+

*Source: Compiled by the authors*

#### 3.2. Methodology

The paper investigates the relationship between the policy rate and bank profitability. Panel data set is used in our study. The fixed-effect model was chosen over the random-effect model since bank characteristics can vary widely from one bank to another. Moreover, as other important bank-specific variables may be omitted besides the already selected ones, the dummy variables generated by the fixed-effect model can be useful and help to mitigate this difficulty. A robust standard error was used in our regression process to minimize some common errors that are frequently found in a panel data set, especially heteroskedasticity.

#### 3.3. Model Specification

Based on several previous studies, i.e. Nguyen (2016), Rao et al (2016), the authors have built and proposed a baseline research model as below:

$$ROE_t = \beta_0 + \beta_1 PR_t + \beta_2 NPL_t + \beta_3 LDR_t + \beta_4 LEV_t + e_t \tag{1}$$

From the baseline model (model 1),  $ROE_t$  refers to the return over equity of a certain bank at time  $t$ .  $PR_t$  represents the refinance rate at time  $t$ .  $NPL_t$ ,  $LDR_t$ ,  $LEV_t$  respectively refer to the non-performing loans ratio, loan-to-deposit, and ratio leverage ratio at time  $t$ .  $\beta_0$  is the intercept,  $\beta_1$  to  $\beta_4$  are coefficients of the independent variables.  $e_t$  is the error term.

The above model  $e_t$  can be used to determine whether the relationship between the policy rate and bank profitability is a positive or negative one using the coefficient of  $PR_t$  ( $\beta_1$  from the baseline model). However, the baseline model is unable to clearly specify the intensity at which the policy rate affects bank profitability. Therefore, to address this challenge, we set up a second model:

$$ROE_t = \beta_0 + \beta_1 PR_t + \beta_2 PR_t^2 + \beta_3 NPL_t + \beta_4 LDR_t + \beta_5 LEV_t + e_t \tag{2}$$

In model 2, all variables are as earlier defined, with the addition of the variable  $PR_t^2$ . This variable refers to the square of the policy rate at time  $t$ . From the derivative of equation 2, we can determine whether the influence of the policy rate on bank profitability is strong or weak using the coefficient of  $PR_t^2$  ( $\beta_2$  from Model 2). A negative  $\beta_2$  implies that the influence of policy rate will weaken and diminish over time, while a positive  $\beta_2$  hints at the opposite.

One more notable aspect is that bank profitability tends to be affected by its profitability in previous periods. This has been mentioned in the literature, i.e. Mbabazize et al (2020), Altavilla et al (2017), etc. To further examine this, the study adapted the two previous models by adding lagged dependent variables of different levels to the new models:

$$ROE_t = \beta_0 + \beta_1 PR_t + \beta_2 PR_t^2 + \beta_3 NPL_t + \beta_4 LDR_t + \beta_5 LEV_t + \beta_6 ROE_{t-1} + \beta_7 ROE_{t-2} + e_t \tag{3}$$

$$ROE_t = \beta_0 + \beta_1 PR_t + \beta_2 PR_t^2 + \beta_3 NPL_t + \beta_4 LDR_t + \beta_5 LEV_t + \beta_6 ROE_{t-1} + \beta_7 ROE_{t-2} + \beta_8 ROE_{t-3} + \beta_9 ROE_{t-4} + e_t \tag{4}$$

$ROE_{(t-1)}$ ,  $ROE_{(t-2)}$ ,  $ROE_{(t-3)}$ ,  $ROE_{(t-4)}$  which are also referred to as ROE(-1), ROE(-2), ROE(-3) and ROE(-4) in latter analysis, are respectively the lagged dependent variable with a lag of one, two, three, and four quarter(s). Model 3 focuses on examining the impact of the profitability of the past two quarters on the performance of the current quarter, while Model 4 covers the previous four quarters.

### 3.4. Descriptive Statistics and Correlation Analysis

**Table 2. Descriptive statistics and Correlation Analysis**

Variable	Obs	Mean	Std. dev.	Min	Max
ROE	440	0.034833	0.025275	-0.04701	0.148375
PR	440	0.059875	0.012195	0.04	0.1
NPL	440	0.020062	0.010784	0.0036	0.066306
LDR	440	0.909728	0.168173	0.542812	1.469094
LEV	440	10.9007	4.826421	0.791616	23.5309

Source: Researchers' computation using STATA 17

Table 2 shows the descriptive statistics of the data collected. The average value of ROE is 3.48%, which means a currency of equity generates a rather good return. The standard deviation of 2.53% shows that the coefficient difference in banks is quite high, implying that ROE varies among banks. The refinance rate has an

average value of 5.99%. The highest and lowest refinance rate are 4% and 10%, respectively, showing that the refinance rate has gone through fluctuations and changes during the research period. NPL ranges from 0.36% to 6.63%. The average NPL is around 2% which meets the requirements of the State Bank. The average LDR is 90.97%, ranging from 54.28% to 146.91%, indicating that banks use a large percentage of their deposits for lending activities. The average LEV is 10.9, which is a fairly high level. A high leverage ratio can help banks increase their ROE in the short term but in the long term, this can lead to a rising insolvency risk.

**Table 3. Pearson Correlation**

	ROE	PR	NPL	LDR	LEV
ROE	1.0000				
PR	-0.2818	1.0000			
NPL	-0.1860	0.2183	1.0000		
LDR	0.3451	-0.2882	-0.0038	1.0000	
LEV	0.0495	0.1176	-0.2064	-0.1585	1.0000

*Source: Researchers' computation using STATA 17*

Table 3 presents the Pearson correlation between the bank profitability index and the explanatory variables. The table demonstrates that there is no significant correlation among the dependent variables, given that the majority of the estimated correlations are less than 0.5. Therefore, it can be concluded significant multi-collinearity does not happen in the model.

ROE is negatively related to PR with a correlation value of -0.2818. This hints that a higher interest rate can be damaging to bank profitability. NPL is also negatively related to ROE, which implies credit risk harms bank performance. On the other hand, a positive relationship exists between ROE and LDR as well as LEV. This implies that banks that have higher LDR and LEV tend to generate higher ROE. From the correlation analysis, it can be seen that the expected relationship between ROE and explanatory variables seems to be correct.

## 4. RESULT AND DISCUSSION

### 4.1. Estimation Results

**Table 4. Estimation Results of Model 1 and Model 2**

	Model 1	Model 2
	ROE	ROE
PR	-0.409** [-2.49]	-1.589** [-2.51]
NPL	-0.289* [-1.86]	-0.285* [-1.85]
LDR	0.0459* [2.14]	0.0453* [2.18]
LEV	0.00135 [1.30]	0.00148 [1.40]
PR_Sq		9.565** [2.35]
_cons	0.0087 [0.32]	0.0426 [1.58]
N	440	440
R-sq	0.212	0.228

Note: \* p<0.1, \*\* p<0.05, \*\*\* p<0.01

*Source: Researchers' computation using STATA 17*

Table 4 showcases the estimates of the models specified in equations 1 and 2. From Model 1’s estimate, it can be seen that the relationships between the dependent variable and the explanatory variables are mostly similar to our a priori expectation. However, only three out of the four variables are statistically significant. At the 5% significance level, PR has a negative relationship with ROE. This result is supported by Rao et al (2006) and Thanh Nhan et al (2016). NPL has an inverse relationship with ROE at 10%. Also at 10%, LDR has a positive effect on ROE. Leverage ratio also has a positive effect on ROE but is not statistically significant.

From Model 2’s estimate, PR has a negative effect on ROE, while the squared variable of PR has a positive effect on ROE, both at a significance level of 5%. This implies that the policy rate hurts the profitability of commercial banks, and this adverse effect is further amplified the longer a high policy rate is in effect. At 10%, NPL has a negative relationship with ROE, while LDR has a positive effect on ROE. LEV remains statistically significant to ROE.

**Table 5. Estimation Results of Model 3 and Model 4**

	<b>Model 3</b>	<b>Model 4</b>
	<b>ROE</b>	<b>ROE</b>
PR	-1.327*** [-3.71]	-0.803** [-2.85]
PR_sq	9.265** [3.14]	4.984** [2.33]
NPL	-0.0932 [-0.64]	-0.0788 [-0.70]
LDR	0.0211*** [3.47]	0.0109 [1.59]
LEV	0.000963* [1.82]	0.000809* [1.99]
ROE(-1)	0.276** [2.88]	0.221* [2.20]
ROE(-2)	0.200*** [3.77]	0.140** [3.09]
ROE(-3)		0.0875* [2.18]
ROE(-4)		0.177** [3.08]

R-sq	0.353	0.382

Note: \* p<0.1, \*\* p<0.05, \*\*\* p<0.01

Source: Researchers’ computation using STATA 17

Table 5 showcases the estimates of the models specified in equations 3 and 4. In Model 3, both ROE(-1) and ROE(-2) – the one lagged and two lagged variables of ROE – are significant at 5% and 1% respectively. This shows that the profitability of previous quarters does indeed affect the profitability of the current quarter. The coefficient of ROE(-1) is greater than that of ROE(-2), which indicates that the impact of a previous quarter’s ROE on the current quarter’s ROE increases with proximity to that quarter.

The result of Model 4 shows that the current quarter’s profitability is influenced by the ROE of the prior four quarters. As the lag lengthens, the values of the lagged variables’ coefficients decrease, with

ROE(-1) having the greatest coefficient at 0.2207. However, compared to ROE(-2) and ROE(-3), ROE(-4) has a greater coefficient. This demonstrates that although ROE(-1) still has the greatest influence on ROE, ROE(-4)'s influence on ROE is unique and notable.

Model 4's finding is complementary to that of Model 3. It suggests that a bank's profitability is significantly influenced by how well the bank has performed financially in the past, going back as far as four quarters. Especially, the profitability of a quarter from the current year will be significantly impacted by the profitability of the same quarter from last year. This can be explained by the seasonality in banking activities. For example, during Tet holiday, as the demand for banking activities increases, banks can earn more profits, and this pattern repeats annually.

#### **4.2. Discussion**

The results show that the policy rate has a negative impact on the ROE of commercial banks. In economic theory, when the Central Bank increases the policy rate, banks' lending activities are tightened. This restricting effect on lending will consequently have an impact on bank profitability as credit activities still account for the majority of Vietnamese commercial banks' profits. This is consistent with the fact that after the SBV decided to increase the rediscount rate and the refinance rate on October 24, 2022, the total outstanding loans of commercial banks in the fourth quarter of 2022 decreased significantly compared to the third quarter of 2022. Declining lending activity results in lower income, which harms bank profitability.

Moreover, the result also suggests that the policy rate not only adversely affects bank profitability but this detrimental effect will also intensify when the policy rate is kept at a high benchmark for an extended time. This shows that Vietnamese commercial banks are still heavily influenced by the policy management of the State Bank.

Regarding the bank-specific factors, non-performing loans have a negative effect on ROE. This is because an increased amount of NPL will lead to difficulties in debt collection, which reduces the profitability of commercial banks. LDR has a positive effect on ROE. This can be explained by the fact that an increase in LDR means that the growth rate of commercial banks' lending activities is stronger than the growth rate of total deposits. At Vietnamese commercial banks, the main source of income is still from lending activities. Therefore, when lending activities increase, the bank's profit also increases.

#### **5. CONCLUSION AND POLICY IMPLICATION**

Inflation control, a key to preserve macroeconomic stability, has been successfully achieved thanks to the SBV's conduct of interest rate policies. However, it's critical to consider the potential impacts of ongoing monetary tightening on the activities of commercial banks. The SBV must carefully evaluate how its monetary policy affects the profitability of commercial banks in order to address these concerns. Achieving a balance between reining in inflation and fostering an environment that allows banks to make a profit should be the goal of the central bank. This can be accomplished by setting an appropriate policy rate that takes into account the requirements for both the management of inflation and the stability of the banking system.

In contrast to developed countries where commercial banks have a higher level of independence, the influence of the central bank on commercial banks can be more pronounced in developing nations like Vietnam. In such circumstances, it is crucial that the SBV take the necessary steps to support the banking system and aid in its recovery after an increase in policy interest rates.

Additionally, the SBV should work closely with commercial banks by injecting targeted liquidity support, encouraging responsible risk management procedures and technological advancements in banking operations.

These initiatives can assist commercial banks in overcoming the difficulties brought on by monetary tightening while preserving their profitability and enhancing the overall stability of the banking industry.

One effective measure that the SBV can employ to support the banking system is implementing open market operations (OMOs) to inject liquidity. Through OMOs, the SBV can lower the liquidity pressures that commercial banks might experience as a result of higher interest.

## RESEARCH ON THE IMPACT OF THE COVID-19 PANDEMIC ON CREDIT RISK AT VIETNAMESE COMMERCIAL BANKS

**Author: Le Thao Nhi<sup>1</sup>, Dao Mai Linh<sup>1</sup>, Nguyen Thu Huong<sup>1</sup>, Dang Thi Trang<sup>1</sup>**

**Mentor: Ta Thanh Huyen<sup>1</sup>**

**ABSTRACT:** *This paper researches the impact of the Covid-19 pandemic on credit risk at Vietnamese commercial banks (including 20 banks). This paper provides theories about credit risk and factors affecting credit risk. In addition, this paper also analyzes the current situation of credit risk before and after the appearance of the Covid-19 pandemic. Through previous research papers in the world as well as in domestic, the authors have built hypotheses and a model of non-performing loans (NPL) towards analyzing the factors impacting credit risk in the period from 2012 to 2021. These factors comprise non-performing loans (NPL) in the last year, return on equity (ROE), loan-to-deposit ratio (LDR), net interest margin (NIM), capital adequacy ratio (CAR), macro factors such as GDP, unemployment rate and other factors such as Covid-19. The NPL model results show that there are 7 factors impacting NL including NPL in the last year, ROE, LDR, NIM, GDP, unemployment rate, and Covid-19. While NPL last year and NIM have positive impacts on NPL, the remaining factors including ROE, LDR, GDP, unemployment rate and Covid-19 have opposite impacts on NPL. From the results gathered from the model, the authors have proposed solutions in order to limit credit risk at Vietnamese commercial banks in the context of the Covid-19 pandemic.*

*Keywords: Covid-19, credit risk, Vietnamese commercial banks.*

### 1. INTRODUCTION

Credit risk refers to the risk of potential loss to the bank if the borrowers fail to meet their obligations (Leo et al, 2019). There are many reasons for credit risk including macro environment (political, economic, social, technological, legal, and environmental factors), customers, banks, and collaterals. Besides these factors, Covid-19 is also a reason for credit risk.

According to WHO (2021), Coronavirus disease (COVID-19) is an infectious disease caused by the SARS-CoV-2 virus. The recent wave of the Covid-19 pandemic has had a negative impact on the overall economy. The economy has been severely affected by the stagnation of production and business activities, and many social and cultural activities have been also severely affected. Many businesses currently have had to declare dissolution or stop business operation due to the fact that they have not had enough financial resources to pay salaries to employees as well as pay debts to the company and banks, and this has been also one of the reasons for the increase in non-performing loans at the bank. According to the General Statistics Office, in the past nine months, 45,100 companies have temporarily suspended operations and 32,400 companies have closed their doors pending dissolution. Meanwhile, operating businesses also have faced many difficulties when revenue and cash flow have declined due to the COVID-19 pandemic.

In addition, the pandemic's lingering impact on households has become apparent. The sharp fall in income has led to financial difficulties, which has led to a sharp increase in household debt in Vietnam. Specifically, this group has accounted for half of the total outstanding loans of the whole market. In 2013, household loans accounted for only 28% of all Big 4 lending, but by 2020 the figure was 46%. This means that household debt has grown rapidly from 25% to 61% of GDP over the same period. The prolonged

---

<sup>1</sup> Banking Academy.

epidemic causes difficulties for businesses and customers, reducing capital turnover, disrupting cash flow, and reducing profits. This leads to an inability to pay debts as they come due and increases the risk of debt collection. According to the financial statements of the third quarter of 2021 of commercial banks, the absolute non-performing loan balance of 27 commercial banks has increased to 111 thousand billion VND, up 26% compared to the beginning of the year. In, ten banks increased their non-performing loans due to difficulties in the lending business because of the outbreak of the Covid-19 epidemic. Non-performing loans at state-owned commercial banks also increased sharply, accounting for most of the total credit of the whole industry.

After the call of the State Bank and Vietnam Banks Association, from mid-July 2021 until now, many commercial banks simultaneously cut loan interest rates to support customers to overcome difficulties caused by the Covid-19 epidemic. In addition, banks are also restructuring loans for affected customers to support customers affected by the COVID-19 pandemic. To support the Government and banks figure out more ideal and specific methods to minimize credit risk during and even after the Covid-19 pandemic, researching the impact of the Covid-19 pandemic on credit risk at Vietnamese commercial banks is extremely important.

Therefore, the aim of this study is to research the impact of Covid-19 on credit risk at Vietnamese commercial banks. So far, there have been very few studies on the impact of the Covid-19 pandemic on credit risk, simply because this pandemic has just appeared at the end of 2019 until now. Hence, this study contributes to a further understanding of how credit risk can be affected by epidemics.

There are seven parts in this research including introduction, theoretical framework, research method, result, conclusion, appendix and reference.

## **2. THEORETICAL FRAMEWORK**

There are very few studies on the impact of the Covid-19 pandemic on credit risk in the world in general and in Vietnam in particular.

### **2.1. In the world**

Previously, several researchers examined the effect of COVID-19 on credit risk in banks across countries such as Aldasoro et al (2020) and Agustin et al (2021). Riani (2021) has researched and shown the significant impact of Covid-19 on credit risk that banks in Indonesia face by quantitative method. The results show that Covid-19 has a negative effect on conventional commercial banks in Indonesia as the presence of Covid-19 increases non-performing loan cases causing the problem of excessive credit generation for conventional banks. During the pandemic, debtors prolong the repayment period of their loans, thus leading to the risk of default (Quanyun, Du, & Wu, 2021). In addition, the report of Ciobu and Tataru (2021) made on the basis of an analysis of the banking sector of the Republic of Moldova shows that the impact of the Covid-19 pandemic on credit risk in the banking sector is still ongoing, and forecasting potential losses. The researcher also pointed out that there were up to five challenges posed by Covid-19 to the credit risk environment, including changing creditworthiness at the sectoral and sub-sectoral levels; difficulty distinguishing between borrowers in the same subsector; lagging data on crisis conditions; the social responsibility policies needed to meet the changing preferences of customers and release a large wave of non-performing loans that needed to be addressed in a new way.

In the United States, regulations or verbal recommendations force banks to suspend dividend payments for 2020 through the end of 2021 due to the impact of the Covid-19 epidemic (Federal Reserve System, 2020). This has brought stability to the banking sector during the Covid-19 period which has been positively

impacted by the actions of financial supervisors. During the early stages of the pandemic, US banks largely lived up to society's expectations as banks served as important conduits for liquidity, credit, and loans (Buehler et al., 2020). With the strength of abundant capital and liquidity, banks moved quickly to protect their employees and customers. As this article predicts, credit losses for US banks could range from \$400 billion to \$1 trillion between 2020 and 2024 (Buehler et al., 2020).

Building on previous analyzes by European authorities, Aiyar et al (2021) created and developed a paper to assess the impact of the Covid-19 crisis on banks in Europe. This research highlights that the longer the crisis lasts, the higher the risk that banks will experience a significant deterioration in the quality of assets in their loan portfolios. Stagnant economic activity due to a delayed reopening will exacerbate borrowers' liquidity problems and increase outstanding loans, especially in vulnerable sectors. This will lead to much more likely credit losses and larger credit losses.

## **2.2. In Vietnam**

According to Dao Minh Tuan (2020), the Covid-19 pandemic has negatively impacted commercial banks' activities. Research has shown that Covid-19 has made many businesses unable to borrow capital or have no need to borrow because they have not signed a contract to sell goods. In 2020, consumer income increased compared to 2019, and deposits also increased despite a sharp decrease in interest rates, plus the increased risk of non-performing loans (especially debt groups with the ability to lose capital), and credit risks at banks and other financial institutions. Commercial banks will also increase, leading to a decline in profits as well as business efficiency of commercial banks. Besides, the study also mentions the difficulty of commercial banks when selling loan collateral to recover old non-performing loans.

In addition, Nguyen Thi My Yen et al (2021) stated that Covid-19 caused an increase in NPLs and a decrease in the credit market. The study also showed that the GDP of the economy in 2020 also increased compared to 2019.

Finally, Nguyen Duc Trung et al (2021) believe that the Covid-19 pandemic can reduce the value of collateral for credits as well as increase the NPLs of commercial banks. The increase in NPL has a negative impact on credit risk tolerance, thereby affecting credit risk at banks when banks have to increase credit provision.

## **2.3. Research gap**

Previous studies have mentioned some aspects of the impact of Covid 19 on the operations of banks. The gap is that some specific aspects of credit risk of commercial banks that have not been explored seem to be important and urgently needed for investigation in the context of the severe impact from Covid 19 in Vietnam. In this study, we seek to expand the factors affecting credit risk at commercial banks in Vietnam by addressing the gap from the impact of Covid 19 along with micro and macro factors.

## **3. RESEARCH METHOD**

### **3.1. Research sample**

The study collects data of Vietnamese commercial banks, but only 20 commercial banks have comprehensively data sources for the period we want to study, from 2012 to 2021. The reason we chose this time period is because the financial statements and annual reports of the 20 selected commercial banks are complete, while the years before 2012 were lacking.

### **3.2. Research data**

In this study, the NPL ratio is a dependent variable because it is used to represent credit risk. The NPL ratio is collected from financial statements over the period from 2012 to 2021 from 20 commercial banks.

There are eight independent variables including five micro-independent variables, two macro-independent variables, and a Covid-19 variable. While the micro-independent variables are gathered from financial statements and annual reports of 20 commercial banks over the period between 2012 and 2021, the macro-independent variables are collected from the General Statistics Office of Vietnam and the World Bank.

**Table 3.1: Measurement method of variables**

	Variables	Symbol	Measurement method
Dependent variable	NPL this year (year t)	NPL	NPL = Total non-performing loans this year/ Total outstanding loans this year
Micro-independent variables	NPL last year (year t-1)	NPL_1	NPL_1 = Total non-performing loans last year/ Total outstanding loans last year
	Return on Equity	ROE	ROE = Net profit/ Equity
	Loan to deposit ratio	LDR	LDR = Total loans/ Total deposits
	Net interest margin	NIM	NIM = (Interest received - Interest paid)/ Average invested assets
	Capital adequacy ratio	CAR	CAR = (Tier 1 Capital + Tier 2 Capital)/ Risk Wrihted Assets
Macro-independent variables	Gross domestic product	GDP	GDP = GDP growth rate of this year compared to last year
	Unemployment rate	UEM	UEM = The unemployment rate this year
Other variables	Year 2020,Year 2021	COVID	Dummy variable takes the value "1" for 2020 and 2021

### 3.3. Research model and hypothesis

#### 3.3.1. Research model

To assess the impact of Covid-19 on credit risk at Vietnamese commercial banks, based on previous research papers, the research group selected and used appropriate variables to build a research model. The research group used the following model:

$$NPL_{i,t} = B0 + B1*NPL_{i,t-1} + B2* ROE_{i,t} + B3* LDR_{i,t} + B4* NIM_{i,t} + B5* CAR_{i,t} + B6* COVID + B7* GDP_{i,t} + B8* UEM_{i,t}$$

In which,  $NPL_{i,t}$  is the dependent variable and the indicator to measure the credit risk of commercial banks.  $NPL_{i,t}$  is the NPL of bank  $i$  at time  $t$  ( $i$  is the symbol for the studied commercial banks,  $t$  is the symbol for the years in the research period). The dependent variable  $NPL_{i,t}$  is calculated by the sum of the substandard debt group (group 3), doubtful debt (group 4) and potentially losing debt (group 5) on total credit balance.

Based on data collection and characteristics of Vietnamese commercial banks, the research group has considered micro factors and macro factors affecting the NPL of commercial banks each year: (1) Group of micro variables tissues include  $NPL_{i,t-1}$ ,  $ROE_{i,t}$ ,  $LDR_{i,t}$ ,  $NIM_{i,t}$  and  $CAR_{i,t}$ . Besides, the group of macro variables includes  $GDP_{i,t}$  and  $UEM_{i,t}$  in Vietnam. The measurement methods and expected signs of the variables are shown in Table 3.1.

In the model, another variable is  $COVID_{i,t}$ , which is an indicator of the Covid-19 pandemic.

#### 3.3.2. Research hypothesis

After referring to some previous research papers, the research group came up with some hypotheses about the relationship between the independent variables and the dependent variable as follows:

**• NPL and NPL of previous year**

According to Nguyen Thi Nhu Quynh et al (2018), through a study on factors affecting non-performing loans at Vietnamese commercial banks, this research has shown that last year's NPL and this year's NPL have a positive relationship. Besides, Pham Hai Nam and Nguyen Ngoc Tan (2021) also show that last year's high NPL can also lead to this year's high NPL.

*H1: NPL and NPL last year have a positive relationship.*

**• NPL and ROE**

From the findings of Takang and Ntui (2008), it can be seen that ROE is negatively related to the NPL of commercial banks. Banks with higher profitability tend to be less motivated to engage in risky lending activities than is optimal, leading to higher NPL (Louzis et al., 2012; Curak et al., 2012). 2013; Makri et al., 2014). In addition, Nguyen Thanh Dat (2018) also showed that ROE has a negative impact on NPL because when increasing profits, banks will avoid risky activities, choose customers with good financial ability and less risk to increase profits. However, according to Tran Vuong Thinh and Nguyen Ngoc Hong Loan (2021), it is shown that ROE has a positive relationship with NPL because when commercial banks want to increase credit activities to increase profits, this means that NPLs increase.

*H2: NPL and ROE have a positive relationship.*

*H3: NPL and ROE have a negative relationship.*

**• NPL and LDR**

According to Buchory (2014), LDR is used to measure the degree of intermediation of the banking system has been implemented, serving to assess the creditworthiness or safety of banks. Cheng et al (2016) argue that the higher the LDR, the larger the total outstanding loans and the higher the non-performing loans. This conclusion is based on "The Moral hypothesis", Lee and Ho (2007) argue that if loans are too readily available in the financial system, financial institutions will absorb these excess funds as quickly as possible. When banks check loans, credit information systems are often inaccurate, and this causes a deterioration in the bank's loan quality and credit risk.

*H4: NPL and LDR have a positive relationship.*

**• NPL and NIM**

NIM is one of the indicators that can be used to measure a bank's performance to generate profits from the management of profitable or productive assets owned by the bank (Buchory, 2014). . According to Puspitasari et al (2021), net interest margin (NIM) is a measure of the difference between interest income earned by a bank or other financial institution and the interest paid by a bank to its lender (e.g. e.g. depositors), relative to their assets earning interest. In addition, Zheng et al (2018) conducted a study on the factors affecting credit risk on 22 banks in Bangladesh and found that NIM has a positive impact on NPL. Specifically, the researchers explain that a higher interest rate margin causes higher credit risk and burdens borrowers with their transactions as they struggle with interest burdens and market competition.

*H5: NPL and NIM have a positive relationship.*

**• NPL và CAR**

According to Demircuc-Kunt and Huizinga (1999), when CAR is high, banks will pursue opportunities

more aggressively, which means that higher risk-taking leads to riskier credit portfolios. The research group believes that CAR has a positive impact on NPL. In addition, through the study of factors affecting NPL at commercial banks in Barbados, Wood and Skinner (2018) also showed that the relationship between CAR and NPL is positive. Vatanserver and Hepsen (2013) also show a positive relationship between CAR and NPL through the study of non-performing loans in Turkey.

*H6: NPL and CAR have a positive relationship.*

#### • **NPL and GDP**

According to Kartikasary et al. (2020), the research group studied the factors affecting NPL in Indonesia and showed that the higher the GDP, the higher the NPL. In addition, according to Beck et al (2015), GDP and NPL have a positive relationship. However, according to Urmar and Sun (2018), through research at Chinese banks, the group has shown that GDP is one of the macro factors affecting the NPL ratio. The higher the GDP, the lower the NPL (Umar and Sun, 2018). Besides, the study of factors affecting NPL in the euro area by Makri et al (2014), at the Bank of Pakistan by Khan et al (2018) also shows that GDP has a negative effect. with the NPL ratio. In addition, research by Nguyen Thi Hong Vinh (2015), Nguyen Hoang Lam (2017), and Nguyen Thi Nhu Quynh et al (2018) also show that GDP and NPL have a negative relationship. The reason is that with higher GDP, the borrower's ability to repay debt is also increasing (Khan et al., 2018).

*H7: NPL and GDP have a positive relationship.*

*H8: NPL and GDP have a negative relationship.*

#### • **NPL and the unemployment rate**

Vatanserver and Hepsen (2013) and Mazreku et al. (2018) have shown that self-interest has a positive effect on NPL because as unemployment increases, the number of people having difficulty meeting debts increases, leading to an increase in NPL. In a study on the factors affecting NPL in Pakistani banks, Khan et al (2018) also show that the higher the interest rate increases, the higher the NPL. In addition, through the study of 14 countries in the euro area by using the regression method, Marki et al (2014) also identified that the increase in NPL is due to the growth of the unemployment rate. However, Nguyen Thi Nhu Quynh et al (2018) stated that NPL and the unemployment rate have an inverse relationship due to two reasons: (1) the low proportion of personal loans to total credit outstanding; (2) The unemployment rate in Vietnam is low, there is not much change.

*H9: NPL and UEM have a positive relationship.*

*H10: NPL and UEM have a negative relationship.*

#### • **NPL and Covid-19 (COVID)**

When studying the factors affecting NPL including Covid-19 in banks in Bosnia and Herzegovina, Zunic et al (2021) showed that the relationship between NPLs and Covid-19 is negative. This is because in Bosnia and Herzegovina, a ban on lending was introduced, which prevented an increase in NPL. However, in studying the impact of Covid-19 on NPL levels at commercial banks in Indonesia, Hardiyanti and Aziz (2021) showed that during the Covid-19 pandemic, NPLs increased. Therefore, Covid-19 and NPL have a positive relationship with each other.

*H11: NPL and COVID have a positive relationship.*

*H12: NPL and COVID have a negative relationship.*

## 4. RESULTS AND DISCUSSION

### 4.1. Results

#### 4.1.1. Descriptive statistics

A descriptive method is a method used to analyze data in a manner that describes or describes data that has been collected as-is, without the intention of applying general or general conclusions. The research group generalized descriptive statistics of the variables in Table 3.2 as follows:

**Table 3.2: Descriptive statistics of variables in the model**

Variables	Observations	Mean	Standard deviation	Min	Max
NPL	200	0,021	0,013	0,000	0,088
NPL_1	200	0,025	0,053	0,000	0,088
ROE	200	0,106	0,071	0,001	0,303
LDR	200	0,805	0,121	0,529	1,092
NIM	200	0,031	0,010	0,006	0,071
CAR	200	0,131	0,038	0,080	0,334
GDP	200	0,056	0,016	0,026	0,071
UEM	200	0,023	0,003	0,020	0,032
COVID	200	0,100	0,301	0,000	1,000

*Source: Compiled from Stata software*

According to Table 3.2, the NPLs of commercial banks from 2020 to 2021 have a mean of 2.11% with a standard deviation of 1.32%, a min value of 0.01%, and a max value of 8.82%. Meanwhile, NPL last year had a mean of 2.52%, a standard value of 5.31%, and min and max values of 0.01% and 8.82%, respectively. Thirdly, ROE has a mean of 10.63%, a standard deviation of 7.12% and a min value of 0.08%, and a max value of 30.3%. Fourthly, LDR has a mean of 80.47% and an LDR of 12.08%, together with a min value and a max value of 52.94% and 109.21%, respectively. Fifth, NIM has a standard deviation of 1.01%, a min value of 0.58%, a max value of 7.09%, and a mean of 3.05%. CAR has a min value of 8% and a max value of 33.42%, a mean of 13.11%, and a standard deviation of 3.84%.

For macro variables, GDP has a mean of 5.59%, a standard deviation of 1.55%, a min value of 2.58%, and a max value of 7.08%. UEM has a mean of 2.32%, a standard deviation of 0.33%, and min and max values of 1.99% and 3.22%, respectively. With the variable COVID, the mean is 0.1, the standard deviation is about 30%, and the min and max values are 0 and 1, respectively.

#### 4.1.2. Results

##### 4.1.2.1. Check correlation and multicollinearity

To check the correlation between variables and multicollinearity, the research group used the Pearson correlation matrix table according to Table 3.3 as follows:

**Table 3.3: Pearson's correlation matrix table**

	NPL	NPL_1	ROE	LDR	NIM	CAR	GDP
NPL	1,000						
NPL_1	0,406	1,000					
ROE	-0,372	-0,260	1,000				
LDR	-0,202	-0,144	0,077	1,000			
NIM	-0,037	-0,124	0,358	0,100	1,000		
CAR	0,259	0,191	-0,403	0,044	0,327	1,000	
GDP	0,029	0,088	-0,187	-0,052	-0,056	0,110	1,000
UEM	-0,219	-0,184	0,260	0,155	-0,040	-0,216	-0,720
COVID	-0,113	-0,136	0,133	0,047	-0,046	-0,195	-0,579

Source: Compiled from Stata software

To check the correlation between variables and multicollinearity, the research group used the Pearson correlation matrix table according to Table 3.3 as follows:

According to Gurajati (2004), if the correlation coefficient between the pairs of variables is greater than 0.8, the estimated model has a high possibility of multicollinearity. After that, the sign of the regression coefficients may be changed, causing the research results to be skewed. In Table 3.3, the correlation coefficients between all pairs of variables have absolute values less than 0.8. This means that the study model is not concerned about the possibility of double multicollinearity defects.

In addition, to quantify the degree of multicollinearity between the independent variables, the research group also used the variable inflation factor (VIF) to estimate (Table 3.4). VIF is used to check for multicollinearity in the regression equation. Multicollinearity will occur if  $VIF > 5$ . The results of the multicollinearity test by VIF are shown in Table 3.4 as follows:

**Table 3.4: Verification table for multicollinearity by VIF**

Variables	VIF	SQRT VIF	Tolerance	R-squared
NPL	1,470	1,210	0,679	0,321
NPL_1	1,270	1,130	0,786	0,214
ROE	1,970	1,400	0,508	0,492
LDR	1,100	1,050	0,910	0,090
NIM	1,760	1,330	0,568	0,432
CAR	1,800	1,340	0,554	0,446
GDP	4,680	2,160	0,214	0,786
UEM	3,480	1,860	0,288	0,712
COVID	2,260	1,500	0,443	0,557
Mean	2,200			

Source: Compiled from Stata software

According to Table 3.4, all variables have  $VIF < 5$ . This shows that the multicollinearity phenomenon occurring in the model is not too serious. Therefore, this is a positive sign for the selection and testing of the appropriate research model.

#### 4.1.2.2. Research model results

Three models Pooled OLS, FEM (Fixed Effect Model) and REM (Random Effect Model) were used in the study (Table 3.5). In which, according to Pooled OLS, the independent variables explain 32.14% of the dependent variable's variation (R square = 32.14%). However, to evaluate the cross-effect of time variables and banks as well as increase the fit of the model, the research group used FEM and REM (Table 3.5):

**Table 3.5: Regression analysis**

NPL	Regression analysis							
	Pooled OLS		FEM		REM		FGLS	
	Coef.	p-value	Coef.	p-value	Coef.	p-value	Coef.	p-value

“Significant level: \*:  $P < 0.1$ ; \*\*:  $P < 0.05$ ; \*\*\*:  $P < 0.01$ ”

Source: Compiled from Stata software

Of the three Pooled OLS, FEM, and REM, the FEM is the most suitable based on the F-test and Hausman test (Appendix 1 and 2). However, the research group tested the correlation phenomenon in the FEM (Appendix 3). Accordingly, the FEM encountered autocorrelation. Besides, the research group also tested the phenomenon of variance in the FEM (Appendix 4). As a result, the FEM also experiences variable variance. Therefore, the FGLS (Feasible Generalized Least Squares Estimators) is used to overcome the problems of the FEM (Table 3.5).

#### 4.2. Discussion

According to Table 3.5, there are 7 variables affecting NPL including NPL\_1, ROE, LDR, NIM, GDP, UEM, and COVID, excluding CAR. While NPL\_1 and NIM have a positive relationship with NPL, the remaining variables have a negative relationship. In which, the negative impact of COVID on NPL is about 1%.

For micro variables, last year's NPL has a positive relationship with this year's NPL at the significance level of 8.1%. Such a relationship has the same view as Nguyen Thi Nhu Quynh et al. (2018) and Pham Hai Nam and Nguyen Ngoc Tan (2021). The reason is that the non-performing loans of the previous year have not been thoroughly handled so far, which will increase non-performing loans this year (Nguyen Thi Nhu Quynh et al., 2018). Secondly, ROE negatively affects NPL. Felix and Claudine (2008), Louzis et al. (2012), Curak et al. (2013), Makri et al (2014), and Nguyen Thanh Dat (2018) also agree that the relationship between ROE and NPL is one reverse relationship. According to Takang and Ntui (2008), in order to increase profitability, banks will tend to avoid risky activities, in the case of credit, banks will consider and choose loans from other banks. customers with good financial capacity and low risk. Thirdly, LDR has a negative relationship with NPL, contrary to the expected sign given by the research group. Finally, NIM has a positive relationship with NPL, which is similar to the conclusion of Buchory (2014), Zheng et al (2018), and Puspitasari et al (2021). The reason is that the higher interest rate margin of commercial banks will lead to higher credit risk and create more burdens for borrowers.

For macro variables, GDP has a negative effect on non-performing loans. Such a conclusion is consistent with the study of Makri et al (2014), Khan et al (2018), Urmar and Sun (2018), Nguyen Thi

Hong Vinh (2015), Nguyen Hoang Lam (2017), and Nguyen Thi Nhu Quynh et al (2018). The higher the economic growth rate, the higher the income of individuals and organizations, therefore, the ability to repay debt and interest is also increasing. On the contrary, when economic growth slows down, borrowers' ability to repay both loans and interest decreases, leading to an increase in non-performing loans. Besides, the unemployment rate and NPL also have a negative relationship. This result is consistent with the studies of Nguyen Thi Nhu Quynh et al (2018). According to Nguyen Thi Nhu Quynh et al (2018), when the number of unemployed people is increasing, the number of customers doing credit transactions with banks decreases, leading to a decrease in non-performing loans. In addition, the unemployment rate in Vietnam is always low and does not fluctuate much. In the Vietnamese market, workers can do any job even if they are not specialized (Nguyen Thi Nhu Quynh et al., 2018).

Finally, similar to the conclusion of Zunic et al (2021), Covid-19 has a negative effect on NPL. The first reason is that the government has controlled the disease very well. Secondly, when the Covid-19 pandemic broke out in Vietnam, the State Bank flexibly and proactively operated monetary policy to remove difficulties for businesses and individuals with the goal of meeting credit capital needs for the economy and drastically dealt with non-performing loans. Thereby, the SBV has supported commercial banks to restructure existing debts for customers, exempting and reducing interest rates for businesses without revenue, and maintaining the same debt group. In addition, during the period of the Covid-19 epidemic, the low credit market, and reduced demand for bank loans of businesses and individuals are also the reasons why Covid-19 and NPL have an inverse relationship. Ultimately, not all industries are adversely affected by Covid-19 but on the contrary, some industries benefit from the pandemic. Banks have focused on making loans to industries benefiting from the Covid-19 pandemic such as medical equipment, telecommunications, etc. to avoid credit risk as well as earn profit.

## **5. CONCLUSION**

It is undeniable that banking is an industry that faces many kinds of risks including market risk, credit risk, operational risk, and liquidity risk, in which, credit risk is faced the most by banks. During the Covid-19 pandemic, credit risk at commercial banks has increased significantly. The reason is because the production and business activities of enterprises are interrupted, people's incomes are reduced, making it difficult to fulfill debt obligations.

The aim of the study is to research the impact of Covid-19 on credit risk at Vietnamese commercial banks. By collecting data from 20 Vietnamese commercial banks over the period from 2012 to 2021 as well as applying the regression analysis, Covid-19 has impacted negatively on credit risk. That means when the Covid-19 breaks out more strongly, credit risk will decrease. This is because of three main reasons. Firstly, the government has controlled the disease very well. Secondly, when the Covid-19 pandemic broke out in Vietnam, the State Bank flexibly and proactively operated monetary policy to remove difficulties for businesses and individuals to meet credit capital demand for the economy and drastically tackle non-performing loans. Moreover, not all industries are negatively affected by Covid-19 but on the contrary, several industries benefit from the pandemic.

In order to limit credit risk, commercial banks need to review and make eligible loans according to Circular 01 and Circular 03. Secondly, commercial banks need to evaluate each loan, Review the recoverability of each customer, ensuring the maximum possible recall. Besides, it is definitely important to have a provisioning plan close to the reality of the restructured credits. In addition, commercial banks should evaluate and review customers and have a selective credit growth orientation, and at the same time, carefully assess their financial situation, industry characteristics, and the business cycle. , etc. Furthermore,

it is essential for commercial banks to promote medium and long-term lending. Finally, Vietnamese commercial banks should focus continually on making loans to industries benefiting during the Covid-19 pandemic such as medical equipment, telecommunications, etc.

For the State Bank of Vietnam, it is necessary to maintain Circular 03. Besides, the State Bank should extend Resolution 42. Finally, it is important to increase capital to increase financial potential for commercial banks.

# IMPACT OF OVERCONFIDENCE ON STOCK MARKET VALUATION: AN EMPIRICAL STUDY ON COMPANIES LISTED ON HO CHI MINH STOCK EXCHANGE (HOSE)

**Author: Do Thanh Phuong<sup>1</sup>**

**Mentor: Pham Tien Manh<sup>1</sup>**

**ABSTRACT:** *This study examines the impact of overconfidence bias among investors on firm valuation of listed firm on Ho Chi Minh stock exchange. The secondary data consists of 264 non-financial firms listed on HOSE in the period of 7 years from 2016-2022. This research employs the change in trading volume variable as a main variable proxy of overconfidence and applies FGLS method as the main estimation. As a result, this study confirms the positively affects of overconfidence bias on firm valuation on HOSE, regarding different investor overconfidence proxies. These empirical results have several implications for market regulators, investors, and academic researchers as well as for investment costs, capital allocation, and market effectiveness.*

**Key words:** *overconfidence, firm valuation, HOSE*

## 1. INTRODUCTION

Much of pioneer research has been conducted to investigate the impact of overconfidence psychology on investment decisions. Accordingly, understanding the impact of overconfidence on investor behavior and firm valuation can help investors, regulators, and policymakers to make informed decisions and reduce potential market distortions. In Vietnam, the number of research related to the nexus between overconfidence psychology among investors and stock valuation is still limited, despite its growing economy and stock market. This research gap presents an opportunity to fill the void in the literature and contribute to the understanding of the effects of overconfidence on firm valuation in an emerging market context.

This study is to identify the extent of overconfidence bias among investors in Vietnam's stock market and its impact on firm valuation. In addition, it is expected to provide practical recommendations for investors, regulators, and policymakers to mitigate the negative effects of overconfidence on firm valuation and promote a fair and efficient market in Vietnam.

## 2. THEORETICAL FRAMEWORK

### 2.1. Overview of overconfidence

#### 2.1.1 Overconfidence in psychology

Up to the 1970s, overconfidence in psychology has been defined as a particular form of miscalibration, for which related to the calibration and probability judgment that the answers given are correct exceeds the true accuracy of the answers. The most important extensions to this definition scope are studies of overconfidence in the context of positive illusions, which is the illusion of control and unrealistic optimism.

Calibration is considered to be appropriate "if over the long run, for all propositions assigned a given probability, the proportion that is true is equal to the probability assigned", (Koriat et al., 1980). Thus, a calibrated judge is capable of accurately estimating the number of errors he commits. Miscalibration is the

---

<sup>1</sup> Banking Academy.

discrepancy between the accuracy rate and probability assigned to indicate that a given answer is correct. The term overconfidence was considered as a specific type of miscalibration since the 1970s.

A number of psychological causes of overconfidence have been discussed in the past. Several reasons for overconfidence were summarized in the research of Dorota Skała (2008) namely self-motivation in cognitive processing, hard-easy effect, presence or lack of clarity.

First, Keren (1997) and J. E. Russo & Schoemaker (1992) assumed that overconfidence as a self-motivating mechanism in cognitive and psychological areas. Many factors within the cognitive process might cause a mismatch of confidence and accuracy. As a consequence of the faulty cognitive processing, heuristics and bias argumentation was marked as a potential origin of overconfidence. A partly cognitive and partly motivational reason for overconfidence is a so-called confirmation bias, widely explored in the literature of Koriat et al. (1980).

Second, the hard-easy effect was demonstrated as a reason for overconfidence when several authors argue that difficult issues are the cause of overconfidence, and that without them no miscalibration occurs. Gigerenzer (1991) argued that when questions are chosen at random, overconfidence diminishes and the hard-easy effect does not always dominate. The author indicated that overconfidence and the hard-easy effect may emerge, disappear, and invert depending on the task. However, numerous empirical researches demonstrated that the prevalence of overconfidence and the hard-easy effect as a general cognitive bias across domains has been strongly reduced and some results were associated with faulty interpretations of regression effects (Dawes & Mulford, 1996).

Third, the existence or absence of clear, quick feedback, which in some situations may lead to flawless calibration, has already been cited as a factor promoting overconfidence.

In addition, several investigations link varying amounts of overconfidence to gender difficulties, which supports the widely held assumption that males are more confident than women given the same level of knowledge (Barber & Odean, 2001). Yet, no definitive relationship has been identified between gender differences and overconfidence.

### **2.1.2 Overconfidence in finance**

According to Dorota Skała (2008), overconfidence in finance is typically described as an overestimation of one's familiarity with or accuracy with private information, or the interpretation of it. As an alternative, an underestimation of signal variance or asset value volatility are also taken into account.

Despite considerable skepticism among economists about the presence and impact of overconfidence, its ubiquity in financial markets has been consistently demonstrated using methodologies ranging from experimental and questionnaire research to formal models and financial market data, according to a study of Dorota Skała (2008). Several difficulties discovered on financial markets that could not previously be answered using normal economic theory were satisfactorily accounted for after investor overconfidence was adopted.

To date, numerous experimental evidences under various circumstances have been presented to support the existence of overconfidence on financial markets. Researchers have examined the presence of overconfidence and their implications on financial markets, such as excessive trade volumes, trading profitability, short and long-term asset misvaluations, and stock returns.

In terms of trading volume, overconfidence is demonstrated to lead to larger market depth and volatility. As demonstrated by Odean (1998), traders exhibit the better-than-average effect, evaluating their

information as better than that of their peers. Market players that are so overconfident boost trading volume. The similar conclusion is reached by Benos (1998).

In terms of trading profits, Kyle & Wang (1997) indicates that overconfident traders with excessively close private signal distribution intervals may be seen as trading more aggressively and may experience bigger profits than their rational competitors. Benos (1998) also came to a similar conclusion, stating that even though both overconfident and rational traders are aware of one another's tendencies, the overconfident traders benefit from a "first mover's advantage" and make higher individual profits. By contrast, Gervais et al. (2001) and Daniel et al. (1998) also show that overconfident informed investors incur losses on average, but they also suggest that overconfident traders may occasionally achieve returns that are higher than those of rational investors.

In terms of asset valuations, K. D. Daniel et al. (2001) proved that an asset pricing model with overconfidence leading to an equilibrium mispricing of securities. Some rational market participants take advantage of the pricing errors through arbitrage, but risk aversion prevents them from being completely eliminated.

## **2.2 Overview of firm valuation**

According to Shrivastava & Kumar (2015) a business valuation is defined as the process of estimating a firm's economic value. Shrivastava & Kumar (2015) confirmed that valuation is important in many aspects of finance. It is useful for portfolio management, mergers and acquisitions, corporate financing, as well as legal and tax considerations.

According to Shrivastava & Kumar (2015), there are three primary methods to valuation, including discounted cash flow valuation, relative valuation and pricing models. In another perspective, Shrivastava & Kumar (2015) expressed that valuation may be generally divided into three categories of asset-based, market-based, and earnings-based. To put it another way, there are two types of valuation procedures: direct valuation methods and indirect valuation methods, according to Shrivastava & Kumar (2015).

## **2.3 Literature review**

Behavioral theory forecasts that overconfident investors underestimate risk while overestimating the accuracy and quality of their information. As a result, they seek a smaller risk premium and have an excessively high demand for risky assets, which drives up asset prices and finally results in firm overvaluation. Several international researches have been conducted to investigate these predictions and majority of them show the positive relationship between overconfidence and firm valuation.

Adebambo & Yan (2018) investigated the relationship between overconfidence of investors and firm valuation by measuring the overconfidence among investors drawn from the characteristics and holdings of US stock mutual fund managers. The data was collected monthly in the period of 1988 – 2010 including stock return, standard industrial classification code, trading volume, share price, and shares outstanding for common stocks except for financial enterprises. As a result, they found that overconfidence among investors is strongly related to firm value and corporate actions. More specifically, Adebambo & Yan (2018) discovered that companies with more overconfident investors are considerably overpriced, according to the market to book ratio and a misvaluation metric.

Zia et al. (2017) further aim to test the overconfidence bias of investors in the Karachi stock exchange (Pakistan) by using a simple random sample approach from 2005 to 2013. Applying market-wide panel

VAR model and econometric techniques, Zia et al. (2017) performed that investors are overconfident in the Pakistani stock market since turnover is strongly related to stock returns. The findings have significant meanings for investors and brokers in terms of designing effective trading strategies. In addition, the study suggested that overconfidence bias tends to hinder portfolio diversification and promote excessive trading in Pakistan's financial market.

According to Bouteska & Regaieg (2020), there was a positive relationship between investor overconfidence on firm valuation. Their research examines how overconfidence and loss aversion biases affect US company performances. The population of insured industrial and service enterprises in the US was the subject of about 6,777 quarterly observations utilized in this study, which ran from 2006 to 2016. The study's hypotheses were tested using two panel data models with ordinary least squares (OLS) regression. In conclusion, the paper proved that the economic success of US firms is shown to be severely impacted by investors' pessimism indicating loss aversion, whereas investors' optimism expressing overconfidence positively impacts company stock market performance.

Overconfidence and disposition effect in the stock market is studied by Trejos et al. (2019) by collecting primary data about the characteristics of participants and the decisions made by them in each of the rounds. By using a methodology of combining qualitative (QCA) and logistic regression techniques, they concluded that overconfidence is explained by gender, career and education level, while age, nationality, and profits are not significant variables. In addition, they illustrated that overconfidence among investors leads to stock overpricing because overconfident investors overestimate the quality of their knowledge while underestimating the risk in the stock. However, this study faced a limitation when they were only able to assemble 77 participants who didn't involve participants that work as professional traders.

A recent research of Aljifri (2023) has investigated how overconfidence influences business value in Saudi Arabia's developing stock market. The fixed-effects panel data model and the dynamic panel data model are applied on a sample of 4004 firm-quarter observations covering 11 years, from 2009 to 2019. To measure the valuation of firms in the Saudi stock market, this study used Tobin's Q ratio as a dependent variable. According to the panel regression model, the author indicated that investor overconfidence positively and significantly affects the valuation of companies in the Saudi stock market. The findings provide an explanation for the nexus between overvaluation and mispricing in emerging markets, especially Saudi Arabia's stock market.

In Vietnam, there is no literature that examines how investor bias affects firm valuation. In order to determine whether biases influence investor decision making, only a few research have looked at the effect of investor bias on decision-making processes. To my best knowledge, just several documents related to the overconfidence in investment while only one Vietnamese research focus on trading behavior of investors and their investment decision such as the paper of Ly Hai Thi Tran & Tuan Pham Le Anh (2012).

In 2012, Ly, T. T. H., & Tuan, P. L. A. tested the existence of excessive optimism and overconfidence among Vietnamese investors on stock exchange and explored its impact on trading behavior of investors. A two-step data collection method is applied on a sample of 150 individual investors with trading accounts at two securities companies in Ho Chi Minh city to examine psychological factors with investors' trading activities. The survey was conducted from February to March 2012 by sending directly to investors or via email. Within 800 questionnaires sent out, only 274 answers were collected. Research results indicated that overoptimism and overconfidence do exist in the majority of investors

and they have a statistically significant effect on the trading turnover ratio of investors. To sum up, these results implied awareness for individual investors in making investment decisions. However, this study only focuses on examining the impact of over-optimism and overconfidence on investors' trading activities and ignores the influence of investor biases on the behavior of stock markets, such as mispricing and market valuation.

### **3. RESEARCH METHOD**

#### **3.1 Definition of variables**

##### **3.1.1. Dependent variable**

This study used Tobin's Q ratio as a dependent variable to measure the valuation of firms. Using Tobin's Q ratio has become a common method of assessing the fair or equilibrium value of the stock market, following by Brainard & Tobin (1968), Buchanan et al. (2018), Daines (2001), Fang et al. (2009), Gompers et al. (2003), Kumar & Singh (2013), Aljifri (2023). At the most basic level, the Q Ratio is a means of estimating whether a given business or market is overvalued or undervalued.

##### **3.1.2. Independent variables**

Independent variables used in this study are overconfidence proxies, including four alternative variables, namely the change in trading volume, turnover rate, excessive trading and the increase in the number of shares outstanding.

First, the change in trading volume (CTV<sub>*it*</sub>) is used as an independent variable, which is calculated from the change in trading volume as either an increase or a decrease in trading volume relative to its prior period. Alsabban & Alarfaj (2020) indicated that overconfident investors believe in their abilities and will act based on the information they obtain, trading volume is affected, therefore, the change in trading volume can be considered as evidence of overconfidence.

Second, turnover rate (turnover<sub>*it*</sub>) is employed as a proxy for the level of overconfidence because if current trading volume can be explained by the past market return, it can be considered as measurement of overconfidence. In addition, this study prefers turnover rate since it is a relative measure which eliminates the influence of growth in the long research period of 2016 - 2022 (Z. Chen et al., 2011).

Third, this study provides alternative variables to evaluate the level of overconfidence, namely excessive trading (ET<sub>*it*</sub>) and change in number of shares outstanding (ISO<sub>*it*</sub>). The reason why these variables are considered as alternative variables is that excessive trading (ET<sub>*it*</sub>) and change in number of shares outstanding (ISO<sub>*it*</sub>) were widely used as a proxy for overconfidence, however, the justification for using the proxy variable of shares outstanding may be less obvious and the manifestation of excessive trading is hazy.

##### **3.1.3 Control variables**

Control variables used in this study consists of market capitalization, return on assets and financial leverage. First, marketcap<sub>*it*</sub> defined as logarithm of the market capitalization is employed as a control variable to control for any influence on environmental strategy and performance. It is expected to be positively associated with corporate valuation, according to Liu & Magnan (2011), Issar (2017). Second, return on assets is added in order to measure financial performance for a particular time period. Third, the current study considers leverage as one of control variables for firm valuations since it represents a company's financial risk profile, according to McGuire et al. (1988) and Orlitzky & Benjamin (2001).

### 3.2. Database

This study investigated the quarterly sample of 264 non-financial companies listed on HOSE in the period of 2016 – 2022.

First, the reason why the quarterly frequency is chosen is that, for calculating Tobin's Q ratio measuring firm valuation and other firm-specific attributes in our sample such as market capitalization, return on assets and financial leverage, a few of these variables are disclosed with the HOSE on a quarterly basis.

Second, the financial and insurance firms are excluded from the current study due to the significant differences in practices and accounting methods as well as the numerous of regulatory restrictions among non-financial and financial firms. It is proved to make capturing the effect of investor psychology on firm valuation more difficult, according to Abed et al. (2012), Estrin et al. (2009) Jiraporn et al. (2009). Similar to previous research of Adebambo & Yan (2018) and Bouteska & Regaieg (2020) indicated that excluding financial firms helps to avoid distorting the results as well as contributes to a better exploration and analysis.

### 3.3 Research methodology

The panel data model is seem to be an optimal method because the cross - sectional and time-series dimensions offered by the panel data model have the benefit of enabling the researcher to compensate for unobserved heterogeneity. However, to guarantee that our conclusions are resistant to both unobserved firm-specific heterogeneity and endogeneity problems, this study uses four different methods to model regression, including least squares regression method (Pooled OLS), fixed factors effect method (FEM), random factors effect method (REM) and random effects model (FGLS) estimation method.

This study applies three different regression models to examine the impact of overconfidence on the valuation of companies listed on the HOSE by focusing on a main model, then 2 alternative models are used to ensure the results are not sensitive for the variable proxy.

Firstly, in the main model this study uses two independent variables measuring overconfident investors, namely change in trading volume ( $CTV_{it}$ ) and turnover rate ( $turnover_{it}$ ), which is popularly used before (Alsabban & Alarfaj, 2020; Asaad, 2020; Barber & Odean, 2001; Deaves et al., 2009; Chuang & Lee, 2006; Griffin et al., 2007; Statman et al., 2006; Tekçe et al., 2016; Trejos et al., 2019; Aljifri, 2023). The main model to examine the effect of overconfidence on the valuation of companies listed on the HOSE is written as follows:

$$Tobinq_{it} = \beta_0 + \beta_1 Marketcap_{it} + \beta_2 ROA_{it} + \beta_3 LEV_{it} + \beta_4 CTV_{it} + \beta_5 Turnover_{it} + \varepsilon_{it} \quad (1)$$

Secondly, this study re-examined the hypothesis using 2 alternative variable proxies for investor overconfidence to ensure the results are not sensitive for the variable proxy and to check the robustness of research's findings. Thus, two alternative models are expressed as below:

$$Tobinq_{it} = \beta_0 + \beta_1 Marketcap_{it} + \beta_2 ROA_{it} + \beta_3 LEV_{it} + \beta_4 ET_{it} + \varepsilon_{it} \quad (2)$$

$$Tobinq_{it} = \beta_0 + \beta_1 Marketcap_{it} + \beta_2 ROA_{it} + \beta_3 LEV_{it} + \beta_4 ISO_{it} + \varepsilon_{it} \quad (3)$$

Where:  $\beta_1$ ,  $\beta_2$ ,  $\beta_3$ ,  $\beta_4$  and  $\beta_5$  are the coefficients of market capitalization, ROA, leverage, and overconfidence proxies, respectively;  $\varepsilon_{it}$  is the error term;  $i$  is a company, which sampled 264 companies listed at the HOSE;  $t$  represents time in quarters that covers the period of 2016-2022.

Our hypothesis is supported by a part of literature reviewing that demonstrated how overconfidence bias affects the valuation of firms listed on the Ho Chi Minh stock exchange (HOSE). The hypothesis of this study is written as below:

*H0: Overconfidence psychology positively affects the valuation of firms listed on the Ho Chi Minh stock exchange (HOSE).*

### 3.4. Model selection

The FEM model, however, is not certain to be an optimal model. Hence, several tests have been conducted to identify the most optimal one for the research.

**Table 1. F-test results**

	F-test	Prob > F
<b>Model 1</b>	71.66	0.0000
<b>Model 2</b>	42.05	0.0000
<b>Model 3</b>	4.86	0.0000

**Table 2. Breusch-Pagan test result**

	chibar2	Prob >chibar2
<b>Model 1</b>	25540.20	0.0000
<b>Model 2</b>	12940.27	0.0000
<b>Model 3</b>	122.98	0.0000

**Table 3. Hausman test results**

	chi2	Prob > chi2
<b>Model 1</b>	158.33	0.0000
<b>Model 2</b>	182.73	0.0000
<b>Model 3</b>	57.16	0.0000

**Table 4. Wald test results**

	chi2	Prob > chi2
<b>Model 1</b>	1.9e+33	0.0000
<b>Model 2</b>	4.6e+06	0.0000
<b>Model 3</b>	1.2e+34	0.0000

**Table 5. Wooldridge test results**

	F-test	Prob > F
<b>Model 1</b>	116.915	0.0000
<b>Model 2</b>	114.883	0.0000
<b>Model 3</b>	3.089	0.1293

*Source: Results from Stata 14*

F-test results indicate that all of Prob > F = 0.000 in three models, which is smaller than the significance level of 5%. Therefore, the thesis has enough conditions to reject H0, accept hypothesis H1. Thus, thesis H0 is rejected and thesis H1 is accepted. It means that a FEM method will be more optimal for model (1), (2), (3) than Pooled OLS. According to Breusch-Pagan test results, in all of three models, Prob > chibar2 = 0.0000 and these are smaller than the significance level of 5%. Therefore, we reject thesis H0 and accept thesis H1. To sum up, a REM method will be more optimal for model (1), (2), (3) than Pooled OLS. Hausman test results show Prob > chi2 = 0.0000 in all of three models, and with p-value of less than 5%, the H0 hypothesis is rejected. It means that FEM is more suitable for model (1), (2) and (3).

After using the F-test, Breusch-Pagan test and Hausman test, the FEM model is selected to be the most suitable model for research data. However, there is a probability that the FEM model has defects which make the regression results ineffective. Thus, this research applies two tests to investigate whether the FEM method has defects or not.

By using results of Wald and Wooldridge test from Stata, it was concluded that using the FEM method is not much significant because of heteroskedasticity and first-order autocorrelation in model 1 and 2 and there is heteroskedasticity in model 3. Therefore, the FGLS method will be applied to improve and eliminate the above disadvantages of the FEM method. To sum up, FGLS is demonstrated to be an optimal method for this study to examine the nexus between overconfidence and firm valuation.

**4. EMPIRICAL RESULTS AND DISCUSSION**

**4.1 Descriptive statistics**

**Table 6. Statistical table of variables**

Variable	Observations	Mean	Standard deviation	Minimum value	Maximum value
Tobinq	7,314	1.2472	0.8071	0.1727	11.0317
Marketcap	7,199	27.5890	1.5774	23.9119	33.3439
ROA	7,230	0.0689	0.0854	-1.0837	0.6127
LEV	7,230	0.4637	0.2154	0.0000	1.2900
CTV	7,114	4.8771	24.4403	-1.0000	1599.8460
ET	4,597	7.7780	30.0104	0.0002	1599.8460
Turnover	7,122	0.0039	0.0066	0.0000	0.0721
ISO	704	0.2515	0.3758	0.0000	4.7850

*Source: Results from Stata 14*

First, Tobin’s Q ratio is the dependent variable in the current study. The mean Tobin’s Q ratio of these examined firms was 1.2472, which is greater than 1. According to the definition of Tobin’s Q ratio, a high Q ratio of greater than 1 implies that a stock is more expensive than the replacement cost of its assets, which indicates that the stock is overvalued. In other words, the majority of 7,314 available observations for Tobin’s Q expressed an overvaluation.

Second, independent variables in this study include change in trading volume ( $CTV_{it}$ ), turnover rate ( $Turnover_{it}$ ), excessive trading ( $ET_{it}$ ) and an increase in the number of shares outstanding ( $ISO_{it}$ ). Firstly, the main variable measures overconfidence is change in trading volume ( $CTV_{it}$ ) had a mean of 4.8771% with a standard deviation of 24.4403, which is significantly huge. It can be explained by the characteristics database which includes all 264 non-financial firms listed on HOSE with different size and industry. Secondly, the standard deviation of turnover rate variable ( $Turnover_{it}$ ) states at 0.0066, which is significantly low. Thirdly, excessive trading ( $ET_{it}$ ) is similar to the change in trading volume since it is defined as a positive value of the change in trading volume only. Finally, there are only 704 observations of an increase in the number of shares outstanding ( $ISO_{it}$ ) throughout the period of 7 years from 2016 to 2022. The reason is that  $ISO_{it}$  will be null if there is no change or a decrease of number of shares outstanding. The maximum value and minimum value of  $ISO_{it}$  are 4.785% and 0% respectively.

Third, there are 3 control variables in the current study, consisting of market capitalization ( $Marketcap_{it}$ ), return on assets ratio ( $ROA_{it}$ ) and financial leverage ( $LEV_{it}$ ). Over 7,199 observations of  $Marketcap_{it}$ , which is defined as logarithm of the market capitalization, the mean value is 27.5890, with the standard deviation of 1.5774. The sample data has a mean ROA of 0.0696, and the average leverage is 0.4687.

**4.2. Correlation analytics**

According to Cohen et al. (2013), the results of a correlation analysis will indicate whether or not there is a relationship between the dependent variable and the independent variables. As shown in table 2, there is a positive relationship between the primary measure of overconfidence ( $CTV_{it}$ ) and Tobin’s Q, at 0.0086. It provides initial evidence that overconfidence of investors is strongly and positively associated with firm valuation. For sample firms, the correlation between turnover and tobinq is negative, which is in contrast with an expectation of the current study. Besides, the Tobin’s Q ratio variable measured market valuation

is positively and highly correlated with market capitalization and ROA, while it is negatively correlated with leverage. It is the same as research's expectation. Finally, the highest correlation is between ROA and Tobinq, which can cause multicollinearity.

**Table 7. Correlation matrix in the main model**

	Tobinq	Marketcap	ROA	LEV	CTV	Turnover
Tobinq	1.0000					
Marketcap	0.4725	1.0000				
ROA	0.6016	0.3080	1.0000			
LEV	-0.2345	-0.0572	-0.4059	1.0000		
CTV	0.0082	0.0245	-0.0325	0.0110	1.0000	
Turnover	-0.1063	0.1000	-0.1051	0.0970	0.0656	1.0000

Source: Results from Stata 14

To guarantee that the research model does not have multicollinearity, this study uses a variance inflation factor (VIF) test. The results from Stata indicate that the VIF values of all variables are at around 1, which is much lower than 10. Meanwhile, a VIF of greater or equal to 10 is often thought to indicate harmful collinearity, though problems are possible with lower VIF values (Franke, 2010). Therefore, it can be concluded that there is no multicollinearity problem among independent variables.

#### 4.3. Regression results

Table 3 summarizes the regression results of the main model by four different research methods of Pooled OLS, REM, FEM, FGLS, respectively. However, this research will focus only on the FGLS result in the result discussions since it is demonstrated as the most optimal model for the current study.

**Table 8. Regression results**

	FGLS (1)	FGLS (2)	FGLS (3)
Marketcap	0.176***	0.158***	0.178***
	-35.13	-28.39	-10.12

#### 4.4. Result discussions

The current research examines the hypothesis H0 stated that overconfidence bias positively affects the valuation of companies listed in the Ho Chi Minh stock exchange. After presenting the regression results, this study focuses on discussing results and then, comparing these results with the findings of other authors. To identify the impact of overconfidence psychology on the valuation of companies listed on the HOSE, the Feasible Generalized Least Squares (FGLS) is employed as clarified in the methodology part.

On the one hand, the regression results in the main model will be examined.

Firstly, investor overconfidence is expected to have a considerable and favorable impact on the value of firms listed on HOSE and, consequently, the value of the stock market. The regression result reports that the primary measure of overconfidence (CTV) has a positive coefficient of 0.0006819 and p-value of  $0.013 < 0.05$ . This value indicates that a rise in the change in trading volume variable of one unit leads to an increase in the Tobin's Q ratio of 0.0006819 units, holding other variables in the model constant. In addition, overconfidence is statistically significant on the valuation of companies listed on HOSE. This result is consistent with the H0 hypothesis of the current study and similar to the research results of Adebambo & Yan (2018), Bouteska & Regaieg (2020), Trejos et al. (2019) and Aljifri (2023). As clarified in the data section, overconfident investors believe in their abilities and will act based on the information they obtain, therefore, overconfident investors trading more actively and taking higher risk than sensible investors, is the reason for the high levels of trading activity on financial markets (Odean, 1998).

Secondly, the turnover rate variable has a negative coefficient of -10.3179 with p-value of lower than significant level of 5%. The value of coefficient is in contrast with an expectation before. According to the research of Statman et al. (2006), Tekçe et al. (2016) and Aljifri (2023), turnover rate is employed as one of independent variables. Turnover rate, defined as the ratio of the number of shares traded to the number of shares outstanding, is calculated quarterly for each period and firm. With this calculated formula, turnover rate eliminates the influence of growth during a long period. In fact, the current research examines a research period of 7 years from 2016 to 2022 while the period of 2019-2022 saw the considerable growth of the Vietnamese stock market. Thus, regression results between turnover rate and firm valuation might not be optimal and realistic.

Thirdly, the coefficients of all control variables are matched with an expectation of the current research. Both market capitalization ( $Marketcap_{it}$ ) and return on assets ( $ROA_{it}$ ) have p-value of 0.0000 and positive coefficient of 0.1759 and 4.4106, respectively. It reports that market capitalization and return on assets are positively affected and statistically significant on the valuation of non-financial firms listed on HOSE. However, leverage variable ( $LEV_{it}$ ) has a p-value of 0.3360 which is higher than a significant level of 5%. Hence, in this model leverage variable has no statistical significance on firms valuation listed on HOSE.

On the other hand, the regression results in the second and third model will be examined. To ensure our results are not sensitive for the variable proxy and to check the robustness of the research's findings, the current study provided alternative variables to measure the overconfidence level of investors, listed as excessive trading ( $ET_{it}$ ) and an increase in the number of shares outstanding ( $ISO_{it}$ ). Two additional regression models are conducted for each of two alternative proxies to capture the effect of overconfidence on the valuation of companies listed on the HOSE. As a result, the study finds that alternative proxy variables are statistically significant at 10% and similar to the H0 hypothesis.

Firstly, the coefficient of excessive trading ( $ET_{it}$ ) states at 0.0004815 and p-value is 0.086. It can be concluded that overconfidence, which is expressed by excessive trading variables, has positively affected the firm values of 264 non-financial listed companies on HOSE, at a significant level of 10%. This result is similar to the nexus between change in trading volume ( $CTV_{it}$ ) and firm valuation since excessive trading is extracted on change on trading volume variables ( $CTV_{it}$ ).

Secondly, overconfidence, in the third model, positively affects the firm valuation of non-financial firms listed on HOSE, which is similar to research findings of Aljifri (2023). It is derived from table 3, when the coefficient of an increase in the number of shares outstanding variable ( $ISO_{it}$ ) is positive, at 0.1255 and p-value is 0.063. In addition, in both additional models, the regression result of other independent and control variables is similar to the main model and matched with the  $H_0$  hypothesis, at a significant level of 10%.

To sum up, the research results on the alternative measurement of investor overconfidence proxies shows that all results are statistically significant. Despite different proxies for investor overconfidence in current investigation, there are consistent results when three of four overconfident proxies indicate the positive impact on firm valuation of listed firms on HOSE. It demonstrates that using the alternative overconfidence metrics has no effect on the report's results. In addition, the positive impact of overconfidence on firm valuation on listed stocks on HOSE is concluded to not be sensitive for the variable proxy. As a result, the current study can arrive at the conclusion that there is a positive and significant relationship between investor overconfidence and the valuation of firms listed on the HOSE thanks to the establishment of reliable measurements for investor overconfidence. This findings are consistent with research results of Bouteska & Regaieg (2020), Adebambo & Yan (2018), Aljifri (2023).

## 5. CONCLUSIONS AND RECOMMENDATIONS

### 5.1. Conclusions

The current study examines the impact of overconfidence of investors on firm valuation on the sample of 264 non-financial firms listed on HOSE in the period of 7 years from 2016-2022. This research employs the change in trading volume variable as a main variable proxy of overconfidence and applies FGLS method as the main estimation.

The current study arrives at several outcomes. Firstly, this paper confirms the positive and significant nexus between investor overconfidence and the firm valuation of sample firms listed on the HOSE. Secondly, to check the robustness of our findings, two additional robustness and sensitivity analyses are provided in this study. As a result, all of the results on two alternative regression models support and confirm the conclusions derived from the main model.

To sum up, regarding different investor overconfidence proxies, all proxies were statistically significant and generated consistent results when used in our analysis. These empirical results suggest that investors in the Vietnamese stock market are affected by overconfidence bias, and such a bias has been neglected by traditional financial theory. These findings are consistent with research's prediction and other related research (Bouteska & Regaieg, 2020; Adebambo & Yan, 2018; Aljifri, 2023).

### 5.2. Recommendations

To my best knowledge, this study is the first quantitative research of investor overconfidence's effects in Vietnam on the valuation of firms listed on HOSE. As a result, the findings are believed to have implications for market regulators, investors, and academic researchers as well as for investment costs, capital allocation, and market effectiveness.

First, the findings of the current study shows that overconfidence psychology of investors positively and significantly affects firm valuation. These results could increase investors' awareness of the influence of their own psychological factors, especially overconfidence bias, on asset pricing and market valuation, leading to more rational stock market decision-making for increased market efficiency. Thus, there are several implications for investors. Firstly, overconfident investors tend to trade more actively and are willing to take higher risk than sensible investors, hence they tend to overvalue stocks and set unrealistic expectations for their investments. As a consequence, this can result in disappointment and frustration. The research findings suggest that investors should set realistic goals and expectations for their investments based on historical performance and market trends. Secondly, overconfidence can lead investors to make hasty decisions without fully understanding the risks and opportunities involved. Hence, to eliminate the impact of overconfidence psychology on investment decisions, investors should keep themselves up-to-date with the latest news and trends in the markets, and conduct thorough research before making any investment decisions. Thirdly, based on behavioral finance theoretical models, overconfident investors often rely heavily on their overestimated knowledge. Additionally, the study indicates that there is an overvaluation phenomenon among overconfident investors on listed firms on HOSE. Therefore, it is necessary for investors to diversify their portfolio across different asset classes and sectors instead of putting all their eggs in one basket that they are highly expecting, which can lead to devastating losses if that one investment fails.

Second, this study implicated several recommendations for market regulators. Firstly, market regulators can reduce the disadvantage of overconfidence psychology on investment decisions of investors by educating. Regulators can introduce investors about the risks of overconfidence and how to avoid it by providing educational resources, such as investor guides, seminars and online tools, which help investors make informed decisions and manage their risks. In addition, market regulators should collaborate with other regulators and stakeholders, such as industry associations, academic institutions, and international organizations, to conduct empirical studies on the impact of overconfidence psychology on investment. Then, share information and aware participants of investment mistakes could be taken due to overconfidence. This can help promote consistency and effectiveness in regulatory approaches across different markets and jurisdictions. Secondly, it is necessary for market regulators to monitor and regulate market activities to prevent fraudulent or manipulative practices, such as insider trading, and other abuses that can contribute to overconfidence among investors. This can help maintain market integrity and protect investors from potential losses.

Final, the results of this study may provide evidence for behavioral theories in academic research that assert investor psychology has an impact on asset pricing, especially stock valuation. These findings suggest investor behaviors, especially overconfidence psychology should be taken into consideration when researching asset pricing models.

### **5.3. Research limitations**

Because of Vietnamese stock market characteristics, a possible limitation of the current research relates to data availability. Due to the lack of data, it is difficult to use more proxies to measure investor overconfidence, such as earnings forecast deviation proxy as research of Lin et al. (2005). In addition, the limited scope of available data presents some obstacles as its interpretation does not always provide answers as expected.

## IMPACT OF ATTENTION ON FINANCIAL TO THE PERORMANCE OF VIETNAM COMMERCIAL BANKS

**Author: Nguyen Thi Luyen<sup>1</sup>, Le Thi Hong Hao<sup>1</sup>**

**Mentor : Le Hai Trung<sup>1</sup>**

*ABSTRACT: Financial technology is developing more and more, the fact that commercial banks instead of “confronting” with financial technology companies have “shaken hands” with them, thereby being able to overcome the shortcomings of traditional business, take advantage of the advantages that financial technology brings and increase the competitiveness of commercial banks themselves. The study evaluates the impact of interest in financial technology on the operation of Vietnamese commercial banks through profitability. In this study, the team took data from 21 commercial banks operating in Vietnam and used the level of search on Google with the keyword “Fintech” in Vietnam from January 2014 to the end of December 2022. use Google Trends. Aim to show that the level of public interest in financial technology in Vietnam has a positive influence on the operation of commercial banks. This is demonstrated by its high profitability. There are recommendations and suggestions to related objects and subjects to overcome the shortcomings and limitations.*

*Keywords: Fintech, commercial bank, profitability, financial technology*

### 1. INTRODUCTION

Breakthroughs in financial technology (Fintech) have been reshaping the way banks operate and provide banking services and have become the foundation of the trend of digitizing banking services. FinTech applications appear in many banking and financial products and services such as retail financial services, payment methods, investment management and consulting, insurance products, and credit provision. , is not only competing with traditional banking and financial services but also promoting the innovation and transformation of commercial banks in service delivery and deployment (An and Rau 2019; Di, Yuan, Zeng 2020; Gai, Qiu, and Sun 2018; Millian, Spinola, and Carvalho 2019; Panos and Wilson 2020). The development and application of new technologies such as Big data, blockchain, eKYC, cloud computing, etc. will help banks collect data, improve service quality, reduce technical infrastructure costs, and reduce networks. branch network, enhancing transparency, but still ensuring safety, speed and efficiency, increasing customer satisfaction (Pham Quang Dung et al., 2022). This is an opportunity and a tool for commercial banks to seize to help improve operational efficiency (Románova & Kudinska, 2016).

Besides the great benefits for customers in improving customer experience, the trend of digitizing banking services also creates great risks and challenges. The trend of digitizing banking services also promotes the participation of financial technology companies (Fintech) and big technology companies (Bigtech) in the banking service market. With the advantage of technology and a large customer base, these companies are expected to change the overall picture of competition in the banking and financial services market in the near future. This may cause traditional banks to also be willing to take on greater risks in their operations to compete, increasing the risk in the market. The trend of digitizing banking activities also increases non-financial risks, such as risks of technology crime, risks with outsourced technology service

<sup>1</sup> Banking Academy.

providers or risks related to over-dependence. dependent on technology in performing activities (Minh and Duc Anh, 2022).

In this study, the authors assess the impact of the development of Fintech on the operation of commercial banks in Vietnam. Specifically, the authors assess the impact of the development of Fintech, through the interest in financial technology from society, on the profitability of Vietnamese commercial banks from 2014 to 2022. Although There have been some studies evaluating the relationship between Fintech and the operation of Vietnamese commercial banks (for example, Hong and Tuan, 2021; Yen et al., 2022), but to the knowledge of the authors, this is The first study evaluates the impact of Fintech on the operation of Vietnamese commercial banks based on the level of public interest in Vietnam in Fintech.

## **2. STUDY OVERVIEW**

The term ‘‘Fintech’’ is a shortened form of the words ‘‘Financial technology’’ or ‘‘finance’’ and ‘‘technology’’, a general description of the interconnection of modern internet technology (e.g. electricity) cloud computing, mobile Internet) with the business activities of financial service providers (e.g. credit services, banking transactions) (Gomber et al., 2017). Thereby contributing to the provision of new and improved financial services, delivering outstanding efficiency and better satisfying customer needs (Thakor, 2020).

A research group shows that Fintech has a positive impact on the operation of commercial banks, improving the operation of commercial banks through the application of new technologies in service provision, assessing risks and advantages from information, big data collected from customers. (Fuster et al., 2019, Goldstein et al., 2019, Berger et al., 2019). Similarly, Wonglimpiyarat (2017) and Navaretti et al (2017) also believe that the application of technological advances will help traditional products and services of commercial banks become more efficient and competitive. Yen et al (2022) argue that Fintech applications help commercial banks reduce costs by taking advantage of data sources from customers through technology applications to analyze customers’ habits and behaviors. , thereby reducing marketing costs and improving profitability from improving the efficiency of cross-selling products. Fintech solutions also help create banking and financial products and services that are more diversified and tailored to the needs of customers, improving access to financial services, thereby helping businesses Commercial banks expand their customer base (Gomber et al., 2017). Hou et al. (2016), Cheng and Qu (2020), Lee et al. (2021), and Wang et al. (2021b) argues that Fintech helps commercial banks improve efficiency in risk management and cost management. Therefore, Jason Yeh (2016) believes that the development of FinTech can bring about compensating, symbiotic effects and improve the profitability of traditional commercial banks.

In addition, some studies show that the development of Fintech has a negative impact on the operation of commercial banks, especially the competition of Fintech companies. Disruptive innovation theory indicates that competitors with technological and innovative advantages in the market will increase the level of competition in the market (Christensen, 2013), creating creating new profitable value chains and directly impacting existing businesses in the market that are offering similar products with less technological and innovative value than Anagnostopoulos, 2018). Buchak et al. (2018) and Thakor (2020) argue that the development of Fintech increases the level of competition and makes the operation of commercial banks become unstable when the level of risk acceptance increases. In fact, Li et al. (2020) indicates that Fintech companies can provide traditional banking products and services with lower costs and higher efficiency thanks to technological advantages. Paulet and Mavoori

(2019) argue that Fintech companies have a competitive advantage over commercial banks thanks to innovative and effective products for customers, while the requirements for management and capital adequacy are much lower than those of commercial banks. NHMs. Guo and Shen (2016), Wang et al. (2021), and Zhao et al. (2022) provides empirical evidence that the development of Fintech causes the asset quality of commercial banks to decline, increasing credit risk because commercial banks accept a higher level of risk to compete with other banks. Fintech company. Similarly, Phan et al (2020) study in the Indonesian market and show that the strong growth of fintech companies has a negative effect on the efficiency of the business operations of the companies. NHM. Similarly, Zhao et al (2021) analyzed the relationship between Fintech application and efficiency in the operation of commercial banks in China and found a negative relationship of Fintech to the profitability of commercial banks. In addition to the negative impact of competition, Nguyen Hong Nga (2020) commented that commercial banks also have to deal with new risks such as strategic risks, outsourcing risks or cybersecurity risks, technical risks, etc. techniques from the application of Fintech, which without appropriate management solutions will negatively affect the operation of commercial banks.

In this study, the authors evaluate the impact of the development of Fintech, through the level of public interest in Fintech on the operation of commercial banks in Vietnam, which is reflected in profitability. The research for the Vietnamese market comes from two reasons. Firstly, Fintech in Vietnam has developed strongly recently. According to the Fintech in ASEAN report 2021 by UOB, PwC Singapore and Singapore Fintech Association (SFA), Vietnam-based Fintech companies have raised more than US\$388 million in investment capital, equivalent to 9% of the total. The value of 167 investments in Fintech in the ASEAN region in the first nine months of 2021, put Vietnam in third place in terms of successful capital raising, creating a strong recovery compared to 2020. Enterprises Fintech in Vietnam has great potential for development, competing with commercial banks with a strong retail market (Pham Quang Dung et al., 2022). However, like businesses in the world, Fintech enterprises have not had the experience and have not built a brand name to expand their operation scale, which leads to the challenge of independent operation of the company. with most businesses (Vu Cam Nhung and Lai Cao Mai Phuong, 2021). Therefore, many Fintech companies have been cooperating with reputable and experienced commercial banks in order to perfect their business plans into reality (Kieu Huu Thien, 2022). Second, although some previous studies have evaluated the relationship of Fintech and the operation of commercial banks in Vietnam such as the study of MSc. Luu Anh Nguyet (2017); Dr. Dinh Thi Thu Hong and Dr. Nguyen Huu Tuan. However, similar to other studies in the world, Fintech development is often approached from the supply side, only from the supply side, through the number of Fintech companies and the amount of investment capital and companies. Fintech companies (eg, Li et al., 2017; Phan et al., 2019, Zhao et al., 2022). However, the use of this indicator to assess the development level of Fintech only stops at assessing the impact of competition from Fintech companies on the operation of commercial banks, instead of assessing Overall, the impact of Fintech in general, from within the application of Fintech by commercial banks as well as the level of Fintech usage by the community (Wang et al., 2020). In this study, the authors assess the level of development of Fintech through the level of information search about Fintech in Vietnam. In the context of the technology boom, the level of information search can help assess the popularity and interest of the community about Fintech, which can then be used to assess the level of development of Fintech in a country. (Askatas and Zimmermann 2009, Wang et al., 2020).

### 3. RESEARCH METHOD

#### 3.1. Research models

Expected regression model to use:

$$ROE_{i,t} = \beta_0 + \beta_1 FIN_t + \beta_2 LnSIZE_{i,t-1} + \beta_3 LIQ_{i,t-1} + \beta_4 CRR_{i,t-1} + \beta_5 LEV_{i,t-1} + \beta_6 NII_{i,t-1} + u_i + e_{i,t}$$

$$ROA_{i,t} = \beta_0 + \beta_1 FIN_t + \beta_2 LnSIZE_{i,t-1} + \beta_3 LIQ_{i,t-1} + \beta_4 CRR_{i,t-1} + \beta_5 LEV_{i,t-1} + \beta_6 NII_{i,t-1} + u_i + e_{i,t}$$

Where,  $i$  is the bank index, and  $t$  is the time index.  $u_i$  is a fixed variable over time to control for the effects of the economy on credit activities in general of commercial banks that have not been shown through individual explanatory variables of each commercial bank and  $e_{i,t}$  is the residual of the regression model. Similar to Kim and Sohn (2017) and Vinh (2018) the explanatory variables were included in the model with a one-stage lag to exclude potential endogenous effects.

The bank's profitability is expressed through two variables, ROE and ROA, the higher these variables are, the greater the profitability of this bank.

$FIN_t$  is the variable representing the development of Fintech in the time period ( $t$ ), is also the variable of most interest in the study. In this study, the group used the level of search on Google with the keyword "Fintech" in Vietnam from January 2014 to the end of December 2022, according to statistics from the Google Trend application. Google Trends statistics the number of public Google searches related to a given keyword with geospatial and time constraints via relative search volume (RSV). Many studies have used RSV to measure public interest in a given topic. Malkiel (2003) & Fama and MacBeth (1973) when studying the theory of efficient markets, said that the stock market is affected by any transparent information. Subsequent researchers such as (Wang, Keswani, & Taylor, 2006) also used these factors to build the investor sentiment index on the Brazilian stock market and the results were similar to the previous author's research. . Ho and Hung (2009) also contributed to empirical research, using the hypothesis of Barker and Wurgler to build a set of indicators to measure market sentiment to test the relationship between market sentiment and profitability of stocks.

To control for the characteristics of commercial banks that can affect profitability, the research team includes a number of control variables in the model as follows.

The first is the bank's size variable ( $LnSIZE_{i,t-1}$ ), which is calculated through the logarithm of the value of total assets. The theory of economies of scale and scope says that large banks have an advantage of size over small banks so they are able to earn more money, and the increase in size allows banks to large increase in bank earnings (Berger et al., 1987; Berger and Humphrey, 1997; Fu and Heffernan, 2008). However, small banks can also rely on small investments on a large scale, and economies of scale do not offset all the losses in the absence of economies of scale and thus , financial performance cannot be improved (Miller and Noulas, 1997).

Next is the variable reflecting the liquidity of commercial banks ( $LIQ_{i,t-1}$ ). Measured by the percentage of highly liquid assets to total assets of commercial banks. Basically, holding too large of liquid assets can allow commercial banks to reduce liquidity (Cornett et al., 2011), but it can also cause commercial banks' loss of profitability. Liquidity has a significant contribution to determining the existence and sustainable

development of entities. With the financial intermediary function, commercial banks always consider and consider liquidity as one of the important goals when making decisions. Diamond and Dybvig (1983) argue that liquidity assurance is necessary to avoid liquidity risks for commercial banks. According to Keynes Liquidity Preference Theory, holding money is not for profit and if you want to make a profit, you must make an investment, such as buying trading securities. Money is the most liquid asset element, so holding a lot of money will be beneficial to increase liquidity, but lose the opportunity to make a profit and therefore, any entity must accept the trade-off between liquidity target and profit target. If you want to achieve high profits, you must reduce liquid assets to invest in less liquid assets, and vice versa.

The explanatory variable representing credit risk in the operation of commercial banks, CRR, is calculated as the bad debt ratio in the credit portfolio of commercial banks. Credit activities still play the most important role in the business activities of Vietnamese commercial banks, so a high credit risk ratio will have a direct impact on the profitability of commercial banks. A higher level of bad debt indicates the existence of financial constraints and the impact on bank management and regulators. NPLs also significantly affect the bank's functions through the weakening of bank assets and the decline in income as uncollectible debts become larger. In a worst-case scenario, a high NPL ratio in the banking system may indicate the existence of systemic risk, which in turn can affect deposits and limit the activities of financial intermediaries. the result will be negative impact on investment and economic growth (Ahmed et al., 2006). Bank performance is often related to the risk-taking behavior of bank managers (Hu et al., 2004; Jimenez and Saurina, 2006; Boudriga et al., 2009; Nikolaidou and others). Vogiazas, 2011).

The variable LEV is calculated as the financial leverage ratio of each commercial bank. Expressed by the ratio of total debt to working capital. High financial leverage will increase pressure on interest payments and thereby reduce the rate of return on total assets, increasing the pressure to reduce bankruptcy at commercial banks.

The variable NII, calculated by the proportion of non-interest income to total income, reflects the diversity of income of each commercial bank. Expanding non-interest service activities helps commercial banks increase sales and income. The banking industry has been facing new banking environment challenges due to increased competition, forcing the industry to adopt a diversification strategy (Hunjra et al., 2020). Well-diversified banks will disperse risks (Hoang Ngoc Tuyen & Vo Thi Hien, 2010). In fact, all over the world, commercial banks have turned to increase their revenue from service business.

To limit the problem of additional variables in the model, the research team used the control variables one period later than the return variable and the variable expressing the public's interest to the public financial technology.

## **3.2. Research data**

### **3.2.1. Data**

The study uses panel data collected from 21 commercial banks in Vietnam with data from quarterly published financial statements of commercial banks from the database of CafeF website. . The team built data on the Fintech development index in Vietnam based on the online search platform Google Trends - a platform that shows the search level of keywords in a range of Vietnam with the keyword "Fintech". Although data from Fintech Enterprises has been available since 2008, but after 2008 and 2009, the growth of Fintech in Vietnam as well as in Asia in particular and globally in general is still extremely low (Cheng et al. associates, 2020). Therefore, in order to limit the status of data and incorrect information, the research

team has collected data since 2014 in order to have more accurate analysis results.

**3.2.2. Descriptive statistics of data sets**

**Table 1: Descriptive statistics of variables used in the model**

Variable	Observed	Mean	Standard Deviation	Minimum Value	Maximum Value
ROA	675	0.003347	0.002602	-0.005450	0.012502
ROE	675	0.040521	0.027312	-0.062408	0.169424
FIN	675	3.221370	1.386067	0	4.503900
LnSIZE	675	12.21497	1.042759	10.01697	14.56718
LIQ	675	0.147573	0.082604	0.034255	1.175210
CRR	675	0.013607	0.004643	6.83E-06	0.033096
LEV	675	0.083825	0.025970	0.030629	0.175878
NII	675	0.075479	0.054494	-0.003239	0.463102

*Source: Calculations of the research team*

Table 1 shows descriptive statistics of the variables used in the article, that is, number of observations, mean (Mean), standard deviation (Std. Dev.), minimum value (Min). and the maximum value (Max). From the results of Table 1 it is shown that there are 675 observations, 0.3347% and 4.0521% are the mean values of ROA and ROE, the max and min values of ROA are 1,2502% and -0.5450% respectively, the max and min of ROE are 16,9424% and -6,2408% respectively, which are relatively low figures. As for the independent variables, FIN was collected by the authors from the online search engine Google Trends - allowing users to see how often specific keywords, topics, and phrases have been queried over a period of time. certain. The frequency of FIN searches or the level of public interest in Fintech with the maximum and minimum values is 4.503900 and 0, respectively, the mean value of 3.221370 is quite high, and the standard deviation between the study periods is 1.3866067.

The average size of commercial banks is 12,21497, the difference between commercial banks is also quite large at 1,042759, while the largest commercial bank is 14,56718, the smallest one is 10,01697. The liquidity ratio has a mean of 0.147573, standard deviation of 0.082604. The average bad debt ratio of commercial banks is 1,3607% and the commercial bank with the largest bad debt ratio is at 3,3096%. The average leverage ratio is 0.083825, standard deviation is 2,5970%. The ratio of non-interest income is assessed to be quite low when the mean is 7,5479%, the standard deviation is 5,4494%, in which the non-interest income ratio of commercial banks is the highest at 46,3102% compared to the total assets of the bank.

**4. RESULTS AND DISCUSSION**

**4.1. Results**

Before performing the graph analysis, the authors checked the multicollinearity between each variable in the article and described the correlation coefficients of each variable with high correlation coefficient that affects the accuracy. of the results. The degree of association between variables is greater when the correlation coefficient is close to 1 or -1. Besides, the association will be considered balanced if the absolute value of the correlation coefficient is greater than 0.8. The results in Table 2 have shown that there is no serious disconnection between the variables measuring the absolute value of each coefficient being less than 0.8 and hence no multicollinearity in this model.

**Table 2: Correlation between variables used in the model**

#### 4.2. Discussion

From the research results, it can be seen that the independent variable Fintech indicates the level and frequency of public search and access to Fintech, which has a positive relationship with the bank’s performance. Aylin and Ahmet (2020), stated that the fact that banks can effectively manage risks, make decisions quickly and accurately, and can improve customer service quality is partly supported by Fintech. In addition, Lucey and Roubaud (2020), stated that customers can reduce borrowing costs, customers can get loans easily, and the operational efficiency of banking services can be improved through getting loans. Fintech support. According to Petralia et al (2019), the rise of Fintech has had a great impact on the traditional business of commercial banks. According to Hoang Duc Sinh et al, the development of Fintech has increased profits, led to innovations and improved risk control for commercial banks.

Banks react differently to emerging challenges in the market, but an increasing number of banks have started collaborating with FinTech startups and scaling in recent years (Horváth 2019). Through cooperation with FinTech, banks can react faster to emerging market changes and be more efficient in developing products and services (Salampasis – Mention 2017; Paleckova 2019). Scott et al (2017) show that the adoption of digital innovations can have a large and lasting positive impact on the performance of banks. Banks may also face challenges in implementing new developments due to their legacy systems. FinTech startups and scalers provide banks with new skills, languages and solutions to meet customer needs and not be hindered by legacy systems (Boratynska 2019).

FinTech can directly connect with potential users via social networks, allowing them to continuously assess customer needs and incorporate feedback into new developments (Anagnostopoulos 2018). Startups are also often less geographically focused. They mainly provide internet-based solutions, so their target market is not limited to one country or region. As a result, they can offer standardized products or services worldwide at little or no extra cost. Partnering with them allows banks to expand their target market

(Romanova – Kudinska 2017). Thus, partnering with FinTech enables banks to innovate value propositions or entire business models through innovative financial technologies, delivering benefits including improved performance and competitiveness. (Zott – Amit 2007; Poetz et al 2015; Salampasis – Mention 2017).

The benefits aren't just for the bank. There is mutual learning potential for both sides, because banks have expertise in financial risk management, retail and corporate lending, while FinTech has innovative ideas in technology (Romanova) – Kudinska 2017). Acquiring customers can also be difficult and expensive, but partnering with banks allows FinTech to reach a large number of existing customers (Dapp 2015; Hill 2018). They can also benefit from banks' access to the global payment system (Chishti – Barberis 2016). Finally, banks have a richer resource base (e.g. capital, people), so they can more easily initiate larger scale projects, while providing investment opportunities and profits. additional benefits during the cooperation period (Bunea et al. 2016; Haddad – Hornuf 2019).

The results also show the impact of the bank's endogenous factors on profitability.

First, the size of the bank has a positive impact on the performance of commercial banks. This is consistent with the research results of Craigwell and Maxwell (2005), banks with large scale will be able to make better use of advantages in terms of marketing conditions as well as economic conditions. In the middle market segment, small banks do not have high performance, this is the opinion of two research groups Macedo and Barbosa (2009); Périco et al (2016) jointly proposed.

Second, liquidity has a positive relationship with bank performance, specifically, the regression coefficient of liquidity with ROE is 0.00499 with significance level above 5%. The efficiency of the fund will be reduced when a commercial bank uses too much idle capital to lend because it has to reduce provisions and payment capacity to increase loan balance. An increase in outstanding loans is one of the factors that help the bank increase interest income, but the decrease in funds is one of the factors that make the bank face higher liquidity risk. The above results are consistent with the research results of Kosmudou (2008) and Brouke (1989).

Third, credit risk has a coefficient of less than zero when running the model with both ROE and ROA variables. It is obvious that the cost of credit provision increases as credit risk increases. When the cost of credit provision increases, profits will decrease, leading to a decrease in ROA. The results of the model are consistent with the business practice of each commercial bank. This result is consistent with the research results of Halil (2012) and Suflan (2009).

Fourth, the regression coefficient of capital adequacy ratio is negative for the dependent variable ROE but positive for the dependent variable ROA. This result is consistent with the study results of Buyukslvarcil and Abdioglu, 2011; Bateni et al., 2014. This relationship means that when a bank's profit increases, it will reduce the bank's minimum capital adequacy ratio, because when the bank wants to achieve more profits, the bank must accept portfolio expansion or choose a portfolio with more risk.

Fifth, non-interest income has a negative impact on profitability indicators (ROE, ROA). With the corresponding coefficient of variation is 0.079634 (significant level less than 1%) with ROE and 0.009538 (statistical significance level less than 1%). Obviously, as non-interest income (including interest income from non-credit services) increases, so will the bank's net return on total assets. The research results of Angela Roman (2013) and Alper & Anbar (2011) are consistent with the above results of the research group. Angela Roma (2013) studied in the period 2003 -2011, what factors affect the profitability of commercial banks in Romania. The results of the study show that non-interest income and loan balance have a negative effect on the ratio of net profit to total assets, but ROA is not affected by interest expenses.

## 5. CONCLUSION

This study aims to systematize the theoretical basis of financial technology (Fintech) and profitability of commercial banks, thereby measuring the impact of Fintech on the profitability of banks. trade in Vietnam, and propose solutions to improve the efficiency of Fintech application in promoting the profitability of the Vietnamese banking system in the future.

Based on the results of the model, the team draws the conclusion that financial technology (Fintech) has a positive impact on the profitability of Vietnamese commercial banks. When this technology is applied and developed in the business activities of commercial banks, the profitability of commercial banks will be improved.

## 6. RECOMMENDATION

The development of Fintech companies negatively affects the performance of commercial banks when the number of these companies in the market is increasing. Therefore, in order to take advantage of opportunities and solve challenges from Fintech, Vietnamese commercial banks need to carefully consider the application and development of financial technology. At the same time, in order to limit the bad effects of Industry 4.0 and Fintech in Vietnam's banking and financial sector, it is necessary to pay attention to the following issues: (1) strengthen cooperation between commercial banks and companies. Fintech for sustainable development of Vietnam's banking system; (2) carefully consider the application and development of financial technology to ensure the profitability of commercial banks; (3) strictly manage the activities of Fintech companies in the market to minimize negative impacts on the performance of commercial banks.

Along with that, it is also necessary to make appropriate solutions and recommendations for participants such as the Government and regulatory agencies, financial - banking institutions (financial intermediaries, commercial banks). ...), other participants.

## RESEARCH ON THE IMPACT OF DIGITAL BANKING SERVICE QUALITY ON CUSTOMER SATISFACTION AT JOINT STOCK COMMERCIAL BANK FOR FOREIGN TRADE OF VIETNAM (VIETCOMBANK)

**Author: Vu Thi Hoai Linh<sup>1</sup>**

**Mentor: Do Thi Thu Ha<sup>1</sup>**

*ABSTRACT: This article aims to determine the factors affecting the quality of digital banking services and the impact of digital banking service quality on customer satisfaction. The study was conducted based on a survey of 218 customers in Vietnam who used or have been using Vietcombank's digital banking services. Through the analysis process, the research has determined that there are five factors that directly affect the quality of digital banking services including: Efficiency and ease of use, Reliability, Security, Response time and Design. The results also show that the quality of digital banking services has an influence on customer satisfaction. In addition, when studying the effects of demographic variables age and sex, the results show that there is a difference in customer satisfaction at different ages. This will help the bank have policies and strategies to complete the service in the near future.*

**Keywords:** digital banking, service quality, customer satisfaction

### 1. INTRODUCTION

The 21st century - the century of dramatical development of technology, so the global economy is also gradually changing to match the industrial revolution 4.0. The rapid technological development has brought benefits and development potential for most industries, and the banking industry is no exception. The integration of technologies into banking products has become a key factor in the success of a bank. The efficiency of banking operations has been improved thanks to the outstanding development of technology and the internet which make banking operations more convenient, faster, and more efficient. Successfully building a digital bank will help the bank create for itself great competitive advantages and easily participate in international integration. Therefore, promoting digital banking is the main and inevitable trend in the coming time.

Digital banking is becoming a staple of banks because it meets most of the needs of customers who want to use electronic devices to make transactions. At the moment, each bank has built and designed its own digital banking service, so the competition from banks is extremely great. The success or failure of the product will mainly come from user feedback. Only products that can satisfy the demands of customers can continue to exist and develop. On the contrary, products that cannot create customer satisfaction could not survive. Therefore, in order to achieve a high position in the field of digital banking, banks need to pay attention to stimulating the intention and satisfaction of customers when using the service and the key to doing this is improve the quality of their services. That is to improve the quality of their services. From there, we can clearly see the important role of providing quality and appropriate services to improve customer satisfaction, this is the best way for customers to stick with the business for a long time. In addition, it also helps the bank create a reputation to attract and expand the portfolio of customers... Therefore, it is

---

<sup>1</sup> Banking Academy.

important to have studies and surveys on customer satisfaction and needs to be done continuously to Banks have the right direction for themselves. With the goal of becoming a member of the largest banks in Asia, they also consider this a top important activity in the bank’s development plan in the coming years.

Stemming from the necessity and importance of the above problem, the research team decided to choose the topic “Research on the impact of digital banking service quality on customer satisfaction at Joint stock Commercial bank for Foreign Trade of Vietnam (Vietcombank)” for research.

## 2. THEORETICAL FRAMEWORK

### 2.1. Digital banking

#### 2.1.1. General overview of digital banking

Digital banking is a form of banking that digitizes all traditional banking activities and services Gaurav Sarma (2017). Accordingly, all banking transactions can be performed anytime, anywhere via the Internet through forms such as 3G/4G/Wifi.

Vietnam is in the early stages of digital transformation and many banks have started implementing digital banking services. Most banks in Vietnam have a digital strategy and digital banking development orientation. Banks all think that digital transformation is extremely important, so up to 96% of banks have been building a development strategy based on 4.0 technology, 92% of banks have developed Internet services and mobile applications.

Most Vietnamese banks have been implementing digital transformation strategies, setting up their own digital banking departments to focus on researching and implementing digital transformation. For example, Nam A Bank (Nam A Commercial Joint Stock Bank) launched a digital transaction space integrating a modern device ecosystem, artificial intelligence application, OPBA robot and the birth of the VTM OPBA digital branch. Another example is Orient Commercial Joint Stock Bank (OCB) established OCB OMNI channel. As a result, digital transaction channels are connected and unified for customers to experience fully, helping customers to use products and services without going to a transaction office...

In addition, banks are implementing cooperation models with technology companies or large technology companies in the financial sector. This partnership brings customers more exciting experiences and diverse services.

Digital banking is growing strongly and has brought many specific benefits to customers such as: convenient transaction, time saving, cost saving, high accuracy, high security.

#### 2.1.2. Compare digital banking and e-banking

Criterion	Digital banking	E-banking
Notion	A form of banking that digitizes all activities and services of a traditional bank.	An online banking service, the bank’s electronic banking, allowing users to look up information and make online transactions.
Nature	Digital banking is broader and more comprehensive than electronic banking.	Reflecting only a part of the application of digitization in the banking sector, it is not required to integrate digitalization for the entire operation of the bank.
Feature	Digital banking has all the features of a real bank, such as: loan, consumer loan, withdrawal, money transfer, account management, investment, insurance,...	E-banking is just a service created to supplement the services of traditional banks, focusing on basic features: money transfer, payment, balance lookup, savings deposit, etc. ..

## **2.2. Service quality and satisfaction**

### **2.2.1. Service quality**

Service quality is the degree of satisfaction with which a service meets the needs and expectations of customers (Lewis and Mitchell, 1990; Asubonteng et al., 1996; Wisniewski and Donnelly, 1996). Edvardsson, Thomsson and Ovretveit (1994) argue that service quality is a service that meets customers' expectations and satisfies their needs. According to Parasuraman et al (1985, 1988), service quality is the gap between customers' expectations and their perception when using the service. Thus, although there are many different definitions, in general, service quality will be evaluated based on the perception of customers.

Research by Parasuraman et al (1988, 1991) is the research that has received much attention when studying service quality. Parasuraman et al. have proposed a model of five gaps and five components of service quality, called SERVQUAL for short. After reviewing and testing the model, the author has proposed 5 basic components that need the most attention when considering service quality, including: Reliability, Responsiveness, Assurance, Empathy and Tangible.

### **2.2.2. Satisfaction**

According to Philip Kotler (2000), "Satisfaction is a person's feeling of satisfaction or disappointment as a result of comparing the actual received product (or outcome) in relation to their expectations". Hoyer and MacInnis (2001) again stated that "Satisfaction can be associated with feelings of acceptance, happiness, helpful, excitement, joy". According to Hansemark and Albinsson (2004), "Customer satisfaction is a customer's overall attitude towards a service provider, or an emotional response to the difference between what the customer expects before and what they receive, for the fulfillment of some need, goal or desire". Thus, it can be understood simply that customer satisfaction is the feeling of customers after using the supplier's products and services and comparing reality with expectations. .

According to Bernd Strauss and Patricia Neuhaus (1997), satisfaction is divided into three categories: active satisfaction, stable satisfaction, and passive satisfaction.

### **2.2.3. The relationship between service quality and customer satisfaction**

If a business wants to survive and develop, they always need to go the extra mile. Therefore, constantly improving service quality to meet customer needs is a good way to succeed in the market. With good service quality, customers will be satisfied, that satisfaction will lead to loyalty and increase the bank's competitiveness in the market. According to Agyapong (2011), customer satisfaction and service quality have a positive relationship. This study shows that good service quality is synonymous with customer satisfaction. From there, the bank can see that identifying and meeting customer needs is the way to improve service and differentiate from competitors.

The financial services industry operates on the trust of consumers, quality is a matter of concern and greatly affects business results. Profits and business growth are mainly guaranteed by customer loyalty (Belas and Gabcova, 2014), which in turn is built from satisfaction with service. Therefore, customer satisfaction is the key factor to bring the relationship of businesses and customers further, longer and more cohesive. Thus, service quality is an important factor determining the satisfaction of commercial bank customers..

## **3. RESEARCH METHOD VÀ MODEL**

### **3.1. Research method**

The study used quantitative research method. Formal quantitative research is based on the calculation of Bolen (1989), the total number of parameters included in the model is 28 , so the sample size needs to be 140 (ratio 5:1). Therefore, the research team made the distribution of 250 votes. Survey subjects are

individual customers in Vietnam who have or are using Vietcombank digital banking services. The study was conducted from January 1, 2023 to May 2023

The scale chosen is based on previous studies. The Likert scale used has 5 levels: strongly disagree, disagree, moderate, agree, and strongly agree.

The authors use SPSS software. The scales were evaluated by Cronbach's alpha coefficient, Exploratory factor analysis (EFA), Pearson Correlation Coefficient, and Linear Regression.

### **3.2. Research model**

#### ***3.2.1. The relationship between efficiency and ease of use and quality of digital banking services***

“The most important factor that causes repeat customers to use the website is ease of use” (Madu and Madu, 2002). “Ease of use is understood as the ease with which users can interact, use and navigate” (Bressolles, 2006). “Many factors such as: site structure, ease of navigation make it easy to use” (Shang, Chen and Shen, 2004). Hammoud et al. (2018) and Sulieman and Warda (2017) stated that “Ease of use has positive effects on customer satisfaction after conducting research and survey”. Not only that, the study of Kayabaşı et al. (2013) also reinforced the correctness of the hypothesis that ease of use positively affects the quality of e-banking services.

According to Lustsik (2004), “The use of electronic services will give bank customers the opportunity to save costs when performing transactions”, “not only by saving money but also by saving time”. (Ho & Ko, 2008). Therefore, efficiency is a factor to consider when observing the relationship with service quality.

Jamil Hammoud (2018) points out that “The efficiency and ease of use of e-banking will help improve service quality and this factor makes the biggest impact”. This result also coincides with the research of Wirtz & Bateson (1995) conducted in other markets, the study shows that a higher level of efficiency will increase customer satisfaction for the E-banking. Therefore, the research hypothesis (H1) is set out as follows:

H1. Efficiency and ease of use have a positive impact on the quality of digital banking services at Vietcombank.

#### ***3.2.2. The relationship between reliability and digital banking service quality***

“The ability to perform exemplary service and on time for the first time is measured by reliability” (Parasuraman, Zeithaml & Berry; 1988, 1985), it is also understood as the ability to meet the promised service. securely and completely reliably. “When participating in transactions, almost all customers want to be assured of safety, completeness, accuracy and error free” (Tuff & Trair, 2021).

“Reliability refers to a company's ability to provide quality information in accordance with timely, accurate, understandable, and relevant criteria, thereby achieving a high level of satisfaction” (Swaid and Wigand, 2007).

“According to customer requirements, banks need to ensure promptness, timeliness, and compliance with commitments made to customers” (Ashraf, 2020). If the above issues cannot be ensured, customers will tend to leave the bank. “Reliability must be built from the first transaction to build trust in customers, this is a factor contributing to the assessment of service quality and has a lot of influence on customer satisfaction” (Pham Thi Kim Yen et al., 2022)

Reliability is a very important part of creating e-banking service quality, which is reflected through the results obtained from the study of Hammoud et al. (2018) and Sulieman and Warda (2017). Therefore, the research hypothesis (H2) is set out as follows:

H2. Reliability has a positive impact on the quality of digital banking services at Vietcombank.

### **3.2.3. The relationship between security and digital banking service quality at Vietcombank**

“The protection of users can avoid potential financial fraud, privacy issues are security issues mentioned” (Bressolles, 2006).

In order for online transactions to be made, website databases often store large amounts of personal information. The lack of face-to-face interaction when using online services further increases the need to be assured of privacy and security in all matters related to customer transactions. Therefore, S.H. HSU (2008) states that “online security is the main concern of customers in deciding whether to conduct an electronic transaction”.

In addition, Madu and Madu (2002) add that “Web-based services provided must be secure and reliable enough to build a sense of credibility and confidence from customers”. Based on that, Jarvenpaa and Todd (1997) consider “The most important feature in establishing e-trust in terms of reducing customers’ worries and worries about transaction information being leaked to the outside world as security. Therefore, when they realize that online privacy is reliable enough to match customers’ expectations, they may be willing to submit their own data and conduct online transactions proactively. and trust”. Therefore, the research hypothesis (H3) is set out as follows:

H3. Confidentiality has a positive impact on the quality of digital banking services at Vietcombank.

### **3.2.4. The relationship between response time and Vietcombank digital banking service quality**

“Regarding the provision of online banking services, the requirements of customers are often high because they place a lot of expectations about the services will be carried out immediately. Any delay in transaction or request processing can frustrate online customers and discourage them from repurchasing, which can lead to negative word-of-mouth and impact customer acquisition. potential customers make decisions” (Le Van Huy et al., 2017).

Therefore, Kim and Stoel (2003) firmly believe that “Fast response time will significantly influence customer satisfaction with online shopping in a positive direction”.

Regarding internet wait times, Weinberg (2000) believes that “Once the homepage loads fast enough and customer requests are thoroughly handled, efforts to achieve customer satisfaction will be successful”.

Therefore, the research hypothesis (H4) is set out as follows:

H4: Response time positively affects the quality of digital banking services at Vietcombank.

### **3.2.5. The relationship between design and Vietcombank digital banking service quality**

“Website design is an aspect that affects the perception of customers and buyers” (Zeithaml et al., 2002) and “website design is understood as providing customers with information in an interesting and have distinctive and attractive website design (Bresselles et al., 2008”).

“Design features represent ease of navigation, and images conveyed to users” (Nguyen Huu Thai Think and Bui Nhat Quang, 2020).

“Elements such as: colors, embedded windows in the screen, graphics, use of images, animations, icons, videos, etc. are issues that the design ethos reflects” (Bressolles, 2006) ).

“To judge the standards of aesthetic appearance on the web, one must question the type, size and clarity of Wemkrueh texts” (Madu and Madu, 2002), as well as for clarity. images, quality and use appropriate images from the website.

In their study, Sulieman and Warda (2017) showed that “service quality is affected by design features and this is also a factor that creates positive impacts on satisfaction”.

From the information above, we can see that the information is arranged, presented visually and attractively is a potential factor to help customers have a good first impression of digital service experience. Therefore, the research hypothesis (H5) is set out as follows:

H5. Design have a positive impact on the quality of digital banking services at Vietcombank

**3.2.6. The relationship between service quality and customer satisfaction**

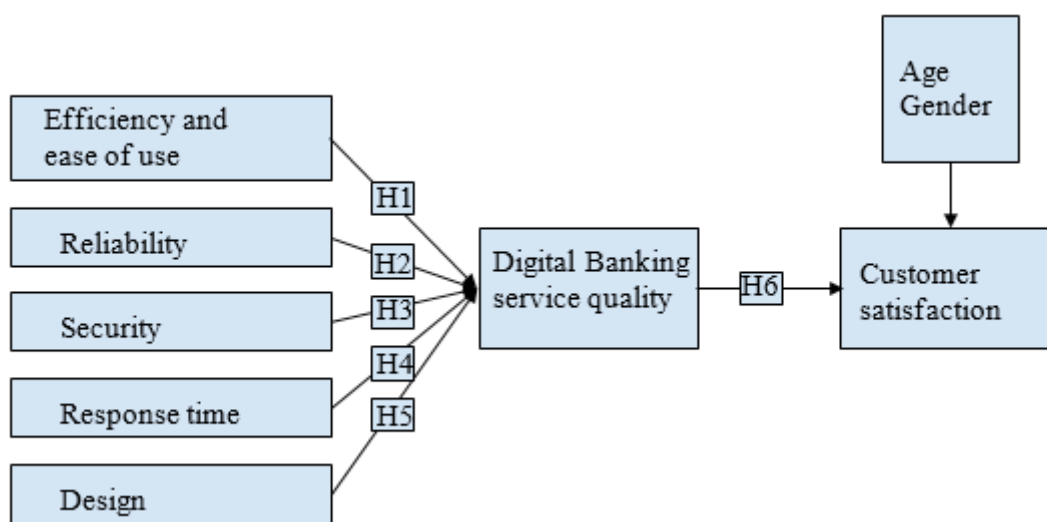

“There is a distinction between service quality and customer satisfaction; while service quality only implies related factors reflecting quality, satisfaction has a broader and more general meaning, influenced by more factors” (Zeithaml and Bitner, 2000).

Cronin and Taylor (1992) showed that “service quality is the bridge to satisfaction”.

Tran Duc Thang (2015) and Kayabaşı et al. (2013) wrote “e-banking service quality positively affects customer satisfaction”. Therefore, the research hypothesis (H6) is:

H6. Digital banking service quality has a positive impact on customer satisfaction using Vietcombank’s banking services.

**Figure 1: Proposed research model**

**4. RESULT AND DISCUSSION**

**4.1. Result**

In general, the reliability coefficient of Cronbach’s Alpha scale is greater than 0.6 and all corrected item-total correlation coefficients are greater than 0.3, these variables will be used for EFA analysis.

**Table 1. Result of Cronbach’s alpha**

Latent Variable	Item Code	Cronbach’s Alpha	Correted Item - Total Correlation	Cronbach’s Alpha if Item Deleted
Efficiency and ease of use	SHQ1	0.781	.612	.724
	SHQ2		.553	.744

Exploratory factor analysis EFA for the independent variable was performed 2 times: In the article, the author has 20 observed variables corresponding to 5 measurement components. The article uses the method of factor extraction Principal Component Analysis and Varimax rotation, the results are obtained as follows: variables STC2 and TG3 are excluded from the model because: Variable STC2 uploaded in both factors is Component 1 and Component 3 with the system. load is 0.636 and 0.592 respectively, the difference in load factor is  $0.636 - 0.592 = 0.044 < 0.2$ ; Variable TG3 upload in both factors is Component 3 and Component 6 with load factor of 0.607 and 0.597 respectively, the difference in load factor is  $0.602 - 0.601 = 0.01 < 0.2$ .

The author excluded all bad variables in the 1st EFA analysis. From the 20 observed variables in the first EFA analysis, remove STC2 and TG3 and include the remaining 18 observed variables in the second EFA analysis for the independent variables. Results obtained KMO coefficient =  $0.852 > 0.5$ , sig Barlett's Test =  $0.000 < 0.05$ , so factor analysis is appropriate. The total variance that these 5 factors extracted was  $69.035\% > 50\%$ , thus, the 5 factors extracted explained 69.035% of the data variation of 18 observed variables participating in EFA.

The regression model will have 5 independent variables including: "Efficiency and ease of use" (SHQ), "Reliability" (STC), "Security" (BM), "Response time" (TG), "Design" (TK).

**Table 2. Result of exploratory factor analysis EFA independent variable**

Exploratory factor analysis EFA for intermediate variables: KMO result =  $0.5 \geq 0.5$ , sig Bartlett's Test =  $0.000 < 0.05$ , so EFA exploratory factor analysis is appropriate. The factor extracted at eigenvalue is  $1,718 > 1$ . This factor explains 85.890% of the data variation of the two observed variables participating in EFA.

**Table 3. Result of exploratory factor analysis EFA intermediate variable**

Pearson correlation analysis: SHQ, BM, TK, TG, STC with dependent variable of service quality less than 0.05. Thus, there is a linear relationship between the independent variables SHQ, BM, TK, TG, and STC with the dependent variable of service quality. Sig correlation of service quality with SHL is less than 0.05. Thus, there is a linear relationship between the independent variable of service quality and the dependent variable SHL. However, the Pearson correlation assessment cannot accurately confirm the impact relationship between the variables, so we need to conduct regression analysis.

**Table 5. Result of Pearson**

Correlations		SHL	CLDV	SHQ	BM	TK	TG	STC

Regression analysis of 6 independent variables affecting digital banking service quality: R<sup>2</sup> adjusted by 0.548. Thus, the variation of quality service is explained by 54.8% of the variation of 5 independent variables TK, SHQ, BM, TG, STC, the remaining 45.2% is the impact of factors other than the given model and random error.

The results of this table also give Durbin–Watson values to evaluate the phenomenon of first-order series autocorrelation. The value DW = 1.617, “between 1.5 and 2.5, the result does not violate the assumption of first-order series autocorrelation” (Yahua Qiao, 2011).

Standardized regression model:

$$CLDV = 0.281*STC + 0.243*BM + 0.222*TG + 0.190*SHQ + 0.123*TK$$

**Table 6. Regression Coefficients**

Model	Unstandardized Coefficients		Standardized Coefficients	t	Sig.	Collinearity Statistics	
	Std. Error	Beta				Tolerance	VIF
(Constant)	.258	.233		1.105	.270		
BM	.221	.050	.243	4.388	.000	.680	1.470

TG	.217	.052	.222	4.185	.000	.741	1.349

SHQ	.155	.043	.190	3.586	.000	.742	1.348
TK	.107	.043	.123	2.501	.013	.863	1.159

Source: Processed from the author's survey data

Univariate regression evaluates the impact of digital banking service quality on customer satisfaction: F-test sig value is  $0.000 < 0.05$ , therefore, the regression model is suitable. corrected to 0.48. Thus, the variation of SHL is explained by 48% of the variation of the CLDV variable. The results of this table also give Durbin–Watson values to evaluate the phenomenon of first-order series autocorrelation. The DW value = 1.673, “between 1.5 and 2.5, the result does not violate the assumption of first-order series autocorrelation” (Yahua Qiao, 2011).

The variable CLDV has a sig test t equal to  $0.000 < 0.05$ , so this variable has statistical significance, or affects the dependent variable SHL.

Standardized regression model:  $SHL = 0.695 * CLDV$

**Table 7. Regression Coefficients**

Analyzing the difference between two gender groups in terms of satisfaction when using Vietcombank’s digital banking services, there is no significant difference between the two gender groups. In other words, between two different age groups, there is no evidence that there is a difference in satisfaction.

Analyzing the difference between age groups in terms of satisfaction when using Vietcombank’s digital banking services: Sig test Levene equals  $0.000 < 0.05$ , there is a difference in variance between age groups, we will use the results Welch test results in Robust Tests of Equality of Means table.

Sig Welch test equals  $0.000 < 0.05$ , accepting the hypothesis  $H_0$ , that is, there is a mean difference in SHL between different age groups. Thus, there is a difference in the satisfaction of digital banking services among individuals of different ages.

**Figure 2. Dependence of satisfaction by age**

## 4.2. Discussion

The research results show that the quality of digital banking services greatly affects customer satisfaction. In addition, the study also shows that there are 5 factors affecting the quality of digital banking services, including: “Response time”, “Reliability”, “Security”, “Efficiency”. and Ease of Use”, “Design”.

“Reliability” is the factor that has the strongest influence on “quality of digital banking services”. With the coefficient  $\beta=0.281$ , we conclude that “reliability” has a positive impact on “digital banking service quality”. This result is consistent with the research results of Nguyen Van Tien (2021), Sundas et al (2015). These studies also concluded that reliability is considered the most important factor in shaping service quality. In the banking sector, transactions are directly related to the financial problems of customers - something that is always valued and valued by most customers, it is perfectly reasonable to take first place. Because, customers in general do not want to have any problems when making transactions related to their finances. If Vietcombank’s digital bank can build high trust for customers, it will be a good factor to help the bank retain customers and improve its competitive advantage. Thus, whether before, during or after the pandemic, the reliability factor is always highly appreciated. Deploying digital banking in the current post-covid-19 period should pay special attention to creating reliability in Vietcombank’s customers.

Security is the second factor assessed by customers affecting the quality of digital banking services. With the coefficient  $\beta=0.242$ , it can be concluded that “security” has a positive impact on “digital banking service quality”. This result is consistent with the study of author Kayabaşı et al. (2013). This result is perfectly reasonable because, people want that the transaction must be completely secure and all their information is safe. From the results of the survey, it is also clear that customers appreciate the role of security and this is also something that has received special attention until now. Therefore, improving security is an important task that needs attention to improve the quality of digital banking services and help Vietcombank have a good place in the market. Because, after the outbreak of the covid-19 epidemic, the number of people choosing digital banking increased and remained until the current post-covid time, but along with it was an increase in criminals taking advantage of security holes of the bank to profit, causing unpredictable consequences for the bank. In addition, during and after the epidemic, many banks have now deployed digital banking, but security still faces many difficulties. Through all of the above, if Vietcombank can build a good security system, it will not only improve customer satisfaction and maintain the number of current customers, but also can acquire a large number of customers in the future.

Response time is the third factor assessed by customers that affects the quality of digital banking services. With the coefficient  $\beta=0.222$ , it can be concluded that “response time” has a positive impact on the quality of digital banking services. Time to respond to complaints and handle issues will make an important contribution to helping the bank succeed in this technology race. Slow response can also make users frustrated and switch to another digital banking system - which is especially easy in the current digital transformation era, from which banks will gradually lose customers. mine. Therefore, banks need to have strategies to not waste customers’ time in waiting. In addition, the majority of customers who come to and use digital banking services are looking for speed and convenience, so if the response time is slow, the bank has lost an important advantage when it comes to digital banking. develop this new service. This result is consistent with the study of Tran Duc Thang (2015). Thus, after the translation, response time is still a factor of high interest to customers using Vietcombank digital banking services.

Efficiency and ease of use is the fourth factor that customers evaluate affecting the quality of digital banking services. With the coefficient  $\beta=0.190$ , it can be concluded that “efficiency and ease” has a positive impact on the quality of digital banking services. This result is consistent with the study of Hammoud et al (2018). Thus, after the pandemic, efficiency and ease of use are still concerned, however, this is not the top concern of customers using Vietcombank digital banking services. This is because the majority of current customers are familiar with using digital banking, so there are not many obstacles when using it. In addition, this is not a factor that can have much impact on customers’ evaluation of Vietcombank’s digital banking service quality better. Because, currently, most of the digital banking services provided by banks are quite effective and easy to use.

“Design” is the fifth factor assessed by customers that affects the quality of digital banking services. With the coefficient  $\beta=0.123$ , it can be concluded that the design feature has a positive impact on the quality of digital banking services. This result is consistent with the study of Sulieman and Warda (2017). This shows that digital banking interface design is also a factor that customers care about when evaluating service quality. The design of a digital bank also partly reflects the bank’s image, so doing the wrong thing to be creative, attractive, and in line with the bank’s image and customer needs is extremely important. In addition, the design to suit each individual also needs the bank to aim for in the near future. Thus, in the present time, design is also a factor that Vietcombank customers are interested in. Although this is not a factor that has a strong impact on service quality, Vietcombank still needs appropriate attention.

“Digital banking service quality” directly affects the “satisfaction” of customers. This result is consistent with the study of Kayabaşı et al. (2013) and Tran Duc Thang (2015). Cronin and Taylor’s study also tested the relationship between service quality and customer satisfaction, and similar conclusions were drawn. This result is reasonable because customers always have great interest in service quality in general and digital banking services provided by Vietcombank in particular. Customers will feel more satisfied when the service is enhanced in line with their wants and expectations and conversely, when the service is not in line with their needs, the customer will feel less satisfied. The fact shows that this is reasonable, because service quality is related to the process of providing, and after using the service, the customer can make an assessment of the satisfaction.

Research results also show that young people are more satisfied with digital banking services than people of other ages in the study. Because, they easily adapt to modern technology and are always ready to open up and experience new services. Moreover, digital banking was also born and developed with the generation of young people, it has characteristics suitable to the needs, interests and habits of young people. In addition, the research results can also be explained by the fact that older customers often find it difficult to use technology services and have higher standards and expectations for quality than younger people, therefore, they find it difficult to accept technology services. The current situation also shows that using digital banking also carries many risks and when the problem occurs, most of the people of the previous generation will be more negatively affected because they have more accumulated assets. This is an audience that needs time to adapt, choose and trust digital banking services. Therefore, after the Covid-19 epidemic, the number of customers looking for digital banking services increased, but those aged 25 and over still need special attention from Vietcombank to be able to provide the best service.

From the results obtained, the team made some suggestions to help Vietcombank improve the quality of digital banking services, on that basis, improve customer satisfaction using the service:

Firstly, improve customers' trust in Vietcombank digital banking services: The bank needs to provide information quickly and transparently on the digital banking interface and through channels such as newspapers, television, news, messages,...; ensure that all services in digital banking are performed as committed to customers from the beginning and solve arising problems in a timely manner; have policies and rules to handle cases where employees do not comply with their commitments and cause harm to customers using the service.

Secondly, to enhance the security of the digital banking system Vietcombank: Vietcombank needs to maintain compliance with regulations of state agencies on cybersecurity such as: Circular 09/2020/TT-NHNN, Law on Security network, ISO 27001, PCI DSS,...; paying special attention to improving the quality of human resources for information security; regularly update security solutions; Artificial intelligence (AI) applications to enhance security should also be noted and developed by Vietcombank in the near future.

Third, information needs to be responded to in a short time: there is a staff to receive and process customer information requested 24/7, in addition, banks can also use chatbots to respond to requests. simple matter; applying digital technology to voice recognition to recognize the name and age of customers calling the switchboard.

Fourthly, improve the efficiency and ease of use of customers: currently, according to the group's observations, customers using Vietcombank's digital banking services even though they can register online accounts, however, customers still need to go directly to the counter to verify information directly within 6 months. This, according to the research team, will affect the user experience and limit the effectiveness of digital banking. Therefore, Vietcombank needs to come up with effective and convenient policies or ways to authenticate information. Vietcombank can apply video authentication so that customers can identify and upgrade account packages anywhere. Customers will be connected to the bank staff through this video call and provide authentication information. Thus, customers can save time and effort.

Fifth, increase the efficiency of digital banking design: Vietcombank can improve the design of its digital banking services by working towards personalizing the user experience; allowing customers to design their own location of available banking facilities and services accordingly; uses Big Data and AI to analyze consumer habits, usage and automatically categorize individual products.

Sixth, providing a separate financial assistant service for each customer: offering new features such as helping customers manage their personal finances, helping customers have an overview of their monthly spending; Personal financial advice is suitable for each customer's condition, from which customers will make reasonable spending, investment and saving decisions.

Seventh, provide services appropriate to each age of use: For example, young people will like to use convenient, youthful, unique services, older ages will want to be trained. Focusing on quality service and safety, security or loan, savings or investment packages, people over 40 will prioritize ease of use and convenience, they are also more interested in safe savings products.

## **5. CONCLUSION**

Digital banking is a development trend in the new era of banks. The authors' research shows that there are 5 factors affecting the quality of digital banking services, including: Reliability has the strongest influence, followed by Confidentiality; followed by Response Time; followed by Efficiency and Ease of Use and finally Design. In addition, the research results also show that service quality also has an impact on customer satisfaction. However, the scientific research paper still has certain limitations that need to be

overcome. The first is that this study mainly collects samples from individual customers using Vietcombank digital banking services in Hanoi, so the sample diversity is not high, the results may not be completely accurate for all regional fish. In addition, the research sample collected is mainly young people or working people under the age of 40, so the analysis results are more suitable for this audience.

Future research could explore this issue with diversity in age, occupation, income and in other more diverse provinces and cities. In addition, new research can also look at how the factors affecting service quality and satisfaction have changed before, during and after the covid-19 epidemic to be able to see the trend in customer consumption, from there, the bank will make appropriate strategies. Future research can explore more about digital banking for corporate customers.

## BUILDING MODEL FOR DETECTING FRAUD IN FINANCIAL STATEMENTS OF VIETNAM COMPANY

**Author: Duong Thi Khanh An, Nguyen Thuy Linh<sup>1</sup>**

**Mentor: Bui Thi Hang**

*ABSTRACT: To prevent fraud in financial statements, the Ministry of Finance has also issued Auditing Standard No.240 (VSA 240), regulating auditors' responsibilities related to financial statement fraud in the field of accounting and finance. Fraud intentionally falsifies economic and financial information by one or more people on the Board of Directors, employees, or third parties, affecting the financial statements. However, applying these standards in practice still has many difficulties. At the same time, companies listed on the stock market cheat in the preparation of financial statements with a large number in the form of "variation" of business results in the financial statements, which is to increase false revenue, reduce costs to increase profits, or raise profits capital is "negative." In contrast, the size of assets does not increase. The study was conducted on constructing a fraud detection model in financial statements in Vietnam. The results show that the study successfully built three fraud identification models with high accuracy and built a matrix model combined with identifying the most fraudulent financial statements. In contrast, the correct prediction rate of fraudulent companies is still high. At the same time, some suggestions propose to improve the detection and prevention of financial statement fraud, thereby helping investors and information users to have more information about understanding fraudulent financial reporting practices and avoiding the unnecessary risks of making decisions based on incomplete information and containing fraud or manipulation of financial statements by managers' enterprises.*

*Keywords: Fraud, Financial Statements.*

### 1. INTRODUCTION

Fraud is an intentional act committed by one or more persons within the Board of Directors, the Board of Directors, employees, or third parties by deceitful actions to obtain an unfair or illegal advantage.

In the United States, the annual loss caused by fraudulent financial statements estimates at 400 billion USD. Businesses lose about 5-6% of their revenue each year due to fraudulent financial statements.

In recent years, there have been many cases of fraud in Vietnam when preparing financial statements of typical enterprises such as Vien Dong Pharmaceutical Company (in 2011) and, Tay Bac Mineral Investment Joint Stock Company (in 2012), Wood Industry Group (2016).

Fraudulent financial reporting has threatened public confidence in market information. Therefore, the truthfulness and accuracy of financial statements in listed companies are essential for shareholders and investors. On that basis, the research team proposed "Building a fraud detection model on financial statements in Vietnam."

- Several models in the world have been built to identify fraud in companies: Beneish (1999) created the M-score model, the model of Burcu Dikmen and Güray Küçükkocaoğlu (2005) in Turkey Turkey, the Model of Tarjo and Nurul Herawati (2015). There have been many studies on the topic of building fraud detection models of financial statements, but the research mainly focuses on the use of a single model as a measure as well as primarily based on quantified information on the financial statements without paying attention to the influence of many other identifiers.

- Subject: Fraud detection model on financial statements

<sup>1</sup> Academy of Finance, CQ58/22.05CLC, Email: thuylinhnguyen160902@gmail.com

- Scope of the study: Companies listed on the stock exchange and research to assess the reality of fraud in financial statements of enterprises in 2019-2022.
- Meaning of the topic: The research is built through surveys, and statistics combined with document research, thereby establishing a general theoretical basis on fraud, pointing out the current state of fraud. Fraud synthesizing techniques beautify the financial statements of listed companies and build fraud identification models.

## 2. THEORETICAL BASIS OF FINANCIAL STATEMENT FRAUD

The research team has presented the concept of financial statement fraud according to VSA 240 and outlined theories to explain fraudulent financial statements: The proxy theory of Jensen & Meckling (1976), the idea of financial statement fraud. Related subjects of Freeman (1984), Fraudulent Triangle Theory by Cressey (1953), and Fraudulent Scale Theory by D.W. Steve Albrecht (1980); present the results of the American Association of Fraud Investigators (ACFE) (1993-2012) on types of fraud in organizations, economic crime and fraud survey in Vietnam in 2018 PwC has realistic data on fraud, clarifying the relationship between fraud and factors inside and outside the company who are likely to cause financial reporting fraud and the extent of their impact. Fraudulent financial statements; clarify the parties' responsibilities in detecting and preventing fraudulent financial statements. At the same time, the research team also presented the work of Beneish (1999), Tan et al. (2014), and Kanapickienė (2015), who synthesize the basic theory of fraud to create a premise to build variables and fraud identification models.

## 3. FRAUDULENT FINANCIAL STATEMENTS IN VIETNAM

In Vietnam, in the past years, a series of fraudulent financial statements were discovered that shocked the market and caused concern to many investors. Many companies listed on the stock exchange have a significant difference between profit after tax and after audit. One of the typical cases of financial reporting fraud in Vietnam must be mentioned in the "mission" of Viet Nhat JVC Medical Joint Stock Company in 2015.

Common tricks used in cheating:

Forgery of revenue: The recording of unrealistic income in the accounting books. Forgery of payment is a common form of fraudulent financial statement preparation.

Recognition of an increase in revenue without accounting estimates

Recording in the wrong accounting year: Recording transactions arising in the bad accounting year is the recording of income/or expense that is not correct at the time of occurring.

**Declare debts and expenses:** Concealing debts and expenses is a way to commit fraud in financial statements to increase the company's profits.

The research team has clarified the adverse effects of financial statement fraud in theory and practice, referring to the main fraud methods of Vietnamese enterprises. Thereby clearly showing the importance of identifying and preventing fraudulent financial statements. It is necessary to have helpful fraud detection tools and effective policies and measures to minimize financial reporting fraud.

## 4. RESEARCH MODEL

The research team used quantitative methods to test the hypothesis: Correlation analysis and multicollinearity test.

The research team used independent variables: AUDREPORT, BIG4, CA/CL, CA/TL, CASH/CA, CASH/CL, CASH/TA, TA/CL, CEO, CFO/CL, CL/TL, EQ/TL, FA/TA, GP/SAL, GP/TA, INV/CS, INV/TA, LEV, OP/GP, REC/REV, NI/TA, NI/EQ, RST, SAL/COST, SAL/CS, SAL/GA, SAL/FA, SAL/TA, WC/TA, and dependent variable FRAUD

#### **4.1. Model 1**

##### **4.1.1. Check the correlation coefficient**

The research team used Eview 8 software to test the correlation analysis between the independent and dependent variables, FRAUD. Variables with little correlation with FRAUD ( $p\text{-value} \geq 0.2$ ) were excluded from the model. The results of the correlation analysis show that most of the independent variables are correlated with FRAUD with a significance level of less than 0.2 (except for variables BIG4, TA<sub>c</sub>/TA, CL/TL, EQ/TL, INV). /CS, INV/TA, NI/EQ, SAL/CS).

##### **4.1.2. Check for multicollinearity**

The research team used Eview 8 software to test the correlation analysis between independent variables. Variables with a correlation coefficient  $\geq 0.8$  have high multicollinearity, whereas variables with a correlation coefficient  $< 0.8$  are considered to have negligible multicollinearity. The analysis results show that CA/CL is highly correlated with CA/TL, CASH/TA is highly correlated with CASH/CA, and EQ/TL is highly correlated with CA/TL. The research team will remove the variables with less statistical significance among the highly correlated pairs after the first model regression.

#### **4.2. Model 2**

##### **4.2.1. Check the correlation coefficient**

The research team used Eview 8 software to test the correlation analysis between the independent and dependent variables, fraud. First, variables with little correlation with the copy ( $p\text{-value} \geq 0.2$ ) were removed from the model. Correlation Analysis results show that most of the independent variables are correlated with FRAUD with a significance level of less than 0.2 (except CS/GP, INV/CA).

##### **4.2.2. Check for multicollinearity**

The research team used Eview 8 software to test the correlation analysis between independent variables. Variables with a correlation coefficient  $\geq 0.8$  are considered to have high multicollinearity, whereas variables with a correlation coefficient  $< 0.8$  are deemed negligible multicollinearity. The analysis results show that the variables are not highly correlated.

#### **4.3. Model 3**

##### **4.3.1. Check the correlation coefficient**

The research team used Eview 8 software to test the correlation analysis between the independent and dependent variables FRAUD. Variables with little correlation with FRAUD ( $p\text{-value} \geq 0.2$ ) were excluded from the model. Correlation Analysis results show that most independent variables correlate with FRAUD with a significance level of less than 0.2 (except for variables GP/FA, NI/CFO, CS/GP, EQ/LA. ).

##### **4.3.2. Check for multicollinearity**

The research team used Eview 8 software to test the correlation analysis between independent variables. Variables with a correlation coefficient  $\geq 0.8$  are considered to have high multicollinearity, whereas variables with a correlation coefficient  $< 0.8$  are deemed negligible multicollinearity. The analysis results show that most of the variables are not highly correlated with each other (except (CA-INV)/CL is positively correlated with CA/TL, CFO/CS is highly associated with CFO/SAL, and EBT/TA is highly correlated with CA/TA. Highly related to NI/TA, NI/CS to NI/SAL, NI/CS to OP/SAL, NI/SAL to OP/SAL).

#### **4.4. Combine models**

From the results of three regression models, I, II, and III, the research team modeled a matrix combining three models. Out of 80 fraud reports:

There were six undetected fraud reports or 7.5%.

There are seven reports that only 1 model can detect signs of fraud, equivalent to 8.75%

There are nine reports of 2 models that can detect signs of fraud, equivalent to 11.25%

There are 58 reports of all three models being detected as cheating, accounting for 72.5%

the combining of three models, 74 financial statements were found to have fraud in financial statements, equivalent to 92.5%

Of 464 non-fraudulent financial statements, 343 were not considered fraudulent when combining the three models, or 73.92%.

## 5. DISCUSSION AND RESULTS

### 5.1. Model results

From the results of the associative matrix model, we see:

With the model I:

Correct prediction rate of fraud report:  $62/80 = 77.5\%$

Correct prediction rate reporting no fraud:  $370/464 = 79.741\%$

Overall correct rate =  $(62+370)/544 = 79.412\%$

With Model II:

Correct prediction rate of reporting fraud:  $68/80 = 85\%$

Correct prediction rate reporting no fraud:  $364/464 = 78.448\%$

Overall correct rate =  $(68+364)/544 = 79.412\%$

With Model III:

Correct prediction rate of reporting fraud:  $69/80 = 86.250\%$

Correct prediction rate reporting no fraud:  $392/464 = 84.483\%$

Overall correct rate =  $(69+392)/544 = 84.743\%$

The combining of three models, 74 financial statements were found to have fraud in financial statements, equivalent to 92.5%

Of 464 non-fraudulent financial statements, 343 were not considered fraudulent when combining the three models, or 73.92%.

### 5.2. Discussion

With this model, it is possible to accurately predict fraudulent reports with a high rate of 92.5% while maintaining a high prediction rate of non-fraudulent financial statements at 73.92%, so the model is suitable for investors who do not want to invest in companies that cheat financial statements.

- ***Fraud identification solution***

With the factors of motivation and pressure, auditors need to pay attention to the indicators showing the company's profitability and ability to generate revenue. Abnormal fluctuations in these ratios indicate the instability of the company's financial position, leading to a higher likelihood of financial reporting fraud.

Given the opportunistic factors, the auditor should consider the debt-to-revenue ratio. If this ratio is higher than the general average, the company will likely inflate revenue through receivables or not recording provisions.

With the attitude factor, the auditor can rely on past audits' results to assess management's attitude and ethics. As a result, the likelihood of fraud in the financial statements is higher.

- ***Solutions to prevent financial reporting fraud***

There are training programs: "Business Ethics and Compliance."

Build an effective internal control system with strict regulations and clear assignment of powers and obligations of internal control.

Strengthen the auditor's responsibility for fraud in the audit of financial statements.

Need to have more understanding of economics, finance, and even accounting and learn more about the company.

Sanctions for financial reporting fraud should be strengthened.

## **6. CONCLUSION**

In the study, the research team focused on understanding the motivations based on Vietnamese auditing standards for fraud assessment. The content introduces fraud theories and sets out the telltale signs that this company is cheating on its financial statements.

The study contributes to the experimentation of the underlying fraud theories by investigating the characteristics of companies that violate accounting standards and make disclosure errors. Honest. After this process, the study provided objective observational evidence about the financial reporting process of potentially fraudulent companies.

The study has built a solid theoretical foundation based on the fraudulent triangle theory to apply to fraudulent financial statements, building models with many observations with high representativeness. The study has successfully built three fraud detection models with high accuracy and created a combined matrix model to identify the most fraudulent financial statements. At the same time, the correct prediction rate for the companies is not high. Fraud is still at a high level, and at the same time, some suggestions are proposed to improve the ability to identify fraudulent financial statements. The research and outputs show that university students, with the proper guidance, can deliver quality academic work at minimal cost and beneficial results (Vuong, 2018).

There are some limitations still exist. The study was only conducted on the data of companies on HOSE in 2019-2022, so the overall reflection of the companies listed on the stock exchange is still limited and has not yet reflected the situation. Financial reporting fraud in the period before 2019.

In addition, the variables representing the fraudulent triangle have limitations. Few variables represent the chance factors for fraudulent behavior, and only the variable REC/REV can distinguish fraudulent behavior. There are no variables representing the method of fraud through inventory. This is because no expenses, etc., can determine fraudulent and non-fraudulent financial statements. In addition, the study does not have variables representing the quality of internal control and lacks variables representing attitudes and ethics. Finally, in the research model, no variables represent assets whose value is less under the power of the enterprise, such as short-term and long-term securities. The above is one of the main cheating methods but has not been shown through the model variables.

## THE IMPACT OF THE CAPITAL STRUCTURE ON PERFORMANCE OF THE MANUFACTURING COMPANIES LISTED ON VIETNAM STOCK EXCHANGE

**Authors: Nguyen Bui Minh Khang<sup>1</sup>, Luu Tran My Linh<sup>1</sup>, Nguyen Quang Minh<sup>1</sup>,  
Pham Minh Thu<sup>1</sup>, Nguyen Khanh Vi<sup>1</sup>  
Mentor: Assoc Prof .Dr. Pham Thi Thanh Hoa<sup>1</sup>**

*ABSTRACT: This study investigates the impact of capital structure on firm performance of manufacturing companies listed on the Vietnam Stock Exchange. Simultaneously, outline the findings of past empirical studies on the influence of capital structure on performance. Create a model and assess the impact of capital structure elements and the link between capital structure and firm performance on 185 Vietnamese manufacturing companies listed on the Vietnam stock exchange from the years 2016 to 2020. The paper indicates that capital structure has a negative impact on firm performance. Moreover, the study points that current ratio have a negative influence on the debt ratio*

*Keywords: Capital structure, firm performance, manufacturing companies, Vietnam's stock exchange.*

### 1. INTRODUCTION

The emergence of numerous businesses has considerably aided Vietnam's economic growth in the framework of the nowadays global economic integration, specifically in the manufacturing sector. The State and the Government are particularly interested in this industry because production is the process of creating goods for use, or for exchange in commerce, and plays the role as a determining factor in the livelihoods of people. The survival and development of humans and society is a fundamental activity that gives rise to and develops human social relationships, it is the basis of the formation, transformation and development of the human society.

A manufacturing enterprise in particular, or all businesses in all fields in general, need initial capital to serve the operational needs of the business. All businesses must balance the optimal capital structure in order to minimize the cost of capital. An enterprise can use the appropriated capital to reduce the burden from the cost of using a bank loan, or take advantage of the tax shield from debt, or issue more common shares to reduce the cost of using retained earnings for reinvestment.

Nevertheless, we can see that capital structure, or capital policy has a significant impact on the performance of listed manufacturing enterprises in Vietnam today, and the study of "The impact of the capital structure on the performance of the manufacturing companies listed on the Vietnamese stock exchange" is an extreme necessity.

The objective of the research paper is to build a regression model in order to determine the influence of capital structure on performance of listed manufacturing enterprises in Vietnam through the use of regression analysis. According to that, the study offers a number of solutions to help enterprises build a reasonable capital structure, thereby optimizing performance efficiency and minimizing cost burden. The subsequent activities must be carried out so as to achieve the target: Firstly, we state the general theory on capital structure and performance of listed manufacturing enterprises in Vietnam. Secondly, we provide

---

<sup>1</sup> Academy of Finance

an overview of capital structure and performance of listed manufacturing enterprises in Vietnam. Thirdly, we propose research hypothesis and regression model to evaluate the influence of capital structure on the performance of listed manufacturing enterprises in Vietnam and finally, we propose a system of solutions aimed at helping enterprises choose the most optimal capital structure, thereby maximizing performance.

The research paper studies the impact of the capital structure on the performance of manufacturing companies listed on Vietnam stock exchange during the 5-year period from 2016 to 2020. The authors selected the period from 2016 to 2020 to assess the impact of capital structure on the performance of listed manufacturing enterprises in Vietnam in two situations: with and without the effects of the Covid-19 pandemic. Assessing the impact of capital structure on the performance both with and without the Covid-19 pandemic is very important because the plan to build the capital structure of manufacturing enterprises is a long-term decision, but the Covid pandemic may cause decisions to change abruptly.

## **2. THEORETICAL FRAMEWORK:**

### **2.1. Theory related to the capital structure of the company:**

#### **2.1.1. M&M theory on the capital structure of a business:**

This theory was proposed by two researchers Franco Modigliani and Merton Miller in 1958, so it is often referred to as M&M theory. M&M theory is based on the following important assumptions: tax assumption, transaction cost assumption, cost of financial distress assumption, and perfect capital market assumption as follows:

In terms of content, M&M theory is stated in two important propositions: The first is about the value of the company, and the second is about the company's cost of capital. These clauses are considered in turn in two cases: with tax and without tax.

The result of the theory argues that in a perfect market, the capital structure does not affect business value. Therefore, there is no optimal capital structure for a business-specific profession. However, the assumptions of such a perfect market as there are no costs transaction fees, no taxes, asymmetric information, and a borrowing rate equal to the risk-free rate are not suitable for the actual operating environment of the enterprise. So, researchers make assumptions about the firm's value and performance are affected by capital structure.

#### **2.1.2. Theory of the optimal capital structure:**

The theory of optimal capital structure is also known as the traditional approach. This theory assumes that the cost of capital depends on the capital structure of the firm and that there is an optimal capital structure where the company's management can increase the value of the firm by using the ratio of appropriate financial leverage.

Under this approach, as the firm increases its use of debt, the firm can reduce its average cost of capital because the cost of debt is lower due to the corporate income tax savings. However, an increase in debt ratio also entails an increase in risk, so investors will demand a higher return on equity. But initially, an increase in the required rate of return will not completely erase the benefits of using debt as a cheaper source of capital until the investor continues to increase the rate of return and claims make the benefits of using debt no longer available. At a debt ratio where the required rate of return is just enough to make the benefits of using debt disappear, the firm has the lowest cost of capital. As the debt ratio continues to increase, the average cost of capital will increase.

The question is how to determine the optimal capital structure? This is always a difficult question for financial planners. Capital structure policy-making involves a trade-off between risk and return. On the one hand, using a lot of debt increases the risk for the company, but a high debt ratio generally leads to high expected returns. On the other hand, increased risk tends to lower the stock price, while high returns tend to increase the company's stock price. Based on the analysis of profit and risk, financial planners can make decisions about the optimal capital structure for the business - the capital structure at which the balance between profit and risk is achieved. that maximizes the company's stock price.

### **2.1.3. Pecking order theory:**

The pecking order theory suggests that managers prefer to finance investment opportunities using three sources: first through the firm's retained earnings, secondly through debt, and choosing shareholders' equity ranks the last.

The pecking order theory starts with asymmetric information - a phrase to show that managers know a lot about the potentials, risks, and values of the business. own business than outside investors.

Asymmetric information affects the choice between internal and external financing, and between new issuance of debt and equity securities.

This would lead to a pecking order, whereby investment projects would be financed first with internal capital, mainly profits for reinvestment, then new debt issuance, and finally by issuing new share capital.

The pecking order theory explains why firms with low profitability tend to take on more debt.

Not because they have higher target debt ratios but because they need more outside funding. Less profitable firms issue debt because they do not have the internal sources of funds for capital investment and because debt financing ranks first in a pecking order of external financing.

In pecking order theory, the attractiveness of the tax shield from debt is seen as the class effect of varying debt ratios in the presence of asymmetries of internal cash flows, and real investment opportunities. Profitable businesses with limited investment opportunities will strive for low debt ratios.

Businesses with greater investment opportunities than internally generated capital are forced to borrow more.

## **2.2. Recent researches of the impact of capital structure on performance and the impact of several factors on capital structure:**

### **2.2.1. Recent researches of the impact of capital structure on the performance of the enterprise:**

The relationship between capital structure and business performance has become one of the topics that attract the most attention and is also studied by many scientists around the world. Recent studies have come to a conclusion that capital structure has a significant influence on the performance of a business.

Weixu has studied the relationship between capital structure and performance based on research data of 1,130 companies listed on the Shanghai Stock Exchange, excluding those operating in financial sectors such as banks, insurance, financial companies. The research results show that the performance efficiency is greatly affected by the debt ratio variable. Debt ratio has a positive effect on operational efficiency at a low debt ratio and negative effect on a high debt ratio. The performance does not have a strong correlation with long-term debt ratio, the reason is that companies in China prefer short-term debt to long-term debt. Firm size variable (SIZE) has a positive effect on performance efficiency quite strongly in the linear model, and in the nonlinear model, SIZE has no effect. The variable growth rate of total assets (GROWTH) has no impact on performance in all 3 models.

Dimitris Margaritis & Maria Psillaki studied the relationship between capital structure, ownership and performance of a French corporation. The authors carried out a 2-way study, two regression models were built: Debt ratio model and factors affecting the commercial efficiency and the CPA model and factors affecting the debt ratio. The research results show that there is a causal relationship between the debt ratio and the efficiency and the efficiency and the impact on the debt ratio and vice versa.

Zeitun & Tian showed that the debt ratio variable has the strongest impact, this result is also consistent with previous studies and companies with a high proportion of fixed assets have low performance because they invest too much in fixed assets without improving operational efficiency. Business lines have a strong impact on operational efficiency in a number of fields: real estate, educational services, chemistry and oil, and tobacco.

Mahfuzah Salim & Dr. Raj Yadav studied the performance of 237 Malaysian companies from 1995 to 2011 from a financial and market perspective. The study gives 4 results: (i) performance measured by ROE, Tobin's Q shows the ratio of short-term debt ratio (STD), the ratio of long-term debt to total assets (LTD), Debt ratio has a negative impact on performance, however, performance measured by ROA shows that STD, LTD and TD have a negative impact on performance for afforestation companies and STD, LTD have a positive impact on performance for consumer goods companies; (ii) performance measured by EPS shows that STD, LTD, TD have a negative impact on performance for companies in the consumer goods, construction, and industrial products sectors, along with performance for companies in the afforestation and service business; (iii) Growth of revenue of total assets (GROWTH) has a positive impact on performance; (iv) Firm size (SIZE) has a positive effect on performance. The authors show that in each different industry, the performance measured by ROE, return on total assets (ROA), Tobin's Q, earnings per share (EPS) is subject to the effect is different in degree, marked by capital structure STD, LTD, TD and SIZE, GROWTH.

Research by Nguyen Hieu Thanh & Nguyen Anh Huu (2020) "The Impact of Capital structure on Firm Performance: Evidence from Vietnam" has assessed the impact of debt ratio on the performance of enterprises in Vietnam, can be shown through 3 models with dependent variables respectively ROA, ROE and EPS (GLS model). The research results show that the debt ratio (Total debt/Total assets) has a negative impact on the performance of enterprises. Unlike this study, when assessing the impact of capital structure on the performance of manufacturing enterprises in Vietnam, the authors use the fixed effect model (FEM) – a more suitable model for panel data.

As is evident, previous studies on the influence of capital structure on the performance of enterprises all lead to the same result that the debt ratio has a strong impact on the business performance of enterprises. However, most of the research period of previous research papers usually stopped at 2017-2018, the period when the Covid pandemic had not yet appeared. Therefore, the authors decided to evaluate the impact of capital structure on the performance of listed manufacturing enterprises in Vietnam in the period from 2016 to 2020 – a long enough time to have can be assessed both with and without the Covid-19 pandemic, thereby creating the novelty and creativity of the topic.

Based on the theories and empirical studies presented above, this study aims to study whether capital structure affects the performance of manufacturing enterprises listed on the Viet nam stock exchange in the period 2016-2020 or not. Therefore, the hypothesis is that capital structure has a relationship with the performance of construction enterprises listed on Vietnam's stock market in the period from 2016 to 2020.

The authors selected the period from 2016 to 2020 to assess the impact of capital structure on the performance of listed manufacturing enterprises in Vietnam in two situations: with and without effects of

the Covid-19 pandemic. Assessing the impact of capital structure on the performance both with and without the Covid-19 pandemic is very important because the plan to build capital structure of manufacturing enterprises is a long-term decision, but the Covid pandemic may cause decisions to change abruptly.

### **2.2.2. Recent researches of several factors that have impacts on the capital structure:**

Frank and Goyal (2009) studied the factors affecting the capital structure of non-financial companies in the US stock market in the period 1950-2000. The authors believe that the factors that positively affect capital structure include industry average debt ratio, collateral, firm size, and expected inflation; The factors that negatively affect the debt ratio are the market-to-book ratio, the bankruptcy risk according to Altman's Z-index, and dividend payments.

Deesomsak et al. (2004) clarifies the factors affecting the capital structure of enterprises operating in 4 countries in the Asia-Pacific region (Thailand, Malaysia, Singapore, and Australia) with an emphasis on financial institutions and legislation. The survey sample includes all non-financial enterprises listed on national stock exchanges during the study period. The study evaluated the impact of 6 independent variables including: ratio of tangible assets, profitability, size of business, non-debt tax shield, liquidity and revenue volatility on the dependent variable. financial leverage. The research results also confirm that the capital structure of enterprises is influenced by micro factors, including asset structure, profitability, size, non-debt tax shield, liquidity and variable. revenue activity.

Le Dat Chi (2013) has researched and tested the factors that play an important role in the capital structure decision of companies listed on the Vietnamese stock market in the period 2007-2010. The author has based on theories of capital structure such as trade-off theory, pecking order and market timing and behavioral finance theory. Research results have pointed out six factors that really play an important role: taxes, inflation, market-to-book ratio, industry leverage, return on assets (ROA), and administrator behavior.

In general, previous studies mostly used the dependent variable as ROA, ROE or EPS to show the performance of the business, besides, most of the studies used the independent variable as the coefficient. debt TDR to reflect capital structure. This is the basis for the authors to select variables and perform model regression. However, in the study, the authors used the dummy variable TDR\*COVID to further assess the influence of capital structure on performance in the context of the Covid-19 epidemic. The selected variables and the model are shown in below:

Applying the theories and empirical studies presented above, the hypothesis H0 of the model will be: Capital structure has an impact on business performance.

The model of the influence of capital structure on performance of listed manufacturing enterprises in Vietnam is built as follows:

**Model 1:**  $ROE_{it} = \beta_0 + \beta_1 TDR_{it} + \beta_2 STD_{it} + \beta_3 GROWTH_{it} + \beta_4 LIQUID_{it} + i.Yeari.id + u_{it}$  (The impact of capital structure measured by debt ratio on ROE in the absence of the Covid-19 epidemic)

**Model 2:**  $ROE_{it} = \beta_0 + \beta_1 TDR_{it} + \beta_2 STD_{it} + \beta_3 GROWTH_{it} + \beta_4 LIQUID_{it} + \beta_5 COVID + \beta_6 TDR*COVID + i.Yeari.id + u_{it}$  (The impact of capital structure measured by debt ratio on ROE in the context of the Covid-19 epidemic)

**Model 3:**  $ROA_{it} = \beta_0 + \beta_1 TDR_{it} + \beta_2 STD_{it} + \beta_3 GROWTH_{it} + \beta_4 LIQUID_{it} + i.Yeari.id + u_{it}$  (The impact of capital structure measured by debt ratio on ROA in the absence of Covid-19 epidemic)

**Model 4:**  $ROA_{it} = \beta_0 + \beta_1 TDR_{it} + \beta_2 STD_{it} + \beta_3 GROWTH_{it} + \beta_4 LIQUID_{it} + \beta_5 COVID + \beta_6 TDR*COVID + i.Yeari.id + u_{it}$  (The impact of capital structure measured by debt ratio on ROA in the context of the Covid-19 epidemic)

In the two models above, the variables ROE (Return on equity) and ROA (Return on assets) are two dependent variables representing performance.

The independent variable (the explanatory variable) is the TDR debt ratio.

**Table 1. Variable definition and Proxies.**

Variable names	Definition	Proxies
Dependent variables		
ROA	Return on Asset	Net income/Total Asset
ROE	Return on Equity	Net income/Shareholders' Equity
Independent variables		
TDR	Debt ratio	Total Debt/Total Asset
Control variables		
GROWTH	Enterprise Revenue Growth rate	Increase in the total Revenues/Total Revenues from the prior year's
LIQUID	Current ratio	Current assets/Current liabilities
Dummy variables		
TDR*COVID	Dummy variable	COVID = 1 when Year = 2020

### 3. RESEARCH METHOD

#### 3.1. Data collection:

For our study, we will focus on the impact of capital structure on firm performance of the manufacturing companies listed on the Vietnam stock exchange. This study would cover the data of 185 manufacturing companies listed on the Vietnam Stock Exchange over the period of 5 years (from 2016 to 2020) which was gathered mostly from company financial statements, corporate associate announcements, reports, and yearbooks from the Stock Exchange and Fin's Pro Exchange computer system. Furthermore, only companies that were active during the examined period were considered. In addition, companies in our dataset are required to have reported a full annual account. The final sample consists of 185 firms with 925 observations.

#### 3.2 Data analysis

We used a package of STATA software version 17 to estimate the regression equations that we proposed above. First off, bivariate relations among variables were explored via examining correlation. Next, we used the Fixed effects model (FEM) to examine the effect of debt ratio on performance. The research also examined some necessary detector regressive assumptions to ensure the result of regression is blue such as autocorrelation and multicollinearity before the conclusion.

### 4. RESULTS AND DISCUSSION:

#### 4.1. Several necessary tests for the model:

*\*Descriptive summary:*

**Table 2. Descriptive summary**

	(1)	(2)	(3)	(4)	(5)	(6)
VARIABLES	N	mean	sd	min	max	p1
ROE	925	0.130	0.121	-0.247	0.494	-0.247
ROA	925	0.0695	0.0663	-0.0872	0.289	-0.0872

LTD	925	0.0525	0.0768	0	0.350	0
TDR	925	0.259	0.181	0	0.625	0
STD	925	0.205	0.154	0	0.577	0
GROWTH	925	0.107	0.343	-0.488	2.132	-0.488
LIQUID	925	2.284	1.901	0.500	12.37	0.500
COVID	925	0.200	0.400	0	1	0
TDR*COVID	925	0.0483	0.124	0	0.619	0
Number of id	185	185	185	185	185	185

Source: Calculation and synthesis of the author team from Stata software.

From the table above, we can see that ROE of listed manufacturing companies in Vietnam in the period from 2016 to 2020 has an average value of 0.130. Compared to many other professions, this is an average return on equity. However, when looking at the min and max values, we can see that many manufacturing firms are not efficient when their ROE is less than 0 and there are also some businesses that perform relatively well when ROE is at 0.494. The average debt ratio is not high (nearly 26%) and ranges from 0 to 0.625. Thus, we can see that besides a large number of businesses that mainly use equity, there are also businesses that use financial leverage. In addition, the dummy variables COVID and TDR\*COVID will clarify the impact of the epidemic on the performance of listed manufacturing companies, and will also demonstrate that COVID will amplify the impact of the pandemic. TDR to ROA and ROE, thereby inferring that in disease conditions, the more businesses borrow, the more financial risks they will face.

\* Correlation matrix:

**Table 3: Correlation matrix**

	ROE	ROA	TDR	STD	GROWTH	LIQUID_w	COVID	TDR*COVID
ROE	1							
ROA	0.876***	1						
TDR	-0.109***	-0.354***	1					
STD	-0.0603	-0.287***	0.898***	1				
GROWTH	0.131***	0.0959**	0.116***	0.0658*	1			
LIQUID	0.0122	0.0260	-0.112***	-0.118***	-0.0334	1		
COVID	-0.0757*	-0.0561	-0.0485	-0.0317	-0.0969**	-0.00156	1	
TDR*COVID	-0.0980**	-0.145***	0.231***	0.214***	-0.0294	-0.0227	0.779***	1

Source: Calculation and synthesis of the author team from Stata software.

The table above shows us the correlation between the variables used in the research model. We can see that most of the variables are relatively closely correlated with each other.

\* Hausman test:

**Table 4. Hausman test for the models**

Model	Hausman test	Selected model
Model 1	P-value = 1.42% (< 5%)	FEM
Model 2	P-value = 0.26% (< 5%)	FEM
Model 3	P-value = 0.6% (< 5%)	FEM
Model 4	P-value = 0.00% (< 5%)	FEM

Source: Calculation and synthesis of the author team from Stata software.

The authors conduct Hausman test in order to consider whether Fixed effect model or Random effect model is chosen. The result shows that the P-value of the 4 models are all less than 5%, which means that the FEM is suitable.

***\*Testing the phenomenon of variable variance with FEM model:***

To test the phenomenon of variable variance with the FEM model, the study uses the test with the following hypotheses:

- Hypothesis H0: The model does not have variable variance.
- Hypothesis H1: The model has variable variance.

After performing the test, if the P-value is greater than 5%, the study will accept the hypothesis H0. Otherwise, the hypothesis H0 will be rejected and the model will have variable variance.

The results are shown in the following table:

**Table 5. Testing the phenomenon of variable variance with FEM model**

Model	Modified Wald test	Results
Model 1	P-value = 100% (> 5%)	The model does not have variable variance
Model 2	P-value = 100% (> 5%)	The model does not have variable variance
Model 3	P-value = 100% (> 5%)	The model does not have variable variance
Model 4	P-value = 72.48% (> 5%)	The model does not have variable variance

*Source: Calculation and synthesis of the author team from Stata software.*

***\*Test the phenomenon of autocorrelation with the FEM model:***

To test the phenomenon of autocorrelation with the FEM model, the study uses Wooldridge test with the following hypotheses:

- Hypothesis H0: The model does not have autocorrelation.
- Hypothesis H1: The model has autocorrelation.

After performing the test, if the P-value is greater than 5%, the study will accept the hypothesis H0. Otherwise, hypothesis H0 will be rejected and the model occurs autocorrelation.

The result of Wooldridge test is as follows:

**Table 6. Test the phenomenon of autocorrelation with the FEM model**

Model	Wooldridge test	Results
Model 1	P-value = 9.89% (> 5%)	The model does not have autocorrelation
Model 2	P-value = 9.58% (> 5%)	The model does not occur autocorrelation
Model 3	P-value = 5.17% (> 5%)	The model does not have autocorrelation
Model 4	P-value = 6.41% (> 5%)	The model does not occur autocorrelation

*(Source: Calculation and synthesis of the author team from Stata software)*

**4.2. Findings and discussion:**

*\* Researching the impact of the capital structure on performance of the manufacturing companies listed on the Vietnam Stock Exchange (with and without the impact of Covid-19 epidemic)*

After several tests for the models, we have concluded that: (i) The Fixed effects model (FEM) is suitable and the models do not have any defect (autocorrelation and variable variance). The quantitative analysis results of the performance efficiency with the dependent variables ROE and ROA with and without the impact of Covid-19 epidemic are as follow:

**Table 7. The quantitative analysis results of the performance efficiency with the dependent variables ROE and ROA with and without the impact of Covid-19 epidemic**

VARIABLES	ROE_w	ROA_w	ROE_w	ROA_w

Adjusted R-squared	0.577	0.728	0.577	0.728

(Source: Calculation and synthesis of the author team from Stata software)

The table indicates the quantitative analysis results of the performance with the dependent variables ROE and ROA with and without the impact of Covid-19 epidemic. We see that the ratio of determination R<sup>2</sup> is quite high (0.557 and 0.728 respectively), indicating that the model's fit is 55.7% and 72.8%, in other words, the independent variables have been selected in the explained model obtained 55.7% of the variation of the dependent variable ROE and 72.8% of the variation of the dependent variable ROA. The selected variables are quite suitable for the research model.

The variable STD (short-term debt ratio) has no statistical significance for the business performance of listed manufacturing companies in Vietnam in the period from 2016 to 2020. Enterprises all use a lot of short-term debt in their total loans, but that number does not significantly affect business performance.

In the case when there is no impact of the Covid-19 epidemic, the debt ratio (TDR) has a negative effect on ROE. These two indicators only affect in the same direction when the BEP is larger than the bank loan interest rate. But as mentioned above, due to the recent trend of increasing interest rates on bank loans, the (BEP - r) is always smaller than 0. This leads to the more the enterprises try to borrow, the more significant the performance decreases. More specifically, when businesses increase TDR by 1%, ROE will decrease by 0.094% (in the absence of epidemics), which is a very large number. Similarly, the TDR indicator also has a negative impact on ROA. Specifically, in the absence of Covid, when TDR increases by 1%, ROA will decrease by 0.141%. Covid 19 pandemic amplifies the effect of debt ratio on ROE and ROA. More specifically, in the case when Covid-19

epidemic occurred, the debt ratio (TDR) has a negative effect on ROE. These two indicators only affect in the same direction when the BEP is larger than the bank loan interest rate. But as mentioned above, due to the recent trend of increasing interest rates on bank loans, the  $(BEP - r)$  is always smaller than 0. This leads to the more the enterprises try to borrow, the more significantly the performance decreased. More specifically, when businesses increase TDR by 1%, ROE will decrease to  $0.0879\% + 0.0311\% = 0.119\%$  (in epidemic conditions), which is a very large number. Similarly, the TDR indicator also has a negative impact on ROA. Specifically, under Covid conditions, when TDR increases by 1%, ROA will decrease by  $0.138\% + 0.0142\% = 0.1522\%$ . These numbers are completely larger than the effect of TDR on ROE and ROA in the absence of disease. This proves that Covid-19 has amplified the effect of TDR on ROE and ROA.

The variable Growth of Revenue (GROWTH) has a positive effect on ROE and ROA, specifically, when revenue grows 1%, ROE grows by 0.0439%, ROA increases by 0.0216% (without the impact of Covid-19 epidemic), and the same level of the increase occurred in the context of the Covid-19 epidemic. A manufacturing enterprise that wants to have growth in ROE and ROA must definitely aim for revenue growth because increased revenue means that the business's market share is expanded, production scale is larger, and freeing up a lot of inventory.

The current ratio also has a positive effect on ROE and ROA. This is reasonable with economic theory and previous studies because when a business is able to pay its debts as they come due, it means that the business has good business performance.

The epidemic can amplify the impact of capital structure on business performance in a negative way, but we can see that TDR is also an effective channel to reduce the impact of the pandemic. Specifically, in disease conditions, when reducing TDR by 1%, ROE will increase to 0.1198% and ROA will increase by 0.1522%. Thus, in the context of the epidemic, the more businesses limit borrowing, the more opportunities they will have to improve business performance.

*\*Research on factors affecting capital structure of listed manufacturing companies in Vietnam:*

Based on the research hypotheses and research model developed in Chapter 1, the results of the study of the factors affecting the capital structure of construction companies in the sample are as follows:

**Table 8. Descriptive summary of the variables that have impacts on capital structure of the enterprise**

VARIABLES	(1) N	(2) mean	(3) sd	(4) min	(5) max	(6) p1	(7) p25	(8) p50	(9) p75	(10) p99
TDR	925	0.259	0.181	0	0.625	0	0.102	0.240	0.403	0.625
GROWTH	925	0.107	0.343	-0.488	2.132	-0.488	-0.0514	0.0466	0.171	2.132
LIQUID	925	2.284	1.901	0.500	12.37	0.500	1.216	1.678	2.559	12.37
COVID	925	0.200	0.400	0	1	0	0	0	0	1
LIQUID*COVID	925	0.456	1.268	0	12.32	0	0	0	0	6.551
Number of id	185	185	185	185	185	185	185	185	185	185

(Source: Calculation and synthesis of the author team from Stata software)

Looking at the table, we can see that the average debt ratio of the listed manufacturing enterprises in Vietnam studied in the period 2016-2020 is 25.9%. This shows that in the research period, the manufacturing enterprises did not depend too much on loans. The average current ratio is greater than 2, showing that the ability to pay debts when they due is very good, they do not have to face financial risks.

**Table 9. Average of several ratios related to the impact of some variables that have impacts on the capital structure of the firm**

Variables	2016	2017	2018	2019	2020
TDR	0.26	0.27	0.27	0.26	0.24
GROWTH	0.26	0.17	0.21	0.09	0.04
LIQUID	2.39	2.66	2.38	2.15	2.28

(Source: Calculation and synthesis of the author team from Excel software)

The table above shows us that the debt ratio over the years of listed manufacturing companies in Vietnam is not high, only about 20% to 30%, tends to increase from 2016 to 2018, then tends to increase again. The current ratio is all greater than 1, showing a slight downward trend from 2018 to 2020. In general, manufacturing enterprises have good financial capacity and do not face payment risks. However, the growth of revenue is not too significant.

**\* Correlation analysis between variables:**

**Table 10. Pairwise correlation test for the variables that have impacts on the capital structure of the company.**

	TDR	GROWTH	LIQUID	COVID	LIQUID*COVID
TDR	1				
GROWTH	0.116***	1			
LIQUID	-0.112***	-0.0334	1		
COVID	-0.0485	-0.0969**	-0.00156	1	
LIQUID*COVID	-0.0569	-0.0490	0.321***	0.719***	1

*t* statistics in parentheses

\*  $p < 0.05$ , \*\*  $p < 0.01$ , \*\*\*  $p < 0.001$

(Source: Calculation and synthesis of the author team from Stata software)

Looking at the table above, we can see that the correlation between the independent variables is not too large. The results table also shows that the debt ratio and solvency have a negative relationship and a positive correlation of the remaining variables compared to the debt ratio. However, the LIQUID\*COVID dummy variable does not have too much statistical significance with the capital structure. This can be explained by the fact that whether there is an epidemic or not, businesses still maintain their solvency at a good level and therefore they do not have much need to depend on loans, especially when the BEP of enterprises is not high.

**\*Quantitative analysis results:**

The table below will show us the results of quantitative analysis of factors affecting the debt ratio of listed manufacturing companies in Vietnam.

**Table 11. The quantitative analysis result for the impact of several variables on the capital structure of the company**

	(1)	(2)
VARIABLES	TDR	TDR
TDR		
GROWTH	0.00989	0.00922
	(1.030)	(0.960)

LIQUID	-0.00962***	-0.0107***
	(-2.939)	(-3.166)
COVID		-0.0283**
		(-2.309)
LIQUID*COVID		0.00466
		(1.287)
2020o.Year		-
Constant	0.504***	0.506***
	(12.93)	(12.98)
Observations	925	925
Adjusted R-squared	0.785	0.785
Number of id	185	185

t-statistics in parentheses

\*\*\* p<0.01, \*\* p<0.05, \* p<0.1

(Source: Calculation and synthesis of the author team from Stata software)

Interpretation of results: The regression value reported in the table shows the regression results of the dependent variable TDR (debt ratio) with the independent variables as GROWTH (growth of revenue), LIQUID (current ratio) and dummy variables COVID and TDR\*COVID

The ratio of determination  $R^2 = 0.785$  is quite high, showing that the independent variables selected in the model explained 78.5% of the variance of the debt ratio.

Through the model regression results, we can see that only the current ratio has an impact on the debt ratio of the enterprise, and has a negative effect both in the presence of an epidemic and in the absence of an epidemic. When there is no epidemic, if the current ratio is increased to 1%, the debt ratio will decrease by 0.00962%, while during the epidemic, the debt ratio will decrease by  $0.0107\% - 0.00466\% = 0.00604\%$ . This shows that in both epidemic and non-epidemic conditions, the current ratio always has a negative impact on the debt ratio. This is completely reasonable and is a good sign that even in complicated disease conditions, listed manufacturing enterprises in Vietnam also have good financial situation and do not depend much on loans. The Covid epidemic does not amplify but reduce the impact of the current ratio on the debt ratio. It can be seen that, in the context of complicated epidemics, when businesses have better ability to pay short-term debts, the debt ratio does not decrease more than in the absence of the epidemic. They still need loan capital to maintain the production capacity of the business, although at that time production activities have slowed down significantly, they still have good control over their debt repayment capacity and still maintain their self-sufficiency.

## 5. CONCLUSION:

### 5.1. Evaluate the research results:

From the above quantitative studies, the authors found that capital structure has an influence on firm value, shown in ROE and ROA variables. Besides, the authors also find that the debt ratio of manufacturing companies in the research period is not high, the companies mainly use short-term debt. This leads to the fact that manufacturing enterprises usually do not borrow much. In fact, this is also an industry on the list of credit squeezes due to increasing bank interest rates. Moreover, in the years of facing the Covid-19 pandemic, getting loans has also become much more difficult.

Research results also show that in the context of the Covid-19 epidemic, when increasing the debt ratio, performance decreases more sharply. This is completely reasonable because then, if you mobilize more loans, it will increase the pressure of debt payment, besides, the production is stalled, can't sell goods, there will be no money to pay. debt repayment, financial autonomy decreased and business performance was no longer maintained. In fact, manufacturing enterprises have done a great job in maintaining stability in difficult times when they still maintain a low debt ratio and current ratio, which is a very good sign for the manufacturing industry in Vietnam in the future.

In order to understand more deeply the causes of not using much debt, the authors have also assessed through a quantitative model and have found the current ratio in the period 2016-2020 that has an impact on the debt ratio of the studied manufacturing enterprises. Specifically, manufacturing enterprises in Vietnam have very good solvency, they have high financial autonomy, which leads to them not having to rely too much on loans. As one of the areas where credit is tight, having to maintain operations in the context of increasing interest rates on bank loans in recent years, the less use of loans, the more benefits for them, and they have very good control over their solvency. Therefore, adjusting or affecting this factor will help businesses achieve an appropriate capital structure.

## **5.2. Solutions to build capital structure to increase the performance of listed manufacturing enterprises in Vietnam:**

### ***5.2.1. Limiting mobilizing additional loans and prioritizing the use of equity:***

Manufacturing enterprises listed in Vietnam in the 5-year period from 2016 to 2020 had low debt ratios, good solvency and financial autonomy even during the pandemic. Therefore, they do not need to raise additional loans. Using borrowed capital to take advantage of the tax shield is a way many businesses use to reduce WACC. However, for manufacturing businesses, it does not seem to be a good way. The fact that interest rates on bank loans have tended to increase in recent years will make the benefit from tax shields no longer useful; even a high interest rate will increase WACC and contribute to a decrease in business efficiency. And yet, as analyzed in Chapter 3, the increase in loans will reduce the performance of manufacturing enterprises in Vietnam because the BEP of these enterprises is not too high and is not higher than the interest rate on a bank loan. Therefore, it is not necessary for manufacturing enterprises in Vietnam to take the risk of borrowing while they have enough equity to finance their capital needs.

### ***5.2.2. Using retained earnings to reinvest:***

The use of retained earnings to reinvest in more modern and advanced production lines has numerous advantages for Vietnamese manufacturing firms. Because their business is efficient and profitable, the remaining profits can be used to invest in fixed assets and modern production lines. Not only does it help to stabilize the capital structure, but reinvesting profits in modern production equipment is a solution that many manufacturing firms use because it provides benefits such as:

- Modern equipment and machinery will help businesses make a strong impression in the eyes of partners, thereby allowing them to sign many production and supply contracts with a higher value and significantly improve their performance.

- Investing in modern equipment and machinery will save a lot of time and money, especially labor costs. Reducing costs will help increase profits and increase the business efficiency of enterprises. In addition, reducing costs can also make a company's BEP higher, thereby creating favorable conditions for enterprises to use financial leverage to amplify ROE, thereby increasing business efficiency. business from the impact of capital structure.

## RESEARCH THE FACTORS AFFECTING THE RISK OF BANKRUPTCY OF THE REAL ESTATE ENTERPRISES LISTED ON VIETNAM STOCK MARKET

**Author: Nguyen Thanh Hang<sup>1</sup>, Nguyen Kieu Trang<sup>1</sup>,  
Bui Trung Thuc<sup>1</sup>, Vu Mai Huong<sup>1</sup>, Ngo Thuy Quynh<sup>1</sup>  
Mentor: PhD. Lam Thi Thanh Huyen<sup>1</sup>**

**ABSTRACT:** *The study shows the impact of factors on bankruptcy risk of real estate businesses. The study was conducted on 60 enterprises listed on the stock exchange in Vietnam in the period 2011 - 2021. The study was carried out on STATA 15 software, using random effects research model (REM), and use related tests to give the results that have 5 variables affecting the bankruptcy risk of enterprises: Current Ratio (CR), Asset Liquid Ratio (ALR), Financial Leverage (FL), Basic Earning Power Ratio (BEP), Fixed Asset Ratio (FA). The objective of the study is to study the factors affecting the bankruptcy risk of enterprises and the applicability of the research to the situation of listed real estate enterprises in Vietnam. Proposals drawn from the results of the study can help real estate businesses come up with appropriate strategies from time to time to prevent and respond to market conditions when businesses appear to sign bankruptcy risk.*

**Keyword:** *Real estate business, Logit model, Factors, Bankruptcy risk*

### 1. INTRODUCTION

According to Clause 1, Article 3 of The Real Estate Enterprises Law 2014: “Real estate business is capital investments to carry out activities that are construction activities; buying or receiving transfer to sell or transferring; property for lease; real estate brokerage services; real estate transaction platform services; real estate consulting services; management of real estate assets to make profits”. The real estate business has significant advantages in the market business that impacts extremely on market economy and influence on various other fields. Hence investors have many opportunities to make profits, which promotes development of real estate business.

Each economic sector has its own unique characteristics that are also found in real estate enterprises. Moreover, real estate is a “special commodity” which is different from normal commodities. Mostly, In this area businesses have unique characteristics such as: comprehensive style investment but regional quality, significant inventory and capital investments, and a long business period. Owner’s equity is small with a long business cycle through many years, long capital recovery and capital is medium to turnover. Therefore their characteristics impact on developing business and also real estate enterprise. On the other hand, in an overheating period, the real estate market has a cycle nature, so businesses can be sold out goods or products which are not available. Beside, the real estate enterprises have to face many misfortunes because of large capital and long cycle business. If administrators can’t judge exactly trends in the market, companies will lose capital or sell low price products. Also government’s policies can put real estate projects on losing advantages. Furthermore The difference between maturity and interest in raising capital and borrowing money causes the risk of financial and real estate markets.

For about ten years in Vietnam, macroeconomics has been stable: low inflation is controlled by the government, economic growth is good which attaches to quality, and economic balances are improved. By contrast, Vietnam is a developing country, so it has to face a lot of difficulties. Nowadays economic opening

<sup>1</sup> Academy of Finance.

has been elevated, which means keen competition. Thus, the risk of liquidity in real estate enterprises is high. According to 51/2014/QH13 Clause 4, Chapter 4 in Law of bankruptcy: “Bankruptcy is a business or organization condition which loses liquidity ability because The People’s Court decides to declare bankruptcy. A business or organization loses liquidity that fails to pay debt obligation during 3 months, beginning maturity”. The risk of bankruptcy in a company is an objective economic phenomenon in the market economy that causes conflict between participants. As a result, the participants in the economy have to comprehend this definition. In conclusion, Bankruptcy is an unwanted condition because that has negative impacts on the company and economy.

The analysis of bankruptcy is an effective tool which manages a company. The risk assessment of bankruptcy makes important sense which supports administration to assess risk of bankruptcy. The analysis results in risk of bankruptcy as a basis to offer management decisions and prevent bankruptcy opportunely. Because of negative impacts, the participants and the real estate company have to recognize the signs of risk of bankruptcy to avoid. Recognizing the signs of risk of bankruptcy have to be acknowledged by different positions which are investors, administrators, investment funds, credit institutions, and the government.

Based on previous research and relevant documents, the group of authors summarize the main factors that assess the level of the risk of bankruptcy in a company: Net Working Revenue (NWC); Return On Asset (ROA); Difference between Total Assets and Total Liabilities (CL). According to the authors’ research, hypothesis claims: If a company gets into one of 3 bad cases above, it will be considered to have the risk of bankruptcy. This article researches the facts that influence the risk of bankruptcy in the real estate enterprises listed on the Vietnam stock market through quantitative research and the Logit model. Therefore, the group of authors proposes suitable solutions to reduce the risks in the real estate enterprises in Vietnam.

## **2. THEORETICAL FRAMEWORK**

### **2.1. Overview**

#### ***2.1.1. The current state of study globally***

Bankruptcy is always a situation that every business has to face, and all over the world, there is much research about bankruptcy risk prediction as well as dealing with its risk using a variety of methods.

Firstly, analyze the bankruptcy risk of businesses based on their financial statements. Some remarkable works based on this method are Beaver (1996), Altman (1968), Ohlson (1980), and so on. To begin with, Edward I. Altman must be mentioned, who researched and used the Z-score model to help businesses evaluate bankruptcy risk based on calculating their annual financial statements. Results had shown that if the Z-score is less than 1.81, the company is at risk of bankruptcy; if the Z-score is between 1.81 and 2.99, it cannot be clearly considered; and if the Z-score is greater than 2.99, the company is not at risk of bankruptcy. However, the original Altman Z-score model does not have high accuracy in predicting bankruptcy over many years of research, so Altman re-evaluated the entire model with the book value of equity replacing the market value of variable  $X_4$ . The adjusted Altman Z'-score model has the following Z'-score threshold points: if Z' is less than 1.23, the company is at risk of bankruptcy; companies with Z'-score from 1.23 to 2.9 are in an undetermined zone; and if Z' is greater than 2.9, the company is not at risk of bankruptcy. Later, Altman, Hatzell, and Peck (1995) conducted a study on the Z''-score model for bankruptcy risk forecasting in economic enterprises, using four very useful variables in the industrial sector, including significant differences in asset sponsorship among companies. The Z''-score index thresholds are as follows: if Z'' is less than 1.1, the enterprise is at risk of bankruptcy; if Z'' is from 1.1 to 2.6, it is not possible to conclusively determine the situation; if Z'' is more than 2.6, the enterprise is not at risk of bankruptcy. This model has been applied by many authors, including Micha (1984), Altman and colleagues (1977, 1995, 2000), Pranee Leksriskul, and Michael Evans (2005), among others. There

are also other notable studies on bankruptcy risk, such as that of Beaver, which began in 1966 with the topic “Financial ratios as predictors of failure”. Through the evaluation of individual financial ratios, Beaver showed that the cash ratio to total debt is the most important criterion in predicting financial distress and bankruptcy of enterprises. In addition to this ratio, the rate of return on assets and the debt ratio reflect the effectiveness of the enterprise’s business operations and the level of financial risk it faces. However, when only individual ratios are studied, it is difficult to assess the overall financial situation; therefore, the assessment of the bankruptcy risk of the enterprise is inaccurate on the overall aspect. Then, James A. Ohlson (1980) developed the logit regression model with the O-score coefficient in the study “Financial Ratios and the Probabilistic Prediction of Bankruptcy” to study the ability to predict bankruptcy. This model requires fewer statistical hypotheses and provides more practical distinctions than Altman’s MDA model, but fundamentally, the experimental results of these two models are relatively consistent. Many authors have also used the Logit model for their studies, such as Aziz and colleagues (1988), Keasey and Watson (1987), and Ooghe and colleagues (1995), among others.

Secondly, analyze the bankruptcy risk of businesses based on market factors. This method combines the leverage structure of the company and the market value of its assets. Hillegeist and his colleagues (2004) concluded that using market factors provides significantly more information about a company’s likelihood of bankruptcy than using accounting factors. A disadvantage of this method is that it relies on the efficient market hypothesis and only considers listed companies, not private ones (Berg, 2007).

Thirdly, analyze the bankruptcy risk of businesses based on artificial intelligence. Odom and Sharda (1990) developed an artificial intelligence model to predict bankruptcy and compared the results with MDA discriminant analysis for classification accuracy. Coats and Font (1993) used an artificial intelligence model to estimate the health of companies, and the result they gave was that the artificial intelligence method is more efficient than the MDA discriminant analysis one.

### ***2.1.2. The current state of study in Vietnam***

In Vietnam, recently, the increasing mention of bankruptcy indicates that the market in general, and the real estate business in particular, have prepared themselves mentally and with necessary conditions for the worst possible situation. There have been many domestic studies on the factors affecting bankruptcy risk, such as author Nguyen Bao Khang (2012) studying the factors affecting business bankruptcy in Dong Nai province. Regarding the Altman Z-score model, authors Nguyen Thanh Cuong and Pham The Anh (2010) conducted a research titled “Risk assessment of bankruptcy for seafood processing companies listed on the Vietnamese stock market”. In addition, there are variety of studies on the bankruptcy risk of businesses such as authors Nguyen Phuc Canh and Vu Xuan Hung (2014) with the topic “Application of Z-score model in credit risk management for Vietnamese commercial banks”; the author Nguyen Thi Tuyet Lan (2019) with the topic “Factors influencing bankruptcy risks of listed construction businesses in Vietnam”; the author Truong The Quang (2022) with the topic “Financial factors affecting bankruptcy risks of listed construction and real estate businesses on the Vietnamese securities market”... In general, the majority of studies focus on the application of the Z-score model for risk management by Edward I. Altman (1968) to assess the risk of bankruptcy based on calculations from annual financial reports. Each study has its achievements but also some limitations. Along with using the Z-score model, many researchers also choose the Logit model to evaluate the impact of factors on bankruptcy risk. An exemplary research paper such as “Study on the factors impacting bankruptcy risk of listed real estate companies in Vietnam” authored by Phan Tran Trung Dung, Nguyen Thi Ha Thanh, Vo Minh Thu. Another research paper titled “Some factors affecting financial risk - Study of real estate listed companies on the Ho Chi Minh Stock Exchange (HSX)”; authored by Vo Minh Long.

## **2.2. Advantages, disadvantages of previous research and the novelty of the topic**

Each research article has its own unique characteristics, but overall, they all have some advantages and disadvantages as follows:

In terms of advantages, foreign research works are considered the foundation for building models for future research articles, as well as the root of the extended models applied to most business models, including real estate businesses. Recently, research has conducted surveys from research businesses and used quantitative methods in studies such as applying the Z-score model of Altman. Moreover, most of the author's domestic studies have focused deeply on analyzing a specific financial aspect of a business, giving researchers many tools to access research issues. Overall, the studies have identified limitations in analyzing the financial situation or in a specific financial aspect to provide remedies under normal circumstances.

Regarding disadvantages, there has not been any research specifically conducted for the listed real estate company, and there is no organization that performs credit ratings and bankruptcy risk warnings for real estate businesses in Vietnam. In Vietnam, there are few studies that consider the overall impact of macro or micro factors on the bankruptcy risk of businesses. Additionally, previous studies still have some issues that can be further explored, and many models have been introduced, such as Z-score, Logit, etc. To predict the risk, but the shortcomings of each model still cannot be overcome. Only since 2020, when the COVID-19 pandemic severely impacted the global economy, have new managers noticed the importance of predicting risk as so many businesses have gone bankrupt due to insufficient net cash flows to maintain operations.

About novelty, by inheriting previous research studies, the chosen variables keep their calculation formula and degree of influence while adding some new variables that are suitable for the specific situation of current businesses. Specifically, the variables in the study include 9 variables, including one dependent variable (RR - Bankruptcy Risk) and eight independent variables (CR - Current Ratio, ALR - Asset Liquid Ratio, FL - Financial Leverage, BEP - Basic Earning Power Ratio, WCT - Working Capital Turnover, SALE - Net Revenue, CFA - Operating Cash Flow On Asset, FA - Fixed Asset Ratio). The authors' group used the latest data from financial reports of 60 out of 81 listed real estate businesses in Vietnam during the period of 2011 – 2021, and the authors' group chose to use high-precision STATA 15 software to reflect the effectiveness of risk management and contribute to making the study more accurate and effective.

In fact, there have been many research studies on the topic of bankruptcy risks of different types of businesses in various fields. However, the topic of "Research the factors affecting the risk of bankruptcy of the real estate enterprises listed on the Vietnam stock market" is a new and not extensively researched one. The research work of this author group will solve the above problem.

## **3. RESEARCH METHOD**

### **3.1. Research model**

Based on foreign research and domestic research, this research focuses on the impacts of 8 factors which lead the risk of bankruptcy of the real estate enterprises: Current Ratio (CR), Asset Liquid Ratio (ALR), Financial Leverage (FL), Basic Earning Power Ratio (BEP), Working Capital Turnover (WCT), Net Revenue (SALE), Operating Cash Flow On Asset (CFA), Fixed Asset Ratio (FA). In this research, the Model is applied to the Logit model (or also known as Binary Logistic) and STATA 15 software. The group of authors collects data and uses Microsoft Excel to calculate financial ratios which come into being financial indicators: Net Working Capital (NWC), Return On Asset (ROA), Difference between Total Assets and Total Liabilities (CL). Therefore, three financial indicators create one dependent variable which is a binary variable, named RR - Bankruptcy Risk, with only two values, (0 - business is not at risk of bankruptcy; 1 - business is at risk of bankruptcy). Regarding the general model:

**Table 3.1: The definitions and describes of variables in model**

Variable names	Formula	Hypothesis
Current ratio (CR)		inversely proportional
Asset liquid ratio (ALR)		directly proportional
Financial leverage (FL)		directly proportional
Basic earning power ratio (BEP)		inversely proportional
Working capital turnover (WCT)		inversely proportional
Net revenue (SALE)	Net revenue	inversely proportional
Operating cash flow on asset (CFA)		inversely proportional
Fixed Asset Ratio (FA)		directly proportional

Source: The group of authors created

### 3.2. Research data

In the Vietnam market, 81 real estate enterprises are listed on stock exchanges. In fact, there are enterprises that lack data, so the group of authors chooses 60 businesses to research during the period 2011 - 2021. The percentage of 60 businesses is large, at 70.07%. The research model includes 8 independent variables and 1 dependent variable. According to the Logit model. The data is collected from various real estate business's financial statements in the State Securities Commission of Vietnam between 2011 - 2021 that are significant transparency.

**Table 3.2: The percentage of the real estate enterprises listed on Vietnam stock market**

Stock exchange	Number of business	Percentage
HNX	18	30.00%
HOSE	42	70.00%
Total	60	100%

Source: The group of authors created

## 4. RESULTS AND DISCUSSION

### 4.1. Results

#### 4.1.1. Stopping test

The Levin-Lin-Chu (2002) standard is used to test the stationarity of variables in the model with respect to table data. The stopping test is to avoid tampering in the regression model, to ensure that all variables considered are stop variables. The test results with the significance level of 1%, all data sequences in the study sample are stopped sequences.

**Table 4.1: Testing table for Stopping**

Variables	Levin-Lin-Chu test		Results
	t-Statistic	P-Value	
CR	-15.9028	0.0000	STAND
ALR	-10.6759	0.0000	STAND
FL	-9.4336	0.0001	STAND
BEP	-11.3513	0.0011	STAND
WCT	-2.1e+02	0.0000	STAND
SALE	-9.1115	0.0158	STAND
CFA	-21.8377	0.0000	STAND
FA	-14.8394	0.0000	STAND

Source: The group of authors created

Table 4.1 shows that all tested variables have t-statistic < 0. In particular, all CR, ALR, FL, BEP, WCT, SALE, CFA, FA variables have a P-value of less than 1%, which explains, the variables are stationary with a significance level of 5% in the given author group model.

**4.1.2. Descriptive Statistical Analysis**

Conduct data analysis of variables in the descriptive statistics table.

**Table 4.2: Results of descriptive Statistical tests**

variable	N	mean	sd	min	max	cv
rr	660	.1984848	.3991616	0	1	2.011043
cr	660	2.414094	2.70396	.226823	30.73874	1.120073
alr	660	3.175278	8.108136	.164716	141.4402	2.55352
fl	660	.5274858	.3436401	.00707	6.071059	.6514679
bep	660	.0536163	.069	-.357725	.479492	1.286922
wct	660	.9206095	88.92572	-1314.35	1762.987	96.5944
sale	660	5.38e+11	1.33e+12	-9.54e+10	2.36e+13	2.473166
cfa	660	.0300969	.1267346	-.470525	.888517	4.210886
fa	660	.0701138	.1354921	6.00e-06	.888657	1.932461

Source: Group of authors calculated on STATA 15 software

Through the statistical table describing the variables, the study had 660 observations. The indicator is statistically described as a risk assessment index through the above indicators, the results of this RR indicator are described as fluctuating from 0 to 1, the average result is 0.198 a large number with a range of above fluctuations, finally the standard deviation of this variable is 0.399.

**4.1.3. Correlation Coefficient analysis**

Correlation coefficient is a measure of the degree of linear correlation between two variables. In principle, correlation will find a line that best matches the linear relationship between the two variables. The correlation coefficient takes the value from -1 to +1. The greater the correlation coefficient is, the closer the relationship between the two variables is shown.

**Table 4.3: Correlation Coefficient test results**

	rr	cr	alr	fl	bep	wct	sale	cfa	fa

Source: Group of authors calculated on STATA 15 software

From the results of Table 4.3, it shows that the dependent variables have a negative correlation with CR, BEP, WCT variables and have a positive correlation with ALR, FL, SALE, CFA, FA variables.

**4.1.4. Checking for Multicollinearity**

When the authors examined the multicollinearity phenomenon in the model, the VIF coefficient of fluctuations was between 1.01 and 1.09 with an average of 1.06. According to Hoang Trong and partners

(2008),  $VIF < 7$  will not have multicollinearity. From the test results obtained on the model, it is concluded that the model does not have multicollinearity.

Variable	VIF	1/VIF
fl	1.09	0.916518
cr	1.07	0.931996
cfa	1.07	0.933328
bep	1.07	0.937227

alr	1.06	0.940850
sale	1.03	0.969596
wct	1.01	0.989023
Mean VIF	1.06	

**Table 4.4: Multicollinearity Test Results**

Source: Group of authors calculated on STATA 15 software

#### 4.1.5. Testing the Predictability of the model

Initially, tests were carried out to choose which of the two FEM and REM models is the most suitable. The model estimation results by both Logit FEM and Logit REM methods are statistically significant with the study sample. Use the Hausman test to choose between FEM or REM models.

**Table 4.5: Hausman test results**

	Coefficients		(b-B) Difference	sqrt(diag(V_b-V_B)) S.E.
	(b) fell	(B) rell		
cr	-.6169442	-1.038676	.4217319	.
alr	.1481908	.1937484	-.0455576	.0097528
fl	.8284421	.8818253	-.0533831	.1639681
bep	-4.95161	-8.490394	3.538784	.3684145
wct	-.0012835	-.0013852	.0001016	.
sale	7.92e-14	8.72e-14	-8.03e-15	3.64e-14
cfa	1.49981	.8137204	.6860892	.
fa	3.873272	2.642629	1.230643	.9696111

b = consistent under Ho and Ha; obtained from xtlogit  
B = inconsistent under Ha, efficient under Ho; obtained from xtlogit

Test: Ho: difference in coefficients not systematic

chi2(7) = (b-B)' [(V\_b-V\_B)^(-1)] (b-B)  
= 9.19  
Prob>chi2 = 0.2393  
(V\_b-V\_B is not positive definite)

Source: Group of authors calculated on Stata 15 software

The P-value estimation results of the Hausman test corresponding to the model by 0.2393 are greater than 5%, so the REM model will be more suitable than the FEM model.

According to the selected REM Logit model, the results indicate that independent variables with  $P > |z|$  less than 5% significance level will be selected into the most optimal model.

The test results showed that there are 5 independent variables (CR, ALR, FL, BEP, FA) that are statistically significant with dependent variables (RR).

Optimal Model:

$$\ln_i \left[ \frac{P(RR = 1)}{1 - P(RR = 1)} \right] = \beta_1 + \beta_2 CR_i + \beta_3 ALR_i + \beta_4 FL_i + \beta_5 BEP_i + \beta_6 FA_i + \varepsilon_i$$

Remove non-statistical variables from the model and continue to estimate the model using the Logit REM model to produce the optimal model results.

Source: Group of authors calculated on Stata 15 software

Table 4.6 results show that the model consists of 5 variables: Current Ratio (CR), Asset Liquid Ratio (ALR), Financial Leverage (FL), Basic Earning Power Ratio (BEP), Fixed Asset Ratio (FA) affect the risk of bankruptcy with a significant level of 5%. In particular, CR, BEP have a negative impact and ALR, FL, FA have a positive impact on the bankruptcy risk of the studied real estate business enterprises. The influence of all five variables is exactly the same as the original hypothesis on economic theory mentioned above.

#### 4.1.6. Testing the predictability of the model

The research results show that in 8 independent variables according to the initial hypothesis that have an impact on the bankruptcy risk of the listed real estate business on the market studied, there are 5 actual variables that have an impact, creating the optimal model as above and in line with the hypotheses as well as those previously pointed out by previous studies: Current Ratio (CR), Asset Liquid Ratio (ALR), Financial leverage (FL), Basic Earning Power Ratio (BEP), Fixed Asset Ratio (FA) on the Logit model to connect the dependent variable is the bankruptcy risk of the enterprise.

Forecasting on the REM logit model after excluding non-affected factors has the following results:

**Table 4.7: Classified test results**

Classified	Model 1		
	1	0	Total
1	17	114	131
0	4	525	529
<b>Total</b>	<b>21</b>	<b>639</b>	<b>660</b>
<b>Sensitivity</b>	<b>12.98%</b>		
<b>Specificity</b>	<b>99.24%</b>		
<b>Rate of type I error</b>	<b>0.76%</b>		
<b>Rate of type II error</b>	<b>87.02%</b>		
<b>Correct classification</b>	<b>82.12%</b>		

Source: Self-calculating group of authors

Using the REM Logit model with Classification testing to forecast the possibility of bankruptcy risk of listed real estate enterprises in Vietnam. From the table above, the fixed-impact REM model indicates 82.12% accuracy classification; Type I and Type II violations are 0.76% and 87.02%, respectively. The forecast results also show that the Logit REM model has a forecast rate of real estate businesses with a risk of bankruptcy of 12.98%, businesses without a risk of bankruptcy is 99.24%.

## 4.2. Discussion

### 4.2.1. Group of variables that have a similar impact on the bankruptcy risk of the enterprise

ALR: The Asset Liquid Ratio has a favorable effect on the bankruptcy risk of the enterprise, which means that when the enterprise increases the overall solvency ratio, it will cause financial risk to increase, leading to the potential for bankruptcy risk to increase. As the overall solvency of the business increases, so does the total assets of the large business. This is a big disadvantage for a real estate business. Because at that time, the inventory of the enterprise is too large to be liquidated, the contracts have not been implemented, the unfinished projects are not completed or there is not enough capital to operate and complete... will bring difficulties to the enterprise in terms of capital, thereby causing obstacles and risks of bankruptcy of the enterprise. Research has shown to support the views of Vo (2020), Simantinee & Phani (2015), Vu (2017)..

FL: Financial Leverage is a combination of equity and loans from banks or financial institutions to increase profit margins for businesses. The financial leverage ratio is one of the business levers that shows the correlation between loan capital and equity. Leverage represents the level of debt utilization in the firm's total capital. The low index shows that investors have the ability to be financially self-reliant, whereas investors have not used the advantages of this tool effectively. Since then, it has been found that financial leverage is proportional to the risk of bankruptcy. Research has shown that it has added correctness to the views of Vo (2020), Vu (2017)...

FA: The Fixed Capital Ratio has a positive impact on the bankruptcy risk of the enterprise. Real estate businesses often invest in high fixed assets while the fixed capital of the business is often low liquidity, the capital turnover of enterprises with long cycles is partly rotated, each stage of the business cycle. Therefore, when the revenue of the real estate business is not enough to offset the fixed costs, it will increase the risk of bankruptcy of the business when it fails to pay its debts in time. This is also consistent with the research hypotheses of the topic and of Gang & Dan (2012), Vu (2017)...

### 4.2.2. Group of variables that have the opposite impact on the bankruptcy risk of the enterprise

CR: Current Ratio has the opposite impact on the bankruptcy risk of a real estate business enterprise. According to the inspection results, the higher the current solvency of the enterprise, the lower the risk of

bankruptcy of the enterprise and the inability to bankruptcy, and vice versa, if the current solvency of the enterprise is low, the risk of bankruptcy of the enterprise will increase. Current solvency relates to whether the business can pay its short-term debts or not, reflecting the financial capacity to handle current debts, contributing to reducing the risk of bankruptcy due to current debts. Therefore, the CR will be opposite to the bankruptcy risk of the enterprise. The results of this study are also in line with the expectations of the author and it is supported by some authors, such as: Gang et al. (2012), Bhunia and Mukhuti (2012), Simantinee and Phani (2015).

BEP: The Basic Earning Power Ratio has the opposite impact on the risk of bankruptcy of real estate enterprises listed on the Vietnam stock exchange. This means that as the economic rate of return of an enterprise's assets increases, the risk of bankruptcy decreases. This variable has a positive impact because when the enterprise improves the rate of return of assets, it will contribute to increasing equity, promoting investment and development, increasing the size, expanding market share and at the same time increasing the ability to pay debts, which means the risk of bankruptcy of the enterprise decreases. This study also supports the view of economists such as Altman (1968), Gu (2002).

#### **4.2.3. Some solutions and recommendations**

*The first is the group of direct solutions:*

Through the results of studying econometric models, the author proposes solutions to reduce financial risks in real estate enterprises. One of the important solutions is to improve the efficiency of financial analysis, including increasing the use of econometric models to clarify the influence of factors on analytical indicators, helping businesses have a scientific basis to offer specific solutions to improve financial management.

*Solutions related to Financial Leverage:* Enterprises need to have a capital structure and use reasonable financial leverage to improve profitability. In particular, enterprises need to set out a specific strategy on the use of financial leverage to improve profitability as follows: there should be a flexible policy in the process of using debt, limiting the use of debt to finance short-term assets when they have not fully exploited their performance; It is necessary to be flexible in the use of capital funding sources, specifically in the period of unstable lending interest rates in the market, in addition to limiting debt borrowing, enterprises can use other forms of capital mobilization such as issuing more shares to employees and strategic investors.

*Solutions related to Current Ratio:* A difficult problem is always set for managers and executives of enterprises that always have reasonable strategies to balance the current solvency (CR) of enterprises, develop and occupy the legal business capital of partners but must ensure to maintain the ability to pay, well control the financial situation in order to avoid falling into insolvency and falling into bankruptcy. A scale of real estate business with appropriate capital structure: reducing short-term liabilities and increasing investment in current assets. Enterprises will promote their strengths to improve the profitability of capital, maintain the reputation and brand of the business, accelerate the speed of inventory turnover, and reduce debt recovery time.

*Solutions related to Asset Liquid Ratio such as:* Strengthening the organization of receivable debt management; Regularly monitoring and managing receivables that have arisen, urging customers to pay debts on time; Take measures to prevent and control the arising of outstanding debts; Ensure a reasonable cash reserve level to meet payment requirements; Adjust the capital structure in a reasonable manner in the direction of increasing the proportion of equity in total capital.

*Solutions related to Fixed Asset Ratio such as:* identifying and maintaining a reasonable asset structure; choosing an appropriate form of capital mobilization; there are times when it is necessary to invest in fixed assets but the financial ability does not allow or consider the investment ineffective, the company should consider the form of financial lease and vice versa; Enterprises need to have a reasonable asset structure orientation, especially the issue of investment and use of fixed assets, thereby increasing the efficiency of management, use and new investment in fixed assets, liquidation of outdated, obsolete, low productivity assets...

*Solutions related to Basic Earning Power Ratio.* Businesses need to pay attention to expanding the size of their businesses, expanding and developing more areas of operation; build trust, maintain and develop the number of customers, increase competitiveness in the market and need to have a flexible policy in the process of using debt.

*Next is the group of complementary solutions:*

Enterprises need to build a competitive strategy; restructure corporate governance; rationally and effectively use financial analysis tools; and finally, real estate businesses need to have a plan and goals that are consistent with their capacity.

*The authors also made some recommendations as follows:*

The State needs to study and gradually improve the synchronous and transparent legal system in real estate, especially the renovation of financial policies on the real estate market. The Ministry of Planning and Investment must improve the quality of land use planning and real estate development investment planning. The State should create a mechanism to strongly attract investment capital, build real estate business with State budget sources or with investment capital of credit institutions.

The State Bank needs to use flexible monetary and financial policies to ensure that it does not create bubbles but also does not tighten causing stagnation and market freeze. It is necessary to form credit forms related to real estate and there should be solutions for foreign investors not only to invest in cash flow, but to combine business - investment - management - marketing projects. The State Bank needs to regularly check and supervise the credit granting situation of credit institutions, and control negative phenomena.

Stock exchanges need to create a safe, transparent and liquid investment environment for investors; always stick to the principles of effective governance and orientation to improve modern technology development, in addition, it is necessary to promote and be more transparent with information.

## **5. CONCLUSION**

*Firstly*, the project has systematized in detail the general reasoning about the risk of bankruptcy and bankruptcy risk analysis. The research has built a system of risk analysis of enterprises in a complete and comprehensive way.

*Secondly*, the work has pointed out and analyzed the research of some countries around the world on the analysis of bankruptcy risk of real estate enterprises. Through studying the experience of some countries, the study has pointed out the lessons that real estate businesses listed on the stock exchange of Vietnam can apply in the current context. This is an important premise to build, orient and develop listed real estate enterprises in Vietnam in the coming time.

*Thirdly*, the study surveyed and analyzed financial statements and information related to 60 listed real estate enterprises in Vietnam to show the overall picture of the bankruptcy risk situation of listed real estate enterprises from 2011 to 2021. The results of the analysis have shown that the risk of bankruptcy of real

estate businesses in Vietnam is still inadequate, reflected in the main points: business efficiency decreases; profitability, solvency is still unstable. The study points out factors that affect the profitability of enterprises including size, asset growth rate, operating profitability, debt ratio, while factors affecting the bankruptcy risk of enterprises include financial leverage, solvency, financing policy, profitability.

*Fourthly*, based on the analysis of the current situation of bankruptcy risk, the research has proposed groups of solutions to improve the risk of bankruptcy of enterprises in the real estate business. Some direct solutions include: current solvency solutions, general solvency solutions, solutions related to financial leverage, solutions related to the economic rate of return of total assets. In addition, some complementary solutions include: building a competitive strategy, restructuring corporate governance, increasing the use of financial analysis tools and restructuring governance in enterprises.

*Fifthly*, in order for the solutions to be put into practice, the study has proposed many policy recommendations to the Government, ministries, departments, branches and management agencies in order to create favorable conditions for business activities of enterprises. Hopefully, with the participation of the whole political system, the proposed solutions will have application conditions and practical results, contributing to improving the financial situation of real estate businesses. With the results of the study, the research has contributed more evidence and supplemented the research on the risk of bankruptcy of listed real estate enterprises in Vietnam.

## SUSTAINABLE GROWTH OF SOME DAIRY INDUSTRY JOINT STOCK COMPANY LISTED IN VIETNAM

**Authors: Le Khanh Huyen<sup>1</sup>, Nguyen Do Hong Ha<sup>1</sup>**

**Mentor: Ph.D. Pham Thi Van Anh<sup>1</sup>**

**ABSTRACT:** *This study clarifying the rationale for sustainable growth in dairy enterprises. Simultaneously, find out the status of sustainable growth in dairy enterprises listed on Vietnam's stock market from the years 2018 to 2021, from which to draw assessments and comments. Lastly, proposing solutions to ensure sustainable growth in dairy companies listed on Vietnam's stock market in the coming time.*

**Keywords:** *Sustainable growth, dairy industry, Vietnam's joint stock company.*

### 1. INTRODUCTION

The world is developing rapidly thanks to efforts to reform and apply scientific and technological achievements, but it is facing many problems such as widening gap between rich and poor, environmental pollution, climate change. ...Part of the cause of these problems is also caused by development. Therefore, prosperous growth coupled with environmental sustainability and social inclusion are the main pillars of developed and developing countries, including Vietnam. Therefore, sustainable growth is always one of the biggest challenges of any business leader. To do that, businesses must create long-term value from their available resources. Regardless of the nature of the industry, operations and organizational structure of the business, all must follow this rule for sustainable growth.

Vietnam's milk and dairy products manufacturing and processing industry in recent years has had a dynamic development, providing a variety of products for the national economic life, meeting domestic demand. , gradually replacing imported dairy products and participating in exports with a variety of models and types. In addition, the industry has made significant contributions to the state budget, creating many jobs for workers, contributing to ensuring people's lives and stabilizing the social situation, becoming an important link of Vietnamese agriculture.

Fast economic growth, a large market and an open and attractive investment environment are favourable conditions for the development of the dairy market in Vietnam. Besides these favourable conditions, Vietnam's dairy industry also faces many challenges such as food safety and hygiene, milk quality, husbandry techniques, technological lines, costs as well as policies and incentives from the State. The investment and development of the dairy industry has created favourable conditions for enterprises to develop production with low labour costs and at the same time provide livelihoods for people who are underemployed and have low income, contributing to hunger eradication and poverty alleviation, social security, linking business interests with the community. Due to being in the group of essential products, despite the gloomy business years of enterprises in the entire economy, listed companies in the dairy industry still maintained strong double-digit growth. However, risks in the industry include higher-than-expected

---

<sup>1</sup> Academy of Finance.

input material prices and a longer-than-expected Covid-19 pandemic leading to supply chain, distribution and transportation disruptions. This shows that the growth of many dairy businesses has not yet ensured sustainability. Stemming from this fact, the authors have chosen the topic: “Sustainable growth of listed dairy companies in Vietnam” as their scientific research topic.

## 2. THEORETICAL FRAMEWORK:

### 2.1. Definition of sustainable growth:

Growth is an economic term that refers to the increase in the amount of wealth that the economy of a business, a country or region, and the globe has acquired over a certain period of time. The commonly used criterion for measuring growth is the rate of increase in the size of gross product in terms of fixed prices. However, if only the goal of quantitative growth is pursued, it can lead to a situation where there is growth without development due to depletion of resources and unfair treatment of different groups of people. Economic development is the transformation of the national economy by an increase in production and an increase in the standard of living of the population. In other words, economic development implies growth and improvement of the living conditions of the population not only economically, but also culturally and socially. Sustainable growth of enterprises is set out within the framework of General Sustainable Growth, taking into account the characteristics of enterprises that are both an economic entity independent of other economic sectors of the locality and an area of concentrated industrial production with high density with metabolic relationships with other sectors of the economy, residential communities and the environment. In this topic, Sustainable growth of enterprises is to ensure continuous, stable and long-term high economic growth of enterprises themselves, enterprises rationally and efficiently use resources, contributing to the implementation of social responsibility and environmental protection inside and outside enterprises.

### 2.2. Sustainable growth models of businesses:

Sustainable growth is a method of socio-economic development that addresses the relationship between economic growth, social problems and environmental protection with the aim of better meeting the needs of the current generation while not hindering the meeting of the needs of future generations. In other words: it is the harmonious development of economic, cultural, social and environmental aspects in enterprises that constantly improve the quality of human life. This perspective can be expanded upon with three basic components of sustainable growth that can be illustrated in the following patterns:

**Model 2.1. Three-circle sustainable growth model**

**Model 2.2. Triangular sustainable growth model**

Model 2.1 and Model 2.2 are widely used in recent sustainable development publications, they have similarities and are collectively called the “three pillars” model because they are both built on the three pillars of sustainable development: economic growth, social justice and environmental protection. However, there are certain differences between these two models: while the three-circle sustainable development model emphasizes that sustainable development necessarily ensures all three objectives: economic, social and environmental, the triangular model emphasizes constraints, dominating and reversibly interacting between three elements: economic goals, social goals and environmental goals for sustainable development.

**2.3. Criteria for evaluating sustainable growth in enterprises**

**2.3.1. Criteria for assessing sustainable economic growth**

The basic measure commonly used to assess sustainable economic growth is the rate of sustainable growth. The sustainable growth rate is understood as the growth rate of profits and dividends to current owners that the business generates that does not originate from external capital. In other words, it is to get profit growth rates and dividends to owners without taking on additional new debt and without raising additional equity from outside. The sustained growth rate is also known as the current owner-to-equity growth rate, which is generated from an additional increase in equity but this capital is formed from reinvested retained earnings.

The formula for calculating the sustainable growth rate is as follows:

$$\text{Sustainable growth rate (g)} = \text{Rate of retained earnings reinvested} \times \text{Return on Equity}$$

**2.3.2. Criteria for assessing social sustainable growth**

Sustainable social growth in enterprises means ensuring fair, humane treatment, respect for human rights in enterprises and participating in social responsibility for localities. Indicators related to labour regime such as salary, bonus, allowance, insurance and labour contract are basic indicators in the CSI Index.

- The level of contribution to society and community
- Ensuring the interests of employees in enterprises
- Creating job opportunities for employees
- Taking care of employees’ health

### **2.3.3. Criteria for evaluating environmentally sustainable growth**

Environmentally sustainable growth requires enterprises to practice measures to minimize the impact of environmental pollution, create an environmentally friendly workspace right in the enterprise. This criterion is shown on the following aspects:

- Comply with Vietnamese laws on environmental protection
- Pollution prevention, troubleshooting, environmental improvement
- Protection of natural resources and environment

### **2.4. Factors affecting sustainable growth in dairy enterprises**

There are many factors affecting sustainable growth in dairy enterprises. In each region, each locality, due to different characteristics, the impact and influence of factors are also different. However, in general, sustainable growth in dairy enterprises is influenced by the following groups of factors:

- Financial management mechanism of enterprises
- Strategic planning and production and business planning activities and selection of investment strategies
- Governance level of enterprises, levels of production organization
- Incentive mechanisms and material responsibilities in enterprises
- Labour and labour quality in the dairy industry
- Science and technology level
- Management capacity, State Administration
- Stable Political
- Legal Environment
- Stable Macroeconomic Environment
- Culture
- Natural Conditions
- Competitors

### **3. RESEARCH METHOD:**

The methodology of dialectical materialism and historical materialism of Marxism-Leninism is uniformly used in the research process of the authors' team. The authors use statistical methods, analysis, synthesis, statistics, comparison, evaluation, description, and cause-and-effect identification as a basis for research. On the basis of aggregation, comparison, analysis,... primary data, methods of description, identification of cause and effect, the topic provides a comprehensive view of sustainable growth in dairy joint stock companies listed on the Vietnam stock market.

### **4. RESULTS AND DISCUSSION**

Dairy enterprises in Vietnam play an important role in socio-economic development. In this chapter, the authors learn an overview of the dairy industry in Vietnam such as: history of establishment and development; basic characteristics of the industry; learn about the research sample as well as an overview of the financial situation of dairy enterprises listed on the Vietnam stock market over the past time. The authors delve into the situation of sustainable growth in dairy enterprises listed on the stock market in Vietnam on

three contents: sustainable economic growth; socially sustainable growth and environmentally sustainable growth. On that basis, the authors make general assessments of sustainable growth in dairy enterprises listed on the stock market in Vietnam from 2018 to now in the following aspects: achievements, limitations and causes of limitations. This is an important basis for the authors to build a system of solutions to ensure sustainable growth in dairy enterprises listed on the Vietnamese stock market in the coming time.

## 5. CONCLUSION

Sustainable growth in enterprises is to ensure continuous, stable and long-term high economic growth of enterprises themselves, enterprises to rationally and effectively use resources, and contribute to realizing social responsibility and environmental protection inside and outside enterprises. This is an issue that attracts the attention of not only businesses, economic managers, economic researchers but also business-related subjects. The topic has gone into depth to give an overview of enterprises in the dairy industry from which to learn about sustainable growth in dairy enterprises. From the concept as well as the connotation of sustainable growth in enterprises, the authors have presented sustainable growth models in enterprises and proposed three groups of criteria for evaluating sustainable growth in enterprises. That is: Criteria for assessing sustainable growth in terms of economy, society and environment. Sustainable growth in dairy enterprises is a broad and complex category, so there are many factors affecting the sustainable growth of enterprises.

Dairy enterprises in Vietnam play an important role in socio-economic development. Currently, sustainable growth in dairy enterprises listed on the stock market in Vietnam has a number of issues that need attention. The topic has evaluated a number of advantages and limitations on the situation of sustainable growth in dairy enterprises listed on the stock market in Vietnam in the period from 2018 on the content and according to the evaluation criteria of the sustainable growth in enterprises. The study has pointed out some causes of the above limitations. This is an important basis to help the authors build a system of solutions to ensure sustainable growth in dairy companies listed on Vietnam's stock market in the coming time. The solution system consists of 2 groups of solutions. That is: a group of solutions from businesses and recommendations to the State and authorities. The group of solutions inside enterprises includes 7 solutions: (i) Expanding markets, promoting export activities and researching new products to improve revenue; (ii) Control costs in the process of production and business activities; (iii) Develop a capital financing strategy suitable to enterprises in the dairy industry to increase financial resources; (iv) Increase self-financing capacity, contributing to the restructuring of capital sources; (v) Focus on releasing inventory; (vi) Focus on sustainable social growth; (vii) Concern for environmentally sustainable growth. There are also recommendations to the State and authorities: (i) Renovating thinking, awareness and strengthening education on sustainable growth in general and sustainable growth in enterprises in the dairy industry in particular; (ii) Improve the quality of planning and strengthen the management role of the state in the sustainable growth of dairy enterprises; (iii) Strengthen linkages and coordination among enterprises in the industry; (iv) Solutions for sustainable social growth; (v) Solutions for environmentally sustainable growth. These are basic and important solutions to ensure sustainable growth in dairy enterprises listed on the Vietnamese stock market in the coming time.

## **SOLVENCY OF THE FOOD AND BEVERAGE INDUSTRY IN THE PERIOD 2012 – 2021**

**Author: Tran Hoa An; Vu Thi Thu Thao<sup>1</sup>; Tran Tuan Vu<sup>1</sup>; Nguyen Duc Tam<sup>1</sup>; Nguyen Thu Trang<sup>1</sup>**

**Mentor: PhD. Dao Hong Nhung<sup>1</sup>**

*ABSTRACT: Solvency of a business is not only to show the business's ability to meet liabilities and other financial obligations but also the measure of that company's financial health since it demonstrates the business's ability to manage operation for the foreseeable future. This study is conducted to analyze the solvency of the faculty of food and beverage industry which includes 31 companies posted up in Viet Nam in the time period 2012 - 2021. The results show that:*

*- For short - term solvency: most F&B companies have it greater than 1, but not too high which means that F&B enterprises mainly mobilize capital from owner equity, the liquidity is very good; at the same time, some F&B enterprises have short-term solvency for many consecutive years of less than 1, which means that these enterprises have a risky financing policy, using short-term debt to support long-term assets.*

*- For quick ratio and current ratio: they are high because the F&B industry tends to be stable of the demand for food and beverages is always necessary.*

*Keywords: Solvency; food & beverage; potential finance;....*

### **I. INTRODUCTION**

The food and beverage industry accounts for a very high proportion of the current industries. The growth trend from 2012 to 2025 is predicted to increase by a total of 3.7%. Worldwide, the total F&B market will reach \$8,049 billion in revenue by 2020. According to Alibaba's report, Asia remains the largest consumption market in the world with 6.1% from 2019 to 2025. With more than 38% of the population (620 million or 235 million) engaged in the agri-food sector, the ASEAN F&B industry is making significant achievements for sustainable growth and development, which is expected to increasing productivity and ensuring consumer demand. Under the impact of the severe economic recession in 2011, 2012, 2013 and the subsequent world economic recovery, the Covid pandemic in recent years led to a dizzying change in all aspects of the economy. industries, not just F&B. Facing the global economic recession, rising inflation and problems related to logistics and distribution, businesses quickly adjust their financial policies to adapt to this situation in a timely manner. The shift from traditional merchandise purchases to automated e-commerce, prompt delivery services and incentives have boosted the consumption of beverages as well as food.

### **II. ANALYSIS OF THE SOLVENCY OF THE BUSINESS**

Solvency is the ability to use the resources of an enterprise to respond to the liabilities of the enterprise according to the appropriate time. The ability of a business to pay its debts also reflects the health of a business. A well-run business is certainly financially able to pay its debts.

Solvency analysis helps to assess the ability to convert resources into cash to pay the debts of the enterprise by appropriate time, thereby assessing the financial situation of the enterprise, seeing the potential as well as risks in mobilizing and repaying debts of enterprises.

When analyzing solvency, use the following indicators:

---

<sup>1</sup> Academy of Finance.

- Solvency ratio

$$\text{Solvency ratio} = \frac{\text{Total assets}}{\text{Total liabilities}}$$

This indicator shows how many times the enterprise is able to pay its debts by total assets or is 1 dong of liabilities secured by several dong of assets. Normally, this ratio must be greater than 1. When this ratio is less than 1, the total assets are less than the total liabilities or the equity is less than 0 which means that the financial situation of the enterprise is bad, the risk of bankruptcy is very high.

On the contrary, if this ratio is too high, it should be considered, because then enterprises use too much equity leading to high cost of capital, or low level of financial leverage, reducing the ability to amplify your business's ROE or EPS.

- Current ratio

$$\text{Current ratio} = \frac{\text{Current Assets}}{\text{Current Liabilities}}$$

This ratio shows how many times the business is able to pay current liabilities with current assets. When the current ratio is greater than 1, the enterprise is using a part of non-current assets to finance current assets after financing long-term assets, providing long-term stability and financial safety for businesses, but potentially increasing the cost of capital.

- Quick ratio

$$\text{Quick ratio} = \frac{\text{Current Assets} - \text{Inventory}}{\text{Current Liabilities}}$$

This is a more rigorous assessment of the solvency of the business. Inventory is excluded because in current assets, inventory is considered a less liquid asset class. This ratio indicates the ability of the business to pay current liabilities without having to make urgent liquidation of inventory.

- Cash Ratio

$$\text{Cash Ratio} = \frac{\text{Cash}}{\text{Current Liabilities}}$$

This ratio shows how many times the business is able to pay its current liabilities with its available cash and cash equivalents. This ratio is especially useful to assess the solvency of enterprises in times of economic crisis when inventories are unsold and many receivables are difficult to collect.

### III. ASSESS THE SOLVENCY SITUATION

In general, the liquidity of listed F&B enterprises tended to decrease slightly in the period 2012 - 2016, then fell sharply in the period 2016 - 2017 and remained stable from 2017 to 2021.

The Short-term solvency measures at the end of 2012 was 3.0478 times, before it dramatically collapses to 2.4053 times at the end of 2017, then in 2016 it reached 2.8959 times, increased again at 2.7183 times in 2020 and decreased to 2,5212 at the end of 2021. The Short-term solvency measures sharply decline starting from 2016 - 2019 and jumping again in 2020 is due to the faster growth rate of liabilities, replaced by a decrease in mobilization from owner equity. Before that, from 2012 to 2016 remained at the same level, especially in 2012 reaching 3.0478. The Short-term solvency measures greater than 2 shows that F&B enterprises mainly mobilize capital from owner equity, the liquidity is very good.

The average short-term solvency of F&B firms fluctuated strongly from 2012 to 2017. In 2012 it decreased from 2,2044 times to 1,9106 times at the end of 2013 and continued to increase to reach 2,3150 times in 2015 but in the next period decreased to 1.6443 times in 2017. Since 2017 – 2021, it has remained stable in the range of 1.6443 – 1.9146 times. Overall, most F&B companies have short-term solvency greater

than 1, but not too high, except for Hanoi - Hai Duong Beer Company and Lam Dong Food Company, which sometimes reached the peak at 6 times. In addition, some F&B enterprises have short-term solvency for many consecutive years of less than 1, which means that these enterprises have a risky financing policy, using short-term debt to support long-term assets.

The average quick ratios of enterprises remained stable from 2012 to 2014 at 1.45 times. From 2014 to 2021, the top out point is 1,7869 times in 2015 and the bottom out point in 2018 is 1,3199 times. The average quick ratios of enterprises is greater than 1, showing that the ability to immediately pay short-term debts of enterprises is at a high level.

The current ratios of F&B enterprises in the period 2012 - 2021 is at a high level of about 0.2 to 0.6 times, showing that the cash reserve is large enough to pay short-term debts. From 2015 to 2019, there is a trend of decrease gradually due to the increase in short-term debt of enterprises, but the amount of cash and cash equivalents does not fluctuate.

The average quick ratios and current ratios of enterprises are high because the F&B industry tends to be stable of the demand for food and beverages is always necessary.

### Solvency of F&B companies listed in Vietnam

Source: Calculation from financial statements of food and beverage companies for the period 2012-2021

Considering each activity array:

For food businesses: The overall solvency coefficient is lower than that of beverage businesses. Most food businesses have an overall solvency of 2 or more and a downward trend from 2012 to 2021 shows that businesses raise more from equity than liabilities. This confirms that food businesses have good debt repayment ability. Regarding the short-term solvency ratio, in most years, most enterprises have this coefficient greater than 1, which means that it ensures the principle of financial balance and relative stability in business activities. However, in contrast to other food businesses, LAF has a short-term solvency of less than 1, which proves that the enterprise cannot afford to pay short-term debts due to importing raw cashew nuts at high prices from abroad but goods cannot be sold.

For beverage companies: Regarding the overall solvency coefficient, all enterprises are greater than 2 except VTL. Most of the enterprises have a high overall solvency ratio, which proves that the enterprises

increase mobilization from equity more than liabilities. Regarding the short-term solvency system, these coefficients are all greater than 2 except for the period from 2017 to 2019. In which, SMB and BHN have short-term solvency ratios of less than 1, showing that enterprises are having policies. venture funding.

## **EFFECTIVE OF USING THE BUSINESS CAPITAL: A CASE STUDY OF VIETNAM'S LISTED STEEL INDUSTRY.**

**Author: Nguyen Khanh Tra<sup>1</sup>; Nguyen Hong Ngoc<sup>1</sup>; Do Minh Phuong<sup>1</sup>;  
Nguyen Huong Mai; Nguyen Huy Quoc Anh.  
Mentor: PhD.Nguyen Thu Ha**

*ABSTRACT: Business capital is a resource that determines the existence and development of an enterprise. The rational use of business capital will help businesses maintain regular production and business, create profitability and preserve capital. The article introduces the effective use of working capital of steel enterprises in Vietnam. The article uses data collected from the financial statements of 14 steel enterprises operating in Vietnam from 2018 to 2022. The efficiency of using business capital is usually shown through the comparative relationship between steel companies. Direct and indirect benefits are obtained from the direct and indirect costs incurred in the course of doing business. If business efficiency is considered as a goal, the efficiency of using business capital is an effective means to achieve that goal. The results of the article are very useful for corporate administrators in general and financial managers, in particular, helping managers make the right financial decisions for the company in order to promote their business efficiency. company.*

*KEYWORDS: efficiency, business capital, steel enterprises.*

### **1. INTRODUCTION**

Working capital is the total amount of money to invest in the input for the production and business process of an enterprise. It is used in the process of production and business activities for the purpose of making profits for business.

The efficiency of using the business capital of an enterprise is an economic category, reflecting the level of exploitation and use of capital of an enterprise in production and business activities in order to achieve maximum profit at the cost of capital. the shortest. The efficiency of using business capital is shown through indicators to evaluate the efficiency of using business capital in enterprises such as: return on working capital (ROA); return on equity (ROE); the ratio of profit after tax to sales (ROS), total capital turnover, etc.

In a market economy, capital will follow the law of supply and demand of the market, from which businesses need to choose an effective investment plan, the required amount of capital and optimal capital attraction. However, effective management and use of capital is the core issue for businesses to maintain business operations, profit growth and development. Therefore, in order to maximize the value of the business and maximize the benefits for the owner, first of all, businesses need to be aware and properly evaluate the use of business capital so that it is effective and sustainable. steady.

Currently, when the Vietnamese economy is gradually walking on the path of integration, the domestic economic sectors are also facing more competition and challenges due to the impact of global issues, especially from the global economy. Covid-19 pandemic. Steel enterprises in Vietnam are no exception. In recent years, listed steel enterprises in Vietnam have developed very rapidly both in terms of number and size of enterprises. However, it can be seen that the financial situation of many enterprises is not really healthy, business performance is unstable and still low. The difficulties of the economy in the past have affected many businesses, causing losses, even falling into bankruptcy.

Steel is not only a construction material but also a staple food of heavy industries and defense. The steel industry has always been identified by the State as a priority industry in the development of the country. The growth of the steel industry always goes hand in hand with the growth of the industry and the economy. In 2022, steel businesses face many difficulties when witnessing a sharp decrease in revenue and profit. Over 50% of enterprises reported losses. This shows that the efficiency of capital use of steel enterprises is at a low level and facing many difficulties and challenges.

Faced with that situation, steel enterprises need to quickly implement solutions to recover their financial situation and increase profits. To be able to improve the efficiency of the working capital of an enterprise, financial managers must design a system of measurement indicators, evaluate the effectiveness of working capital, and understand the mechanism of impact of factors on the efficiency of the enterprise. In order to come up with appropriate solutions to improve the efficiency of working capital. Although there have been many studies on the efficiency of working capital of enterprises in the world, the results of these studies are not really consistent with the situation of Vietnamese steel enterprises in recent years. Therefore, the author writes this article for the purpose of analyzing and finding out the factors affecting the efficiency of working capital and assessing the extent of the influence of those factors on steel enterprises in the past. With the research results, the managers of the steel industry can come up with specific measures to affect each factor to gradually improve the efficiency of capital use, which is an urgent issue for enterprises in particular. In general and of listed steel companies in Vietnam in particular.

## **2. LITERATURE REVIEW AND HYPOTHESIS**

### **2.1. Literary magazine**

Khatab et al. (2011) test the relationship between corporate governance quality and business performance of the company through ROA, ROE and Tobin' Q coefficients with explanatory variables as financial leverage, model business and asset growth rate of 20 companies listed on Karachi Stock Exchange, Pakistan based on data collected from 2005-2009. The research results show that financial leverage and asset growth have a statistically significant effect on ROA, ROE and Tobin's Q, while firm size has no effect on the above criteria. This study shows that the business performance of enterprises is determined by governance policy.

San and Heng (2011) studied 49 construction companies listed on the Malaysian stock market in the period 2005-2008, divided into 3 types of large, medium and small scale. Research results show that for large firms, return on capital to debt per share, market value and earnings per share with long-term debt per share are often positively correlated. While earnings per share and debt to equity are negatively related; only marginal operating profit with long-term debt per share is often positively related in mid-sized firms, and earnings per share with debt-to-equity are negatively related in large firms. Small company.

Pouraghajan and Malekian (2012) studied the impact of capital structure on firm performance with a sample of 400 companies in 12 industries listed on the Tehran Stock Exchange in the years 2006–2010. Using qualitative research methods combined with quantitative methods, the author identifies dependent variables, representing the performance of enterprises - ROA and ROE. Research results show that there is a significant negative relationship between debt ratio and firm performance. Asset turnover, company size, tangible asset structure and growth rate have a positive and statistically significant relationship with the

company's business performance (ROA and ROE). There is no statistical relationship between firm age and firm performance. Firms in the industrial sector such as non-metallic mineral producers, F&B companies, base metals, auto parts and auto parts companies have a negative relationship with firm age, while companies in the materials and chemical industries show a positive and significant correlation between firm age and firm performance.

Saeed et al. (2013) studies and evaluates the impact of capital structure on operational efficiency through ROA, ROE, and EPS with independent variables as short-term debt, long-term debt, total debt on equity and the two control variables are firm size. and the growth rate of total assets of 25 banks listed on the stock exchange of Karachi, Pakistan, based on data collected from 2007 to 2011. The results show short-term debt ratio, total debt and size. firms have the same effect, while long-term debt ratio has a negative effect on ROA, ROE and EPS, while asset growth rate has no effect on ROA and ROE. In addition, there are many other studies on the impact of these factors on business performance of enterprises. However, there has been no research focusing on the factors affecting the efficiency of working capital of Vietnamese steel enterprises in the period 2018-2022. Therefore, this article contributes to help Vietnamese steel enterprises improve the efficiency of using business capital.

## 2.2. Hypothesis

Profit after tax on working capital (ROA): ROA ratio reflects how much profit after tax is generated for each dollar of capital used in the period.

→ Profit after tax on working capital (ROA) = (Profit after tax) / (Average working capital in the period) × 100%.

Return on Equity (ROE): This ratio measures the after-tax profit earned per dollar of equity of the owner during the period.

→ Return on equity (ROE) = (Earnings after tax) / (Average equity) × 100%.

Profit after tax on sales (ROS): This ratio reflects the ability to manage and save costs of the enterprise. This indicator reflects the relationship between profit after tax and net revenue in the period of the enterprise. This indicator shows how much profit a business can earn in a period of revenue.

→ Rate after tax on sales (ROS) = (Profit after tax) / (Net revenue in the period) × 100%.

Total Capital Turnover: This turnover shows how much net sales a business generates in one round of capital.

→ Total capital turnover = (Net revenue) / (Average working capital).

## 3. RESEARCH METHODS

The provided data is collected from audited financial statements of 14 steel industry enterprises listed on HNX and HOSE from 2018 to 2022 on the prestigious website <https://cafef.vn/>; <https://vietstock.vn/>. Companies that publish full and continuous annual financial statements ending on December 31 are the sample selection criteria in this study and in the manufacturing sector companies have not suffered consecutive losses in the period 2018- 2022. Thus, this study has 14 companies \* 5 years = 70 observed variables, which have been processed by Excel. We choose HNX and HOSE because they are two of the leading stock exchanges in Vietnam.

4. RESULTS AND DISCUSSION

4.1. Descriptive statistics

Chart 1: ROS of steel companies by asset size

Source: Calculation from financial statements of steel companies in the period of 2018 - 2022

Steel enterprises show great difficulties in generating revenue and controlling costs effectively, especially in 2022. The main reason for the low ROS of steel enterprises is low and volatile. This is because the difference between the selling price of steel and scrap steel for production is low, causing companies to reduce the volume of billet production and increase the volume of billet purchased from outside. In addition, the increase in capacity far exceeds the demand, which makes the price competition in the steel industry increase, along with the negative influence from the price of raw materials, so these companies sometimes have to production cuts. In addition, it is impossible not to mention that the cost management level of the enterprise is still limited. The most significant difference in the sample, where Hoa Phat Steel is assessed as having the ability to generate large and stable revenue and control costs effectively is due to the advantages of scale, business strategy and investment. in a reasonable depth as well as focusing on the application of modern technology, saving energy and renewable energy.

Net Profit to VKD (ROA)

Chart 2: ROA of groups of steel enterprises by capital scale in the period 2018-2022

Source: Calculation from financial statements of steel companies in the period of 2018 - 2022

It can be seen that Steel enterprises have low ROA. This is also relevant because activities in the heavy industry sector such as steel and cement often have a very large amount of fixed assets, so the

ROA will be relatively low, which is in stark contrast to other industries. Technology services companies, consumer goods do not need to operate with a large amount of fixed assets, so the ROA of companies in this industry is often high.

**Chart 3: ROE by groups of listed steel companies by capital size**

Source: Calculation from financial statements of steel companies in the period of 2018 - 2022

### ROE of groups of steel enterprises by size:

Similar to profitability indicators BEP, ROA. Enterprises with large capital scale have higher ROE than medium and small sized enterprises in the same period. The difference in ROE in groups of different sizes as well as in each enterprise is very large. This is because ROE depends on many factors, in addition to the general characteristics of the whole industry in certain business contexts, ROE depends on production characteristics and unique factors of each enterprise such as the level of exploitation and use. asset use or level of financial leverage.

Typically, in enterprises with capital scale of over 10,000 billion VND, we can easily see two clear trends in return on equity between enterprises using BOF furnaces (Hoa Phat) and enterprises using furnaces. EAF ( Pomina ).

For long steel enterprises using BOF furnaces, as is typical in the case of Hoa Phat Group, the ROE of this enterprise is high mainly due to its wide operating profitability and high short-term capital turnover. Meanwhile, the company's short-term investment coefficient is relatively low. Hoa Phat in general has large total assets and is in the process of investing in strong assets. Hoa Phat Dung Quat Iron and Steel Complex project with a total investment of VND 52,000 billion has entered the stage of formation and completion, which has significantly increased the value of assets, especially long-term assets. Hoa Phat's profitability comes mainly from operational management and short-term capital management.

Meanwhile, enterprises using EAF furnaces have lower ROE, recording a negative index in 2019-2021 of only about 1-5%. The average short-term capital turnover of 2 rounds and the average leverage of about 2-3 times are at the industry average. However, the net profit margin of this group is very low and this is also the main reason why enterprises using EAF furnaces have low ROE in the steel industry.

Flat steel enterprises have quite high ROE thanks to high leverage, averaging 4 times and short-term capital turnover speed, at 2.5 rounds, although net profit margin is only 1% on average. Return on equity of flat steel enterprises comes mainly from capital mobilization policy as well as short-term capital management level.

To clearly see the factors affecting ROE of steel enterprises, the research team used Dupont -ROE analysis technique.

**Table 1: Dupont analysis - factors affecting ROE of steel enterprises**

	2018	2019	2020	2021	2022
ROE	6.84%	3.54%	11.23%	22.55%	-8.54%
ROS	1.42%	0.73%	2.71%	4.87%	-2.19%
Svq	2.40	2.38	2.25	2.29	2.12
Average debt ratio	0.5	0.51	0.46	0.51	0.46

*Source: Calculation from financial statements of steel companies in the period of 2018 - 2022*

The data table shows that the ROE of steel enterprises is most affected by the ROS factor. The fluctuation of ROE over the years is mainly due to the change in ROS. Vietnamese steel enterprises are also focusing on capital investment, production technology, and increasing production capacity. During the last 5 years, we see that the average efficiency of capital use of steel enterprises has decreased slightly over the years. In 2018, the average total capital turnover of the whole industry was 2.4 rounds per year. In 2022, it will be reduced to 2.12 cycles/year. Regarding the use of financial leverage of Steel enterprises in general, there is flexible fluctuation from year to year in a positive direction. The general trend of Steel enterprises is to reduce debt over the years. from 0.51 to 0.46. In good business years, Steel enterprises increased debt to increase ROE. On the contrary, in a difficult period like 2022, steel enterprises also adjusted their average debt to reduce somewhat the negative impact on ROE.

**In summary :** By looking at the profitability on capital of listed steel companies, we can see that: Most of the listed steel companies in Vietnam have a relatively high ROE compared to manufacturing companies. other. Any enterprise has a reasonable financial structure; know how to use financial leverage flexibly; implement good cost management; Reasonable allocation and use of capital will achieve high ROE or EPS. Businesses with good sales policies and reasonable commercial discount policies will save costs and increase ROE. Enterprises with poor cost management, unreasonable investment and use of capital, and poor financial leverage, have low ROE.

#### 4.2. Result

In terms of business scale: Steel companies constantly invest in expanding business capital scale, raising the average VKD from VND 10,000 billion to VND 18,000 billion. This is an important basis for capital to increase financial potential as well as to meet capital needs for growth.

Regarding the positive business results when the Steel enterprises increased revenue and profit. Although in the period of 2019-2022, Steel enterprises faced difficulties due to the epidemic situation, economic recession and political instability in the world, Steel enterprises still maintained a high revenue growth rate in the period of 2019- 2021 and will hold steady in 2022. Profit accordingly has a strong growth with an average growth rate of 82.67%/year continuously from 2018 to 2021.

In terms of capital allocation and capital mobilization: Steel enterprises mostly have a capital allocation suitable to industry characteristics, on average, current assets account for 72% to 78% of total assets. Large companies in the industry have been pioneering in rational restructuring when investing heavily in fixed assets to increase production capacity and increase initiative in production. In addition, businesses have mobilized a large amount of capital to meet the needs of continuous business, well exploit the capital source and reduce the amount of credit.

The efficiency of capital use of listed steel companies in recent years has been stable and highly effective. Steel businesses have high profitability with a continuous uptrend in the period from 2019-2021.

This is the efforts of enterprises in adapting to the developments of the Covid-19 epidemic as well as receiving favorable conditions from the business environment, in the face of rapid fluctuations in steel prices and the increase in prices of steel products. export value. In the context of the economic recession, it is the fact that steel enterprises always maintain the combined efficiency indicators such as BEP, ROS, ROA, ROE at high and stable levels. This shows the great efforts and efforts of the leadership and management team of the steel enterprise, as well as the collective employees in the steel enterprise in striving to continuously increase the quantity and quality of products. . . export, meet the strict requirements of the market, conquer difficult markets such as the US, EU, Japan...

#### **4.3. Discuss**

The majority of steel enterprises have business results showing a lack of stability, great dependence on the external environment and competition. The change in steel price and input material costs or export value greatly affects the business results of Steel enterprises in the period. .

The efficiency of using capital of many enterprises is still too low.

The material and technical facilities of enterprises are a factor that greatly affects labor productivity, output, revenue and profits of enterprises. However, at present, there are many steel companies that have not fully exploited their existing production capacity, as shown by the amount of net revenue made per dollar of investment in fixed assets of the company is too low.

The inventory management of some enterprises has not been properly focused, capital is stagnant, and rotation is slow. This clearly reflects the lack of sensitivity in the organization of searching for markets, changing production methods, and lack of flexibility in product consumption policies. These shortcomings need to be remedied soon in the near future.

The level of use of financial leverage is not appropriate: The analysis shows that although Steel enterprises are ensuring their ability to pay interest well, the level of using financial leverage is not reasonable in some enterprises.

Business results and capital efficiency in 2022 decreased sharply and cost control of many steel enterprises was not really good. The analysis shows that the revenue in 2022 has decreased slightly, but the profit after tax of Steel enterprises has decreased dramatically, down to 84% compared to the same period in 2021. The main reason is that the control of costs of enterprises has not been. efficiency, especially cost of capital. Many enterprises have very high cost of goods sold (over 80%). As a result, in 2022, about 50% of Steel enterprises in the sample reported a loss, capital efficiency recorded a negative number.

### **5. PROMOTION PROPOSAL AND CONCLUDE THESIS**

#### **5.1. Promotion proposal**

- Coordinate many measures to maximize existing production capacity, improve efficiency and effectiveness of using fixed capital: strengthen market forecast analysis, organize production flexibly, in line with developments of the market. Steel enterprises are promoting new investment or expanding production, however, enterprises should only invest in the production of product lines that Vietnam has not yet produced, to form a closed production line. Steel enterprises need to continuously improve and innovate to improve productivity, product quality and competitiveness. The association needs to gather steel production and business establishments, create conditions for establishments to unite, support each other, exchange experiences, improve production and business efficiency, and do good work together. construction and development of Vietnam's steel production and trading industry

- Striving to continuously improve the efficiency of using working capital: enterprises need to develop the

input material production industry, reduce dependence on foreign imports, and need to invest in developing the material production industry. , especially materials that are currently imported in large quantities such as iron ore, scrap steel, coking coal, graphite electrodes... Enterprises need to manage receivables in detail according to each customer, strengthen monitor and compare debts with customers, thereby closely monitoring the repayment term of debts to take measures to urge and remind customers when the debt is due for payment so that customers can take the initiative enough money to repay the loan on time. In addition to increasing search for new export markets, steel enterprises need to closely monitor developments in the world and domestic markets to flexibly adjust production plans and develop the most appropriate sales policies.

- Developing a product distribution system, handling inventory steel: To sell goods, businesses need to apply sales discount and payment discount policies to encourage customers to pay early for goods. businesses soon have money to cover the cost of buying raw materials. The Vietnam Steel Association and the Ministry of Industry and Trade cooperate to have better management, direction and assignment solutions in production and business activities. The Ministry of Industry and Trade needs to organize trade promotion activities in domestic and foreign markets, in order to support enterprises to promote their brands, seek to expand markets, link, cooperate, and invest to bring the steel industry to life. breakthrough. production and export strengths. Promote the activities of association, consolidation and merger between domestic steel distributors and foreign enterprises in order to build large and professional enterprises and distributors capable of conquering the market.

- Investment in renewal of production lines, upgrading of specialized machinery and equipment to increase production capacity and save costs: In the context of global integration and fierce competition among enterprises in the domestic market. domestic and international, domestic and foreign, technological innovation, production lines, application of management systems and tools to improve productivity and quality are solutions to help steel enterprises improve productivity, product quality, improve the position, reputation and image of enterprises in the market

## 5.2. Conclusion

Improving the efficiency of capital use is always a topic of great significance in both theory and practice. This is a prerequisite for businesses to survive and develop. The main research results of the topic “Efficiency in using working capital of listed steel companies in Vietnam” are: Systematizing the theory of working capital and efficiency in using working capital of enterprises. Karma; Assessment of the effective use of business capital of 14 steel enterprises listed in Vietnam in the period 2018-2022; Proposing some key solutions to improve the efficiency of using business capital for listed steel enterprises in the coming period, 2023-2025.

## BUSINESS CAPITAL EFFICIENCY: A CASE STUDY OF THE VIETNAMESE STEEL INDUSTRY

**Author: Nguyen Khanh Tra, Nguyen Hong Ngoc, Do Minh Phuong,  
Nguyen Huy Quoc Anh, Nguyen Huong Mai  
Mentor: Nguyen Thu Ha<sup>1</sup>**

**Abstract:** *This study aims to identify and analyze the impact of internal factors on the business efficiency of steel firms in Vietnam. The article uses data collected from the financial statements of 14 steel firms operating in Vietnam from 2018 to 2022. We apply E-view software in quantitative analysis to build regression models on the table data (panel data), and the study has built a regression model identifying the relationship and impact level of internal factors affecting the business efficiency of steel firms in Vietnam. In the study, the dependent variable is business efficiency, determined by the average amount of working capital and fixed capital of an enterprise.*

*The independent variables are business size, growth rate, liquidity ratios, financial leverage, economic growth, and interbank interest rate. The research results show that the four factors of firm size, and the growth rate of assets have a positive impact on business efficiency, while two factors including payment capacity and financial leverage do not affect the business efficiency of enterprises. The results of this article are very useful for corporate executives in general and for financial managers in particular, helping managers make the right financial decisions for the company to promote the business efficiency of the company.*

**Keywords:** *Steel Firms; Business Efficiency; Capital*

### 1. INTRODUCTION

Business capital is a prerequisite for businesses to be able to carry out their production and business activities. Without capital, there would not be any production and business activities, business capital is the basis for enterprises to calculate and plan business strategies and plans.

Steel is not only a construction material but also a staple food of heavy industries and defense. The steel industry has always been identified by the State as a priority industry in the development of the country. The growth of the steel industry always goes hand in hand with the growth of the industry and the economy. In 2022, Steel enterprises face many difficulties when witnessing a sharp decrease in revenue and profit. Over 50% of enterprises reported losses. This shows that the efficiency of capital use of steel enterprises is at a low level and facing many difficulties and challenges.

Therefore, the analysis and evaluation of the effectiveness of using business capital to proactively take appropriate solutions to improve the efficiency of capital use is an urgent issue for enterprises in general and for enterprises in the industry. listed steel in Vietnam in particular.

### 2. LITERATURE REVIEW

Many studies have been carried out to find and study the factors that affect steel firms' business capital efficiency. Despite all efforts to investigate factors that the construction business capital efficiency influenced by some researchers.

**R Azhagaiah, C Gavoury (2011)** examined eight companies working in the basic material sector in Saudi Arabia during the period 2009 to 2018. The results show that the long-term and short-term

<sup>1</sup> Academy of Finance.

debt ratio shows a negative relationship with profitability while the total debt ratio shows a positive relationship with profitability.

**Zhang Y, Zhang Z (2011)** studied capital structure, corporate governance, and operations of corporate activities in medium-sized listed companies and small based on panel data of 381 companies small and medium-sized companies listed on the stock market shares listed on the Shanghai Stock Exchange and the Shenzhen for domestic investors of China from 2003 to 2009. The study analyzes the influence of structure capital and corporate governance on operations companies and discovered that the general debt structure and performance of listed small and medium listings companies have a negative correlation.

**Ali S. Hassoon (2018)** illustrates the correlation between manpower, project plans, working equipment, and materials, management, and safety with the productivity of steel enterprises. This research concludes that some factors have crucial effects on the productivity of steel companies such as the working environment's safety, working hours, team skills and experiences, and planning the work of the site respectively.

**Adamu Yahaya (2019)** researched 10 Nigerian manufacturing firms in the period from 2011 to 2016 with multiple regression in data analysis. The study concludes that the accounting receivable collection period and cash conversion cycle have a crucial influence on these firms, while the accounts payables payment period was not significant and cannot affect the firm's profitability.

### 3. METHODOLOGY

#### 3.1. Sample and data

The research sample includes data over 5 years (from 2018 to 2022) from 14 steel firms in Vietnam. Data collected come from information on exchanges, securities companies, and data collected directly from companies. These are sources of information are reliable according to the author. The data used in the study are constructed from the financial statements and financial information of firms in the steel industry. The financial statements of these companies are established based on compliance with the Vietnamese accounting standards system and have been audited.

#### 3.2. Research model

##### Overall model:

$$ROE_{it} = f(SIZE_{it}, GROW_{it}, PR_{it}, LR_{it}, GDP_{it}, RATE_{it})$$

In which:

ROE<sub>it</sub>: The business efficiency of enterprise i, measured in the time t

SIZE<sub>it</sub>: The size variable of enterprise i, measured in the time t

GROW<sub>it</sub>: The growth rate of total assets of enterprise i, measured in the time t

PR<sub>it</sub>: The payment capable of the enterprise i, measured in the time t

LR<sub>it</sub>: The financial leverage of the enterprise i, measured in the time t

GDP<sub>it</sub>: The gross domestic product rate according to General Statistics Office, measured in the time t

RATE<sub>it</sub>: The interbank interest rate of the 12-month term, measured in the time t

##### Hypothesis:

Based on theoretical and empirical research on the business efficiency of enterprises, the author has set up 6 assumptions about the factors affecting the business efficiency of steel enterprises in Vietnam as follows:

**Business size:** Measured by the logarithm of total assets. Small businesses often perform poorly in generating revenue (R Azhagaiyah, C Gavoury - 2011). However, as businesses expand, management becomes more difficult and more costly. There will come a time when economies of scale no longer

work, increasing output exceeds market demand, not increasing profits (Goddard et al. - 2005). For Steel enterprises, qualitative analysis shows that the larger the enterprises, the higher the capital efficiency. The hypothesis is as follows:

**H1: Business size is positively correlated with business efficiency.**

**The growth rate of assets, and revenue:** The more assets a firm holds, the more profits it has, and the greater its revenue is likely to generate more profits (Agiomirgianakis et al., 2006; Yazdanfar, 2013). However, some studies have shown that the relationship between growth and profitability is in conflict (Glancey, 1998). To grow, businesses must increase costs. If this increase in costs exceeds the growth rate, it can cause profits to decrease.

For Steel enterprises, increasing revenue is an important basis for increasing profits due to low-profit margins in the industry. The hypothesis is as follows:

**H2: Growth rate is positively correlated with business efficiency.**

**Liquidity ratios:** Measures a business's ability to pay its obligations as they come due. One of the coefficients commonly used to measure current payments. The current ratio assesses the solvency of current assets and liabilities (Sari, 2020). Managers will find the company's performance to be good when the current ratio is high (Rusdin, 2008). However, if this ratio value is too high, it is also not good as it shows a large amount of idle money and reduces the profitability of the money and thus producing a lower return (Subramanyam, 2014). The hypothesis is as follows:

**H3: Liquidity ratios are positively correlated with business efficiency**

**Leverage ratios:** This ratio is used to assess the extent to which company assets are financed with debt (Fraser & Ormiston, 2016; Sajiyah, 2016). In the context of the economic crisis, many companies reduce production activities due to the decline in people's purchasing power, and the performance of business activities decreases. Therefore, during economic crises, companies tend to reduce their debt ratio. For steel enterprises, it is showing that the level of financial leverage is having both positive and negative impacts on businesses. This impact is different in different enterprises, the hypothesis of the correlation between leverage ratios and business efficiency is:

**H4: Leverage ratios are negatively correlated with business efficiency.**

**Economic growth:** Steel production is the input material of the construction industry. The economic development and raise in public investment demand led to an increase in steel manufacturing capacity and production. The hypothesis is as follows:

**H5: Economic growth is positively correlated with business efficiency.**

**Interest rate:** If interest rates tend to increase, businesses have to use capital at a higher cost. Especially for Steel enterprises, the debt ratio is higher than equity. Therefore, the higher the interest rate, the more costs businesses lose. Therefore, capital efficiency will tend to fluctuate inversely with interest rates.

**H6: The interest rate is negatively correlated with business efficiency.**

#### 4. RESULT

Running the model using E – view software, it expressed that:

**Table 1** Interprets the Pearson correlation for the variables used in the regression model which the firm's profitability has a positive relationship with the size growth and the growth rate of enterprises 0.2448 and 0.5285 respectively, negative relationship with the payment capacity and financial leverage -0.0484 and -0.0637 respectively. The positive correlations illustrate that the size growth and growth rate of enterprises improve the firm's profitability and payment capacity and financial leverage downwards the profitability.

	roe	size	grow	pr	lr
roe	1.0000				
size	0.2448	1.0000			
grow	0.5285	0.1987	1.0000		
pr	-0.0484	0.1922	-0.1757	1.0000	
lr	-0.0637	-0.2265	0.0935	-0.7899	1.0000

**Table 2: The Hausman – test is applied.**

For testifying whether the Fixed Effects Model (FEM) model or the Random Effects Model (REM) model is a more suitable model for studying the factors affecting the efficiency of using the working capital of steel enterprises, the authors use the Hausman test.

Test of hypothetical pairs:

H<sub>0</sub>: There is no correlation between FEM and REM (choose the Random Effects Model)

H<sub>1</sub>: If Prob (chi-square) < 0.05, which means there is a correlation between explanatory variables and random components (choose the Fixed Effect Model)

	Coefficients		(b-B) Difference	sqrt(diag(V <sub>b</sub> -V <sub>B</sub> )) S.E.
	(b) fe11	(B) re11		
size	7.70e-10	7.92e-10	-2.17e-11	1.97e-09
grow	.2611003	.2734024	-.0123021	.0222554
pr	-.1462263	-.0581786	-.0880477	.0803243
lr	-.1369535	-.033616	-.1033374	.0772255

b = consistent under H<sub>0</sub> and H<sub>a</sub>; obtained from xtreg  
 B = inconsistent under H<sub>a</sub>, efficient under H<sub>0</sub>; obtained from xtreg

Test: Ho: difference in coefficients not systematic

$$\begin{aligned} \text{chi2}(3) &= (b-B)'[(V_b-V_B)^{-1}](b-B) \\ &= 3.18 \\ \text{Prob} > \text{chi2} &= 0.3647 \end{aligned}$$

From the above model, Prob (chi-square) = 0.3647 > 0.05, which means we accept the H<sub>0</sub> hypothesis and select the Random Effects model.

_cons	.1351862	.0869029	1.56	0.120	-.0351405 .3055128

The growing rate of a total asset has a positive correlation with the profitability of enterprises. This variable is the most influential one to profitability. If GROW increases by 1%, ROE will increase by 0.296%. This correlation means enterprises with more asset turnovers than average have a greater possibility of enduring macro impacts and solving financial risks.

Besides, the payment capacity and financial leverage are negatively correlated with profitability. If LR increases by 1%, ROE will decrease by 0.035%. During 2018 – 2022, steel enterprises were facing considerable difficulties and many of them used financial leverage to decrease expenses. However, if the financial leverage is overused, the company's profit will not be enough to compensate for the high level of interest expenses. **5. Discussion and recommendations**

### **5.1. Discussion**

We focus on the observed variables of factors in the research model that affect the business capital efficiency of steel production companies in Vietnam:

First of all, steel firms need to take advantage of the business size and the growth rate of total assets in order to improve their business capital efficiency. Enterprises with larger sizes and more asset turnovers are more capable of handling financial risks and are more profitable.

Additionally, the solvency factor has a negative impact on the efficiency of the enterprise's working capital. With high solvency, businesses tend to borrow less and use less debt. On the contrary, when enterprises use high financial leverage, their solvency will be low, pushing up ROE, thereby increasing the use of debt will increase ROE. From there, orienting to use financial leverage appropriately and effectively for enterprises in the steel industry.

Moreover, the results found above indicate that the steel production company in Vietnam needs to be aware of the role of capital structure for business efficiency. Currently, the debt capital of these companies accounts for billions of a relatively high proportion of the total capital (nearly 50%) and the research results show that the level of leverage used has a negative impact on the performance of the business. As leverage ratios are negatively correlated with business efficiency, steel firms should consider choosing the appropriate level of financial leverage by reducing the debt ratio in the company's capital structure.

Finally, since the growth variable has a positive correlation to business capital efficiency. Vietnamese steel firms' managers should also focus on market development, and promote consumption to increase revenue: exploit the domestic market and export markets regional & internationally.

### **5.2. Recommendations**

From the discussion, some recommendations can be made to help steel enterprises improve their business capital efficiency as follows:

#### **Recommendation on firm size and asset growth rate**

According to a survey by Vietnam Report, the reasons firms assess factors that contribute the most to the growth rate in the past 5 years (2018–2022) are due to the growth of the domestic and regional markets. Next is the development of new product lines; expansion of existing markets; development of new market segments with ready-made and cost-competitive skilled labor. Steel firms need to diversify their products, develop new product lines, and expand existing markets, develop new market segments.

#### **Recommendation on financial leverage**

To improve and take advantage of the financial leverage, the Vietnamese steel firms should seek the optimal structure of capital for their business to make a profit from the loans they made. They may also increase the speed of working capital has the effect of reducing the need for capital, hence firms are not

under the pressure to borrow for investment activities as well as to settle debts such as suppliers' debts, and bank loans. Determining the funding sources: determining which business activities the enterprise's internal capital cannot meet or if borrowed capital will bring higher profits to make reasonable decisions. In addition, firms need to reduce short-term loans and utilize long-term loans.

## 6. CONCLUSION

The research has many limitations that have not been overcome. The scope of the research sample is small and there are still many limitations that make the obtained results incomplete and not highly accurate. The research variable can only address a part of the entire steel business market and need to include more featured macro variables of the industry.

In summary, the article has studied the factors affecting the business efficiency of steel firms in Vietnam through data collected from 14 steel firms in the period 2018-2022. The empirical model shows the correlation between internal factors and business efficiency, including firm size, the growth rate of assets, liquidity ratios, leverage ratios, and economic growth working in the same direction on business efficiency, while interest rate has a negative effect on the business efficiency of steel firms. The results of this study have provided useful information for steel firms in finding solutions to improve their business efficiency.

## OVERVIEW OF THE REAL ESTATE MARKET IN VIETNAM

**Author:** Tran Phuong Anh<sup>1</sup>, Nguyen Thi Thu Ha<sup>1</sup>, Bui Gia Khanh<sup>1</sup>

**Mentor:** Vuong Minh Phuong<sup>1</sup>

**ABSTRACT:** *The Vietnamese real estate market has been growing rapidly in recent years. The study is conducted to analyze Vietnam's real estate in the period 2014–2022. Through the analysis of practical issues, the topic has pointed out the advantages as well as the remaining limitations of the real estate market. In addition to the achieved results, the real estate market still has many limitations, such as commodity prices that fluctuate between hot and cold, speculation, and corruption, to name a few. The real estate market is still inadequate, such as in terms of limitations in planning, limitations in inspection, examination, and handling of violations in the market, and lack of mayor support services.*

**Keywords:** *real estate market; Ho Chi Minh city; Ha Noi; Features.*

### 1. INTRODUCTION

Along with the development of the economy, the real estate market is increasingly expanding and developing. The real estate market has become one of the most important components of the market economy. The birth and development of the real estate market have made significant contributions to the socio-economic development of each country, including Vietnam. Vietnam is a country with a rapidly growing economy, and the real estate market is no exception. It is home to more than 96 million people and is expected to have a population of more than 100 million by 2025. This population growth has led to an increase in demand for housing, commercial real estate, and infrastructure. infrastructure.

### 2 OVERVIEW OF VIETNAM'S REAL ESTATE MARKET

#### 2.1 Features of Vietnam's real estate market

The real estate market in Vietnam has the following characteristics:

Firstly, real estate prices, especially housing prices, are always at a high level and are complicated and difficult to control, which is a big challenge for market management as well as efforts to solve housing problems for people. low-income subjects. The price movement is extremely complicated; it no longer depends solely on the supply-demand relationship like other commodities, but the price is pushed up thanks to crowd investment psychology, foreign exchange rate fluctuations, and the political policy of pumping and withdrawing money from the state bank. According to a report by the Ministry of Construction, housing prices in Hanoi and Ho Chi Minh City have increased. Ho Chi Minh City increased sharply in the first quarter of 2022. in the city. In Hanoi, apartment prices increased by 1.53%, individual housing increased by 2.24%, and ground land for housing construction increased by 2.85%. in the city. In Ho Chi Minh City, apartments increased by 2.48%, individual housing by 2%, and land for housing construction increased by 3.6%. The uptrend slowed down and showed signs of slowing down at the beginning of the second quarter of 2022, with the participation of local governments and ministries. However, real estate prices do not seem to show any signs of slowing down but fluctuate in an upward direction, continuously establishing new price levels.

---

<sup>1</sup> Academy of Finance.

Secondly, the real estate market has developed in terms of quantity, quality, scale, and scope. The real estate market segments are increasingly active, in which the new urban housing market, apartments, and offices for rent are the most visible and vibrant segment in recent years. However, the supply of apartments in Hanoi’s market has continuously decreased in the past 3 years. According to CBRE’s report, the total new supply in Hanoi in 2022 decreased by 12.3% compared to the same period in 2021, reaching about 15,100 units. In particular, in the coming time, the level of new sales in 2023 is expected to decrease slightly or be equivalent to the opening level of 2022, which is expected to reach about 14,000–16,000 units.

**Table 2.1: Number of newly opened and sold apartments in Hanoi from 2019 to 2022**

Source: CBRE

Thirdly, the real estate market occupies an increasingly important position in the economy, with investment projects of increasing quantity and quality. According to the Hanoi People’s Committee, currently in the city, there are 219 investment projects to build houses and urban areas under the Hanoi Housing Development Plan for the 2021–2025 period. Among those projects are 140 commercial housing projects in urban areas, equivalent to nearly 41.5 million square meters of residential floor and 221,507 apartments; 48 projects of social housing, housing for workers, corresponding to nearly 2.9 million square meters of housing floor and 3,900 apartments; 21 resettlement housing projects with about 817,700 square meters of floor space and 10,232 apartments; and 10 projects to renovate and rebuild apartment buildings.

Fourthly, the structure of the real estate market is not yet complete; many market factors are still spontaneously forming (such as the mortgage market, real estate bonds, etc.). Supply and demand in the market are always in a state of huge imbalance in both type and quantity. Experts say that the real estate market in Ho Chi Minh City is strong. The supply-demand gap in Ho Chi Minh City last year was quite serious; almost all projects moved to the higher price segment. Specifically, in 2019, about 30% of the supply was in the high-end, luxury segment; by 2022, this figure will be 75%. While mid-end and affordable projects are increasingly “absent” from the market. In addition, the widespread speculation has increased virtual demand, pushing real estate prices in many areas higher than reality; “underground” transactions also account for a large proportion. This situation in the real estate market not only causes a loss of tax revenue for the state but also contributes to limiting the number of successful transactions. In addition, information about real estate is incomplete, lacking in transparency, and difficult to access. The procedures in real estate transactions are still complicated, have to go through many intermediary stages, take a lot of time, and have high transaction costs. The rights and obligations of the parties involved in the transaction are not guaranteed, and there is a phenomenon of fraud in business and real estate brokerage services...

Fifthly, for many years, in Hanoi as well as in major cities in the country, the state of suspended planning and suspended projects has taken place in many places, making it impossible for people to invest in building houses and developing the economy. Over the past time, the Hanoi city's inter-sectoral working group has organized to work with the people's committees of districts and towns to inspect, review, post-audit, and classify projects. In the city, there are more than 700 non-budget projects using land that are slow to deploy, with a total land area of over 5,000 hectares scattered throughout the districts. From works serving the people to even projects located in the city center that are considered "golden land," they all fall into the category of "covering mats." Although this situation has been going on for decades, dealing with suspended projects is not a simple matter.

Sixthly, the investment in and development of social housing has achieved some initial results, but not as expected. According to the general report of the Ministry of Construction, in 2022, the whole country will have completed about 250 projects of social housing in urban areas and housing for industrial park workers, with a construction scale of more than 100,000 units and a total area of about 7,000 square kilometers. 7.79 million square meters of social housing, while the claim is 12.5 million square meters. The land fund for social housing only meets 36.34%.

## **2.1. Overview of developments in the real estate market from 2013 to the present**

### **2.1.1. The period from 2014 to 2018**

2014 is the year with many effective policies aimed at the benefits of customers and investors. These policies directly affect the housing market. The beginning of the recovery phase of the real estate cycle

On July 1, 2014, the amended Law on Land officially took effect, with many new points in land acquisition, land valuation, and land use planning.

According to the report of the Ministry of Construction, the real estate market has started to show signs of recovery since the last months of 2013. In 2014, the market continued to recover positively, as reflected in the increased transaction volume, relatively stable prices, and the continued decrease in inventory of real estate goods. The structure of real estate goods has been shifted in a reasonable direction, more suitable to the needs of the market. Although real estate credit growth is higher than general credit growth, real estate is still an attractive capital channel.

Specifically, in terms of transactions, in the whole year, there were about 11,450 successful transactions in Hanoi (an increase of more than two times compared to 2013), and in Ho Chi Minh City, there were about 10,350 successful transactions (an increase of about 30% compared to 2013). The housing price level is generally stable; in many projects in the period 2011–2013, prices have fallen deeply (over 30%); in the past 12 months, prices have stabilized and have not decreased further. In Hanoi, a number of projects with good locations were completed or were about to be put into use, and prices increased slightly (about 1–2%) compared to 2013. Regarding real estate inventory, as of 15/15, In December 2014, the total value of real estate inventory was about VND 73,889 billion, down VND 20,569 billion (down 21.8%) compared to December 2013 and down VND 54,659 billion (down 42.5%) compared to the beginning of the reporting period in quarter 1 of 2013. In addition, the structure of real estate goods was adjusted reasonably when there were 60 projects registered to convert from commercial housing to social housing nationwide with a construction scale of about 38,897 apartments and 74 projects registered to adjust apartment structure (reduce area) to better suit market demand.

**Table 2.1: Real estate inventory as of November 2014**

Chỉ tiêu	Chung cư (căn)	Giá trị (tỷ đồng)	Nhà thấp tầng (căn)	Giá trị (tỷ đồng)	Tồn kho BĐS giảm so với tháng 12/2013
Cả nước	15.774	24.114	13.058	21.344	17.62%
Hà Nội	1.911	2.136	2.582	7.550	25.32%
TP.HCM	6.618	11.267	716	2.004	14.64%

Source: Ministry of Construction

Notably, real estate credit outstanding as of October 31, 2014 reached VND 299,020 billion, up 14% compared to December 31, 2013, higher than the overall credit growth of the economy (13%).

As a result of the implementation of a credit package of VND 30,000 billion to support social housing, as of December 15, 2014, the total amount of loans committed by 5 banks was VND 9,417 billion, reaching 31.4% (as of June 2014). reached 13.47%; disbursed was VND 4,882 billion, reaching 16.27% (only 7.63 percent in June 2014).

Disbursement speed in the last 6 months of 2014 more than doubled compared to the period from June 2014 and earlier, especially after the Ministry of Construction presided over and coordinated with the State Bank to submit to the Government for promulgation Decree No. Decision No. 61/NQ-CP dated August 21, 2014, amending and supplementing Resolution No. 02/NQ-CP dated January 7, 2013, which expanded the loan object, extended the loan term, At the same time, there are many social housing projects being implemented to create more supply for the market.

The real estate business ranked second in terms of attracting FDI (in 2014, there were 35 newly licensed FDI real estate projects; newly and additionally registered capital reached US\$2,540 million, accounting for 12.6% of total FDI capital; in 2013, there were 23 new projects with registered capital of 757 million USD).

2014 is considered the most exciting year of mergers and acquisitions in the real estate sector ever. Dozens of sales, project transfers, company mergers and acquisitions, and investment cooperations were successfully transacted. In which prominent are large corporations and companies that have successfully acquired many projects such as Novaland, Vingroup, FLC Group, Him Lam, et al. Besides, large foreign corporations are not outside the country, such as Daibiru and Creed of Japan and Beerli Jucker of Thailand.

**Table 2.2: Some real estate projects bought and sold in 2014**

Dự án	Bên mua	Bên bán	Địa chỉ	Quy mô	Giá trị
Metro Cash & Carry	Berli Jucker (Thái Lan)	Metro			877 triệu USD

Skypark Residence	Tcty xây dựng Thanh Hóa	Licogi 16	25D Khu đô thị mới Cầu Giấy	2 tòa 25 tầng	285 tỷ

Source: Ministry of Construction

The reasons for the recovery of the market during this period were as follows: the macroeconomic situation has gradually improved, the production and business activities of enterprises have begun to show signs of

recovery, and the number of enterprises with losses has decreased. reduce; inflation and low bank interest rates contribute to capital inflows into the real estate market; the government has taken measures to positively affect the market, such as loosening legal regulations and implementing support packages; and confidence in the real estate market is recovering. At the same time, the above positive changes are solutions to market problems, according to Resolution 02 of the government associated with the implementation of the national housing development strategy. Besides, customers' confidence in the market has gradually been restored; many people have no longer felt the psychological need to wait for the next price but have instead decided to buy a house.

In the first 6 months of 2015, foreign investors poured more than USD 465 million into the real estate sector, with 11 newly registered projects and 7 capital increase projects. Many experts believe that in 2015, the flow of money from abroad into real estate will increase rapidly due to many open legal policies, especially the opening to foreigners in Vietnam. According to the Foreign Investment Agency, 2015 is also the year many new economic policies in the direction of more openness and openness officially took effect, especially the amendment and supplement of the Law on Real Estate Business and the Law on Investment. In the field of real estate business, Ho Chi Minh City is the province that attracts the most FDI in this field, with more than 190 projects and 13.4 billion USD of investment capital. Hanoi ranked second with 92 projects and 8 billion USD of investment capital. Ba Ria-Vung Tau ranked third with 10 projects and 6.1 billion USD of investment capital. The next provinces are Binh Duong, Quang Nam, Dong Nai, Hai Phong... In December 2015, Hanoi had about 1,600 successful transactions, equivalent to the same period in 2014 but increased by about 3% compared to the previous month. Ho Chi Minh City had about 1,650 successful transactions, an increase of about 3% compared to the previous month and an increase of about 20% over the same period in 2014. Accordingly, for the whole of 2015, Hanoi achieved about 19,300 successful transactions, an increase of about 70% compared to the same period in 2014. Ho Chi Minh City achieved about 18,550 successful transactions, about 82% compared to the same period in 2014.

Vietnam Real Estate Association (VNREA) has announced the "Report on Inventory of the Real Estate Market for the First Six Months of 2016." In Hanoi, there were about 7,800 successful transactions, and in Ho Chi Minh City, there were about 7,500 successful transactions. labour. In June 2016, the amount of real estate inventory decreased by approximately VND 3,000 billion compared to May 2016. Generally, in the first 6 months of 2016, real estate inventory decreased by 13,400 billion VND, equivalent to 26.33%, bringing the total value of real estate inventory nationwide as of the end of June 2016 to about 37,489 billion VND. This value decreased by 1,935 billion VND compared to the same period last year and nearly halved compared to nearly 2 years ago (about 74,000 billion VND in December 2014).

In Hanoi, the value of real estate inventory was about 5,888 billion dong, down 858 billion dong compared to the end of December 2015, a corresponding decrease of nearly 13%. Meanwhile, in Ho Chi Minh City, the value of real estate inventory is currently 6,815 billion VND, down about 3,292 billion VND compared to the end of December 2015. The real estate market has had a positive recovery and has developed quite steadily. However, nationwide property inventories continued to decline, but the rate of decline has slowed. Inventories are mainly land plots in projects far from the center that do not have adequate infrastructure. Currently, the total value of real estate inventory in Hanoi is lower than that of Ho Chi Minh City and is estimated at 927 billion VND.

In 2017, Vietnam's real estate market witnessed a positive development with an increase in apartment transactions and a decrease in real estate inventory.

According to the report of the National Financial Supervisory Commission on the financial market in 2017, the market has not changed much in real estate prices.

Prices increased mainly in the segment of high-end and mid-end apartments. Prices increase from 3–10% for some high-end apartment projects in urban areas with convenient locations, synchronous infrastructure, construction on schedule, reputable investors, sales policies, and promotions that attract the market. Prices of high-end apartments increased the fastest by 7–10%, mid-end apartments increased by 5-7%, and affordable apartments increased by 3-5%. In the domestic market in 2017, the transaction volume increased significantly compared to 2016, the report noted. The high-end and mid-end apartment segments have the highest number of transactions. The number of successful transactions is estimated at 68,000 units.

Meanwhile, the report said that Vietnam's real estate inventory was about VND 25.7 trillion, down 17% compared to December 2016. Hanoi and Ho Chi Minh City continue to be the cities with the largest inventory of real estate, accounting for 40% of the total inventory of the country. inventory.

In 2017, credit to real estate and construction businesses decreased slightly, accounting for 15.8% of total credit. According to CBRE Vietnam's quarterly report on the Hanoi real estate market published on January 4, 2018 in Hanoi, the end of 2017 marked the positive development of the apartment market in Hanoi. In the fourth quarter of 2017, the market welcomed a record 9,500 new apartments, bringing the total new supply in 2017 to 35,000 units, up 16% over the same period last year. This is also the highest number of new apartments entering the market in a year since the last five years. Sources of fresh goods are scattered throughout the districts in the city.

The market witnessed improved infrastructure and suburban expansion, while two new apartment projects hit the market for the first time in Dong Anh district. The mid-end and affordable segments continued to dominate the market with a total of 80% of new supply in 2017.

The Hanoi real estate market had more than 23,000 successful transactions in 2017, an increase of 12% over the same period last year. Although some projects are not located in prime locations, they still achieve good business results thanks to reasonable investment in product development, product design improvement, and the provision of convenient services for residents. people.

In 2017, primary prices in the market increased slightly due to a high supply of new apartments and changes in demand in the affordable segment. The average selling price from developers stood at \$1,344 per square meter, down 2.4% year-on-year.

With the future development of the market and supply in most areas of the city, apartment developers will be under pressure to professionalize their sales teams and perfect their marketing activities. market for greater competitiveness and revenue.

### ***2.1.2. Period from 2018 to the present***

In 2018 and 2019, the market witnessed local land fever in markets such as Phan Thiet, Bao Loc, and Binh Phuoc, causing land prices in these areas to increase 2-3 times within just 3 months. In addition, land prices also increased by 30–50% in developed tourist areas such as Phu Quoc, Da Nang, Nha Trang, Da Lat, et cetera. The reason is due to the behavior of all agents and brokers, who take advantage of information about project investment, planning, etc. to push up land prices in order to gain illicit profits.

By 2019–2021, the COVID-19 pandemic will have a heavy impact on the economy, making the real estate market quiet. In addition to the emergence of a number of luxury apartment segments (Branded Residence) with a relatively high number of transactions, tourism real estate and investment land seem to have few transactions for real estate businesses. conduct sales due to social distancing.

Stepping out of the COVID-19 pandemic, the 2022 real estate market has had many opportunities to recover and develop. The first quarter of 2022 is the clearest example. According to statistics from the Vietnam Real Estate Brokers Association, right from the beginning of the first quarter, the domestic economy has started to maintain its recovery momentum, production activities have been promoted, supply chains have been strengthened, and businesses have been stimulated. In particular, after implementing Resolution No. 128/NQ-CP dated October 11, 2021, on safe, flexible adaptation and effective control of the COVID-19 epidemic and Resolution No. 11/NQ-CP dated October 11, 2021, On January 30, 2022, the government announced the Socio-economic Recovery and Development Program, and most sectors, fields, and localities have entered the trend of recovery and growth again. According to the Report of the First Quarter of 2022 of the Vietnam Real Estate Brokers Association, the business and service industries in general still face many risks, especially after unexpected events in geopolitics and real estate. is still a market attracting significant cash flow.

Real estate has risen to the No. 2 position (in 2021, real estate ranks 3rd), attracting foreign direct investment totaling nearly 600 million USD. The real estate M&A value in the first quarter of 2022 is also the highest in the past 5 years. Specifically, in the first 3 months, real estate businesses spent nearly 1 billion USD to acquire projects, nearly equal to the number recorded throughout 2017 and 2018. In addition, the first quarter of 2022 also witnessed the situation of local land fever in some localities with infrastructure planning information such as airports, industrial parks, bridges, and roads.

From the middle of the second half of 2022, the real estate market began to show signs of calm. A series of tightening policies on credit and corporate bonds and the leaders of some businesses entangled in labor have made the general sentiment in the market afraid; all transactions are delayed, and projects are underway. must press the “pause” button. This situation not only lasted for a month or two but took place throughout the second half of 2022, and later on, the “health” of the market as well as the business community deteriorated. According to the actual survey, many real estate corporations and businesses recorded a sharp decline in profits, even losses; some real estate stocks are “on the floor,” especially because there is a risk of a deep drop in liquidity or possibly a loss of liquidity, as shown by the fact that some businesses are having to take “painful” measures to “exist.”

According to the 2022 real estate market report of the Vietnam Association of Realtors (VARs), the supply of products to the market reached about 48,500, equivalent to about 90% of the total number of products offered for sale in 2021, the year of the market. The market was heavily affected by the COVID-19 epidemic and was only up 28% compared to 2018 (180,000 products).

**Figure 2.2: Housing supply and transactions in the period 2018–2022.**

VARIS said that in 2022, the real estate market will rarely have new projects. In the rare number of approved projects, no housing projects appear; only service projects are approved. Therefore, the market lacks housing products that are suitable for the “pockets” of the majority of people.

The supply of high-end apartments increased sharply over the years, while the supply of mid-range and affordable apartments decreased by 90% and 79%, respectively, compared to 2019. Supply recorded the highest level in the land plot segment (accounting for 44%). The future supply will be more and more diversified with the appearance of new real estate products, in line with trends such as healthcare, therapy, medical...

**Figure 2.3: New supply and housing transactions in 2022**

**BIỂU ĐỒ 6: Lượng cung mới, giao dịch nhà ở 2022**

Source: VARIS

The overall consumption rate of the whole market is about 39%, equivalent to 19,000 transactions, or 69% of the consumption in 2021 (about 27,600 products). The total volume of transactions for the whole year decreased by 31% compared to 2021, accounting for only 17% of the transaction volume of 2018, the year before the outbreak of COVID 19.

### About real estate supply

In 2022, the number of newly licensed real estate projects will continue to decrease compared to 2021, making the supply of real estate and housing, especially for low-income people, still limited. as follows:

+ In terms of the number of licensed, ongoing, or completed housing development projects, real estate projects

For commercial housing development projects, the whole country has 126 projects with 55,732 licensed apartments (the number of projects is about 52.7% higher than in 2021); there are 466 projects with 228,029 apartments under construction (equivalent to about 47.7% higher than in 2021); and there are 91 projects with 18,206 apartments completed construction (equivalent to about 55.2% higher than in 2021). shown in the following table:

**Table 2.3: Number of licensed, ongoing, and completed housing development projects and real estate projects**

	Được cấp phép		Đang triển khai		Hoàn thành	
	Số lượng dự án	Quy mô (căn)	Số lượng dự án	Quy mô (căn)	Số lượng dự án	Quy mô (căn)
<b>Quý I</b>	39	18.660	1.216	332.387	22	5.217
<b>Quý II</b>	29	6.753	1.091	327.125	24	5.608
<b>Quý III</b>	36	24.324	1.148	324.511	17	4.123
<b>Quý IV</b>	22	5.995	466	228.029	28	3.258
<b>Cả năm</b>	126	55.732			91	18.206

Source: Ministry of Construction

*For social housing projects, there are nine newly licensed projects nationwide with a scale of 5,526 apartments; 114 projects with 6,196 apartments have completed construction; and there are 27 projects with 8,245 apartments eligible to sell houses in the future, as announced by the Department of Construction.*

*For worker housing projects, there are: 02 newly licensed projects nationwide with a scale of 1,729 apartments; 1 project with 32 apartments completed construction; and 4 projects with 2,328 apartments eligible to sell houses in the future, as announced by the Department of Construction.*

*- For tourism and resort projects: There are 12 licensed projects nationwide; the number of projects is about 23% higher than in 2021; 30 projects have completed construction.*

*+ About the number of projects and apartments eligible to sell houses formed in the future*

*Across the country, there are 252 projects with 65,909 apartments eligible to sell houses formed in the future as announced by the Department of Construction (a decrease of nearly 50,000 apartments and an increase of about 58% compared to 2021).*

*+ About the number of transactions for apartments, individual houses, and land plots*

*There are 785,637 successful real estate transactions nationwide. In which: the number of successful transactions of apartments and individual houses is 154,756; the number of successful land plot transactions is 630,881; in Hanoi alone, there are 7,662 successful transactions; in Ho Chi Minh City, there are 10,780 successful transactions.*

**Table 2.4: Transaction volume of apartments, detached houses, and land plots**

	Tổng lượng giao dịch căn hộ chung cư, nhà ở riêng lẻ và đất nền				
	Quý I	Quý II	Quý III	Quý IV	Cả năm 2022
<b>Căn hộ chung cư, nhà ở riêng lẻ</b>	20.325	69.079	51.003	14.349	154.756
<b>Đất nền</b>	153.537	213.018	115.129	149.197	630.881

*Source: Ministry of Construction*

The total number of successful transactions of apartments and individual houses is about 138.6% higher than in 2021. The summary table shows that the number of successful apartment and single-house transactions in the quarters of 2022 is unstable; the number of successful apartment and single-house transactions increases the most in the second quarter of the following year, then decreases and reaches its lowest in the fourth quarter.

The total number of successful land transactions is about 370% higher than in 2021. The summary table shows that the number of successful land transactions in the quarters of 2022 is not stable; the number of land transactions increases the most in the first quarter, then declines sharply in the second quarter, before slightly increasing in the fourth quarter compared to the previous quarter. third quarter. Transactions in the second half of 2022 decreased sharply compared to the first half of the year, only by 50%. The main reason is the difficulty of real estate capital flow and rising interest rates, which make investors hesitant in their investment decisions. The selling price showed signs of slowing down; some projects had to use flexible sales policies, discounting, interest rate support, a grace period for principal, loan commitments, etc. Regarding bond capital flows, period At the end of the year, the bond comes to its final settlement period, forcing the bond issuer to pay both principal and interest to investors. Meanwhile, enterprises are not allowed to is-

sue bonds for the purpose of debt restructuring and debt reversal, showing great pressure on cash flow. It is estimated that the real estate industry currently accounts for 59% of the total value of mature corporate bonds. In 2022 alone, up to 35.56 trillion dong of debt mobilized through corporate bonds will mature and increase sharply to 61.37 trillion dong in 2023. Meanwhile, as of August 2022, the scale of bond issuance by real estate enterprises decreased by 84% compared to the same period in 2021. accumulated in the first 9 months of this year, the total value of bonds bought back by businesses was VND 142,209 billion, accounting for 11.8% of the outstanding bond market. The early repurchase of bonds has partially reduced the maturity of corporate bonds. However, the reality shows that the ability to reverse the bond debt of the real estate group is quite low. It is time for the authorities and the issuers themselves to join hands to find a satisfactory solution to this problem.

In 2022, legal problems will be solved and completed by state agencies. The government and the National Assembly have had many overall solutions to remove difficulties for the real estate market, such as: establishing a working group under the Prime Minister; Draft amendments to Decree 65/2022/ND-CP amending and supplementing a number of articles in Decree 153/2020/ND-CP on offering and trading individual corporate bonds in the open direction and appropriate roadmap; Dispatch 1164/CD-TTg on removing difficulties for the real estate market and housing development... to restore investor confidence. For financial matters, the government has issued Decree 65/2022/ND-CP amending Decree 153/2020/ND-CP regulating the private offering and trading of corporate bonds in the direction of control. more closely, as a basis for enterprises to continue to issue bonds.

The policy to promote disbursement of public investment, of which the group of infrastructure projects accounts for a large proportion, will create many economic zones, promote tourism, develop urban areas, etc., leading to a demand for houses and vacations. maintenance services, offices, etc. Especially the industrial real estate segment in the trend of shifting industrial facilities of multinational corporations around the world. The market will enter a phase of rebalancing and continue to develop sustainably when the state well regulates policies and tools to regulate supply and demand of real estate, such as taxes, credit, land, and finance, or attracts investment.

## THE IMPACTS OF AUDIT QUALITY TO THE PERFORMANCE OF LISTED FIRMS IN VIETNAM

**Author: Quach Dinh Nghien<sup>1</sup>**

**Mentor: PhD. Nguyen Truong Giang<sup>1</sup>**

**ABSTRACT:** *This paper reviews empirical research on audit quality, with a particular focus on defining the quality of audit and categorized indicators of audit quality following to some well-known previous framework. It, then, moves to listing some measurements that can be feasible to applied in Vietnamese markets. The last part will create a model and assess the impact of audit quality through its indicators and the link between audit quality and firm performance on 713 listed companies on the stock exchange from 2000 to 2021. The results indicates that the level of audit quality does not have significant impact on the firm performance but it considerably impact to the cost of debt.*

**Keyword:** *Audit quality, audit indicators, firm performance, cost of debt, listed companies, Vietnam's stock exchange*

### 1. INTRODUCTION

Information about an enterprise's financial statement is a crucial basis for various different users to make economic decisions. Especially, in the stock market, financial information provided by the issuer must be trustworthy, accurate, comprehensive and timely manner. This is a key factor in gaining investors' trust, thus, independent audit activities that evaluate and validate the accuracy and reasonableness of financial accounts are particularly significant.

Indeed, auditing is valuable for its ability to provide independent assurance of the accuracy of accounting information, which helps to ensure efficiency in contracting and resource allocation. A failure in auditing can cause a disruption to staff, and day-to-day business, presenting a financial burden to the company. The collapse of Enron and WorldCom in the 2000s was a model of audit failure leading to the losses of 5.000 Enron employees. In the long term, this event lowers the esteem of the auditing profession in the eyes of the world, specifically, it erodes the confidence of investors, making them doubt the authenticity of reports published and increasing their costs of capital. Besides, the ex-post case of audit failure also raises questions of the quality of audit in economic systems. Indeed, after the Enron scandal, there has been a large number of research on the audit quality issued making many aspects of the topic clear, hence, enhancing perception of readers about the discussion. Despite the essential of the auditing, it has always been a challenge to define, measure and assess the quality of audit because it is difficult to identify the criteria of audit quality evaluation and there is no general recognition or universal acceptance for these criterions.

As mentioned above, audit quality captures great attention from researchers, we are far away from a consensus of how to define and measure it. The paper, therefore, will focus on reviewing two basis aspects of audit quality, that is, the definition of audit quality explained by researchers and the ways to quantify it. The last part of this paper, then, examine the impact of audit quality indicators and the relationship between audit quality and firm performance

---

<sup>1</sup> Academy of Finance

## **2. THEORETICAL FRAMEWORK**

### **2.1. Existing definitions of audit quality**

Audit quality is a complicated topic and hard to achieve a converging definition. Despite more than two decades of research, there is currently no definition of audit quality that achieves recognition and consensus. One of the main reasons is that: The perception of audit quality can depend very much on whose eyes one looks through (Knechel *et al.*, 2013). This led to the difficulty in identifying a homogenous concept and resulting in numerous opinions offered by authorities and individuals about the definition of audit quality over the past 20 years.

From the beginning, DeAngelo (1981) describes audit quality as a result conditioned on the presence of specific attributes of auditors. The author divided the quality of audit into two components: (1) the likelihood that auditors can identify the errors and (2) their actions in response to the discovery (appropriate or not). However, Knechel *et al.* (2013) indicate some issues arise from this definition: (1) it has not reconciled with the risk model, which is used to guide the audit and reflect the auditor's perceptions and (2) there would be some deviations in the perception of market participants. The definition of Francis in 2004 mainly from the United States, in order to assess what we currently know about audit quality with respect to publicly listed companies. The evidence indicates that outright audit failure rates are infrequent, far less than 1% annually, and audit fees are quite small, less than 0.1% of aggregate client sales. This suggests there may be an acceptable level of audit quality at a relatively low cost. There is also evidence of voluntary differential audit quality (above the legal minimum share the view with DeAngelo L (1981) that audit quality can be conceptualized as a theoretical continuum spanning from very poor to very high audit.. In the study of 2011, Francis emphasis and confirmed the importance of audit characteristics through breaking down the notion of audit quality in specific components. Specifically, the quality of audit can be defined through the quality of these stages: Audit inputs; Audit process; and Audit outcomes.

According to (Knechel *et al.*, 2013), all stakeholders including investors, debt holders, suppliers, customers, auditors, and regulators may have very different perspectives as to what forms audit quality. The user of financial reports may think that high audit quality indicates the absence of material misstatements. The auditor may define high quality of audit as satisfactorily completing all engagements required by the firm's audit methodology. The audit firm may assess a high-quality audit as one for which the work can be defended against challenge in an inspection or court of law.

Besides, some researchers define audit quality in terms of failure (Peecher & Piercey, 2008). However, in reality, there are relatively few cases of detectable audit failures (J. R. Francis, 2011).

In sum, the definition highlights the significance of various aspects of audit quality. Each of them is deemed necessary for adequate measurement. However, in many situations, a widely accepted definition of audit quality is less important than agreeing on indicators of the construct that would be useful for users.

### **2.2. Common framework for audit quality assessment**

Although audit quality captures great attention from researchers, we are far away from a consensus of how to define and measure it. To gain an insight about audit quality, many researchers have constructed their own theoretical frameworks discussing its components (Deis and Giroux, 1992; Francis, 2011; Knechel *et al.*, 2013; Christensen *et al.*, 2016).

The first formal attempt to develop an audit quality framework was undertaken by the U.K's Financial Reporting Council (FRC) in 2006. And in 2008, after extensive consultation, the FRC identified five drives of audit quality: (1) the culture within an audit firm; (2) the skills and personal qualities of audit partners

and staffs; (3) the effectiveness of the audit process; (4) the reliability and usefulness of audit reporting, and (5) factors (typically abnormal accruals) outside the control of auditors affecting audit quality (Knechel *et al.*, 2013). Depending on that, several papers then have defined audit quality in terms of audit inputs, audit processes, outputs and opinions and audit context (Bedard, Johnstone and Smith, 2010; Francis, 2011; Knechel *et al.*, 2013; DeFond and Zhang, 2014). This framework is also mainly proposed by the PCAOB (2013), IAASB (2013), and KPMG (2011) as their general audit quality framework. Figure 1 depicts the general audit quality framework referencing components consistent with those listed above.

**Figure 1.1: General audit quality framework**

The Figure 1 is now examined in detail:

#### ***Audit inputs***

There are two main inputs to the audit process that are people who do audits, and the audit tests used to gather evidence (J. R. Francis, 2011). Consistent with this definition, Knechel *et al.*, (2013) also defined the inputs to an audit that are reflected in the individual characteristics of the audit team and inherent to the audit process. Specifically, the input information needed for an audit depends on the personnel available for an engagement, the abilities, and expertise of the audit team, the audit technology and the methodology being used. As a result, the inputs of audit cannot be defined in quantitative terms and the judgements of the auditor will directly influence the audit quality. To improve the quality of the evidence on which the auditor bases decisions, the inherent reliability of the evidence used in the audit and the relevance or attribution of the audit evidence to the ultimate claim being audited, i.e., the client's claim requires a rigorous research program that systematically examines (J. R. Francis, 2011). In sum, the quality of audit is significantly influenced by the level of its inputs.

#### ***Audit process***

The audit process includes many phases, representing the implementation of audit inputs (Francis, 2011; Knechel *et al.*, 2013). Therefore, the quality of the audit process is dependent on the quality of auditor judgements throughout each phase. Moreover, in the term of assessing risk, fraud risk assessments are more likely to be underestimated when auditors use holistic methodologies rather than approaches that independently analyze the risks of fraud for distinct components (Wilks & Zimbelman, 2004; Zimbelman, 1997). Furthermore, the judgements of an auditor also influence other phases of the audit process, e.g., when performing analytical procedures, and obtaining and evaluating audit evidence (Knechel *et al.*, 2013).

#### ***Outcomes***

Many literatures have viewed the level of audit quality in terms of having certain negative outcomes on companies and external users (Bailey, 1982; Chang *et al.*, 2009; J. R. Francis, 2004). These outcomes are sometimes direct, including the informativeness of the audit report, the auditor's opinion of the going-concern issue, and the auditor's opinion on the effectiveness of the client firm's internal controls over financial reporting (Zhang, 2018). In practice, the "misreporting" rate of the auditor in issuing a going-concern report have a negative effect to audit quality (J. R. Francis, 2004).

### *Contextual factors*

Besides different factors mentioned from these above perspectives (inputs, progress, outcomes), there are also many contextual features have been found to influence the quality of audit, some of remarkable features are listing below:

#### *Abnormal audit fees*

Researchers have documented that excessive audit fees can create incentives for auditors to acquiesce to client pressure for substandard reporting; thus eroding audit quality and leading to a higher cost of capital (Hope et al., 2009; Reynolds & Picconi, 2010; Stanley, 2011).

#### *Auditor tenure*

The length of the auditor client relationship can potentially impact the audit quality. DeAngelo L (1981) argued that audit tenure can cause a negative impact on both two main components of audit quality, that is: auditor competence and audit independence. The deterioration in audit quality in a short tenure audit can be attributed to either a lack of competence or a loss of independence, but degradation in audit quality in a long tenure audit is most likely attributed to a loss of independence.

#### *Individual auditor industry specialization*

When being out of specialization, the auditors are not effecting at detecting errors, and real teams perform below the nominal team benchmark in the detection of both mechanical and conceptual errors (Nelson et al., 1995). The result is vice versa if the auditors work within their industry specialization.

#### *Audit firm size*

(DeAngelo L, 1981) argued that audit quality is directly related to the size of audit firm. Large firms stand to lose more economic benefits than small ones, because they have more clients. From that reason, they have a greater incentive to supply higher quality audit in order to avoid a loss in reputation, and thus accounting firm size serves as a proxy for audit quality.

### **2.3. Understand of Vietnamese stock market**

The stock market is a key component of the economy. Levine (1991) discovered a positive relation between the economic growth and the stock market through issuing new financial resources to the companies. Spears (1991) argues that financial intermediation stimulated economic growth in the early phases of development. An efficient stock market also help attract more investment through financing productive projects that lead to economic growth; mobilizing domestic savings allocating capital effectively; minimizing risk via diversification and facilitating the exchange of goods and services (Caporale et al., 2004; Mishkin, 2001).

About stock market in Vietnam, it is quite young that has a lower market capitalization and less liquidity comparing with other markets. However, the Vietnamese stock market still plays its essential role in mobilizing medium to long-term capital for economic development. The market consists of two stock exchanges: Ho Chi Minh stock exchange (HSX) and Hanoi Stock Exchange (HNX). In the initial stage (2000 – 2005), the capitalization of Vietnam's stock market was only 1% of GDP. After the global financial crisis in the period of 2008 - 2009, the stock market started booming and attracting a large number of foreign investors, then, the stock market capitalization to GDP increased rapidly from 12.4% in 2008 to 72.6% in 2019. Overall, just in a period of 20 years, the Vietnamese stock market has significantly been increasing in the quantity of the companies listed, market capitalization and trade volume, with an average growth rate of approximately 30% per year.

## **2.4. The impacts of audit quality in Vietnamese stock market**

The topic of audit quality has caught attention from researchers in Vietnam. PHAM et al. (2020) find a significant impact on the stock synchronicity in the case of the Vietnamese market. The quality of the audit is positively related to stock price synchronicity. This finding can be explained through the mechanism: Audit quality improves the transparency of the corporate reporting and disclosure, which in turn makes stock prices more synchronous.

The effect of audit quality to financial statements users in the Vietnamese financial market (Do & Trung, 2015). The development of a market economy, especially the financial markets is asking for transparency and truthfulness of the financial information with high quality. Accordingly, financial information users, such as investors, etc. consider auditing reports the base for decisions. They primarily rely on the guarantee that information in financial reports is precise, complete and unbiased. Hence, to lessen corporate finance risks and increase public trust, the quality of auditing is essential.

## **3. DATA AND RESEARCH METHOD**

### **3.1. Data collection**

For my study, I will focus on the impact of audit quality to the performance of listed enterprise in Vietnam stock exchange. The paper would cover the data of 713 enterprises listed on the HSX and HNX over the period of 21 years (from 2000 to 2021) which was gathered mostly from audited financial statements, transparency reports of audit firms and yearbooks from the Stock Exchange and Finpro computer system. Furthermore, only enterprises which were active during the examined period were considered. In addition, companies in our dataset are required to have reported a full annual account. The final sample consists 713 firms with 14,973 observations.

### **3.2. Variable construct and research method**

#### **3.2.1. Variable construct**

The most crucial to my paper is to estimate audit quality. The quality of audit is unobservable. Following the literature on audit quality, I construct measure to capture audit quality following the auditing firm reputation (BIG4) and the quality of clients' earning.

#### *Audit quality measured by the auditing reputation*

Regarding auditing reputation, I simply code auditing firms who belong to big 4 group 1 and 0 for the others. This measure is widely used in audit quality literature which includes Nguyen, Vu and Yin (2020) 482 U.S. firms between 2000 and 2009, we demonstrate that high audit quality is associated with lower innovation output, measured by patent counts and patent citations. The effect remains valid after a series of tests for endogeneity issues, alternative measures of audit quality, and different subsamples. We also find that firms with high audit quality attract more non-dedicated institutional investors and financial analysts, who often exert excessive pressure on managers for short-term performance. These pressures, in turn, exacerbate managerial myopia and lead them to forgo investments in innovation. Our findings provide new insights into audit quality by showing its undesirable, most likely unintended, consequences.”, ”author”: accruals quality, and the cost of equity in the context of Vietnam. Particularly, we examine the impact of auditor size and accruals quality on the industry-adjusted earnings – price ratio. Using a sample of Vietnamese listed companies, the study shows that firms audited by a Big Four auditor are associated with a lower cost of equity than firms with a non-Big Four auditor. The results indicate that the auditors’

information role is more relevant than the insurance role in a civil law context with a relatively low auditor litigation risk. In addition, the findings show that companies with better accruals quality are associated with a lower cost of equity. The study has implications for managers and regulators. The findings highlight the importance of ensuring sound auditing practices and maintaining high-quality financial reporting for corporations.”;”author”: (Le et al., 2021 study the effect of audit quality on cost of capital.

In addition, the Big 4 audit firms are known for providing higher quality audits than non-Big 4 firms<sup>1</sup>. Indeed, Big 4 auditors are considered to have more independence than smaller audit firms for several reasons. Firstly, their reputation is at greater risk if they are negligent. Secondly, they depend less on the revenue from a single client; therefore, they less likely to be influenced by them. Lastly, their larger revenue base means they face a higher risk of litigation (DeFond & Zhang, 2014; Palmrose, 1988). In Vietnam, the Big 4 firms (Deloitte, Ernst & Young, KPMG, and PricewaterhouseCoopers) audit 40% of publicly traded companies<sup>2</sup> that account for a large share in Vietnamese audit market. Hence, the author expect *Big 4 indicator* would be a suitable proxy to measure the quality of audit in Vietnam environment.

*Audit quality is measured by the number of professional auditors in audit firms*

Prior research indicated that the quality of audit can be extracted from four factors related to human capital of audit firms, including: Educational of auditors; work experience of auditors; professionalism and continuing professional education of auditors (Lee et al., 1999). Two indicators of the level of auditors are used to derive audit quality: *hour* representing the total training hours for auditors and *KTV* representing the number of professional auditors in audit firms.

*Audit quality is measured by the size of audit firms*

Despite the wide range of adopted measures, “size” can be considered as the most effective indicator of audit quality determination (C. S. Lennox, 1999). Consequently, higher quality of audit can be easier achieved by the larger audit firm (J. R. Francis, 2004) mainly from the United States, in order to assess what we currently know about audit quality with respect to publicly listed companies. The evidence indicates that outright audit failure rates are infrequent, far less than 1% annually, and audit fees are quite small, less than 0.1% of aggregate client sales. This suggests there may be an acceptable level of audit quality at a relatively low cost. There is also evidence of voluntary differential audit quality (above the legal minimum, because of their ability to discover and detect the misstatements (DeAngelo L, 1981). The thesis, then, use the size of audit firms that represent through their revenue (*asale*) to measure the quality of audit.

*Audit quality measured by the accounting information quality – Discretionary accruals*

A large abnormal or discretionary component of accruals is indirect evidence of earnings management behavior and lower earning quality (J. R. Francis & Yu, 2009). Since we do not examine any specific managerial incentives, therefore, we use the absolute value of discretionary accruals (|DA|) as the independent variable in the next test. Discretionary accruals (DA) are deflated by total assets and estimated by year and for each industry through the cross-sectional modified version of the Jones model (Dechow et al., 1995; Jones, 1991). The model to estimate discretionary accruals is described below:

$$TACC_{ijt} = \alpha_0 + \alpha_1 \left[ \frac{1}{A_{ijt-1}} \right] + \alpha_2 \left[ \frac{\Delta SALE_{ijt} + \Delta REC_{ijt}}{A_{ijt-1}} \right] + \alpha_3 \left[ \frac{PPEGT_{ijt}}{A_{ijt-1}} \right] + \alpha_4 ROA_{ijt} + \epsilon_{ijt} \quad (1)$$

<sup>1</sup> How Big-4 Firms Improve Audit Quality | Management Science (informs.org)

<sup>2</sup> Big Four audit 40% of public companies in Vietnam - VnExpress International

As many prior study, we measure total accruals (TACC) through the difference between net profit after tax and net cash flow from operation activities, deflated by lagged assets (Becker et al., 1998; Jones, 1991; Kothari et al., 2005). The fomula is described below:

$$TACC_{ijt} = \left[ \frac{\Delta CA_{ijt} - \Delta CL_{ijt} - \Delta CASH_{ijt} + \Delta STD_{ijt} - \Delta DEP_{ijt}}{A_{ijt-1}} \right] \quad (2)$$

where  $\Delta CA_{ijt}$  is the change in current asset;  $\Delta CL_{ijt}$  is the change in current liability;  $\Delta CASH_{ijt}$  represent for the change in cash and cash equivalent in the balance sheet;  $\Delta STD_{ijt}$  is the change in short-term debt;  $\Delta DEP_{ijt}$  is the change in the accumulated depreciation.

The orther variables of the model (1) are defined respectively:  $A_{ijt-1}$  is total asset of prior year;  $\Delta SALE_{ijt}$  is change in sale of the current year;  $\Delta REC_{ijt}$  is the change in accounts receivable of the current year;  $PPEGT_{ijt}$  is property of the current year, plant and equipment (gross total); and  $ROA_{ijt}$  is return on asset of the current year. Then TACC minus the predicted value (non-discretionary accruals) from the below regression (Asthana & Boone, 2012) resulting discretionary accruals (DA), thus:

$$\frac{NDA_{ijt}}{A_{ijt-1}} = \beta_1 \left[ \frac{1}{A_{ijt-1}} \right] + \beta_2 \left[ \frac{\Delta SALE_{ijt} - \Delta REC_{ijt}}{A_{ijt-1}} \right] + \beta_3 \left[ \frac{PPEGT_{ijt}}{A_{ijt-1}} \right] + \beta_4 ROA_{ijt} \quad (3)$$

where  $NDA_{ijt}$  is non-discretionary accruals predicted;  $\beta_1, \beta_2, \beta_3, \beta_4$  can be estimated by using OLS regression with (1) Equation ( $\alpha_1, \alpha_2, \alpha_3, \alpha_4$ ).

The above model is one of many variations of DA model. Even so, these model all inspired from the model of Jones (1991). In different conditions, we can adjust (1) Equation flexibly to comfort with our objectives, such as McNichols (2002) added cash flow from operation (CFO) as an independent variable in (1) Equation<sup>1</sup>. In addition, the level of discretionary accruals also depend on the size of audited companies, hence, the level of audited firm's equity added in their DA equation (J. Francis et al., 2005)"abstract": "We investigate whether investors price accruals quality, our proxy for the information risk associated with earnings. Measuring accruals quality (AQ).

This modification can be considered as an another proxy for estimating the DA. Thus, the model to estimate discretionary accruals is described below:

$$TACC_{ijt} = \beta_1 \left[ \frac{1}{A_{ijt-1}} \right] + \beta_2 \left[ \frac{\Delta REV_{ijt} - \Delta REC_{ijt}}{A_{ijt-1}} \right] + \beta_3 \left[ \frac{PPE_{ijt}}{A_{ijt-1}} \right] + \beta_4 \left[ \frac{CFO_{ijt}}{A_{ijt-1}} \right] + \beta_5 DCFO_{ijt} + \beta_6 \left[ \frac{CFO_{ijt}}{A_{ijt-1}} \times DCFO_{ijt} \right] + \varepsilon_{ijt}$$

where  $TACC_{ijt}$  is also calculated following the Equation (2);  $CFO_{ijt}$  represent the cash flow from operation in year t;  $DCFO_{ijt}$  is a dummy variable that equals 1 if  $CFO_{ijt}$  is negative; and 0 otherwise; and  $\varepsilon_{ijt}$  is the error term. In addition, the  $\varepsilon_{ijt}$  also represent the estimation of DA.

<sup>1</sup> However, the residual captures in the part of current accrual that is not attributed to the time series of cash flows and other fundamentals (Horton et al., 2020). It, therefore, proxies for managerial discretion in accruals.

**3.2.2. Research method**

This section provides the estimation techniques used in quantifying the effect of audit quality on multiple aspects of the firm. We used a package of STATA software version 16 to estimate the regression equations that we proposed above. Firstly, bivariate relations among variables were explored via Person correlation maix. Next, I analysis the effect of audit quality to firm performance, stock market performance and cost of debt.

The general model is specified as follows:

$$Firm_{i,t} = \beta_0 + \beta_1 Auditquality_{i,t-1} + \sum_{j=2}^n \beta_j X_{j,i,t-1} + f_i + y_t + \epsilon_{i,t} \quad (5)$$

In model (7), *Firm* is the dependent variable captures three aspects of the firm which include: financial performance (ROE, ROA), stock market performance - stock liquidity (alliq) and cost of debt (cdebt). Auditquality is the main variable of interest which captures the quality of auditing services. This variable represents big 4 audit indicator (big4), number of training hours provided by auditing firm (hour), number of auditors (ktv), auditing firm sale (asale) and DA. *Xj* is a set of controlling variables which include firm growth rate (growth), leverage ratio (lev) and firm size (size).  $\epsilon_{i,t}$  is the error term.  $f_i$  and  $y_t$  are firm and year indicator variables, respectively. The dependent variable is lead 1 year to avoid simultaneity issue.

**4. RESULTS AND DISCUSSION**

**4.1. Results**

**4.1.1. Descriptive Statistics**

Table 2 provides descriptive statistics for the variables used in this study. On average, auditing firms report 49.8 auditors, with the median of 48. It shows the data is pretty symmetrical. The other audit quality measures show the similar pattern. For example, the number of training hours shows the mean of 7.466 and the median is of 7.637.

Regarding the other firm financial variables, it is pretty consistent with the other studies focus on the Vietnamese market. For example, the average return on asset (ROA) of my sample is 0.04 (4%), the average return on equity (ROE) is 0.063 (6.3%).

**Table 2: Descriptive statistics This table provides descriptive statistics for the variables used in this study.**

**Table 2** provides the Person correlation matrix of the variables used in the study. The first 5 variables measure audit quality. They show the strong and positive correlation, DA is an exception. Within 4 other variables, ktv (measures number of auditors) shows the significant but negative relation with DA, big4 (captures whether the firm is audited by big4 auditing firms or not) shows the insignificant relation. This causes a doubt on the reliability of DA in measuring audit quality. The primary correlation result is consistent with previous studies on the accuracy of audit quality measurement.

**Table 3**

\*\*\* p<0.01, \*\* p<0.05, \* p<0.1

The **Table 3** shows us the correlation between variables used in the research model. We can see that most of the variables are relatively closely correlated with each other. The results tables also shows that the Big 4 audit firms and the audit firm's sales have a positive relationship. Besides, the training hour of auditors also face a positive relationship with the number of auditors and audit firm's sales. These results are explained by the fact that the Big 4 audit firm in Vietnam commonly get a higher revenue than non-Big 4 audit firms and the larger of the audit firm size, the higher of its sales.

#### 4.1.2. Regression analysis

##### 4.1.2.1. Effect of audit quality on firm financial performance

This section analyses the effect of audit quality to firm performance, stock market performance and cost of debt. To measure financial performance, we rely on the profitability measures include return on equity (ROE) and return on asset (ROA).

**Table 4: The effect of audit quality on firm financial performance**

**Table 4** reports the regression result of firm performance measured by ROA and ROE on audit quality. Audit quality measures present an inconsistent impact on firm performance as there is one variable shows an insignificant and negative impact and there are other three other shows a positive and significant. The variable *da* captures the accrual quality shows the strongest impact of audit quality on both of the variables measure firm performance

**4.1.2.2. The effect of audit quality on firm stock market performance**

This section studies the effect of audit quality on the performance of stock in the market. Firm stock behavior is measured by market liquidity. The assumption is that if audit quality enhances information quality, stock will be more liquid as investors are more active in there trading.

**Table 5: Effect of audit quality on stock market performance**

Sources: Self compiled by the author

Although the effect of audit quality on stock liquidity is suggestive, I do not find evidence supports this assumption. All my five measures of audit quality show insignificant impact on the level of market liquidity. This seems contradicting with the findings in the developed markets where audit quality is proven to have positive impact on market performance.

#### 4.1.2.3. Effect of audit quality on cost of debt

This section investigates the effect of audit quality on the cost of debt which is measured by dividing interest expense to total debt bearing cost (short and long-term borrowing). The result is reported in the table below:

**Table 6: The effect of audit quality on the cost of debt**

Sources: Self compiled by the author

In this table, all five audit quality measures show consistent and negative effect on cost of debt. However, there are two of them that are accrual quality (DA) and the sale of auditing firm have significant effect. The other variables have negative but insignificant effect.

## 4.2. Findings and discussion

For the results that I test the quality of five audit quality indicators which was conducted on the theory framework. The statistic results show that the quality of audit is insignificant impact to the market liquidity and have a negative impact on cost of debt. The findings is not cope with the theory of audit quality in developed country about the positive impact on market performance. This can be explained by the fact that Vietnam is still an frontier markets whereas those studies conducted in developed market that can lead to the mismatch with the characteristics of the practical situation in Vietnam.

## 5. CONCLUSION

The paper investigated the impact of audit quality on performance on the sample of 713 Vietnamese listed enterprises in the period of 2000 – 2021. According to the statistics, audit quality has a little influence on market liquidity and a negative impact on cost of debt. The findings contradict the hypothesis of audit quality in developed countries about the favorable influence on market. This is due to the fact that Vietnam is still a frontier market, whether research countries may result in a mismatch with the features of the actual situation in Vietnam.

Some limitations of this paper should be commented, as follows: this research carried out using a convenience sampling method, leading that the results were mainly subjective by the research author, which reduced the objectivity and generalization. Therefore, the further researchers should consider the use of probability sampling method to ensure higher representations and increase the size of the research sample for more accurate and more general analysis result. Secondly, the research scope has only been conducted just in several index of profitability of audit quality, so the results of the empirical research only provided some short-term conclusions and recommendations. The further researchers can expand the scope of the thesis both space and time for a more complete and comprehensive assessments.

## FACTORS AFFECTING THE EFFECTIVENESS AND GROWTH OF LISTED COMMERCIAL BANKS IN VIETNAM

**Author: Nguyen Thi Kim Duyen<sup>1</sup>, Luong Thi Thu Ha<sup>1</sup>, Pham Cong Tien<sup>1</sup>, Nguyen Thai Duong<sup>1</sup>**

**Mentor: Assoc. Prof.PhD. Nghiem Thi Tha<sup>1</sup>**

*ABSTRACT: The growth and efficiency of listed commercial banks have a significant impact on the safety and stability of the financial market. Therefore, there have been numerous studies on this topic. The authors' research topic involves using a research sample of 16 listed commercial banks in Vietnam during the period of 2005-2021 based on table data to evaluate factors related to Return On Assets (ROA) and Return On Equity (ROE), the author group proposes solutions to enhance the effectiveness and growth of listed commercial banks in Vietnam.*

*Keywords: Efficiency and growth, Influencing factors, Commercial banks.*

### 1. INTRODUCTION

Commercial banks are financial intermediaries that play a role as a bridge between investment sectors and savings sectors, assisting the central bank to implement monetary policy, support money supply regulation in the economy, and curb inflation to achieve national growth objectives. However, there are quite a few commercial banks that operate with low efficiency and slow growth. To find solutions to enhance the efficiency and growth of listed commercial banks in Vietnam in the current context, the study focuses on examining the impact of financial characteristic factors of listed commercial banks on ROA and ROE, using a sample size of 16 listed commercial banks in Vietnam during the period from 2005 to 2021. Building on the research of authors such as Athanasoglou and partner (2008); Alexiou and Sofoklis (2009), Nghiem Thi Tha and partner (2021), Pasiouras and Kosmidou (2007); Kosmidou and Pasiouras (2008); Sufian and Habibullah (2012); Chronopoulos and partner (2015); Caporale and partner (2017); Chen and partner (2018)... The research team proposes using three indicators: ROA, ROE, and CGROWTH to reflect the efficiency and growth of listed commercial banks in Vietnam and focuses on examining the impact of financial characteristic factors on these indicators. The research model is as follows:

### 2. THEORETICAL FRAMEWORK AND HYPOTHESIS

#### 2.1. Research model on efficiency

The model used to study the factors influencing the business efficiency of commercial banks is as follows:

$$ROA_i = \beta_1 + \beta_2 CAEQ_i + \beta_3 NPL_i + \beta_4 BASZ_i + \beta_5 PROD_i + \beta_6 INF_i \quad (1)$$

$$ROE_i = \beta_1 + \beta_2 CAEQ_i + \beta_3 NPL_i + \beta_4 BASZ_i + \beta_5 PROD_i + \beta_6 INF_i \quad (2)$$

$ROA_i, ROE_i$ : Dependent variables reflecting the efficiency of listed financial institutions;  $\beta_0$ : Regression coefficient,  $\beta_1, \beta_2, \dots, \beta_6$ : Coefficients representing the impact of independent variables on the dependent variable in the regression model,  $i$ : Investigated listed financial institutions; Research hypothesis: if the positive direction of the independent variables' impact on the dependent variable, the sign (+) is used, and if

the direction of the independent variables' impact on the dependent variable is negative, the sign (-) is used. The research hypotheses in table 1 of the two research models are summarized as follows:

**Table 1: Research theory, name of variables in the model**

Variables	Meaning	Formula	Expectation sign
ROE (Dependent Variable)	Return On Equity	Net Profit After Tax/Average Total Equity	
ROA (Dependent Variable)	Return On Assets	Net Profit After Tax/Average Total Assets	
CAEQ	The ratio of mobilized capital to equity	Mobilized Capital/ Equity	+
NPL	Non-performing Loan	Loans hasn't paid more than 90 days/Total Loans	-
BASZ	Asset Size	Total Assets	+/-
PROD	Productivity	Net Profit After Tax/Labors	+
INF	Inflation	Inflation Rate	+

## 2.2. Research model on growth

The regression model is used to examine the impact of factors on the financial performance of Vietnamese commercial banks as follows:

$$CGROWTH_i = \beta_0 + \beta_1 NPL_i + \beta_2 LIQUIDITY_i + \beta_3 DEPOSIT_i + \beta_4 ROE_i + \beta_5 NIM_i + \beta_6 GDP_i + \beta_7 INF_i + \beta_8 RATE_i$$

In this equation,  $CGROWTH_i$  represents the dependent variable reflecting the growth of listed commercial banks;  $\beta_0$  is the regression coefficient,  $\beta_1, \beta_2, \dots, \beta_8$  are the coefficients of the independent variables on the dependent variable in the regression model, and  $i$  is the indexed listed commercial bank under study. The research hypothesis states that if the direction of the positive impact of the independent variables on the dependent variable is observed, it will be denoted by a positive sign (+), and the direction of the negative impact of the independent variables on the dependent variable will be denoted by a negative sign (-). The synthesis of the research hypotheses in Table 2 of the research model is as follows:

**Table 2: Research theory, name of variables in the model**

Variables	Meaning	Formula	Expectation sign
CGROWTH (Dependent Variable)	Annual Credit Growth	$[(\text{Loans To Customers} + \text{Investment Securities})_t / (\text{Loans To Customers} + \text{Investment Securities})_{(t-1)}] - 1$	
NPL	Nonperforming Loan	Loans hasn't paid more than 90 days/Total Loans	-
LIQUIDITY	Liquidity of Bank	Outstanding Balance/ Total Assets	+
DEPOSIT	Annual Deposit Growth	$(\text{Deposits from customers}_t / \text{Deposits from customers}_{t-1}) - 1$	+
ROE	Return On Equity	Net Profit After Tax/Average Total Equity	+
NIM	Net Interest Margin	Net Interest Income/ Average Earning Assets	-
GDP	GDP Growth	GDP Growth Rate	+
INF	Inflation	Inflation Rate	-
RATE	Average Loan Interest Rate	Average Loan Interest Rate	-

## 3. RESULT

Descriptive statistics of the variables in the model: The data used in the study were synthesized and calculated from the financial reports of 16 listed commercial banks during the period 2005-2021. The listed commercial banks were studied on a scale of two groups: large (1) and small (2), as shown in the following table:

**Table 3: Lists of commercial banks in Vietnam classified by assets size in 2021**

*Unit: Millions*

Order	Ticker Symbol	Assets	Group
1	BID	1.761.695.792	1
2	CTG	1.531.587.398	1
3	VCB	1.414.672.587	1
4	MBB	607.140.419	1
5	TCB	568.728.950	1
6	VPB	547.409.439	1
7	ACB	527.769.944	1
8	STB	521.117.123	1
9	HDB	374.611.571	2
10	VIB	309.517.129	2
11	TPB	292.827.078	2
